A previously healthy 6-year-old boy who recently immigrated to the United States from Honduras presented with a history of fever, abdominal pain, and headache. When first evaluated in the emergency department, his vital signs were normal, but his temperature spiked to 41.6°C (axillary), and he vomited 3 times. The physical examination revealed a child of normal height and weight for his age and was remarkable for a palpable spleen tip and a liver that extended 1 cm below the right costal margin. A complete blood count was performed by use of an automated blood-cell analyzer (Cell-Dyn 4000 [Abbott]); figure 1 shows the resulting scattergram.
