In Reply—All the pregnant women included in our study were non-smokers and were referred to our hospital from different parts of the State of Tennessee. All patients spent 4–6 h in a smoke-free environment in our hospital before the blood samples were obtained.

Our own results from a previous study showed that carboxyhemoglobin levels of 3–6% decrease P_{ScO2} by 2.5–4 mm Hg.1 We certainly agree that carboxyhemoglobin levels of about 3% is not the principal mechanism for a decrease in P_{ScO2} in preeclamptic pregnant patients. We did conclude in our paper that elevation in COHb levels was partly responsible for a decrease in P_{ScO2} in preeclampsia. In addition to COHb, certain hormones including prostaglandins may be responsible for a decrease in P_{ScO2} seen in patients with preeclampsia. Several of these hormones are known to cause shifts in P_{ScO2}.2,3

Finally, we agree that 2,3-DPG levels play a role in oxygen dissociation from hemoglobin. However, measurement of 2,3-DPG levels is not necessary for P_{ScO2} determinations. However, studies from various investigators show that 2,3-DPG levels are either unchanged or slightly elevated in pregnancy.1

Polyvinylchloride Endotracheal Tubes are Hazardous for CO₂ Laser Surgery

To the Editor—In their report on 523 patients who underwent general endotracheal anesthesia with plain polyvinylchloride (PVC) endotracheal tubes for operations using the CO₂ laser, Pashayan et al.4 report one tube fire and near misses in 50% of their cases. The latter were cases where the laser had contacted PVC endotracheal tube but no combustion occurred. Their protocol of using a reduced inspired fraction of oxygen in helium is prudent, but the authors’ adherence to the use of PVC endotracheal tubes is puzzling.

Pashayan et al. cite a study5 indicating that PVC tubes are less flammable than red rubber tubes on contact with a propane torch. However, the opposite conclusion has been reported by Patel and Hicks6 using a CO₂ laser in vitro and by another study of the effects of tube fires caused by the laser on dog tracheas.4 Furthermore, PVC can produce copious toxic combustion products, such as HCl.5

The use of either a red rubber tube wrapped with appropriate metal foil tape or a metallic endotracheal tube would improve patient safety in these cases. Foil wrapping is inexpensive and, if done carefully, a relatively smooth exterior can be achieved. These tubes will allow greater laser energy and a higher P_{ScO2} than that allowed in the protocol of Pashayan et al. to be employed. Their use should be considered mandatory in CO₂ laser endoscopic surgery.
