Increasing children’s physical activity levels during recess periods in elementary schools: the effects of providing game equipment

Stefanie J. M. Verstraete, Greet M. Cardon, Dirk L. R. De Clercq, Ilse M. M. De Bourdeaudhuij

Background: During recess, children can be active on a daily basis, making it an important school environmental factor for the promotion of health-related physical activity. The aim of the present study was to investigate the effects of providing game equipment on children’s physical activity levels during morning recess and lunch break in elementary schools. Methods: Seven elementary schools were randomly assigned to the intervention group (four schools), including 122 children (75 boys, 47 girls, mean age: 10.8 ± 0.6 years), and to the control group (three schools), including 113 children (46 boys, 67 girls, mean age: 10.9 ± 0.7 years). Children’s activity levels were measured before and three months after providing game equipment, using MTI accelerometers. Results: During lunch break, children’s moderate and vigorous physical activity significantly increased in the intervention group (moderate: from 38 to 50%, vigorous: from 10 to 11%), while it decreased in the control group (moderate: from 44 to 39%, vigorous: from 11 to 5%). At morning recess, providing game equipment was effective in increasing children’s moderate physical activity (from 41 to 45%), while it decreased in the control group (from 41 to 34%). Conclusion: Providing game equipment during recess periods was found to be effective in increasing children’s physical activity levels. This finding suggests that promoting physical activity through game equipment provision during recess periods can contribute to reach the daily activity levels recommended for good health.

Keywords: children, game equipment, health promotion, physical activity, school playtime

Regular physical activity (PA) during childhood and adolescence is associated with improvements in physiological and psychological health. Nevertheless, a substantial proportion of young people have lower PA levels than recommended for good health. The Health Behaviour in School-aged Children (HBSC) survey, executed in approximately 1500 11-, 13- and 15-year-olds in each of the 35 participating countries in Europe and America, revealed that only 27% of all girls and 40% of all boys reported PA levels that met the guideline of ‘one hour or more of at least moderate intensity activity on five or more days a week’. Furthermore, it is well documented in the literature that PA levels decline from childhood to adolescence and adulthood, and tracking studies have revealed that low levels of PA remain stable from adolescence into adulthood. Therefore, the promotion of regular PA among youth is an important public health challenge.

Schools are ideal settings for the promotion of PA since all children can be reached. Schools can provide opportunities to engage in PA during physical education (PE) classes, during recess periods and after school hours (extracurricular activities). Furthermore, informing children and their parents about the importance of lifelong PA and the possibilities to be active in the community can contribute to the development of an active and healthy lifestyle.

A lot of intervention studies have focused on PE classes to increase children’s PA levels at school. However, in most countries PE classes can not provide sufficient activity for children to meet the health-related recommendation of 60 min or more of moderate to vigorous physical activity (MVPA) engagement each day. While school time allocated to PE is limited, recess is scheduled for more periods each day, making it an important school environmental factor for the promotion of PA. During recess, all children can be active on a daily basis. Furthermore, children are typically engaged in unstructured PA during recess, preparing them for adult engagement.

Moreover, during recess is mostly limited to the toys children bring along from home. Providing game equipment for everyone and having teachers encouraging the children to use the equipment may promote children’s MVPA engagement during recess. Scruggs et al. found that structured fitness training breaks provide high-activity levels for both boys and girls. Furthermore, some authors suggested that providing extra game equipment during recess and lunch break may promote high-activity levels. In most schools, the availability of game equipment during recess is mostly limited to the toys children bring along from home. Providing game equipment for everyone and having teachers encouraging the children to use the equipment may promote children’s MVPA engagement during recess. However, in the literature, no study could be located evaluating the effect of providing extra game equipment on children’s activity levels at recess periods. Since most European elementary schools organize several recess periods per day, stimulating PA during recess
Accelerometers were used to measure children’s PA levels. The accelerometer has been shown to be a valid, reliable and objective method for monitoring PA in children.24 In the present study, the MTI Actigraph model 7164 (Manufacturing Technologies Inc., Shalimar, FL) was used. The MTI Actigraph is a uniaxial accelerometer designed to measure and record time varying vertical accelerations ranging in magnitude from 0.05 to 2 Gs, with a frequency response ranges from 0.25 to 2.5 Hz. These frequencies were chosen to detect normal human motion and to reject motion from other sources. For the present study, a one-minute sampling interval was used. The one-minute movement counts were downloaded into a personal computer and converted into an Excel file for subsequent analyses. To convert the total activity counts into light (<3 METs), moderate (3.0–5.9 METs) and vigorous intensity activity (>6.0 METs), the accelerometer count cutoffs of Trost et al.7 were used. MODerate and vigorous intensity activities were summed to indicate MVPA engagement. To control for the differences in recess length, accelerometer data were expressed in percentages of recess time.

Children’s PA levels in both groups were measured before (pretest) and three months after providing the game equipment in the intervention schools (posttest). A research staff member put the accelerometers on in the morning (before the lessons started) and collected them the same day at school after lunch break. The accelerometer data of morning recess and lunch break were used. The accelerometer was worn just above the right hipbone underneath clothes and was held in place by an elastic belt. To prevent the children from increasing their activity level by wearing the accelerometer, they were only informed about the purpose of the measurements after the posttest measurement. Pretest and posttest measurements were organized on days with dry weather conditions, allowing the children to play outdoors.

**Results**

Descriptive data of the total sample at pretest showed that the children were engaged in MVPA during 56% (SD 26) of the time at recess and during 51% (SD 24) of the time at lunch break. Boys engaged in MVPA during 68% (SD 21) of the time at recess and during 57% (SD 24) of the time at lunch break. Girls engaged in MVPA during 42% (SD 23) of the time at recess and during 44% (SD 22) of the time at lunch break.

Table 1 presents the percentages of time spent on low, moderate, vigorous and moderate to vigorous intensity PA during morning recess for the intervention and the control group at pretest and posttest measurements. Significant intervention effects were found for the time spent on low ($F = 4.7$, $P < 0.05$), moderate ($F = 10.6$, $P < 0.001$) and moderate to vigorous intensity PA ($F = 6.5$, $P < 0.01$). The time spent on moderate intensity activities increased significantly in the intervention group, while it decreased in the control group. The time

Table 2 presents the percentages of time spent on low, moderate, vigorous and moderate to vigorous intensity activities during lunch break for the intervention and the control group at pretest and posttest measurements. Significant intervention effects were found for low (F = 50.5, P < 0.001), moderate (F = 28.3, P < 0.001), vigorous (F = 44.2, P < 0.001) and moderate to vigorous (F = 42.7, P < 0.001) intensity activities. The time spent on moderate, vigorous and moderate to vigorous intensity PA increased significantly in the intervention group, while it decreased in the control group. The time spent on low intensity PA decreased in the intervention group and increased in the control group. No significant gender differences (time x group x gender) were found for the accelerometer data during lunch break. No significant differences between ‘active’ and ‘less active’ children were found (F < 1.6, ns).

Discussion

The aim of the present study was to evaluate the effects of providing game equipment on children’s PA levels during morning recess and lunch break. At pretest, children in the present study were engaged in MVPA for about half of the time during morning recess (36%) and lunch break (51%). These results were slightly higher than those reported in other studies, using objective measures. 16-20, 26-28 McKenzie et al. 18 found that elementary school children in the United States (mean age 6.6 year) engaged in MVPA during 48% of recess time. In a study by Stratton 19 5- to 7-year-old British children spent 35-41% of total recess time (including morning, lunch and afternoon playtime) engaged in MVPA. Slep et al. 29 found lower activity levels in 5- to 11-year-old British children during lunch break (46%), but similar MVPA engagement during recess (ranging from 55 to 59%). Furthermore, the results of the present study confirmed previous findings that boys were more active than girls during unstructured recess periods. 18,21,25

The higher percentages MVPA engagement in the present study is a positive finding. However, since children spent only an average of 50% of recess time engaged in MVPA, increasing children’s activity levels during recess periods is an essential and realistic objective. The results of the present study clearly indicated that providing game equipment was effective in increasing children’s activity levels during recess and lunch break. During lunch break, the intervention was effective in

 increasing the proportion of time children engaged in MVPA by increasing the time spent on moderate and high intensity activities and by decreasing the time spent on low intensity activities. The mean proportion of MVPA engagement increased with 13% in the intervention group (from 48 to 61%), while it decreased with 10% in the control group (from 55 to 45%). At recess, providing game equipment was effective in increasing children’s moderate intensity activities and reducing the decrease in the time spent on moderate to vigorous intensity activities. No effects were found on vigorous intensity activities. As no other studies evaluated the effect of providing game equipment on children’s activity levels during recess periods, the present results cannot be compared with other studies.

The stronger intervention effects during lunch break, compared with the morning recess, may be due to the length of the lunch break. The longer duration of lunch breaks may enable the children to organize and to play complete games with the equipment resulting in higher proportions of active time. However, more research is needed to investigate the effect of the duration of recess periods when game equipment is provided.

In both recess periods, the game equipment increased especially children’s moderate intensity activities, while children’s vigorous PA only slightly increased during lunch break (1.5%). This could be explained by the nature of the chosen game equipment, stimulating moderate intensity activities (e.g. flying discs, angle-stick, juggling material, etc.). Other game equipment may be needed to increase children’s vigorous PA engagement.

According to the present study and the literature, girls are less active than boys during recess periods. Therefore it is a challenge for schools to promote PA among both boys and girls. During lunch break, the intervention was as effective in boys as in girls, suggesting that the intervention suited both genders. At morning recess, providing game equipment was effective in girls, but not in boys. A possible explanation could be that boys were already very active at pretest, making it difficult to find significant improvements. In addition, the game equipment in the present study may mainly respond to girls’ interests, which can also explain this finding. Furthermore, the results of the present study indicated that providing game equipment was as effective in ‘active’ as in ‘less active’ children during morning recess and lunch break.

A drawback of the present study was the quasi-experimental design of the study. Another limitation of the study was that the influence of teacher’s encouragement to be active with the game equipment was not investigated. Since children seem to be responsive to encouragement for PA from adults, further research is needed to explore the role of teacher encouragement in using the game equipment. Further research should also examine the effect of increased activity levels at school on children’s activity levels at home since it is suggested in the literature that children compensate increased activity levels at school by decreasing their activity levels at home. On the other hand, Dale et al. indicated that children did not compensate for a sedentary school day by increasing their activity levels after school, emphasizing the importance of providing opportunities to be active at school.

Since all children can be active on a daily basis during recess, recess periods are important opportunities to promote PA at school. The results of the present study demonstrated that providing game equipment can increase children’s activity levels during recess periods. To our knowledge, this is the first demonstration that providing game equipment can be effective in increasing children’s PA levels during recess periods. Since a lot of European children are less active than recommended for good health, providing game equipment during recesses and lunch breaks are an easy way to improve children’s physical activity levels. Additionally, schools should also maximize children’s activity levels during PE classes and after school hours (extracurricular activities) and promote lifelong PA
participation at home. Evaluating the effects of providing game equipment over longer time periods is recommended.

Acknowledgements

This study is part of a broader research project entitled Sport, Physical activity and Health (Sport, Beweging en Gezondheid), carried out by the Policy Research Centre, a consortium of researchers from KULeuven, Ghent University and VUBrussel, and funded by the Flemish Government.

Key points

- A lot of young people have lower activity levels than recommended for good health.
- Recess periods are an important school environmental factor for the promotion of health-related physical activity in elementary school children.
- In the present study, the effect of providing game equipment during recess periods on children’s activity levels was evaluated.
- Game equipment provision significantly increased children’s activity levels during morning recess and lunch break.
- Providing game equipment during recess periods is recommended from a public health perspective.
