Re: Impact of Stromal Sensitivity on Radiation Response of Tumors

In regard to our earlier report (1), we recently discovered by karyotyping that the cell line derived from tumor cell line HGL9, which was originally derived from a human glioblastoma multiforme and maintained in tissue culture, now consists of murine cells. Unfortunately, the early passage of this cell line from which the experimental cells were derived is no longer available. The other human tumor cell lines used in this study have also been karyotyped and confirmed to be human. Because the aim of the study was primarily to evaluate the impact of stromal radiation sensitivity on tumor response, our discovery does not change the conclusions in any way.
