ABSTRACT α-Lipoic acid (LA) has demonstrated antioxidant effects in humans and laboratory animals. The objective of this study was to determine whether the effects of LA are similar in horses. Five Thoroughbred geldings were supplemented with 10 mg/kg/d of α-L-lipoic acid in a molasses and sweet feed carrier and five received only the carrier as a placebo (CON). Blood samples were obtained at baseline (0 d), after 7 and 14 d of supplementation, and 48 h postsupplementation (16 d). Blood fractions of red and white blood cells (RBC and WBC, respectively) and plasma were analyzed for glutathione (GSH), glutathione peroxidase (GPx) and total plasma lipid hydroperoxides (LPO). An experienced veterinarian observed no adverse clinical effects. Plasma LPO baselines differed between groups ($P = 0.002$). When covariates were used, there was a decrease over time in the LA group ($P = 0.015$) and concentrations were lower in the LA group than in the CON group at 7 and 14 d ($P = 0.022$ and $P = 0.0002$, respectively). At baseline, GSH concentration was $69 \pm 7$ in WBC and $113 \pm 13$ mmol/mg protein in the RBC, with no differences resulting from either time or treatment. The GPx activity was $47 \pm 4$ and $26 \pm 5$ u/g protein at baseline WBC and RBC, respectively, with a lower concentration in the LA group’s WBC at 7 ($P = 0.019$) and 14 d ($P = 0.013$). The results show that 10 mg/kg LA had no evident adverse effects, and moderately reduced the oxidative stress of horses allowed light activity. These findings encourage studying of LA in horses subjected to strenuous exercise.

KEY WORDS: oxidative stress • horse • lipid hydroperoxides • glutathione • dihydrolipote

\textsuperscript{1} Presented as part of the Waltham International Symposium: Pet Nutrition Coming of Age held in Vancouver, Canada, August 6–7, 2001. This symposium and the publication of symposium proceedings were sponsored by the Waltham Centre for Pet Nutrition. Guest editors for this supplement were James G. Morris, University of California, Davis, Ivan H. Burgler, consultant to Mars UK Limited, Carl L. Keen, University of California, Davis, and D’Ann Finley, University of California, Davis.

\textsuperscript{4} Abbreviations used: α-TOC, α-tocopherol; CON, control supplemented group; DHLA, dihydrolipoic acid; GSH, glutathione; GPx, glutathione peroxidase; HBSS, Hank’s balanced salt solution; LA, lipoic acid; LPO, lipid hydroperoxides.

α-Lipoic acid (LA)\textsuperscript{4} and its reduced form, dihydrolipoic acid (DHLA), have received widespread attention as antioxidants with both preventative and therapeutic uses in humans and laboratory animals (1). They have potential value in production and companion animals during periods of oxidative stress. α-Lipoic acid is an eight-carbon structure that contains a disulfide bond as part of a dithiolane ring with a five-carbon tail. It is a cofactor in the conversion of pyruvate to acetyl CoA as part of the pyruvate dehydrogenase complex. Both LA and DHLA also protect the integrity of cell membranes by interacting with antioxidants—glutathione (GSH) and vitamin E and C (1). In vitro, intracellular GSH was positively correlated to the concentration of LA, which may play a role with cysteine (2,3).

Lipoic acid is both water- and fat-soluble, and thus may regenerate water- and fat-soluble antioxidants, such as vitamin C and vitamin E. Rats consuming a vitamin E–deficient diet with added LA had no symptoms of vitamin E deficiency, unlike the rats on a vitamin E–deficient diet alone (4). The low α-tocopherol (α-TOC) concentrations in the tissues of LA-supplemented rats suggest that LA eliminates symptoms of vitamin E deficiency by sparing α-TOC.

Another function of LA and DHLA is to scavenge free radicals. Both LA and DHLA eliminate hydroxyl radicals and hypochlorous acid with a potency comparable to that of glutathione and N-acetylcysteine (5,6). However, only DHLA eliminated superoxide, peroxyl and ascorbyl radicals. Both LA and DHLA did not interact directly with chromanoxyl radicals of vitamin E; however, DHLA did reduce ascorbyl radicals and showed a DHLA/ascorbic acid–mediated reduction of chromanoxyl radicals (7,8). These studies demonstrate the importance of LA as a protective compound during oxidative metabolism.

Lipoic acid has been shown to have effects during exercise.
stress, aging and metabolic disease. Khanna et al. (9) compared rested and exercised rats supplemented with or without LA. The LA supplemented rats, both rested and exercised, had a higher GSH concentration, and a lower lipid peroxidation level measured by thiobarbituric acid reactive substances compared to those of nonsupplemented rats. During aging, mitochondria use oxygen inefficiently in ATP synthesis. Old rats supplemented with LA had a higher mitochondrial membrane potential, ambulatory activity, GSH and ascorbate concentration; furthermore, the malondialdehyde concentration was five times higher in the nonsupplemented rats (10). Lipoic acid was also used in humans to test its effectiveness on relieving diabetic symptoms (11). Three different doses of LA were compared to a placebo over a period of 19 d. After 5 d patients dosed with 1200, 600 or 100 mg LA had a greater decrease in the severity of their symptoms than patients given a placebo. Other human tests also show positive results when tested the severity of their symptoms than patients given a placebo. Focus on the effects of time, treatment and time by treatment interaction (P = 0.031). The area under the LPO curve was found to be greater (P = 0.004) for the LA group (96.9 ± 15.7 μM d⁻¹) than for the CON group (28.2 ± 7.1 μM d⁻¹). At baseline, the GSH concentration was 69 ± 7 and 115 ± 13 nmol/mg protein in the white and red blood cells, respectively, and was not significantly different between groups. Red blood cell GSH tended to increase with time (P = 0.074) and white blood cell GSH increased with time (P = 0.017) and tended to increase with treatment (P = 0.071). There were no significant interactions between time and treatment for either red blood cell or white blood cell GSH. The GPx activity in the white blood cells (Fig. 2) was 50.6 ± 1.6 μmol/min/mg protein for CON and 43.6 ± 0.33 μmol/min/mg protein for LA at baseline (P = 0.041). The change in concentration was higher in the LA group at 14 d (P = 0.019) and 16 d (P = 0.013) than that in the CON group. The red blood cell GPx showed no differences for time or treatment.

**RESULTS**

An experienced veterinarian observed no adverse clinical signs, including gastrointestinal distress, in the group supplemented with LA. Total plasma LPO (Fig. 1) was 9.32 ± 0.78 μM for CON and 13.56 ± 0.45 μM for LA at baseline (P = 0.0016). The concentrations decreased over time in the LA group (P = 0.015) and were lower in the LA group than in the CON group at 7 and 14 d (P = 0.022 and P = 0.0002, respectively). There was also an effect of treatment and time by treatment interaction (P = 0.031). Other than the effects of time, treatment and time by treatment interaction (P = 0.031). The area under the LPO curve was found to be greater (P = 0.004) for the LA group (96.9 ± 15.7 μM d⁻¹) than for the CON group (28.2 ± 7.1 μM d⁻¹). At baseline, the GSH concentration was 69 ± 7 and 115 ± 13 nmol/mg protein in the white and red blood cells, respectively, and was not significantly different between groups. Red blood cell GSH tended to increase with time (P = 0.074) and white blood cell GSH increased with time (P = 0.017) and tended to increase with treatment (P = 0.071). There were no significant interactions between time and treatment for either red blood cell or white blood cell GSH. The GPx activity in the white blood cells (Fig. 2) was 50.6 ± 1.6 μmol/min/mg protein for CON and 43.6 ± 0.33 μmol/min/mg protein for LA at baseline (P = 0.041). The change in concentration was higher in the LA group at 14 d (P = 0.019) and 16 d (P = 0.013) than that in the CON group. The red blood cell GPx showed no differences for time or treatment.

**DISCUSSION**

The results showed that LA had antioxidant effects on horses, similar to that shown in other species (1). Our study raises the possibility that LA may have potential benefits in horses during periods of oxidative stress, such as endurance...
exercise (13). Oral supplementation of LA at 10 mg/kg daily did not result in any adverse signs over a 14-d period.

The dose of 10 mg/kg body weight was chosen by referring to LA's effectiveness in other species. It is effective in the rat at a dose of 10 to 100 mg/kg or about 40 to 200 mg/kg (9,10) and in humans at a dose of 600 to 1200 mg (about 8.5 to 17 mg/kg) or about 25 to 50 mg/kg (11). It caused gastrointestinal distress, however, at the high dosage (11). Our hypothesis was that a dose of 10 mg/kg or about 50 mg/kg (11) would diminish oxidative stress in horses after being supplemented for 14 d, which is the average duration studied in other species, without causing any clinical signs of toxicity.

In humans LA was used in 260 non-insulin-dependent diabetic patients to determine whether it relieved symptoms of diabetic neuropathy including pain, burning, paralysis and numbness (11). Three different doses of LA were compared to a placebo over a period of 19 d. Patients were tested and symptom score than with the placebo, and after 12 and 19 d the decrease was found in the 1200 and 600 mg dosed patients. A series of studies focusing on the LA interaction with GSH performed by Han et al. (2,3) stimulated our interest in this same interaction in red and white blood cells. In vitro, human T-lymphocytes cells, bathed in various concentrations of LA, increased the intracellular level of GSH; this increase had a positive correlation to the concentration of LA added to the medium (3). When 100 µM LA was added, GSH increased 45.8% over that of the control group after 24 h, and DHLA and GSH levels were positively correlated (r = 0.57, P < 0.01). This result suggests that DHLA is a contributing factor to the GSH increase after the addition of LA.

In our study, however, the GSH concentration might have changed transiently in response to LA then reverted to normal values after 24 h when the next blood sample was taken. Lipic acid is rapidly converted to DHLA once inside the cell; it is then transported out of the cell and used as an antioxidant (1). Dihydrolipoic acid is very reactive and rapidly used so the effects on antioxidant may not be long lasting. Further studies are planned to see whether the same dose of 10 mg/kg LA would have antioxidant effects on antioxidant status and oxidative stress from immediately after supplementation up to 48 h post-supplementation.

In our study, the decrease in white blood cell GPx activity in the CON group, and the slightly less marked decrease in the LA group may be attributable to the weather conditions. During wk 1 of the study (mid-January) the weather was mild with sunny conditions, into wk 2 of the study, for the last two sample times, temperatures dropped to near freezing and precipitation increased to freezing rain/snow. It is possible that the weather played a role in the level of oxidative stress in these geldings, which are housed outside 24 h/d. This environmental stress would increase activity level and oxygen consumption, thus increasing reactive oxygen species and oxidative stress, and might explain why the LA group had less of a change in the GPx activity compared to that of the CON group.

Other studies have used GPx as well as other antioxidant enzymes to measure the effects of oxidative stress. Superoxide dismutase, catalase and GPx, along with a few nonenzymatic antioxidants, were used to determine whether LA decreased lipid peroxidation and increased antioxidant status in the mitochondria of aged rats (17). They found that with LA supplementation there was a lower level of lipid peroxidation and increased level of antioxidant action in the mitochondria, as determined by enzymatic and nonenzymatic antioxidants. In horses, Ji et al. (15) found that superoxide dismutase, catalase, glutathione reductase and GPx were numerically increased with an exercise protocol of 12 min of trotting at 4.5 m/s on a grade of 11%; however, these values were not significant. They also found that, after supplementing with vitamin E before exercise, these oxidative stress measures were also unchanged. This could possibly be because these horses were conditioned to the protocol and the amount of work was not great enough to induce oxidative stress.

Implications

The supplementation of α-lipoic acid has been shown previously to increase antioxidant status and decrease oxidative stress in the horse and in other species. It favors regeneration of antioxidants including vitamin E and C, and glutathione, and thus decreases the need for their supplementation. The present findings encourage testing of lipoic acid supplementation in horses subjected to oxidative stress, for example, during strenuous exercise and prolonged transport.
