**Keywords:** Pulmonary aspergilloma • Tuberculous cavity • Haemoptysis • Tracheobronchial fistula

A 76-year old male presented with haemoptysis and a known tuberculosis infection in the medical history. The computed tomography showed a large cavity in the right apex with access to the apical segmental bronchus (Fig. 1). Bronchoscopy showed a fungus ball in this cavity as the source of haemoptysis (Fig. 2).
