Keywords: Bone cyst; Chest wall; Fibrous dysplasia; Trauma

A 39-year-old woman with a painfull mass of right chest wall (Fig. 1) is presented. Her ribs had been broken, 13 years ago during the delivery. We performed chest wall resection and reconstruction with a graft (Fig. 2).

![Fig. 1. CT scan demonstrated both cystic (C) and solid (S) lesions at the sixth rib. The solid lesion was in the anterior and lateral portion, whereas the cystic lesion was located in the middle, and inner part.](image1)

![Fig. 2. The inner surface of the resection material is seen. Cystic (C) and solid (S) areas are in close vicinity. The cortex of the rib was very soft and thin over the cystic area. Approximately 50 ml yellowish-brown clear fluid was aspirated. No malignancy was found in the fluid and pathologic examination of the specimen revealed fibrous dysplasia.](image2)
