Fifty-two-year-old male with paroxysmal atrial fibrillation underwent Holter ECG 3 weeks after flecainide treatment had been initiated. The recording showed two episodes of very rapid activity of ~30 s duration—one just before going to bed (Figure) and another one in the morning after getting out of bed. Upon closer inspection of the recording high notches with the same cycle as the sinus QRS complexes were noted (arrows). Further questioning of the patient revealed that he was brushing his teeth with a manual toothbrush at the very same time when the episodes were recorded.
