INTRODUCTION

Machado–Joseph Disease (MJD) is the most prevalent autosomal dominantly inherited cerebellar ataxia. It is caused by an expanded CAG repeat in the ATXN3 gene, which translates into a polyglutamine tract within the ataxin-3 protein. Present treatments are symptomatic and do not prevent disease progression. As calpain overActivation has been shown to contribute to mutant ataxin-3 proteolysis, translocation to the nucleus, inclusions formation and neurodegeneration, we investigated the potential role of calpain inhibition as a therapeutic strategy to alleviate MJD pathology. For this purpose, we administered orally the calpain inhibitor BDA-410 to a lentiviral mouse model of MJD. Western-blot and immunohistochemical analysis revealed the presence of N- and C-terminal mutant ataxin-3 fragments and the colocalization of large inclusions with cleaved caspase-3 in the mice brain. Oral administration of the calpain inhibitor BDA-410 decreased both fragments formation and full-length ataxin-3 levels, reduced aggregation of mutant ataxin-3 and prevented cell injury and striatal and cerebellar degeneration. Importantly, in correlation with the preserved cerebellar morphology, BDA-410 prevented motor behavioural deficits. In conclusion, BDA-410 alleviates Machado–Joseph neuropathology and may therefore be an effective therapeutic option for MJD.

mouse model leads to a worsening of behavioural and neuropathological abnormalities (13), suggesting that calpastatin depletion, meaning the lack of the internal inhibitor regulator, would contribute to calpain dysregulation leading to a calcium homeostasis imbalance, influencing the rate of ataxin-3 proteolysis and the subsequent neurodegeneration process (12–16). Together, these studies strongly suggest that calpain inhibition may be a promising strategy to alleviate MJD.

Gene therapy with viral vectors for overexpression of calpastatin is particularly adequate and translatable to clinical setting to treat well-defined CNS regions. However, as the neuropathology of MJD involves multiple systems such as cerebellar systems, substantia nigra, cranial nerve motor nuclei (17,18) and the striatum (19–22), a strategy able to reach broader distribution, while minimizing invasiveness, such as an orally administered low-molecular weight drug is also needed either as a single or complementary therapy. Therefore, in this study, we investigated whether a novel and highly specific cysteine protease inhibitor termed BDA-410 (23–26) would alleviate MJD. Using a lentiviral mouse model of MJD (12,19), we investigated whether this orally administered compound mediated neuroprotection.

Our results show that BDA-410 inhibited calpain-mediated proteolysis and decreased mutant ataxin-3 aggregation. In addition, this calpain inhibitor prevented cell injury, degeneration in the mouse brain resulting in the alleviation of behavioural deficits, suggesting that it may provide a new therapeutic choice for MJD.

RESULTS

BDA-410 inhibits calpain activity and decreases mutant ataxin-3 levels in vitro

Several evidences indicate that calpains cleave ataxin-3 producing proteolytic fragments that trigger MJD pathology (10–13), suggesting that calpain inhibition may provide an effective therapy for MJD. Therefore, we first investigated whether calpains could be inhibited by the novel oral calpain inhibitor BDA-410 (Fig. 1A) (23–26), in cultures of cerebellar granule neurons.

When calcium concentration increases in the intracellular compartment, a subset of axonal structural proteins is vulnerable to calpain activity, including αII-spectrin, a potential biomarker for neuronal cell injury (27). Interestingly, levels of the calpain-generated 150/145 kDa fragments of αII-spectrin were further increased when cerebellar granule neurons were transduced with lentiviral vectors encoding the mutant ataxin-3 (ATX-3 72Q) in opposition to wild-type ataxin-3 (ATX-3 27Q) and non-infected cultures (O). Importantly, BDA-410 (50 and 100 nm) mediated a decrease of the αII-spectrin fragments in cultures expressing mutant ataxin-3 (Fig. 1B and D). Furthermore, this calpain inhibition translated into a significant 21% decrease in immunolabeling of full-length mutant ataxin-3 (Fig. 1C and E).

Since the concentration of BDA-410 used in this experiment was very low (50 and 100 nm), much below the required to inactivate other proteases than calpains (typically in the μM range; see Materials and Methods for IC50 information), we conclude that the decreased levels of mutant ataxin-3 are due to a specific calpain inhibitory action. As a consequence, a reduced calpain-mediated cleavage of ataxin-3 might prevent the full-length protein and its fragments from escaping the cytoplasmic quality control mechanisms.

BDA-410 reduces cleavage of mutant ataxin-3 in a lentiviral mouse model of MJD

Therefore, in order to investigate whether orally administered BDA-410 would inhibit ataxin-3 cleavage in vivo, we daily administered the compound BDA-410 (30 mg/kg in 1% Tween80 saline in a volume equal to 5 ml/kg) by oral gavage to a lentiviral mouse model, wherein lentiviral vectors encoding for wild-type ataxin-3 (ATX-3 27Q) were injected in the left striatum hemisphere and mutant ataxin-3 (ATX-3 72Q) in the right hemisphere, a strategy that we use to generate models of disease (12,19,28–30). As a control, a group of animals received only the vehicle in which BDA-410 was resuspended for the treated group. After 4 weeks of treatment, mice were sacrificed and striatal tissue processed for western-blot analysis.

Two ataxin-3 fragments of ~26 and ~34 kDa were detected at high levels in the brain hemispheres expressing mutant ataxin-3, or less and not detected, respectively, in the brain hemispheres expressing wild-type ataxin-3 protein (Fig. 2A–C, arrowheads). In addition, the ~26 kDa fragment was detected using any of the three antibodies targeting ataxin-3 protein, namely: (i) Ab 1H9 (Fig. 2A), which recognizes the human ataxin-3 fragment from amino acids E214-L233, (ii) Ab 1C2 (Fig. 2B), an antibody specific for the polyQ stretch, present at ataxin-3 C-terminal and (iii) Ab myc (Fig. 2C), an antibody for a myc tag located at the N-terminal of the protein. In turn, the ~34 kDa fragment was only detected for the mutant protein and when using Ab 1H9 and Ab 1C2 (Fig. 2A and B), suggesting that while the ~26 kDa might be both a N- or C-terminal fragment, the ~34 kDa fragment is only C-terminal. Notably, calpains inhibition by BDA-410 administration significantly decreased by 50 and 37.6% the formation of the 26 kDa fragment of the wild-type and mutant ataxin-3, respectively (Fig. 2A and D). Furthermore, upon calpains inhibition, the levels of the ~34 kDa fragment despite not reaching significant difference (P = 0.068) tended to decrease (≈22.5%, Fig. 2A and E).

However, as we observed a general decrease of the different ataxin-3 species: aggregates (Figs 2A and 3G), fragments (Fig. 2D and E) and even a slight decrease of full-length (Fig. 2F), we hypothesized whether inhibition at the transcription level could be occurring. RNA extraction was then performed using the same experimental paradigm. Real-time PCR confirmed that the decreased fragmentation is not a consequence of a decreased mRNA expression, indicating that the reduction of mutant ataxin-3 fragment levels was not due to inhibition of transcription.

BDA-410 inhibits mutant ataxin-3 aggregation in vivo by decreased fragmentation

To investigate if reduced calpain-mediated production of fragments by BDA-410 would prevent the subsequent phenomena predicted by the toxic fragment hypothesis, namely seeding of intranuclear inclusions and neurodegeneration (5–7,10–12), we performed a similar experiment but now sacrificing the mice at a later time point (8 weeks post-injection) and processing the brains for immunohistochemistry.

Vehicle group transduced with ATX-3 72Q displayed a large number of mutant ataxin-3 (Fig. 3A and C) and ubiquitin (Fig. 3E) inclusions. Daily oral gavage of the calpain inhibitor
during 8 weeks promoted a 38% significant decrease in the number of mutant ataxin-3 inclusions (Fig. 3A–D and G) and a similar tendency regarding the number of ubiquitinated inclusions (Fig. 3E and F). No alteration was observed between treated and vehicle groups when ATX-3 27Q was expressed (Supplementary Material, Fig. S1A–F). These results support the idea that ataxin-3 cleavage by calpains is required for the subsequent aggregation process and that calpain inhibition can reduce mutant ataxin-3 aggregation by suppressing the formation of toxic cleavage fragments.

**Mutant ataxin-3 aggregates of specific size have different toxic properties**

To clarify these findings, we further analyzed the size of mutant ataxin-3 aggregates and correlated with cytotoxicity by...
Figure 2. BDA-410 decreased ataxin-3 fragmentation in vivo. Western-blot of mice 4 weeks post-injection of lentiviral vectors encoding for wild-type ataxin-3 (ATX-3 27Q; left hemisphere) and mutant ataxin-3 (ATX-3 72Q; right hemisphere) in the striatum after daily gavage of vehicle (1% Tween80 saline; n = 4) or BDA-410 (n = 4). Depicted are blots of a pool of four animals for each condition using several antibodies to detect different epitopes of ataxin-3 protein: (A) Ab 1H9, which recognizes amino acids E214-L233; (B) Ab 1C2, specific for the polyglutamine stretch, present at the C-terminal of ataxin-3; and (C) Ab myc, which recognizes myc tag located at the N-terminal of mutant ataxin-3. (D–F) Densitometric quantification of ~26 kDa fragment, ~34 kDa fragment and full-length levels of ataxin-3, using Ab 1H9, relative to actin (n = 4, *P < 0.05, **P < 0.01).
evaluation of cleaved caspase-3 immunoreactivity, an end-stage effector of apoptotic cell death. Calpains inhibition by BDA-410 administration mediated a small decrease in aggregates size of 0.22 μm (Fig. 4A–F and M). Even though fragments and soluble oligomers are thought to be the toxic species and contribute to aggregation (6), we found that larger aggregates (mean diameter: 4 μm) co-localized significantly more with cleaved caspase-3 than smaller aggregates (mean diameter: 1.6 μm) (Fig. 4G–L and N) for both groups. However, upon calpains inhibition, the number of mutant ataxin-3 positive cells co-expressing cleaved caspase-3 significantly decreased by 14% (Fig. 4G–L and O). Interestingly, in common cases where mutant ataxin-3 remained perinuclear, such as the representative cell pointed with an arrow in Figure 4L, no cleaved caspase-3 immunoreactivity was observed suggesting that ataxin-3 nuclear localization is necessary for caspase-3 activation. These results show that mutant ataxin-3 aggregates of specific size have different toxic properties and suggest that BDA-410-mediated calpain inhibition decreases fragmenta- tion, mutant ataxin-3 seeding and aggregation, with a small effect in aggregates size but promoting an important decrease in cytotoxicity.

BDA-410 mediates neuroprotection

To confirm that BDA-410 mediates neuroprotection, we monitored the effects of its oral administration over neuronal dysfunction, which may precede degeneration and clinical symptoms induced by mutant ataxin-3 (31). In this sense, we performed an immunohistochemical analysis for DARPP-32, a regulator of dopamine receptor signaling (32), as we have previously shown that it is a sensitive marker to detect early neuronal dysfunction (19,28). Accordingly, the volume of the region depleted of DARPP-32 immunoreactivity was robustly and significantly reduced by 46% in the treated group when compared with the vehicle group (Fig. 5A–D and G).

Additionally, cresyl violet-stained sections further demonstrated that calpain inhibition promoted a significant reduction of 30% in the number of shrunken hyperchromatic nuclei (Fig. 5E, F and H), induced by mutant ataxin-3 expression in the brain of adult mice. No loss of DARPP-32 staining or increase of degenerated shrunken hyperchromatic nuclei was observed in the hemispheres of mice expressing ATX-3 27Q treated or not with the calpains inhibitor compound (Supplementary Material, Fig. S1G–J).

Overall, these results are indicative of a neuroprotective effect provided by BDA-410 in a genetic mouse model of MJD.

BDA-410 alleviates motor disabilities

To analyze if the neuroprotection mediated by BDA-410 would be translatable to an improved phenotype, motor behaviour was assessed in a cerebellar lentiviral model of MJD that presents extensive motor deficits induced by lentiviral-mediated expression of mutant ataxin-3 in the cerebellum (33). Non-injected mice (Ø) of the same age were used as a control.

Fine motor coordination was evaluated using a beam-walking test, which essentially examines the ability of mice to remain upright and to walk on an elevated and narrow beam without falling. Therefore, four beams of increasing difficulty of square and round cross-section were used and the time mice spent to cross them in order to reach an enclosed safety platform was recorded. Mice expressing ATX-3 72Q spent more time to cross the elevated beams along with a progressive walking
disability accompanying an increasing beam difficulty. Calpain inhibition by BDA-410 administration significantly improved performance of animals (Fig. 6A).

To further realize whether a modulation of the neuromuscular transmission would be operated by calpain inhibition, a grip strength test was performed. Initially, all mice displayed equal muscle strength, but within the following 10 weeks post-injection, ATX-3 72Q promoted loss of strength that was prevented by BDA-410 administration (Fig. 6B). Finally, quantitative analysis of footprint pattern revealed tendency for shorter stride length in mice injected with ATX-3 72Q at 10 weeks post-injection that could be slightly ameliorated by calpains inhibition (Fig. 6C).

Taken together, fine motor function deterioration and grip strength loss were alleviated with the use of the calpain inhibitor BDA-410.

BDA-410 prevents cell loss

To determine whether the phenotypic modifications were due to cerebellar morphological preservation, several parameters in the transduced region were analyzed: lobule V volume (Fig. 7A–C and J), molecular layer thickness (Fig. 7D–F and K) and number of Purkinje cells (Fig. 7G–I and L).

To examine lobule V volume, cresyl violet-stained cross-sectional areas were used for volume extrapolation. Mice injected with lentiviral vectors encoding for ATX-3 72Q and administered with vehicle exhibited a significant 61% reduction of lobule V volume. Calpain inhibition by BDA-410 oral administration was able to prevent 25% of the decreased volume (Fig. 7A–C and J).

In order to associate the cerebellar reduction with morphological modifications of specific cellular layers, cresyl violet-stained sections were also used to measure the molecular layer thickness. At 13 weeks post-injection, vehicle mice presented a significant two-third reduction of the molecular layer thickness of lobule V. Oral administration of BDA-410 was able to prevent the aforementioned decrease to one-third (Fig. 7D–F and K).

Immunofluorescence labelling of cerebellar sections with an anti-calbindin antibody revealed that vehicle mice displayed 87% reduction of Purkinje cell number and that administration of the calpain inhibitor BDA-410 protected 39% of the cell loss (Fig. 7G–I and L).

Overall, these data provide evidence that BDA-410 might contribute to morphological homeostasis leading ultimately to an improved phenotype.

**DISCUSSION**

Present treatment of MJD is only supportive and no medication has been able to slow the course of disease. There is an urgent need for a disease-modifying therapy. The recent identification of the role of calpains in MJD pathogenesis provided the rationale to the use of the calpain inhibitor BDA-410, which we show in the present work to robustly alleviate the neuropathology and motor deficits in a mouse model of this disorder.

Growing evidence suggests that calcium signalling is deranged in MJD (14), which coupled to decreased levels of the endogenous inhibitor of calpains—calpastatin (12), creates favourable
Figure 5. BDA-410 prevents cell injury and striatal degeneration. conditions for activation of these calcium-dependent cysteine proteases, proteolysis of mutant ataxin-3, generation of toxic fragments, translocation to the nucleus, aggregation and neurodegeneration (10–13). We have recently shown that calpastatin overexpression by viral gene therapy alleviated MJD neuropathology, providing the proof of principle that inhibition of calpains may be a potential new target for therapy of MJD (12). Therefore, in this study we investigated whether the oral compound BDA-410 (23–26) would be able to block calpain-mediated cleavage of ataxin-3 and alleviate MJD.

We found that BDA-410 reduced cleavage of the calpain natural substrate α-spectrin in cultures of cerebellar granule neurons only expressing mutant ataxin-3 (Fig. 1B and D), confirming its calpain inhibitory activity. Interestingly, in the same in vitro model, calpain inhibition was translated into a decrease in immunolabeling of full-length mutant ataxin-3 (Fig. 1C and E), which might be explained by a better clearance of mutant ataxin-3 by normal quality control mechanisms, preventing further accumulation of the non-cleaved full-length ataxin-3 through clearance by the UPS and autophagy-lysosomal pathways (29,34).

According to the toxic fragment hypothesis, the aggregation process associated with inclusion formation and cellular dysfunction is initiated by the proteolytic cleavage of the full-length polyQ-protein (5–7). We have therefore analyzed ataxin-3 fragmentation upon BDA-410 administration and we observed a significant reduction of the ~26 kDa fragment and a decreasing trend of the ~34 kDa fragment formation (Fig. 2). Real-time PCR confirmed that the decreased fragmentation is not a consequence of a decreased mRNA expression. In fact, BDA-410 was able to suppress mutant ataxin-3 proteolysis by calpains independently of mRNA levels of mutant ataxin-3 (data not shown). Cleavage of mutant ataxin-3 at amino acid 259 might lead to the formation of an N-terminal (Fig. 2C) and a C-terminal (~26 kDa) fragment, respectively. Cleavage of mutant ataxin-3 before polyglutamine expansion might also give rise to the observed ~26 kDa fragment (Fig. 2A). Cleavage at amino acid 200 may generate a wild-type N and C-terminal fragments of ~26 kDa (Fig. 2A–C). The reduction of both the N- (35) and...
C-terminal (7,36) fragments formation of mutant ataxin-3 may have a contributive effect to neuroprotection mediated, in this study, by the calpain inhibitor BDA-410 (Fig. 2D and E).

BDA-410 mediated a reduction within the mouse brain of the number of mutant ataxin-3 intranuclear inclusions (Fig. 3), which are a hallmark of the pathology (37–39). We have previously shown that the diameter of mutant ataxin-3 inclusions decreased, as calpastatin levels increased (12). Even though BDA-410 had a minor effect on inclusions size (Fig. 4A–F and M), the number of mutant ataxin-3 positive cells co-expressing cleaved caspase-3 significantly decreased upon its administration, suggesting a neuroprotective role for the drug (Fig. 4G–L and O). Neuroprotection was further confirmed by a dramatic 46% decrease of the volume of the region depleted of DARPP-32 immunoreactivity and of the number of pycnotic nuclei in the treated group, when compared with the control group (Fig. 5). Importantly, BDA-410 was able to preserve cerebellar morphology (Fig. 7), one early target of the degenerative process of MJD (40).

On one hand, our results suggest that the fragments are the toxic species (Fig. 2) and that intranuclear inclusions might have a protective function, in agreement with the toxic fragment hypothesis (5,6,30,41). On the other hand, intranuclear inclusions do not solely comprise the polyglutamine protein. Functionally relevant proteins are sequestered such as ubiquitin (Fig. 4A–C), chaperones and proteasome components that are involved in quality control of protein surveillance machinery (42–44). Furthermore, inclusions might compromise cell integrity and disrupt axonal transport, through motor protein titration or physical interruption (45). Our studies thus demonstrate that despite being the fragments pernicious, larger aggregates present increased colocalization with cleaved caspase-3 (Fig. 4G–L and N) suggesting increased cytotoxicity as compared with smaller aggregates. Therefore, our results suggest that both theories might coexist. Nevertheless, BDA-410 is able to suppress fragmentation decreasing consequent aggregation.

Notably, this study demonstrates that calpain-mediated inhibition of the proteolytic event, allied with the neuroprotective effect can limit the worsening of the phenotype (Fig. 6). As MJD can be diagnosed by genetic testing, a therapeutic intervention, once available, might be initiated before the onset of symptoms, turning BDA-410 a viable choice.

Calpain inhibition might affect their physiological function and be consequently a matter of concern causing adverse side effects. However, calpastatin-deficient and transgenic mice did not present any defect in development, fertility, morphology or life span (15,46). Moreover, under normal conditions, calpains cleave substrates at a limited number of sites leaving large and often catalytically active fragments, indicating that prior to a digestive function, calpains display a regulatory or signaling role (47). Thus, the occurrence of adverse side effects may be restricted. In fact, our results show neither alteration in subcellular localization of wild-type ataxin-3, nor cell injury or striatal degeneration (Supplementary Material, Fig. S1), upon BDA-410 administration.

In conclusion, the oral calpain inhibitor BDA-410 reduced fragmentation of mutant ataxin-3, decreased inclusion number, prevented cell injury and neurodegeneration and alleviated phenotypic impairment in a model of MJD. This study shows for the first time that a low-molecular weight drug orally administered may provide a viable therapeutic option to block progression of MJD.

MATERIALS AND METHODS

Drug treatment

Calpain inhibitor BDA-410 was kindly provided by Dr Hiroshi Kinoshita from Mitsubishi Tanabe Pharma Corporation, Yokohama, Japan. The chemical name of this compound is (2S)-N-(1S)-1-[{(S)-hydroxy(3-oxo-2-phenyl-1-cyclopropen-1-yl)methyl]-2-methyl[4-benzensulfonfylamino-4-methylpentanamide (C26H32N2O5S; molecular weight 484.61). BDA-410 has a potent and selective inhibitory action against calpains: calpain 1/calpain 2, IC50 = 21.4 nM; papain, IC50 = 400 nM; cathepsin B, IC50 = 16 μM; thrombin, IC50 > 100 μM; cathepsin G, IC50 > 100 μM; cathepsin D, IC50 = 91.2 μM; proteasome 20S, IC50 > 100 μM.

BDA-410 was orally administered (30 mg/kg in 1% Tween 80 saline in a volume equal to 5 ml/kg), with a 20 G gavage needle, every day since 2 days before stereotaxic injection until sacrifice.

Cultures of cerebellar granule neurons

Primary cultures of rat cerebellar granule neurons were prepared from P7 post-natal Wistar rat pups. Cerebella were dissected and dissociated with trypsin (0.01%, 15 min, and 37°C, Sigma, T0303) and DNase (0.045 mg/ml, Sigma, D5025) in Ca2+/Mg2+-free Krebs buffer (120 mM NaCl, 5 mM KCl, 1.2 mM KH2PO4, 13 mM glucose, 15 mM 4-(2-hydroxyethyl)piperazine-1-ethanesulfonic acid (HEPES), 0.3% BSA, pH 7.4). Cerebella were then washed with Krebs buffer containing trypsin inhibitor (0.3 mg/ml, Sigma, T9128) to stop trypsin activity. The cells were dissociated in this solution, centrifuged and then resuspended in Basal Medium Eagle supplemented with 25 mM KCl, 30 mM glucose, 26 mM NaHCO3, 1% penicillin-streptomycin (100 U/ml, 100 μg/ml) and 10% fetal bovine. Cells were plated on 6 or 12-well plates (1 × 105 or 5 × 105 cells/well) coated with poly-D-lysine. Cultures were maintained on a 12 h light/12 h dark cycle. Food and water were provided ad libitum. The experiments were carried out in accordance with the European Union Directive 2010/63/EU covering the protection of animals used for scientific purposes.

Viral vectors production

Lentiviral vectors encoding human wild-type ataxin-3 (ATX-3 27Q) or mutant ataxin-3 (ATX-3 37Q) (19) were produced in 293T cells with a four-plasmid system, as previously described (48). The lentiviral particles were resuspended in 1% bovine serum albumin (BSA) in phosphate-buffered saline (PBS). The viral particle content of batches was determined by assessing...
HIV-1 p24 antigen levels (RETROtek, Gentaur, Paris, France). Viral stocks were stored at −80°C until use.

**Lentiviral infection of cerebellar granule neurons**

The cell cultures were infected with lentiviral granule vectors at ratio of 10 ng of p24 antigen/10^5 cells 1 day after plating (1 DIV) (49). At 2 DIV, medium was replaced with freshly prepared culture medium and calpain inhibitor BDA-410 was added in two different concentrations (50 and 100 nM in DMSO). DMSO was used as a control. Medium plus inhibitor or DMSO was replaced every 3 days.

**In vivo injection in the striatum and cerebellum**

Concentrated viral stocks were thawed on ice. Lentiviral vectors encoding human wild-type (ATX-3 27Q) or mutant ataxin-3 (ATX-3 72Q) were stereotaxically injected into the striatum in the following coordinates: antero-posterior: +0.6 mm; medial–lateral: ± 1.8 mm; dorso-ventral: −3.3 mm; and into the cerebellum in the following coordinates: antero-posterior: −2.4 mm; medial–lateral: 0 mm; dorso-ventral: −2.9 mm. Animals were anesthetized by administration of averin (200 μg/g, intraperitoneally).

For western-blot procedure and RNA extraction, wild-type mice received a single 1 μl injection of 0.3 mg of p24/ml lentivirus in each side: left hemisphere (ATX-3 27Q) and right hemisphere (ATX-3 72Q). For immunohistochemical procedure, wild-type mice received a single 1 μl injection of 0.4 mg of p24/ml lentivirus in each side: left hemisphere (ATX-3 27Q) and right hemisphere (ATX-3 72Q). Mice were kept in their home cages for 4 or 8 weeks, before being sacrificed for western-blot analysis and RNA extraction or immunohistochemical analysis, respectively.

For behavioural analysis and cerebellar morphologic assessment, wild-type mice received a single 4 μl injection of 0.25 mg of p24/ml lentivirus encoding ATX-3 72Q. Non-injected mice (O) of the same age were used as a control.

**Behavioural assessments**

Mice were subjected to locomotor tests starting at 4 weeks of age. Animals were habituated for 1 h to a quiet room with controlled temperature and ventilation, dimmed lighting, and handled prior to behavioural testing to overcome the animals’ natural fear and anxiety responses, which could have a major effect on performance. All devices were wiped clean with a damp cloth of a 10% ethanol solution and dried before evaluating the next mouse.

**Beam balance/walking**

Motor coordination and balance of mice were assessed by measuring the ability of the mice to traverse a graded series of narrow beams to reach an enclosed safety platform (50). The beams consisted of long strips of wood (1 m) with an 18 or 9 mm square wide and a 9 or 6 mm round diameter cross-sections. The beams were placed horizontally, 25 cm above the bench surface, with one end mounted on a narrow support and the other end attached to an enclosed box (20 cm square) into which the mouse could escape. A 60 W desk lamp was positioned above near the start of the beam to create an aversive stimulus (bright light) to induce mice to cross it. Mice performed two consecutive trials on each beam, progressing from the widest to the narrowest beam and the mean taken to analysis. The mean latency each animal spent to cross all the beams was considered.

**Grip strength**

The mouse limb strength was measured as an indicator of neuromuscular function. The setup consisted of a 300 g metal grid, which was on a scale. The animal was hung with its forepaws on the central position of the grid. Its strength was determined as the weight pushed (g) from the scale. The grip test was performed three times and the mean taken to analysis. Mice body weight was used as a normalization factor.

**Footprint test**

Gait analysis was assessed by the footprint test. To obtain footprints, the hindfeet and forefeet of the mice were coated with black and white non-toxic paints, respectively. Mice were allowed to walk on a greenish paper along a 100 × 10 × 15 cm runway. Stride length was measured as the average distance of forward movement between each stride. A sequence of six consecutive steps for both hind and forefeet was chosen for evaluation. The mean of the 12 strides for each animal was considered. DBP

**Immunohistochemical procedure**

After an overdose of averin (2.5 × 200 μg/g, i.p.), transectional perfusion of the mice was performed with a phosphate solution followed by fixation with 4% paraformaldehyde (PFA). The brains were removed and post-fixed in 25% sucrose/phosphate buffer for 48 h. The brains were frozen, 25 μm coronal striatal sections and 35 μm midsagittal cerebellar sections were cut using a cryostat (LEICA CM3050 S) at −21°C. Slices throughout the entire brain regions were collected in anatomical series and stored in 48-well trays as free-floating sections in PBS supplemented with 0.05 μM sodium azide. The trays were stored at 4°C until immunohistochemical processing.

Sections from injected mice were processed with the following primary antibodies: a mouse monoclonal anti-ataxin-3 antibody (1H9, 1:5000; Chemicon, Temecula, CA), recognizing the human ataxin-3 fragment from amino acids F112-L249; a rabbit polyclonal anti-ubiquitin antibody (Dako, 1:1000; Cambridgeshire, UK); and a rabbit anti-DARP-32 antibody (1:1000; Chemicon, Temecula, CA), followed by incubation with the respective biotinylated secondary antibodies (1:200; Vector Laboratories). Bound antibodies were visualized using the Vectastain ABC kit, with 3,3'-diaminobenzidine tetrahydrochloride (DAB metal concentrate; Pierce) as substrate.

Double stainings for Ataxin-3 (1H9, 1:3000; Chemicon, Temecula, CA), nuclear marker [4',6-diamidino-2-phenylindole (DAPI), blue] and ubiquitin (Dako, 1:1000; Cambridgeshire, UK), cleaved caspase-3 (Asp175, 1:2000; Cell Signaling) or calbindin (Abi778, 1:500; Chemicon, Temecula, CA) were performed. Free-floating sections from injected mice were at room temperature (RT) for 2 h in PBS/0.1% Triton X-100 containing 10% NGS (Gibco), and then overnight at 4°C in blocking solution with the primary antibodies. Sections were washed three times and
onto microscope slides with Eukitt. Sections were then differentiated in 70% ethanol, dehydrated by passing twice through 95% ethanol, 100% ethanol and xylene solutions, and mounted.

Cresyl violet staining

Premounted sections were stained with cresyl violet for 30 s, differentiated in 70% ethanol, dehydrated by passing twice through 95% ethanol, 100% ethanol and xylene solutions, and mounted onto microscope slides with Eukitt® (Sigma).

Evaluation of the volume of the DARPP-32 depleted volume and lobule V volume

The extent of ataxin-3 lesions in the striatum or the cerebellar lobule V volume was analyzed by photographing, with a 1.25 × objective, 8 DARPP-32 stained sections per animal (at 200 μm intervals) or 8 cerebellar cresyl violet sections per animal (at 210 μm intervals), selected so as to obtain complete sampling of the striatum or hemicerebellum, and by quantifying the area of the lesion or the lobule with a semiautomated image-analysis software package (Image J software, USA). The volume was then estimated with the following formula: volume = d(a1 + a2 + a3 ...), where d is the distance between serial sections and a1 + a2 + a3 are the areas for individual serial sections.

Cell counts and morphometric analysis of ataxin-3 and ubiquitin inclusions, and lobule V molecular layer

Coronal sections showing complete rostrocaudal sampling (1 of 11 sections) of the striatum were scanned with a 20 × objective. The analyzed areas of the striatum encompassed the entire region containing ATX-3 and ubiquitin inclusions, as revealed by staining with the anti-ataxin-3 and anti-ubiquitin antibodies. All inclusions were manually counted using a semiautomated image-analysis software package (Image J software, USA). Inclusions diameter was assessed by scanning the area above the needle tract in four different sections, using a 63 × objective. At least 100 inclusions per animal were analyzed using LSM Image Browser. Inclusions diameter was further assessed by double staining of ataxin-3 inclusions with cleaved caspase-3 by scanning the area above the needle tract in three different sections, using a 63 × objective. At least 100 inclusions per animal were analyzed using LSM Image Browser.

Midsagittal sections of hemicerebellum were scanned with a 20 × objective. All calbindin-positive Purkinje cells of lobule V of six sections at 210 μm intervals were manually counted. Lobule V molecular layer thickness was assessed by the mean of four different measures. In each image, a boundary line around the molecular layer from, but excluding, the Purkinje cell bodies to the pial surface was drawn by hand using a semiautomated image-analysis software package (Image J software, USA).

Western-blot analysis

For assessment of ataxin-3 proteolysis in the lentiviral model of MJD, transcardial perfusion of the mice was performed with ice-cold phosphate buffered saline containing 10 mM ethylene diaminetetraacetic acid (EDTA) and 10 μM of the alkyllating reagent N-ethylmaleimide, to avoid post-mortem calpain overactivation. The injected striata were then dissected and immediately sonicated in radiolabel precipitation assay buffer (RIPA) buffer (50 mM Tris–HCl, pH 7.4, 150 mM NaCl, 7 mM EDTA, 1% NP-40, 0.1% sodium dodecyl sulphate (SDS), 10 μg/ml dithiothreitol (DTT), 1 mm phenylmethylsulphonyl fluoride (PMSF), 200 μg/ml leupeptin, protease inhibitors cocktail).

One week before cell lysis, cerebellar granule neurons were treated with 200 μM N-methyl-D-aspartate (NMDA) plus 2.5 mM CaCl2 in Krebs buffer without MgCl2 for 1 h for excitatory stimulation and subsequently cultured in fresh medium plus inhibitor or DMSO until harvest and sonication in RIPA buffer, as described above.

Equal amounts (20 µg of protein) were resolved on 12% SDS-polyacrylamide gels and transferred onto polyvinylidene difluoride (PVDF) membranes. Immunoblotting was performed using the monoclonal anti-ataxin-3 antibody (1H9, 1:1000; Chemicon, Temecula, CA), monoclonal anti-polyglutamine antibody (1C2, MAB1574, 1:1000; Chemicon), monoclonal anti-myc tag (clone 4A6, 1:1000; Cell Signaling), monoclonal anti-spectrin antibody (MAB1622, 1:1000; Chemicon) and monoclonal anti-β-actin (clone AC-74, 1:5000; Sigma) or monoclonal anti-β-tubulin I (clone SAP.4G5, 1:15000; Sigma). Semi-quantitative analysis was carried out using Quantity-one 1-D image analysis software version 4.5. A partition ratio with actin or tubulin was calculated.

Purification of total RNA from striata of mice and cDNA synthesis

Mice were sacrificed by cervical dislocation and injected striata were dissected and stored at −80°C in tubes containing RNA later RNA stabilization reagent (QIAGEN). Samples were then kept at −80°C until extraction of RNA. Total RNA was isolated using the RNeasy Mini Kit (QIAGEN) according to the manufacturer’s instructions. Briefly, after cell lysis, the total RNA was adsorbed to a silica membrane, washed with the recommended buffers and eluted with 30 µl of RNase-free water by centrifugation. Total amount of RNA was quantified by optical density (OD) using a Nanodrop 2000 Spectrophotometer (Thermo Scientific) and the purity was evaluated by measuring the ratio of OD at 260 and 280 nm. Complementary DNA (cDNA) was then obtained by conversion of 1 μg of total RNA using the iScript Select cDNA Synthesis Kit (Bio-Rad) according to the manufacturer’s instructions and stored at −20°C.

Quantitative real-time polymerase chain reaction (qRT-PCR)

Quantitative PCR was performed in an iQ5 thermocycler (Bio-Rad) using 96-well microtitre plates and the Quantifect...
SYBR Green PCR Master Mix (QIAGEN). The primers for the target human gene (ATXN3, NM_004993) and the reference mouse genes (Hprt, NM_013556 and Gapdh, NM_008084) were pre-designed and validated by QIAGEN (QuantiTect Primers, QIAGEN). A master mix was prepared for each primer set containing the appropriate volume of QuantiTect SYBR Green PCR Master Mix (QIAGEN), QuantiTect Primers (QIAGEN) and template cDNA. All reactions were performed in duplicate and according to the manufacturer’s recommendations: 95°C for 15 min, followed by 40 cycles at 94°C for 15 s, 55°C for 30 s and 72°C for 30 s. The amplification efficiency for each primer pair and the threshold values for threshold cycle determination (Ct) were determined automatically by the iQ5 Optical System Software (Bio-Rad). The mRNA fold increase or fold decrease with respect to control samples was determined by the Pfaffl method, taking into consideration different amplification efficiencies of all genes.

Statistical analysis
Statistical analysis was performed using unpaired Student’s t-test or one-way ANOVA followed by Bonferroni test for selected pairs comparison. Values of P ≤0.05 were considered statistically significant; P < 0.01 very significant; and P < 0.001 extremely significant.

SUPPLEMENTARY MATERIAL
Supplementary Material is available at HMG online.

ACKNOWLEDGEMENTS
The authors wish to thank Luisa Cortes from the CNC—MICC Imaging facility for image acquisition assistance on confocal microscopy. This work was supported by funds FEDER through the Competitive Factors Operational Program—COMPETE and by national funds through the Portuguese Foundation for Science and Technology, PTDC/SAU-NEU/099307/2008, PEst-C/SAU/LA0001/2013 – 2014 and E-Rare-2, the ERA-Net for Research on Rare Diseases, The Richard Chinn and Lilly Lock Machado-Joseph disease Research Fund and Programa Mais Centro (CENTRO-07-ST24-FEDER-002002, 002006, 002008).
