(Received November 3, 2000)

We show that an effective Abelian gauge theory can be obtained as a renormalizable theory from QCD in the maximal Abelian gauge. The derivation improves in a systematic manner the previous version that was obtained by one of the authors and was referred to as the Abelian-projected effective gauge theory. This result supports the view that we can construct an effective Abelian gauge theory from QCD without losing characteristic features of the original non-Abelian gauge theory. In fact, it is shown that the effective coupling constant in the resulting renormalizable theory has a renormalization-scale dependence governed by the $\beta$-function that is exactly the same as that of the original Yang-Mills theory, irrespective of the choice of gauge fixing parameters of the maximal Abelian gauge and the parameters used for identifying the dual variables. Moreover, we evaluate the anomalous dimensions of the fields and parameters in the resultant theory. By choosing the renormalized parameters appropriately, we can switch the theory into an electric or a magnetic theory.

§1. Introduction

It is widely believed that quantum chromodynamics (QCD) as a non-Abelian gauge theory with color gauge group $SU(3)$ can describe quark and gluon confinement and more generally color confinement, although there is no rigorous proof to this time. Various physical phenomena that we can observe in experiments should be gauge independent. However, the quantized gauge field theory is consistently formulated only in gauge-fixed form, at least in the continuum formulation, in contrast to the lattice formulation. Even QCD is not an exception. Therefore, the continuum QCD with a gauge-fixing term and the associated Faddeev-Popov (FP) ghost term can be written only in a specific (although arbitrary) gauge. Traditionally, the Lorentz gauge $\partial_\mu A^\mu = 0$ has been extensively examined as a manifest covariant gauge, perhaps because quantum electrodynamics (QED) was successfully formulated in this gauge. Therefore there are numerous works on the Lorentz gauge. However, it turns out that the Lorentz gauge in the non-Abelian gauge theory is plagued by Gribov ambiguities. It is not clear how the color confinement criteria in the Lorentz gauge are compatible with intuitive pictures of quark confinement represented by the dual superconductor picture¹ and QCD strings.

The developments in the understanding of quark confinement in the last decade²)

Renormalizable Abelian-Projected Effective Gauge Theory

indicate that, within the present technology, the maximal Abelian (MA) gauge\(^4\) realizing the idea of the Abelian projection\(^3\) seems to be the most promising gauge in which the dual superconductor picture of QCD vacuum could be derived directly from QCD. Abelian dominance in the low-energy region of QCD has been confirmed. This was conjectured in Ref. 5) and its discovery, based on lattice simulations, was reported in Ref. 6). Moreover, the MA gauge is expected to be free from the Gribov problem, due to its nonlinearity.

In a previous paper,\(^7\) we derived an effective Abelian gauge theory directly from QCD in the MA gauge by integrating out all the off-diagonal fields. The resulting theory is called the Abelian-projected effective gauge theory (APEGT). This derivation supports the view that one can construct an effective Abelian gauge theory from QCD without losing characteristic features of the original non-Abelian gauge theory. In fact, it was shown\(^8\),\(^7\) that the effective coupling constant \(g(\mu)\) in the APEGT has a renormalization scale \(\mu\) dependence governed by the \(\beta\)-function \(\beta(g) = \mu \frac{dg(\mu)}{d\mu}\) that is exactly the same as that of the original Yang-Mills theory, exhibiting asymptotic freedom. These results suggest in the analytical approach the Abelian dominance in the low-energy region of QCD. Investigations along this direction have been carried out by one of the authors and his collaborators.\(^9\)-\(^15\)

In the derivation of the APEGT,\(^7\) we have introduced an auxiliary anti-symmetric tensor field \(B_{\mu\nu}\) to convert the quartic off-diagonal gluon interaction into a quadratic form in the off-diagonal gluon fields. This procedure enabled us to perform the integration over the off-diagonal gluons exactly for the gauge group \(G = SU(2)\). Moreover, the Abelian tensor field \(B_{\mu\nu}\) can be regarded as a Hodge dual of a composite field that consists of the electric field (gauge potential). This viewpoint becomes quite important in obtaining the dual theory, which is expected to be the dual Ginzburg-Landau theory (see Ref. 7)).

However, there was an ambiguity as to the identification of the dual field \(B_{\mu\nu}\). In fact, the resulting APEGT can depend on how the \(B_{\mu\nu}\) is identified as the dual, although two choices were considered in the previous paper.\(^7\) Moreover, the resulting APEGT does not have a renormalizable form in the sense that the integration (or radiative correction) induces new terms which are absent in the original Lagrangian. The failure of preserving renormalizability implies the impossibility of performing a systematic evaluation based on the APEGT.

In this paper, we remove this ambiguity and the difficulty mentioned above by deriving a renormalizable APEGT. This renormalizable APEGT has a definite meaning irrespective of manner in which \(B_{\mu\nu}\) is identified. The renormalizable APEGT presents a promising way for performing higher-order calculations, e.g., recovery of the two-loop \(\beta\)-function of the original Yang-Mills theory based on the APEGT (see Ref. 16)). In this sense, this paper supplements and improves the previous work.\(^7\) In this paper, it is shown that the \(\beta\)-function of the original Yang-Mills theory is obtained in the APEGT, irrespective of the choice of gauge-fixing parameters for the MA gauge and also of the parameters introduced for identifying the dual variables. Moreover, we calculate the anomalous dimensions for the diagonal (Abelian) fields. The renormalization-group functions obtained in this way determine the scaling be-
behavior of the vertex function in the APEGT.

This paper is organized as follows. In §2, we introduce the MA gauge fixing in the Yang-Mills theory and discuss how we can identify the dual Abelian variables in the APEGT, which will be obtained in the final step. In §3, we explain the meaning of APEGT and its renormalizability. In §4, we explain the procedure of renormalization (at the one-loop level) to obtain the renormalizable APEGT. Then we give the Feynman rule in the framework of the renormalized perturbation theory. Finally, we evaluate the renormalization group β-function and the anomalous dimensions. In the final section we give the conclusion of the paper and discuss the issues to be clarified in the future.

§2. Lagrangian in the MA gauge

2.1. The gauge invariant part

The Yang-Mills Lagrangian is given by

\[ L_{\text{YM}} = -\frac{1}{4} (F^A_{\mu\nu})^2, \]  

(1)

where \( F^A_{\mu\nu} \) is the non-Abelian field strength defined by

\[ F^A_{\mu\nu} = \partial_\mu A^A_\nu - \partial_\nu A^A_\mu + g f^{ABC} A^B_\mu A^C_\nu. \]  

(2)

Now we consider the decomposition of the non-Abelian gauge fields into diagonal and off-diagonal components. In the following we distinguish the indices as follows:

\[ \begin{cases} 
A, B, C, \cdots \to SU(N), \\
i, j, k, \cdots \to U(1)^{N-1} \text{ (diagonal)}, \\
a, b, c, \cdots \to SU(N)/U(1)^{N-1} \text{ (off-diagonal)}. 
\end{cases} \]  

(3)

We write the decomposition of the gauge potential into the diagonal and off-diagonal components as

\[ A_\mu = A^A_\mu T^A = A^i_\mu T^i + A^a_\mu T^a. \]  

(4)

First, the Yang-Mills Lagrangian is decomposed as

\[ L_{\text{YM}} = L^{(i)}_{\text{YM}} + L^{(a)}_{\text{YM}}, \quad L^{(i)}_{\text{YM}} = -\frac{1}{4} (F^i_{\mu\nu})^2, \quad L^{(a)}_{\text{YM}} = -\frac{1}{4} (F^a_{\mu\nu})^2. \]  

(5)

Next, we introduce the auxiliary tensor field \( B^i_{\mu\nu} \) of rank two in such a way that the \( L^{(i)}_{\text{YM}} \) piece is recovered after the \( B^i_{\mu\nu} \) is integrated out. Suppose \( B^i_{\mu\nu} \) is anti-symmetric in the indices \( \mu \) and \( \nu \) and takes values in the Cartan subalgebra; that is, \( B^i_{\mu\nu} \) is an anti-symmetric Abelian tensor field.\(^1\) We would like to identify \( B^i_{\mu\nu} \) with

\(^1\) We could start from the BF-YM theory by introducing the non-Abelian anti-symmetric tensor \( B_{\mu\nu} \) as the Hodge dual of \( F_{\mu\nu} \), as discussed in Refs. 17 and 7). However, this approach does not lead to a renormalizable result in the sense explained below.
the Hodge dual* of the Abelian tensor field $Q^{i}_{\mu\nu}$,

$$^*Q^{i}_{\mu\nu} := \frac{i}{2} \epsilon_{\mu\nu\rho\sigma} Q^{\rho\sigma i},$$  \hspace{1cm} (6)

which is assumed to be a composite operator constructed from the gauge potential $A_{\mu}^{A}$, i.e.,

$$B^{i}_{\mu\nu} = i^*Q^{i}_{\mu\nu}.$$  \hspace{1cm} (7)

Therefore, $Q^{i}_{\mu\nu}$ should be a $U(1)^{N-1}$ invariant anti-symmetric tensor written in terms of the gauge potential $A_{\mu}^{A}$. The simplest choice for $Q^{i}_{\mu\nu}$ is a linear combination of $f^{i}_{\mu\nu}$ and $f^{abc}A_{\mu}^{b}A_{\nu}^{c}$ with two parameters $\rho$ and $\sigma$, since $Q^{i}_{\mu\nu}$ is expected to be at most quadratic in the gauge potential from the renormalizability:

$$Q^{i}_{\mu\nu} = \rho f^{i}_{\mu\nu} + \sigma g f^{abc}A_{\mu}^{b}A_{\nu}^{c}$$

$$= \rho(\partial_{\mu}A_{\nu}^{i} - \partial_{\nu}A_{\mu}^{i}) + \sigma g f^{abc}A_{\mu}^{b}A_{\nu}^{c}.$$  \hspace{1cm} (8)

The advantages of this choice will be clarified shortly. The diagonal piece of the YM Lagrangian is expanded as

$$L_{YM}^{(i)} = -\frac{1}{4} \left[ f^{i}_{\mu\nu} + g f^{ibc}A_{\mu}^{b}A_{\nu}^{c} \right]^{2} - \frac{1}{2} g f^{i}_{\mu\nu} f^{ibc}A_{\mu}^{b}A_{\nu}^{c} - \frac{1}{4} g^{2} \left( f^{ibc}A_{\mu}^{b}A_{\nu}^{c} \right)^{2}.$$  \hspace{1cm} (9)

Thus the simplest form satisfying (7) and (8) is given by

$$L_{YM}^{(i)} = -\frac{1}{4} \rho^{2} \left( f^{i}_{\mu\nu} \right)^{2} - \frac{1}{2} \rho \sigma g f^{i}_{\mu\nu} f^{ibc}A_{\mu}^{b}A_{\nu}^{c} - \frac{1}{4} \sigma^{2} g^{2} \left( f^{ibc}A_{\mu}^{b}A_{\nu}^{c} \right)^{2}$$

$$- \frac{1}{4} \left( B^{i}_{\mu\nu} \right)^{2} + \frac{i}{2} B^{i}_{\mu\nu} \ ^*Q^{i}_{\mu\nu}.$$  \hspace{1cm} (10)

In particular, when $\rho = \sigma$, $Q^{i}_{\mu\nu}$ is nothing but the diagonal component of the non-Abelian field strength, $Q^{i}_{\mu\nu} = \rho F^{i}_{\mu\nu}$, and hence $B^{i}_{\mu\nu} = i \rho *F^{i}_{\mu\nu}$. In view of this, the choice (8) is a generalization of that of the previous paper,7) in which two special cases, $\rho = \sigma = 1$ and $\rho = 0$, $\sigma = 1$, are discussed (Eqs. (2.9) and (2.12), respectively).7) The latter case was first discussed by Quandt and Reinhardt.8)

On the other hand, by defining the covariant derivative with respect to the Abelian gauge field,

$$D_{\mu}A^{A} := (\partial_{\mu} \delta^{AB} + g f^{AiB}A_{\mu}^{i}) \Phi^{B},$$  \hspace{1cm} (11)

the off-diagonal piece can be rewritten as

$$L_{YM}^{(a)} = -\frac{1}{4} \left[ D_{\mu}A_{\nu}^{a} - D_{\nu}A_{\mu}^{a} + g f^{abc}A_{\mu}^{b}A_{\nu}^{c} \right]^{2}.$$  \hspace{1cm} (12)

---

* The definition of the Hodge dual (6) used in this paper differs from the conventional one by the factor of the imaginary unit $i \equiv \sqrt{-1}$. 

---

7) The latter case was first discussed by Quandt and Reinhardt.8)
2.2. Maximal Abelian gauge fixing

By making use of the Becchi-Rouet-Stora-Tyutin (BRST) transformation $\delta_B$, the gauge fixing and Faddeev-Popov (FP) ghost term is obtained as

$$L_{GF+FP} = -i\delta_BG, \quad G = \bar{C}^a \left(F^a + \frac{\alpha}{2}\phi^a\right) + \bar{C}^i \left(F^i + \frac{\beta}{2}\phi^i\right), \quad (13)$$

for the gauge fixing condition $F^a$ of the off-diagonal piece and $F^i$ of the diagonal piece, with gauge fixing parameters $\alpha$ and $\beta$, where $\bar{C}^A$ is the anti-ghost field and $\phi^A$ is the Nakanishi-Lautrup (NL) Lagrange multiplier field. We adopt the MA gauge for the off-diagonal piece,

$$F^a = D^\mu A^a_\mu, \quad (14)$$

whereas the Lorentz gauge is chosen for the diagonal piece,

$$F^i = \partial^\mu A^i_\mu. \quad (15)$$

Here, the BRST transformation is given by

$$\delta_B A^A_\mu = (D^\mu C)^A, \quad \delta_B C^A = -\frac{g}{2} f^{ABC} C^B C^C, \quad \delta_B \bar{C}^A = i\bar{C}^A, \quad \delta_B \phi^A = 0. \quad (16)$$

It should be remarked that the covariant derivative $D^\mu := D^\mu [A^i]$ is defined for the diagonal gauge field $A^i_\mu$ as

$$D^\mu \Phi^a := \left(\partial^\mu \delta^{ab} + gf^{abi} A^i_\mu\right) \Phi^b, \quad (17)$$

while we define

$$(D^\mu \Phi)^A := (\partial^\mu \delta^{AC} + gf^{ABC} A^B_\mu) \Phi^C = (D^\mu \Phi)^A + gf^{ABC} A^B_\mu \Phi^C. \quad (18)$$

Thus we obtain

$$L_{GF+FP} = \frac{\alpha}{2} (\phi^a)^2 + \phi^a F^a + i\bar{C}^a D^2 C^a - ig^2 f^{abi} f^{jcd} \bar{C}^a A^b_\mu A^c_\mu C^d + i g f^{abc} \bar{C}^a D^\mu (A^b_\mu C^c) + i\bar{C}^a g f^{abi} F^b C^i \quad \frac{\beta}{2} (\phi^i)^2 + \phi^i F^i + i\bar{C}^i \partial^2 C^i + i\bar{C}^i \partial^\mu (gf^{ibc} A^b_\mu C^c). \quad (19)$$

§3. The meaning of the renormalizability of the APEGT

In order to confirm the necessity of the new parameters $\rho$ and $\sigma$ introduced in Eq. (8), we first deal with the case of choosing the parameters $\rho = 0$ and $\sigma = 1$ at the tree level of the Lagrangian (10). Moreover, to simplify the discussion, we consider the $SU(2)$ case. Then our Lagrangian is given by

$$\mathcal{L} = \mathcal{L}_{\text{inv}}[a_\mu, B_{\mu\nu}, A^a_\mu] + \mathcal{L}_{GF+FP}[a_\mu, A^a_\mu, \bar{C}^A, C^A], \quad (20)$$
where $L_{\text{inv}}$ is the gauge invariant part of the Lagrangian,
\[ L_{\text{inv}} = -\frac{1}{4} (f_{\mu\nu})^2 - \frac{1}{4} (B_{\mu\nu})^2 - \frac{1}{2} g \epsilon^{ab} (f - i^* B)_{\mu\nu} A^a A^b \]
\[ -\frac{1}{4} (D_\mu A^a_\nu - D_\nu A^a_\mu)^2, \]
(21)
and $L_{\text{GF+FP}}$ is the gauge fixing and FP ghost term,
\[ L_{\text{GF+FP}} = \frac{\alpha}{2} (\phi^a)^2 + \phi^a (D^\mu A^a_\mu) + \frac{\beta}{2} (\phi)^2 + \phi (\partial^\mu a_\mu) \]
\[ + ig^a_2 \epsilon^{ab} \epsilon^{cd} \tilde{C}^a A^b_\mu A^{\mu c} C^d \]
\[ + i \tilde{C}^a g \epsilon^{ab} (D^\mu A^b_\mu) C^3 + i \tilde{C}^3 \partial^\mu C^3 + i \tilde{C}^3 \partial^\mu (g \epsilon^{ab} A^a_\mu C^b). \]
(22)
Since there is only one diagonal component in the $SU(2)$ gauge group, we omit the diagonal index and replace the structure constant $f^{ABC}$ by an anti-symmetric tensor $\epsilon^{ab} := \epsilon^{ab3}$.

It may seem that this theory with the total Lagrangian (20) is renormalizable, because it appears to be equivalent to the ordinary Yang-Mills theory, since $B_{\mu\nu}$ is the auxiliary field. However, this is not the case. Actually, we will show that undesirable divergent terms which are absent in the original Lagrangian are induced as quantum effects; that is, the renormalizability of this theory is spoiled. For this reason, we should modify this theory by requiring renormalizability.

First, we consider the gauge invariant part, $L_{\text{inv}}$. There are two kinds of undesirable divergence in this theory. One of them comes from the quartic off-diagonal gluon interaction through the process (a) of Fig. 1. The other is the bilinear term of the diagonal gluon $a_\mu$ and the auxiliary field $B_{\mu\nu}$ represented by the process (b) of Fig. 1. Neither of these interactions exists in the original Lagrangian (20), and hence we cannot absorb such divergences into the original theory by means of any renormalization procedure.
Even though we choose the parameters $\rho$ and $\sigma$ appropriately so that the above two interaction terms are included in the theory from the beginning, we cannot absorb all divergences into the original theory. The reason is as follows. The gauge invariant part of the Lagrangian (obtained by choosing the parameters $\rho$ and $\sigma$ appropriately),

$$L_{\text{inv}}' = -\frac{1}{4} f_{\mu\nu}^2 - \frac{1}{2} \rho g^{ab} f_{\mu\nu} A^\mu A^\nu - \frac{1}{4} \sigma^2 \left( \epsilon^{ab} A^\mu A^\nu \right)^2 - \frac{1}{4} (B_{\mu\nu})^2 - \frac{1}{2} g B_{\mu\nu} \left( \rho f_{\mu\nu} + \sigma \epsilon^{ab} A^\mu A^\nu \right) - \frac{1}{4} \left( D_\mu A^\mu_a - D_\nu A^\mu_a \right)^2,$$

possesses the interaction terms that we want. However, as compared with the original $SU(2)$ gauge theory, three more divergences $\langle B_{\mu\nu} B_{\xi\eta} \rangle$, $\langle a_\mu B_{\xi\eta} \rangle$ and $\langle A^a_\mu A^b_\nu B_{\xi\eta} \rangle$ are induced by introducing the auxiliary field $B_{\mu\nu}$. Therefore we cannot absorb completely the three new divergences only in the auxiliary field $B_{\mu\nu}$. Of course, if there are some relations between these three divergences, like the Ward identity, it may be possible to do so. However, regrettably, as shown explicitly in the next section, there is no such relation, at least between two propagators $\langle B_{\mu\nu} B_{\xi\eta} \rangle$ and $\langle a_\mu B_{\xi\eta} \rangle$. Therefore we must take into account the renormalization of the two additional parameters $\rho$ and $\sigma$ to preserve the renormalizability of our theory so that we have totally three renormalizable quantities together with $B_{\mu\nu}$. Thus it is possible to absorb all divergences and we can obtain a renormalizable Lagrangian. In other words, by taking account of not only the renormalization of the auxiliary fields $B_{\mu\nu}$ but also that of the two parameters $\rho$ and $\sigma$, the renormalizability of our original Lagrangian is preserved.

Next, we proceed to examine the gauge fixing part $S_{\text{GF+FP}}$. Because of the non-linearity of the MA gauge, this gauge fixing part (22) has a significant distinction from that in the covariant gauge, the existence of the $CCAA$ interaction, which is the fourth term of the integrand of Eq. (19). Since this interaction is shown to induce a divergent quartic ghost interaction term through the process (c) in Fig. 1, in spite of the absence of such terms in the original Lagrangian, we should introduce the quartic ghost interaction term from the beginning. The way of introducing such an interaction is not unique, and hence we have proposed the modified MA gauge fixing condition in Ref. 15. According to the modified MA gauge fixing, the gauge fixing term (22) is rewritten as

$$L_{\text{GF+FP}}' = \alpha \left( \phi^a \right)^2 + \phi^a (D^\mu A^a_\mu) + \beta \left( \phi^a \right)^2 + \phi (\partial^\mu a_\mu) + i \bar{C}^a D^2 C^a - i g^2 \epsilon^{ab} \epsilon^{cd} \bar{C}^a A^b_\mu A^{\mu c} C^d + i C^a g^{ab} (D^\mu A^b_\mu) C^3 + i \bar{C}^3 \partial^2 C^3 + i \bar{C}^3 \partial^{\mu} (g^{ab} A^a_\mu C^b). - i g^{ab} \phi^a \bar{C}^b C^3 + \frac{\zeta}{4} g^2 \epsilon^{ab} \epsilon^{cd} \bar{C}^a \bar{C}^b C^c C^d. \ (24)$$

The only difference between the ordinary MA gauge (22) and the modified one (24) is the last two terms in the latter. Owing to the existence of the quartic ghost
interaction term in the original Lagrangian, the gauge fixing part of the Lagrangian restores its renormalizability.

Moreover, the introduction of the quartic ghost interaction is very important from a more physical viewpoint. When a quartic ghost interaction exists, we find that ghost condensation occurs. Then the off-diagonal gluons and the off-diagonal ghosts acquire their masses in the ghost condensed phase. Therefore, the Abelian dominance which was previously postulated is understood as a natural result of these phenomena. However, we do not give further explanation of the ghost self-interaction terms here, because they do not affect the results obtained in this paper. More detailed discussion is given in Ref. 15).

Since our starting Lagrangian \( \mathcal{L} = \mathcal{L}'_{\text{inv}} + \mathcal{L}'_{\text{GF+FP}} \) is renormalizable after taking account of renormalizations of the auxiliary field \( B_{\mu\nu} \) and the two parameters \( \rho \) and \( \sigma \), the \( \beta \)-function and the anomalous dimensions are well-defined, so that we can obtain them unambiguously. Because of the existence of quantum corrections of \( B_{\mu\nu}, \rho \) and \( \sigma \), quantum corrections to propagators and vertices are different from those in the ordinary Yang-Mills theory. However, we expect that the individual anomalous dimensions of the quantities included in the original Yang-Mills theory, in particular the \( \beta \)-function, remain the same. In fact, after the calculations in the next section, the resulting \( \beta \)-function, the anomalous dimensions of diagonal gluon, \( \gamma_a \) and those of the Abelian gauge fixing parameter \( \gamma_\beta \) are seen to be the same as the original ones. Thus these results obtained in the next section are far from trivial.

We define the APEGT as an Abelian gauge theory, which is expressed in terms of only the diagonal components \( a_i^\mu \) and \( B_{i\mu\nu} \) (and diagonal ghosts \( \bar{C}^i \) and \( C^i \)). Therefore, in order to obtain the APEGT, the off-diagonal components \( A^a_\mu, \bar{C}^a \) and \( C^a \) must be integrated out in a certain sense, which is discussed in the next section. Hence, the “renormalizability” of the APEGT implies that all the divergent terms made of only diagonal fields in the APEGT can be removed consistently after the prescription of the renormalization. Therefore, in order to obtain a renormalizable APEGT, we have only to worry about the contribution of the divergent graphs with only diagonal fields as external legs. Of course, miscellaneous terms with off-diagonal fields and higher derivative terms are generated as quantum effects, but we are concerned with the situation in which such terms are not relevant (see Ref. 22 for more details). According to Abelian dominance, we can expect that such a situation is realized in the low-energy regime of QCD. In fact, Abelian dominance is understood as a consequence of dynamical mass generation of off-diagonal gluons and off-diagonal ghosts, as shown in Ref. 15).

\section{Renormalization and renormalization-group functions}

\subsection{The total Lagrangian and the \( U(1)^{N^{-1}} \) symmetry}

The total Lagrangian is obtained by summing up (10), (12) and (19):

\[
\mathcal{L} = -\frac{1}{4} \rho^2 \left( f_{\mu\nu}^i \right)^2 - \frac{1}{2} \rho \sigma g f_{\mu\nu}^i f^i_{\mu\rho} f^i_{\rho\nu} A_{\mu b} A_{\nu c} - \frac{1}{4} \sigma^2 g^2 \left( f_{ibc} A_{\mu b} A_{\nu c} \right)^2
\]
\[-\frac{1}{4} \left( B^i_{\mu\nu} \right)^2 + \frac{i}{2} B^i_\nu i \mu \nu i - \frac{1}{4} \left[ D_\mu A^\mu_a - D_\nu A^\mu_a + g f^{abc} A^b_a A^c_\nu \right]^2 \]
\[+ \frac{\alpha}{2} (\phi^a)^2 + \phi^a F^a + \frac{\beta}{2} (\phi^i)^2 + \phi^i F^i \]
\[+ i C^a D^2 C^a - i g^2 f^{abi} f^{cd} C^a A^b \mu A^c \nu C^d + i g f^{abc} C^a D^\mu (A^b_\mu C^c) \]
\[+ i \bar{C}^i \partial^2 C^i + i \bar{C}^i \partial^\mu (g f^{abc} A^b_\mu C^c) + i \bar{C}^a g f^{abi} F^b C^i. \] (25)

We separate each field $\Phi$ into the background (classical field) $\Phi$ and the quantum fluctuation field $\tilde{\Phi}$ as $\Phi = \Phi + \tilde{\Phi}$. We then have

$$A_\mu = \bar{A}_\mu + \tilde{A}_\mu, \quad B_{\mu\nu} = B_{\mu\nu} + \tilde{B}_{\mu\nu}, \quad \phi = \bar{\phi} + \tilde{\phi}, \quad C = Cl + \tilde{C}, \quad \bar{C} = Cl + \tilde{\bar{C}}.$$  

(We have used different notation for the ghost and anti-ghost field to avoid unnecessary confusion.) Here the background field $\Phi$ is assumed to satisfy the equation of motion. Substituting this decomposition into (25), we find that the terms linear in the fluctuation field $\tilde{\Phi}$ vanish due to the equation of motion**)

$$\frac{\partial S[\tilde{\Phi}]}{\partial \tilde{\Phi}} = 0,$$ (26)

since

$$S[\Phi + \tilde{\Phi}] = S[\Phi] + \tilde{\Phi} \frac{\partial S[\Phi]}{\partial \Phi} \bigg|_{\Phi = \tilde{\Phi}} + O(\tilde{\Phi}^2).$$ (27)

By taking into account

$$(D_\mu \Phi)^a = \partial_\mu \Phi^a + g f^{abi}(\bar{A} + \tilde{A})^i_\mu \Phi^b = (\bar{D}_\mu \Phi)^a + g f^{abi} \tilde{A}^i_\mu \Phi^b$$ (28)

and

$$\partial_\mu \tilde{\Phi}^i = (\bar{D}_\mu \tilde{\Phi})^i,$$ (29)

it turns out that the derivative $\partial_\mu$ in the Lagrangian can be replaced by the covariant derivative $\bar{D}_\mu := D_\mu[\bar{A}^i]$ with respect to the background Abelian gauge field $\bar{A}^i$. After this replacement, the background Abelian gauge field $\bar{A}^i_\mu$ appears only in the gauge fixing term $\bar{\phi}^i \partial_\mu \bar{A}^i_\mu$ for the background Abelian gauge field $\bar{A}^i_\mu$. Therefore, $\mathcal{L} - \bar{\phi}^i \partial_\mu \bar{A}^i_\mu$ is invariant under the following $U(1)^{N-1}$ rotation:

$$\left\{ \begin{array}{l}
\delta \bar{A}^i_\mu = \partial_\mu \theta^i, \\
\delta \bar{\Phi}^i = 0, \quad (\Phi = \bar{B}, \bar{\phi}, Cl, \bar{C} cl, \bar{A}, \bar{B}, \bar{\bar{\phi}}, \bar{C}, \bar{\bar{C}}) \\
\delta \Phi^a = -g f^{abi} \Phi^b \theta^i. \quad (\Phi = \bar{A}, \bar{\phi}, Cl, \bar{C} cl, \bar{A}, \bar{\bar{\phi}}, \bar{C}, \bar{\bar{C}}) \end{array} \right.$$ (30)

That is to say, under the residual gauge transformation, all the diagonal fields but $\bar{A}^i_\mu$ are invariant, while an off-diagonal field behaves as a charged matter field. (Note that

---

** This standpoint is different from that adopted in the previous paper. However, it is always possible to translate between the results obtained there and here. (See the footnotes below.)

** Even if $\Phi$ does not satisfy the equation of motion, the cross term between the diagonal field and the off-diagonal field can disappear, as $\text{tr}[(\Phi^a T^a) f(\Phi^i) T^i] = \Phi^a f(\Phi^i) \text{tr}(T^a T^i) = 0$. This is the case for the MA gauge, where the background field has a diagonal component alone, and the fluctuation field is given by the off-diagonal components alone, i.e., $\Phi = \Phi T^i, \tilde{\Phi} = \Phi^a T^a$.}
After integrating over $\tilde{\phi}^i$ the effective Lagrangian reads $\mathcal{L}_{\text{eff}} - \tilde{\phi}^i \partial^\mu A^i_\mu$ has a residual symmetry given by
\[
\begin{align*}
\delta \tilde{A}^i_\mu &= \partial^\mu \theta_i, \\
\delta \tilde{\phi}^i &= 0, \quad (\Phi = \tilde{B}, \tilde{\phi}, \tilde{C}_{\text{cl}}, \tilde{\bar{C}}_{\text{cl}}) \\
\delta \tilde{\phi}^a &= -gf^{abi}\Phi^b \theta_i. \quad (\Phi = \tilde{A}, \tilde{\phi}, \tilde{C}_{\text{cl}}, \tilde{\bar{C}}_{\text{cl}})
\end{align*}
\]

The resulting effective Lagrangian reads
\[
\mathcal{L}_{\text{eff}} - \tilde{\phi}^i \partial^\mu A^i_\mu = - \frac{Z_A^{-1}}{4} \left( \tilde{f}_{\mu\nu}^i \right)^2 - \frac{Z_B^{-1}}{4} \left( \tilde{B}_{\mu\nu}^i \right)^2 + i \frac{Z_A^{-1}}{2} \tilde{B}_{\mu\nu}^i \tilde{f}_{\mu\nu}^i
\]
\[
- \frac{Z_A^{-1}}{4} \left( \tilde{D}^a_\mu \tilde{A}^a_\nu - \tilde{D}^a_\nu \tilde{A}^a_\mu \right)^2 + \cdots. \quad (32)
\]

We can observe that the renormalization for $g$ and $\tilde{A}^a_\mu$,
\[
g = Z_g g_R, \quad \tilde{A}^a_\mu = Z_A^{1/2} (\tilde{A}_R)_\mu, \quad \tilde{A}^a_\mu = Z_A^{1/2} (\tilde{A}_R)_\mu,
\]
leads to
\[
\tilde{D}^a_\mu \tilde{A}^a_\nu = \left( \partial^\mu \delta^{ab} + gf^{abi} \tilde{A}^i_\mu \right) \tilde{A}^b_\nu
\]
\[
= Z_A^{1/2} \left[ \partial^\mu \delta^{ab} + Z_g Z_A^{1/2} g_R f^{abi} (\tilde{A}_R)_\mu \right] (\tilde{A}_R)_\nu. \quad (34)
\]

Hence, renormalizability requires the relation
\[
Z_g Z_A^{1/2} = 1. \quad (35)
\]

This relation can also be derived from the Ward-Takahashi identity for the residual $U(1)^{N-1}$ symmetry, which is preserved due to the nature of the background field method,\(^{18}\) as has been demonstrated in the $SU(2)$ case ($N = 2$).\(^7\)

### 4.2. General consideration

If we perform the functional integration over the fluctuation fields, a divergence appears as a quantum effect. This divergence can be removed by renormalization of the fields ($\tilde{\phi}, \tilde{\Phi}$), the coupling constant $g$, and the two parameters $\rho$ and $\sigma$. To simplify the argument, we first consider the divergence appearing in the sub-graph with external lines $\tilde{\phi}$. Since $\Phi$ does not appear in the internal lines, we can set $\tilde{\phi} = 0$. Hence we consider $\tilde{\mathcal{L}}$, which is obtained from (25), by replacing $\tilde{\Phi}$ with $\tilde{\phi}$. After integrating over $\tilde{B}$ and $\tilde{\phi}$ in $\tilde{\mathcal{L}}$, we obtain
\[
\tilde{\mathcal{L}} = - \frac{1}{4} \left( \tilde{f}^A_{\mu\nu} \right)^2 + \tilde{\mathcal{L}}_{\text{GF+FP}}, \quad (36)
\]
\[
\tilde{\mathcal{L}}_{\text{GF+FP}} := - \frac{1}{2\alpha} \left( \tilde{F}^a_\mu \right)^2 - \frac{1}{2\beta} \left( \tilde{F}^a_\nu \right)^2
\]
\[
+ i \tilde{\phi}^a \tilde{D}^2 \tilde{C}^a - ig^2 f^{abi} f^{cid} \tilde{C}^a A^b_\mu \tilde{A}^c_\mu \tilde{C}^d + ig f^{abc} \tilde{C}^a \tilde{D}^\mu (\tilde{A}^b_\mu \tilde{C}^c)
\]
\[
+ i \tilde{\phi}^i \partial^\mu \tilde{C}^i + i \tilde{\phi} \partial^\mu (gf^{ibc} \tilde{A}^b_\mu \tilde{C}^c) + i \tilde{\phi}^a f^{abi} \tilde{F}^b_\mu \tilde{C}^i, \quad (37)
\]
where $\tilde{D}_\mu := D_\mu [\tilde{A}_\mu]$. Thus we find that $\tilde{\mathcal{L}}$ depends on neither $\rho$ nor $\sigma$. It can be shown that the divergence can be absorbed into the renormalization of $\tilde{A}_\mu^A$, $\tilde{C}_A$, $\tilde{C}^A$ and $g$ by multiplicative renormalization. Then the renormalization constant $Z_g$ of $g$ is independent of $\rho$ and $\sigma$, and hence the $\beta$-function is also independent of $\rho$ and $\sigma$. The simplest way to determine the renormalization of $\tilde{A}_\mu^A$, $\tilde{C}_A$, $\tilde{C}^A$ and $g$ is to consider the renormalization of the propagators of $\tilde{A}_\mu^A$, $\tilde{C}_A$ and $\tilde{C}^A$ and of the $\tilde{A}_\mu \tilde{C} \tilde{C}$-vertex. Nevertheless, it would be rather difficult to calculate the higher-point vertex when we consider the higher loop effect. In any case, $\tilde{\mathcal{L}}$ does not depend on $\rho$ and $\sigma$, and therefore we do not have to consider the renormalization of the internal lines hereafter.

Next, we evaluate the graph which has only $\tilde{A}_\mu^i$ and $\tilde{B}_{\mu\nu}^i$ as its external lines. We do not have to consider the renormalization of internal lines $\tilde{\Phi}$, since $\tilde{\Phi}$ appears only in the internal lines, and the renormalization of $\tilde{\Phi}$ has been performed in the previous step. This fact is well known in the context of the background field method (see Ref. 18)). We have only to consider the renormalization of $\tilde{A}_\mu^i$, $\tilde{B}_{\mu\nu}^i$, $g$, $\rho$ and $\sigma$. Setting $\tilde{\Phi}_\rho^c = 0$ (the absence of off-diagonal background fields) and integrating over $\tilde{B}_{\mu\nu}^i$ and $\tilde{\phi}$ in the Lagrangian, we obtain

$$
\mathcal{L} = \mathcal{L}_c - \frac{1}{2} \rho \sigma g_f \bar{f}_{i\mu} f_{i\rho} \tilde{A}_\mu^a \tilde{A}_\rho^c - \frac{1}{4} \sigma g e^{\mu\nu\rho\sigma} \tilde{D}_\mu \tilde{A}_\nu \tilde{D}_\rho \tilde{A}_\sigma \\
- \frac{1}{4} \left( \tilde{D}_\mu \tilde{A}_\mu - \tilde{D}_\nu \tilde{A}_\nu \right)^2 - g f^{abc} \left( \tilde{D}_\mu \tilde{A}_\nu \right) \tilde{A}_\mu \tilde{A}_\nu \\
- \frac{1}{4} \left( \tilde{F}_{\mu\nu}^i \right)^2 + \tilde{\mathcal{L}}_{\text{GF+FP}}[\tilde{D} \to D],
$$

where the last term $\tilde{\mathcal{L}}_{\text{GF+FP}}[\tilde{D} \to D]$ is obtained by replacing $\tilde{D}$ with $D$ from $\tilde{\mathcal{L}}_{\text{GF+FP}}$ and

$$
\mathcal{L}_c = - \frac{1}{4} \left( \bar{f}_{i\mu} f_{i\mu} \right)^2 - \frac{1}{4} \left( \tilde{B}_{\mu\nu}^i \right)^2 + \frac{i}{2} \rho \beta \left( \tilde{B}_{\mu\nu}^i \right)^2 - \frac{1}{2} \beta \left( \partial_\mu \tilde{A}_\mu^i \right)^2.
$$

It is not difficult to see that the renormalization of $\tilde{A}_\mu^i$, $\tilde{B}_{\mu\nu}^i$, $g$ and $\rho$ is sufficient at the one-loop level. In fact, the classical (background field) part is given by $\mathcal{L}_c$, which does not contain $\sigma$. The renormalization of $\sigma$ does appear at the two-loop level. An advantage of the background field method is that we have only to calculate the vertex function at the one-loop level to know the renormalization of $\sigma$ at the two-loop level. Furthermore, it is enough to consider the three propagators $\tilde{A}_\mu^i - \tilde{A}_\mu^j$, $\tilde{B}_{\mu\nu}^i - \tilde{B}_{\mu\nu}^j$ and $\tilde{A}_\mu^i - \tilde{B}_{\mu\nu}^j$ in order to obtain the $\beta$-function (at the one-loop level). The reason

---

*1 This could correspond to the Abelian dominance in the sense that the off-diagonal components are negligible in the low-energy region of QCD. In other words, the off-diagonal component does not have a low-energy mode from the viewpoint of the Wilsonian renormalization group. In contrast to the off-diagonal component, the diagonal component has both high-energy and low-energy modes. In the present treatment, the high-energy modes of the diagonal and the off-diagonal components are integrated out, although the integration of the diagonal high-energy mode was ignored in the previous treatment. However, the result is unchanged, at least at the one-loop level (see Ref. 16) for more details).
is as follows. At first glance, we need five relationships that completely specify the renormalization of $\tilde{A}_i^\mu, \tilde{B}_i^{\mu\nu}, g, \rho$ and $\sigma$. However, we have an additional relation (35) between the renormalization constants for $\tilde{A}_i^\mu$ and $g$, and we do not have to consider the renormalization of $\sigma$ at the one-loop, as mentioned above. In order to determine all the renormalization factors, therefore, we need only three independent relations (at least at the one-loop level), which are provided by the renormalization conditions (counterterms) of three propagators, as calculated below.

4.3. Feynman rules

The Feynman rules are given as follows (see Fig. 2). We give only those rules that are necessary for the renormalization at the one-loop level. The two-loop result will be given in a subsequent paper.\(^{16}\)

4.3.1. Propagators

(a) Fluctuation off-diagonal gluon propagators:

$$iD_{\mu\nu}^{ab} = -\frac{i}{p^2} \left[ g_{\mu\nu} - (1 - \alpha) \frac{p_\mu p_\nu}{p^2} \right] \delta^{ab}. \quad (40)$$

(b) Fluctuation off-diagonal ghost propagators:

$$i\Delta^{ab} = -\frac{1}{p^2} \delta^{ab}. \quad (41)$$

Fig. 2. The graphs in (a) and (b) represent fluctuation-field propagators. The (rapidly vibrating) wavy line denotes the fluctuation off-diagonal gluon $\tilde{A}_a^\mu$, and the broken line denotes the fluctuation ghost $\tilde{C}_a$ or anti-ghost $\tilde{\bar{C}}_a$. The graphs in (c), (d) and (e) are three-point vertices, and those in (f) and (g) are four-point vertices. The (slowly vibrating) wavy line corresponds to the background diagonal gluon $\tilde{A}_i^\mu$, while the zig-zag line corresponds to the background anti-symmetric tensor field $^{\ast}B_{i\mu\nu}^\rho$.\(^{16}\)
4.3.2. Three-point vertices

(c) One diagonal and two off-diagonal gluons:

\[ i \left\langle \bar{A}_\mu^i(p) \tilde{A}_\sigma^a(q) \tilde{A}_\sigma^b(r) \right\rangle_{\text{bare}} = g f^{iab} \left[ (q - r)_\mu + \left\{ r - (1 - \rho) p + \frac{\alpha}{4} \right\}_\rho + \left\{ (1 - \rho) p - q - \frac{\rho}{4} \right\}_\sigma \right], \quad (42) \]

where we have introduced the abbreviated notation

\[ [A_\mu + B_\rho + C_\sigma] = A_\mu g_{\rho\sigma} + B_\rho g_{\sigma\mu} + C_\sigma g_{\mu\rho}. \quad (43) \]

(d) One diagonal gluon, one off-diagonal ghost and one anti-ghost:

\[ i \left\langle \bar{A}_\mu^i \tilde{C}_a^i (p) \tilde{C}_b^a(q) \right\rangle_{\text{bare}} = i(p + q)_\mu g f^{iab}. \quad (44) \]

(e) One diagonal tensor and two off-diagonal gluons:

\[ i \left\langle \bar{A}_\mu^i \tilde{A}_\rho^a \tilde{A}_\sigma^b \right\rangle_{\text{bare}} = -\sigma g (g_{\mu\rho} g_{\nu\sigma} - g_{\mu\sigma} g_{\nu\rho}) f^{iab}. \quad (45) \]

4.3.3. Four-point vertices

(f) Two diagonal gluons and two off-diagonal gluons:

\[ i \left\langle \bar{A}_\mu^i \tilde{A}_\rho^a \tilde{A}_\sigma^a \tilde{A}_\sigma^b \right\rangle_{\text{bare}} = i g^2 f^{ai\sigma} f^{bj\sigma} \left[ 2 g_{\mu\nu} g_{\rho\sigma} - \left( \frac{1}{2} - \frac{1}{\alpha} \right) (g_{\mu\rho} g_{\nu\sigma} + g_{\mu\sigma} g_{\nu\rho}) \right]. \quad (46) \]

(g) Two diagonal gluons, one off-diagonal ghost and one anti-ghost:

\[ i \left\langle \bar{A}_\mu^i \tilde{A}_\rho^a \tilde{C}_b^a \tilde{C}_b^a \right\rangle_{\text{bare}} = -2 g^2 f^{ai\sigma} f^{bj\sigma} g_{\mu\nu}. \quad (47) \]

4.4. Counterterms

By substituting the following renormalization relations into the Lagrangian (39),

\[ \bar{A}_\mu^i = Z_A^{1/2}(\bar{A}_R)^i_\mu, \quad \bar{B}_\mu^i = Z_B^{1/2}(\bar{B}_R)^i_\mu, \quad \rho = Z_\rho R, \quad g = Z_g g_R, \quad (48) \]

we obtain

\[ \bar{L}_{AB} = -\frac{1 - \rho^2}{4} \left( \bar{f}_{\mu\nu}^i \right)^2 + \frac{i}{2} \rho \bar{B}_\mu^i \ast \bar{f}_{\mu\nu}^i - \frac{1}{4} \left( \bar{B}_\mu^i \right)^2 \]

\[ = -\frac{1 - \rho^2}{4} Z_A \left[ \langle \bar{f}_R^i \rangle_{\mu\nu} \right]^2 + \frac{i}{2} Z_\rho Z_A^{1/2} Z_B^{1/2} \rho R (\bar{B}_R)^i_\mu \ast (\bar{f}_R)^i_{\mu\nu} \]

\[ -\frac{1}{4} Z_B \left[ \langle \bar{B}_R^i \rangle_{\mu\nu} \right]^2. \quad (49) \]

On the other hand, the renormalized Lagrangian with the counterterm is written as

\[ \bar{L}_{AB} = -\frac{1 - \rho^2}{4} \left[ \langle \bar{f}_R^i \rangle_{\mu\nu} \right]^2 + \frac{i}{2} \rho R (\bar{B}_R)^i_\mu \ast (\bar{f}_R)^i_{\mu\nu} - \frac{1}{4} \left[ \langle \bar{B}_R^i \rangle_{\mu\nu} \right]^2 \]

\[ -\frac{1}{4} \left[ \langle \bar{f}_R^i \rangle_{\mu\nu} \right]^2 + \frac{i}{2} \delta R (\bar{B}_R)^i_\mu \ast (\bar{f}_R)^i_{\mu\nu} - \frac{1}{4} \left[ \langle \bar{B}_R^i \rangle_{\mu\nu} \right]^2. \quad (50) \]
By equating (49) and (50), we find

\[ \delta_1 = Z_A^{(1)} - \left(Z_A^{(1)} + 2Z_{\rho}^{(1)}\right)\rho_R^2, \]

\[ \delta_2 = \left(Z_{\rho}^{(1)} + \frac{1}{2}Z_A^{(1)} + \frac{1}{2}Z_B^{(1)}\right)\rho_R, \]

\[ \delta_3 = Z_B^{(1)} , \]  

(51)

where we have used the expansion of the renormalization factor \( Z_\Phi = 1 + Z_\Phi^{(1)} + Z_\Phi^{(2)} + \cdots \), with \( Z_\Phi^{(n)} \) being the \( n \)-loop contribution.

### 4.5. \( \beta \)-function and anomalous dimension

The three propagators \( \left\langle (\bar{A}_R)^i_\mu (\bar{A}_R)^j_\nu \right\rangle, \left\langle (\bar{A}_R)^i_\mu *(\bar{B}_R)^j_\xi \right\rangle \) and \( \left\langle *(\bar{B}_R)^i_\mu*(\bar{B}_R)^j_\xi \right\rangle \) are obtained by calculating the Feynman graphs shown in Fig. 3, based on the Feynman rule given in Fig. 2. Consequently, (a1)+(a2)+(a3)+(a4), (b) and (c) give the counterterms of the respective propagator defined by

\[ i \left\langle (\bar{A}_R)^i_\mu (\bar{A}_R)^j_\nu \right\rangle_{\text{counter}} = -i\delta_1(q^2 g_{\mu \nu} - q_{\mu} q_{\nu})\delta^{ij}, \]

\[ i \left\langle (\bar{A}_R)^i_\mu *(\bar{B}_R)^j_\xi \right\rangle_{\text{counter}} = i\delta_2(q_\xi g_{\mu \eta} - q_\eta g_{\mu \xi})\delta^{ij}, \]

\[ i \left\langle *(\bar{B}_R)^i_\mu*(\bar{B}_R)^j_\xi \right\rangle_{\text{counter}} = -i\delta_3(g_{\mu \xi} g_{\nu \eta} - g_{\mu \eta} g_{\nu \xi})\delta^{ij}. \]  

(52)

Straightforward but somewhat tedious calculations employing dimensional regularization determine \( \delta_1, \delta_2 \) and \( \delta_3 \) as

\[
\delta_1 = \delta_{a1} + \delta_{a2} = \left[ (2 - \rho_R\sigma_R)^2 - \frac{1}{3} + \frac{1 - \alpha_R}{2} (2 - \rho_R\sigma_R)\rho_R\sigma_R \right] \frac{(\mu^{-\epsilon} g_R)^2}{(4\pi)^2} \frac{C_2(G)}{\epsilon},
\]

\[
\delta_{a1} = \frac{1}{3} \left[ \frac{(\mu^{-\epsilon} g_R)^2}{(4\pi)^2} \frac{C_2(G)}{\epsilon} \right],
\]

\[
\delta_{a2} = \left[ (2 - \rho_R\sigma_R)^2 - \frac{2}{3} + \frac{1 - \alpha_R}{2} (2 - \rho_R\sigma_R)\rho_R\sigma_R \right] \frac{(\mu^{-\epsilon} g_R)^2}{(4\pi)^2} \frac{C_2(G)}{\epsilon},
\]

\[
\delta_2 = \left[ (2 - \rho_R\sigma_R)^2 - \frac{1}{3} + \frac{1 - \alpha_R}{2} (2 - \rho_R\sigma_R)\rho_R\sigma_R \right] \frac{(\mu^{-\epsilon} g_R)^2}{(4\pi)^2} \frac{C_2(G)}{\epsilon},
\]

\[
\delta_3 = \left[ (2 - \rho_R\sigma_R)^2 - \frac{2}{3} + \frac{1 - \alpha_R}{2} (2 - \rho_R\sigma_R)\rho_R\sigma_R \right] \frac{(\mu^{-\epsilon} g_R)^2}{(4\pi)^2} \frac{C_2(G)}{\epsilon},
\]

Fig. 3. Vacuum polarization graphs that are necessary to obtain three propagators (52) at the one-loop level.
\[ \delta_2 = \left[ \sigma_R (2 - \rho_R \sigma_R) - \frac{1 - \alpha_R}{2} \sigma_R (1 - \rho_R \sigma_R) \right] \frac{(\mu^{-\epsilon} g_R)^2 C_2(G)}{(4\pi)^2} \epsilon, \]
\[ \delta_3 = -\frac{1 + \alpha_R}{2} \frac{\sigma_R}{\sigma_R} \frac{(\mu^{-\epsilon} g_R)^2 C_2(G)}{(4\pi)^2} \epsilon, \]

where \( \delta_{a1} \) and \( \delta_{a2} \) are the contributions from the graphs (a1) and (a2) in Fig. 3 respectively. \(^1\) \( C_2(G) \) is a quadratic Casimir operator defined by \( C_2(G) \delta^{AB} = f^{ACD} f^{BCE} \) and \( C_2(G) = N \) for \( G = SU(N) \). For a special choice of the parameters, \( \rho = \sigma = 0 \) and \( \alpha = 0 \), \( \delta_1 \) has been calculated by Quandt and Reinhardt, \(^8\) at least for \( SU(2) \). Finally, by equating (51) and (53), we obtain

\[ Z_A^{(1)} = \frac{11}{3} \frac{(\mu^{-\epsilon} g_R)^2 C_2(G)}{(4\pi)^2} \epsilon, \]
\[ Z_B^{(1)} = -\frac{1 + \alpha_R}{2} \frac{\sigma_R}{\sigma_R} \frac{(\mu^{-\epsilon} g_R)^2 C_2(G)}{(4\pi)^2} \epsilon, \]
\[ Z_\rho^{(1)} = \left[ -\frac{11}{6} - \frac{\sigma_R}{2} + 2 \frac{\sigma_R}{\rho_R} - \frac{1 - \alpha_R}{2} \left( \frac{\sigma_R}{\rho_R} - \frac{\sigma_R}{2} \right) \right] \frac{(\mu^{-\epsilon} g_R)^2 C_2(G)}{(4\pi)^2} \epsilon. \]  

The renormalization factor of the coupling constant is obtained from (35) as

\[ Z_g^{(1)} = -\frac{1}{2} Z_A^{(1)} = -\frac{11}{6} \frac{(\mu^{-\epsilon} g_R)^2 C_2(G)}{(4\pi)^2} \epsilon. \]  

This implies that the renormalization of \( g \) is independent of \( \rho, \sigma \) and the gauge parameter \( \alpha \). Therefore, the beta-function is also independent of the choice of \( \rho, \sigma \) and the gauge parameter \( \alpha \). The resulting beta-function coincides exactly with the one-loop beta-function of the original \( SU(N) \) Yang-Mills theory,

\[ \beta(g_R) := \frac{\partial g_R}{\partial \mu} = -g_R \frac{\partial}{\partial \mu} \ln Z_g = -\frac{b_0}{(4\pi)^2} g_R^3 + \mathcal{O}(g_R^5), \quad b_0 = \frac{11}{3} C_2(G), \]  

exhibiting asymptotic freedom. Moreover, the anomalous dimensions of the fields \( A'_\mu \) and \( B'_{\mu\nu} \) and the parameters \( \rho \) and \( \beta \) are obtained as

\[ \gamma_A(g) = \frac{1}{2} \frac{\partial}{\partial \mu} \ln Z_A = -\frac{11}{3} C_2(G) \frac{g_R^2}{(4\pi)^2}, \]
\[ \gamma_B(g) = \frac{1}{2} \frac{\partial}{\partial \mu} \ln Z_B = \frac{1 + \alpha_R}{2} \sigma_R C_2(G) \frac{g_R^2}{(4\pi)^2}, \]
\[ \gamma_\rho(g) = -\rho_R \frac{\partial}{\partial \mu} \ln Z_\rho \]
\[ = -2 \rho_R \left[ \frac{11}{6} + \frac{\sigma_R}{2} - 2 \frac{\sigma_R}{\rho_R} + \frac{1 - \alpha_R}{2} \left( \frac{\sigma_R}{\rho_R} - \frac{\sigma_R}{2} \right) \right] C_2(G) \frac{g_R^2}{(4\pi)^2}, \]
\[ \gamma_\beta(g) = -\beta_R \frac{\partial}{\partial \mu} \ln Z_A = -2 \gamma_A(g) \beta_R. \]  

\(^1\) In fact, the contributions from (a1) and (a2) are transverse, as suggested by the background field method.\(^18\) By contrast, both contributions from (a3) and (a4) vanish in the dimensional regularization.
It turns out that the anomalous dimension depends in general on the gauge parameter \( \alpha \). But \( \gamma_A \) is independent of \( \alpha \), as expected from the background field method.\(^{18}\)

§5. Conclusion and discussion

By requiring renormalizability, we have derived a renormalizable APEGT as a low-energy effective theory of QCD. The essential part is given by

\[
\mathcal{L}_{\text{APEGT}} = - \frac{1}{4} \rho_R^2 \left[ (\bar{f}_R)^i_{\mu
u} \right]^2 - \frac{1}{4} \left[ (\bar{B}_R)^i_{\mu
u} \right]^2 + \frac{i}{2} \rho_R (\bar{B}_R)^i_{\mu
u} * (\bar{f}_R)^{\mu\nu i} . \tag{58}
\]

The coupling constant \( g_R \) in the APEGT runs according to the \( \beta \)-function, which is exactly the same as in the original Yang-Mills theory. The obtained \( \beta \)-function is independent of the parameters \( \rho \) and \( \sigma \) and the gauge fixing parameter \( \alpha \) of the MA gauge.

The advantages of the renormalizable APEGT are as follows. Thanks to the renormalizability, the relation between the dual field \( B_{\mu\nu} \) and the original field \( f_{\mu\nu} \) is preserved after the renormalization:

\[
(\bar{B}_R)^i_{\mu\nu} = i \rho_R * (\bar{f}_R)^i_{\mu\nu} . \tag{59}
\]

Note that \( \sigma \) does not appear in this relation, simply because we have set \( \bar{A}_a^\mu = 0 \) in the derivation of (39). Moreover, we can switch the APEGT to the electric theory by putting \( \rho_R = 0 \), in which case we have

\[
\mathcal{L}_A = - \frac{1}{4g_R^2} \left[ (\bar{f}_R)^i_{\mu\nu} \right]^2 , \tag{60}
\]

where we have rescaled the field by the coupling constant. Hence we can avoid the unnatural argument used for deriving this form given in Eq. (2.58) of Ref. 7). We thus find that the APEGT is expected to be closed at each loop.

In a similar way, we can switch the APEGT to another theory by setting \( \rho_R = 1 \), which yields

\[
\mathcal{L}_B = - \frac{1}{4} \left[ (\bar{B}_R)^i_{\mu\nu} \right]^2 + \frac{i}{2g_R} (\bar{B}_R)^i_{\mu\nu} * (\bar{f}_R)^{\mu\nu i} , \tag{61}
\]

without an unusual renormalization factor. This is a candidate of the magnetic theory, as demonstrated in §IV of Ref. 7). Moreover, after decomposing the antisymmetric tensor \( B^i_{\mu\nu} \) into the (dual) gauge field \( \bar{b}_i^\mu \) using the Hodge decomposition and integrating out \( \bar{b}_i^\mu \),\(^{\ast}\) we obtain the monopole action,

\[
S_M[k] = \int d^4x \int d^4y \frac{1}{g_R} k^\mu(x) D_{\mu\nu}(x,y) k^\nu(y) , \tag{62}
\]

where \( D_{\mu\nu}(x,y) \) is the massless vector propagator and \( k^\mu \) is the magnetic monopole current defined by

\[
k^\mu := \partial^\nu * \bar{f}_R^{\mu\nu} . \tag{63}
\]

\(^{\ast}\) To be more precise, we must integrate out the moduli characterizing the solution of the equation of motion when \( \bar{b}_i^\mu \) is regarded as a solution of the equation of motion.
This derivation should be compared with that of Eq. (4.4) in Ref. 7.

An off-diagonal gluon mass is generated by the quartic ghost interaction, which is necessary for renormalizability, \(^{19}\) since the MA gauge is a nonlinear gauge (see Refs. 15, 20 and 21 for details). It is desirable to include this effect in the APEGT within the above framework. Such a study will be reported in Ref. 16). Another important question to be answered is whether the above derived structure of the APEGT is preserved at the two-loop level. These issues too will be discussed in Ref. 16).
