

genetics, and evolution. DNA is carefully described and even embryology is taken up in some detail. Yet the ecological approach is not ignored for there are beautifully written chapters on it. Approximately half the book is on genetics, embryology, and evolution.

A most unusual elementary biology book which reflects current trends in more sophisticated and advanced treatments. Every elementary teacher will want this book.

PLANTS, VIRUSES, AND INSECTS, Katherine Esau, viii + 110 p., \$3.75, Harvard University Press, Cambridge, Massachusetts, 1961.

The title of this book is misleading, since most of the text is devoted to a review of our knowledge of the translocation of organic materials in plants. Viruses and insects rate a chapter each, but they are considered principally in relation to our knowledge of the vascular tissue of plants.

Esau has given us an excellent discussion of the structure and probable function of the components of the phloem. Conduction of organic material is effected in the enucleate sieve elements at rates of 50 to 100 cm/hr or more. She believes that the mechanism is a mass-flow rather than diffusion, and that the movement into and out of the sieve elements is brought about by the activities of nucleate cells associated with them.

This book is recommended to teachers as a means for stimulating student interest in plant structure and physiology.

PLANT LIFE OF PALESTINE, Michael Zohary, Ed., 262 pp., \$8.00, The Ronald Press Company, New York 10, 1962.

This book presents a geographical and ecological survey of the vegetation of the area comprising Israel, Jordan, and the Gaza Strip. The land is a strange combination of desert, sand dunes, calcareous hills, heavy clay soils, and extensive swamps and marshes, a part of it occupying the deep rift of the Jordan valley and the Dead Sea. The annual rainfall ranges from scarcely an inch to as much as 40 inches, with wide fluctuations from year to year, especially in the desert regions. The area has been the meeting point of three great floras, one from the north, one from the Mediterranean, and one from Africa and Asia to the south and southeast. All these factors of soil, climate, and geographic position have given it a far richer flora than is to be found in most areas of similar size. The more than

2200 species, at least 160 of them endemic, are distributed among 718 genera. Centuries of human occupation have also had profound influences on the flora.

The book utilizes the heavy language of modern ecology, much of which could have been avoided without loss of clarity. It will give much new meaning to the taxonomic data already available for the area. The Bible student will probably find it disappointing. The typography and illustrations are excellent. The price for 226 pages of text and illustrations seems high, but this may be unavoidable in a book which is so highly specialized.

RADIATION BOTANY, A. H. Sparrow, Ed., 100 pp., \$10.00 yearly, Pergamon Press, London, 1961.

The first issue of this journal "devoted to plant radiobiology and closely related fields" is a collection of excellent papers which, at first glance, seems to justify the addition of another journal to the already burgeoning list. Closer inspection reveals that many of the papers would have been more closely associated with similar research areas if they had been published in journals devoted to cytology, physiology, or morphogenesis. In these papers, radiation enters the picture as a tool for the investigation of some fundamental problem. As a consequence the papers are quite substantial, but the coherence within the journal seems artificial.

Nevertheless the first issue does credit to the publishers, to the editors, and to the authors. Although all the papers in this issue are in English, the journal will be multilingual and each article is provided with summaries in French, English, and German. Typographical errors abound in the German but the French and English summaries, as well as the text, are singularly free of them. There are few reproductions of photographs, but those included are very clear. If the high quality is maintained the new journal should provide a valuable reference for the effects of radiations on plants. It is also possible, with some reservations, to regard as a service the grouping together of investigations in various disciplines which employ radiations as a tool.
