The purpose of this study was to analyze the role that sensory impairment (whether or not one had visual and/or hearing problems, and if so, how much do these problems limit one’s day-to-day functioning), and social resources (e.g., having someone with whom to confide, the number of times one speaks with someone, etc.) played in participants of the Georgia Centenarian Study. These variables were analyzed to determine whether they predicted loneliness. Blocked regression analyses were utilized in this study. In the first block, we used sex, ethnicity, and past schooling. In our second block, we provided the four variables tied to visual and auditory impairment, and had in the final block a summary score for social provisions. Results indicated that hearing impairment that limits one’s activities significantly predicted loneliness, ß = 432, p<.05. In essence, the more that hearing problems limit one’s day-to-day activities, the higher the loneliness score. Moreover, social resources was a significant predictor of loneliness, ß = -2.95, p<.05. The lower the amount of social resources, the higher the level of loneliness. These results not only add to our understanding of the link...
between sensory impairment and loneliness, but also provide new insight into how social resources in the lives of centenarians influence loneliness as well.

PREFERENCES IN VISUAL FIXATION AND EFFECTIVE EMOTION REGULATION IN ADULTHOOD AND OLD AGE
E.S. Allard, E.A. Kensinger. Boston College, Chestnut Hill, Massachusetts

Recent research suggests emotion regulation abilities are maintained or even improve well into old age. The current study investigated the effective use of specific emotion regulation strategies in young adulthood and old age. We assessed young (age: 18-25) and older adults’ (age: 60-85) reactions to a series of positive, negative, and neutral video clips while their eyes were tracked. Subjects viewed the videos in a passive viewing and a guided-selective attention regulation condition. Effective emotion regulation was indicated by hedonic gaze preferences (preference for positive and avoidance of negative interest areas within the videos) and self-reported mood throughout the experiment. Age differences in fixation preferences emerged in the passive viewing condition where older adults fixated more within positive interest areas as compared to young adults. Both age groups displayed significant preferences within positive interest areas in the emotion regulation as compared to the passive viewing condition. While young adults displayed greater preferences toward negative relative to positive interest areas in the passive viewing condition, both young and older adults showed greater positive relative to negative preferences in the emotion regulation condition. Both age groups also displayed improved mood from the passive viewing to the emotion regulation condition; however no age differences in mood emerged. Our results are discussed in terms of using gaze as an effective emotion regulation strategy in adulthood and old age.

THE RELATIONSHIP BETWEEN MENTAL WELL-BEING AND RESILIENCE FOR MATURE WOMEN IN A LEISURE-BASED CONTEXT: A LOOK AT THE RED HAT SOCIETY
P. Chang, C.M. Yarnal, Pennsylvania State University, University Park, Pennsylvania

Recent leisure literature has examined how leisure activities improve mental well-being for mature women, but has paid less attention to the understanding of how and why the individuals change over time. Psychological researchers have also discussed the relationship between resilience and mental well-being, but the pathway from resilience to mental well-being is blurred. We argue that resilience may be a state process when individuals are engaged in a leisure activity. Thus, the purpose of this study is to examine within-person processes of mental well-being and resilience among mature women engaging in a leisure activity over 5-month period. Participants from the Red Hat Society (RHS; N=202, age over 55) completed on-line monthly questionnaire about monthly resilience, mental well-being and demographic information for five months. We estimated growth curve models to examine within-person differences in resilience and mental well-being. Results indicated a correlation between resilience and well-being. Individuals with higher resilience had higher scores of mental well-being when engaged in leisure activity than lower resilience individuals. In addition, this function showed slight increase over the five months of data collection. These findings suggest that resilience is not stable but changeable over time when individuals engaged in a leisure activity. This study provides preliminary evidence for leisure as a pathway to resilience and mental well-being among mature women and begins to bridge the gap between the resilience and leisure literatures.

OLDER AND YOUNGER ADULTS SHOW OPPOSITE MNEMONIC BENEFITS FOR INTEGRATING EMOTIONAL AND NEUTRAL WORD PAIRS
B. Murray, E. Kensinger. Boston College, Chestnut Hill, Massachusetts

It has been demonstrated that when two pieces of information are well-integrated with one another at encoding, there is a mnemonic benefit for the association between those items. However, formation of novel associations (e.g., face-name pairings) is among the most significant memory deficits experienced by older adults. It has been proposed that this deficit arises because older adults do not engage the same elaborative processes as young adults when attempting to bind information together. A recent study (Murray & Kensinger, submitted) demonstrated that imagining two neutral items as a single unit required more elaborative effort than integrating an emotional and a neutral item: Young adults required more time to imagine neutral than emotional pairs and reported more difficulty in generating images for neutral pairs. The automatic binding of emotional information came at the cost of retaining those words pairs, however: Young adults showed a disproportionately larger mnemonic benefit for those integrated neutral pairs over integrated emotional pairs, suggesting that young adults engage more elaborative processes for the binding of neutral items compared to emotional items, and that the engagement of these additional processes helps to create a more durable associative memory. Data presented here show that older adults demonstrate a significant reversal of this effect: pairs containing an emotional item show a disproportionately larger mnemonic benefit from integration than do pairs containing two neutral items. This suggests that older adults may not recruit the elaborative processes necessary to boost their associative memory for neutral pairs, but can still automatically integrate emotion pairs.

HAPPINESS AND LONELINESS OF OLDER ADULTS LIVING IN A MID-SIZED CITY: DO NEIGHBOURHOOD SOCIAL CAPITAL PERCEPTIONS MATTER?
N. Newall, V. Mencic, University of Manitoba, Winnipeg, Manitoba, Canada

This project explores perceptions of neighborhood social capital and the loneliness and happiness of younger (45-64 yrs) and older (65-95 yrs) adults living in a mid-size city (Winnipeg, Manitoba, Canada; pop. ~680,000). Social capital measures (e.g., helpfulness of neighbours) were analysed in the context of sociodemographic characteristics (e.g., marital status). Data (N = 1015) were from in-person interviews conducted in 2007/08. For adults aged 45-56 years, results showed that none of the sociodemographic or social capital perceptions predicted happiness. In contrast, for adults aged 65+ years, although none of the sociodemographic variables accounted for the variance in happiness, with perceiving that seniors are treated with respect, and knowing many neighbours being significant predictors. In terms of loneliness, for adults aged 45-64, only marital status was a significant predictor. In contrast, for those aged 65+, sociodemographic variables accounted for 14% of the variance in loneliness, with social capital perceptions explaining an additional 6%. Being married, having lived in the neighbourhood for longer, and having done a favour for a neighbour in the last 6 months predicted less loneliness. Results suggest perceptions of social capital do matter in terms of the happiness and loneliness of older (65+ yrs) adults. These study findings add to research on connections between the neighbourhood environment of city-dwellers and emotional well-being. Ideally, as efforts are made to change our neighbourhoods through, for example, age-friendly initiatives, these changes may also have a positive impact on older adults’ loneliness and happiness.

EXAMINING THE ROLE OF POSITIVITY EFFECTS IN OLDER ADULTS’ INTERPRETATION OF EMOTIONALLY AMBIGUOUS FACES
M. Larcom, D. Isaacowitz, Psychology, Brandeis University, Waltham, Massachusetts

Research suggests that older adults better remember and attend more to positive emotional information as compared to negative information. In the current study, we wanted to determine whether these positivity effects extend to the interpretation of ambiguous facial expressions which contain both positive and negative emotions. Older (M = 72.16 years of 64th Annual Scientific Meeting
age, SD = 7.38) and younger (M = 18.81 years of age, SD = 1.05) adults were shown blended expressions of anger/happiness, disgust/happiness, and fear/happiness where the percent of negative-to-positive emotion was 40/60 and 60/40. Participants rated the faces on 3 separate 9-point scales. They were asked, “Does this expression look more like anger or like happiness?”, “How angry does this expression look to you?”, and “How happy does this expression look to you?” The same question format was used for disgust/happiness and fear/happiness blends. When comparing the ratings of the two age groups, our results suggested positive effects in older individuals’ emotion ratings; however, this depended on the specific emotion blend and the percent of negative-to-positive emotion within blends. At both 40%/60% and 60%/40% disgust-to-happiness ratios, older adults interpreted faces as being less disgusting as compared to younger adults (p < .01 for both). The strongest evidence for positivity effects was found for blends of fear/happiness such that at both fear-to-happiness ratios, older adults rated faces as being less fearful (p < .01; p < .001), happier (p < .01; p < .001), and looking more like happiness than like fear (p > .05; p < .001).

DAILY MEMORY FAILURES AND NEGATIVE AFFECT: ANOTHER SOURCE OF DAILY STRESS?

J. Mogle1, E. Munoz2, J. Smyth3, M. Slivinski1, 1. Gerontology Center, Penn State University, University Park, Pennsylvania, 2. Syracuse University, Syracuse, New York

Previous research has found that the experience of daily stress is typically characterized by increases in negative affect and decreases in positive affect (see Almeida, 2005); effects that are often exacerbated in older adults (Mroczek & Almeida, 2004; Slivinski et al., 2009). One potential source of daily stress, particularly for older adults, is the experience of memory failures. Memory failures can lead to personal consequences (e.g., forgetting to take a medication) and may have implications for older adults’ ability to live independently. The current study examined whether daily memory failures also negatively impact daily well-being. Participants (N=157, Mage=48 years, range 20-83) completed 7 days of assessments including measures of affect, stress, and memory failures. On days when individuals reported forgetting to take a medication, complete an errand, where something was placed, an appointment, a name or directions to a location, they also reported significantly higher negative affect. Additionally, on days when individuals reported forgetting to complete a household chore, where something was placed, an appointment, a personal date, or a name they also reported significantly lower positive affect. This effect remained even after controlling for experience of daily stressors and trait levels of neuroticism. Unlike the research on daily stressors, older adults tended to experience smaller changes in positive and negative affect in response to memory failures compared to younger adults. This implies that memory failures may act as another form of daily stressor with all of the associated negative effects, particularly for younger adults.

NOT ALL EVENTS ARE THE SAME: AGE DIFFERENCES IN NEGATIVE AFFECT ACCORDING TO APPRAISAL OF DAILY EVENTS

E. Munoz1, J. Mogle1, J. Smyth2, M. Slivinski1, 1. Pennsylvania State University, State College, Pennsylvania, 2. Syracuse University, Syracuse, New York

Previous research on daily experiences has focused primarily on the effects of stressful events on daily well-being (c.g., Almeida et al., 2002). However, other daily events may also impact well-being even if they are not perceived as stressful. The current study allowed individuals to report events even if they did not consider them as stressful. Participants (N=170 Mage=49, range 20-79) reported on their daily experiences and affect 5 times per day for 7 days. Participants reported a total of 1134 events throughout the study (74% stressful). Both types of events were related to significant increases in negative affect (NA), though stressful events were related to significantly more NA compared with non-stressful events. Older and younger adults reported similar numbers of events regardless of event type and experienced similar increases in NA in response to both types of events. Participants also reported the specific subtype of event experienced (e.g., interpersonal, work-related). Older adults were more likely to report network-related stressful events but there were no other significant age differences in the subtypes of the events reported. Event subtype also differentially influenced events in response to both types of events to greater increases in NA compared to work and home stressors. Work and home-related events interacted with age resulting in greater increases in NA among younger compared to older adults. Thus, not all events influence mood in the same way and appraisal of specific type of events as stressful or not is differently associated with NA among younger and older adults.

THE INFLUENCE OF BACKGROUND CONTEXT ON MEMORY IN YOUNGER AND OLDER ADULTS

M. Fernandes, Psychology, University of Waterloo, Waterloo, Ontario, Canada

How does the context in which information is presented influence memory? Are there any specific strategies that healthy older adults can use to enhance the quality of memory? In this talk I will review evidence from behavioral studies of normal aging, and divided attention, showing that provision of meaningful context during encoding selectively influences the richness of information that can be retrieved. In the reported studies, younger and older adults studied words presented with a rich (intact face) or weak (scrambled face) context, and subsequently made ‘Remember’, ‘Know’, or ‘New’ judgments to words presented alone. Younger, but not older, adults showed higher Remember (i.e. recollection) accuracy to words from rich- than weak-context encoding trials. Dividing attention in young, during encoding, reduced overall memory, though the recollection boost from rich encoding contexts remained. The age-related deficit in recollection occurred even when encoding time was doubled in older adults, suggesting it cannot be accounted for by lack of available attentional resources or processing time. Explicit encoding instructions to “bind” contexts to words (matching decisions) did significantly increase recollection in older adults. Results suggest age deficits in recollection stem from a lack of spontaneous binding of context to target information, which can be alleviated by instructions to arbitrarily link context to target information, during encoding. After attending this talk, participants will 1) be able to identify the cognitive processes critical for successful memory and 2) be able to identify which specific strategies can be used to enhance the quality of memory.

SESSION 985 (POSTER)
HEALTH LITERACY

MULTIPLE TRAJECTORIES OF HEALTH BEHAVIORS AMONG THE MEN AND WOMEN TAIWANESE ELDERLY

H. Hsu1, D. Lu’2, W. Chang3, 1. Department of Health Care Administration, Asia University, Taichung, Taiwan, 2. Chung-Shan Medical University, Taichung, Taiwan, 3. National Taiwan University, Taipei, Taiwan

Purpose: Research about health behavior trajectory is popular in recent years. However, the joint trajectories of multiple health behaviors are little studied. This study was to identify the multiple trajectories of four health behaviors among the Taiwanese elderly: smoking, betel chewing, alcohol drinking, and regular exercise, and to examine the joint trajectories these behaviors by gender and risk factors. Methods: Data were from a nation-wide, 4-wave longitudinal survey data among the Taiwanese elderly, year 1996 to 2007. Group-based trajectory analysis and multinomial logistic regression were used for analysis. Results: Four trajectories groups of men elders were identified: inac-
tive, healthy lifestyle, smoking and betel chewing, and alcohol drinking. Compared to the inactive group, having better physical health and participating in social groups were less likely to be in the inactive group. In addition, having lower education, lower economic satisfaction, without a spouse and participating in social groups were more likely to be in smoking and betel chewing group. Three groups of women elders were identified: inactive, unhealthy lifestyle, and healthy lifestyle. The women elders of the healthy lifestyle group were more likely to be younger, higher educated, having better physical function, less depressive symptoms, better economic satisfaction, and participated in social groups. No significant difference was found between the inactive group and the unhealthy lifestyle group among the women. Discussion: Health behavior trajectories are different between men and women elders. Social participation may cause different effects to health behavior to men and women. Socio-economic status is related to health behavior trajectories.

LEVELS OF HEALTH LITERACY AMONG HISPANIC ELDERLY PATIENTS AND THEIR CAREGIVERS

C. Garcia1, S.E. Espinosa2,3, H.P. Hazuda2,3, 1. University of Texas Health Science Center at San Antonio, San Antonio, Texas, 2. South Texas Veterans Healthcare System, San Antonio, Texas

Background: Poor health literacy is associated with poor health outcomes and is highly prevalent among Hispanic elderly. We examined levels of health literacy among dyads of Hispanic elderly patients (Pts) ≥65 years and their caregivers (CGs) and the social factors associated with these levels. Methods: 54 Pt-CG dyads were recruited from 3 community clinics and 6 senior centers in San Antonio. Health literacy was assessed using the S-TOFHLA. Level education (EL), acculturation (ACC), age, and Pt-CG relationship were collected by self-report. Results: Males comprised 51.8% of Pts but only 24.1% of CGs. Pts’ mean age was 75.9 years (range: 65-89); CGs’ was 64.8 (range: 33-84). 63% of CGs were spouses; 29.6% were children or grandchildren, and 7.4% were siblings or hired CGs. CGs had higher mean ED compared to Pts (11.4 vs. 8.9; p<0.05) and were more acculturated (2.8 vs. 2.4; p<0.05); higher scores (1-4) indicate greater English vs. Spanish language use. Over half of the CGs (59.3%) and 27.8% of CGs had low HL. In univariable analyses among CG’s, age, ED and ACC were associated with lower likelihood of poor HL. In multivariable logistic regression, only age (OR=1.13; 95% CI 1.03-1.25) and ACC (OR=0.36; 95% CI 0.13-0.99) were independently associated with poor CG HL. Conclusion: Younger age and higher ACC are protective in CGs against poor HL. CGs’ higher literacy levels may protect Pts with lower health literacy from poor health outcomes. Thus, both CG’s and Pt’s should be included in HL interventions designed to improve Pt outcomes.

DEMENTIA: FEAR OF THE KNOWN OR UNKNOWN?

K.S. Page, B. Hayslip, D. Wadsworth, Department of Psychology, University of North Texas, Denton, Texas

Current estimates for Alzheimer’s disease are at 5.1 million older adults, with the number of diagnoses expected to increase (Alzheimer’s Association, 2010). Numerous agencies and organizations are working to fulfill a public education need on the general knowledge about Alzheimer’s. This study examined predictors of fear of dementia among a sample of middle-aged (n = 439) and older adults (n = 291). Participants completed surveys designed to assess their current knowledge about aging, fear of aging, knowledge of Alzheimer’s, depression, memory self-efficacy, and personal exposure to the disease. Hierarchical regression was used to assess the ability of the above measures to predict levels of fear of dementia. This information was entered in various steps, with the final model showing four variables as statistically significant, adjusted R2 = .11, F(14, 469) = 5.23, p < .001. Results indicated that believing you are at a greater risk for the disease, perceiving a greater amount of memory problems, and fearing aging were associated with a higher level of fear of dementia. Furthermore, scoring higher on a test of Alzheimer’s knowledge was significantly related to a greater endorsed fear of dementia. We believe this research points to important factors to consider when educating the public about Alzheimer’s and can serve as a stimulus for discussion and future research.

PREDICTORS OF OLDER MEN’S KNOWLEDGE OF OSTEOPOROSIS

K.A. Marx2,3, J.M. Gaines1, A.L. Gruber-Baldini1, 1. Erickson Living Foundation, Catonsville, Maryland, 2. University of Maryland Baltimore County, Catonsville, Maryland, 3. University of Maryland at Baltimore, Baltimore, Maryland

Numerous studies have explored the factors that predict women’s knowledge of osteoporosis. Few studies have examined men’s knowledge of osteoporosis. The purpose of this study is to investigate the predictors of older men’s knowledge of osteoporosis. 1,518 older men (mean age 78.6 years, S.D.=7.6; 3.6 % black) were surveyed about their knowledge of osteoporosis and their risk factors. Overall knowledge was poor (mean=13.15 out of a possible 26, S.D.=5.85). Two multiple linear regressions were conducted. The first examined the relationship of demographic variables and total known risk factors on knowledge of osteoporosis. The regression was found to be statistically significant, F(6, 1511)=14.91, p<.001, R2=.056. Age, race, education, and total known risk factors were significant predictors of knowledge of osteoporosis. Education was the largest predictor (β=0.136) with more educated men having better knowledge A second regression was run to explore the relationship of 18 individual risk factors on knowledge of osteoporosis. The regression was statistically significant, F(18, 1267)=6.88, p<.001, R2=.089. Five of the risk factors (personal diagnosis of osteoporosis or low bone mass, a parent experiencing a fracture after 50 years of age, participation in strength exercises, self reported health, and vitamin D intake) were found to be significant predictors of knowledge of osteoporosis scores. Vitamin D intake was the largest predictor (β=-0.124) such that knowledge was better with higher intake. A greater emphasis on educating older men about their risk for developing osteoporosis is needed, and should target men with lower education and osteoporosis risk factors.

EFFECTS OF KNOWLEDGE AND ANXIETY ON WILLINGNESS TO SCREEN FOR ALZHEIMER’S DISEASE

T. Lundquist, R. Ready, Psychology, UMass Amherst, Amherst, Massachusetts

A barrier to screening for Alzheimer’s disease (AD) is lack of knowledge about the disease (Ayalon & Arean, 2004). Another potential barrier to screening is anxiety about AD but it is not known how anxiety might predict screening preferences. This study measured knowledge about AD, trait anxiety, and anxiety about AD in adults (N = 73; M age = 62.00; SD = 7.19; 80.80% female) to determine how knowledge and anxiety might be associated with willingness to screen for AD. Greater knowledge about AD, greater trait anxiety, and greater anxiety about AD in particular were correlated with a higher likelihood of screening (rs = .38, .29, and .46, respectively, ps < .05). A regression indicated that knowledge about AD (b = .36, p < .01) and trait anxiety (b = .07, p < .05) were each significant predictors of screening for AD; a second regression indicated that knowledge about AD (b = .38, p < .01) and anxiety about AD (b = .19, p < .01) also were significant predictors of screening. Thus, it is not just knowledge about the disease that affects screening preferences for AD but also trait anxiety and anxiety about AD in particular. Increasing knowledge is an effective way to promote AD screening but might have limited utility among persons who are less anxious. Greater understanding of the impact of anxiety on screening behavior might eventually lead to more effective means to promote AD screening in midlife and older adults.
THE IMPACT OF HEALTH LITERACY ON SELF-RATED HEALTH STATUS AMONG ELDERLY KOREAN IMMIGRANTS

H.Y. Lee, School of Social Work, University of Minnesota, Twin Cities, St. Paul, Minnesota

Although health literacy has been considered to be a critical factor in impacting health disparity among elderly immigrant populations, there is a dearth of empirical research on this topic particularly among elderly minority immigrants. Little is known about the role of health literacy as a potential contributor to an older adult’s self-rated health status. This study sought to investigate whether elderly minority immigrants with limited health literacy are more likely to report poor health status and whether health literacy is an independent predictor of health status. A total of 205 elderly Korean immigrants residing in New York City were surveyed using a quota sampling strategy. The Chew et al.’s 16-item health literacy screening questions were utilized to measure health literacy. Multiple regression analysis indicated that those who had poorer health literacy were more likely to have lower level of self-rated health status after adjusting relevant factors. The findings confirmed health literacy as a potential determinant of health status. The study’s findings suggest that particular need for intervention is seen among immigrants who have limited health literacy. Health-care professionals and social service providers who work with these vulnerable populations have a valuable opportunity to improve health outcomes. A patient-centered approach that focuses on each older immigrant’s particular language needs and cultural health beliefs can help reduce health disparity among immigrants with limited health literacy.

SENSE OF CONTROL AND PHYSICAL CHECK-UP AMONG OLDER ADULTS

M. Inoue, T. Tran, School of Social Work, Boston College, Chestnut Hill, Massachusetts

Purpose: In recognizing the importance of sense of control on older adults’ health maintenance behavior, this study examined the association between sense of control and physical checkup among older adults aged 60 and older. Methods: We used the 2004-2006 second wave data from the Midlife Development in the United States. Our analysis involved 260 older adults who perceived their health as fair or poor and 1,155 older adults who perceived their health as average, good, or excellent. Sense of self-control measured a person’s sense of self-mastery and perceived constraints. Physical checkup measured the likelihood of having physician visits for physical examination. Two separate logistic regression analyses for each group were conducted. Results: Our analysis revealed that having higher levels of sense of control increased the odds of getting a routine checkup for only those with poor health or fair health status (OR=4.72, p<.05). In addition, having health insurance significantly increased the likelihood of having a physical checkup for individuals with poor and fair health status (OR=3.75, p<0.01) and healthy individuals (OR=5.75, p<0.001). Implications: This study suggests that sense of control can be viewed as a motivational factor for better health care maintenance among individuals with poor health status. Thus, providing self-efficacy interventions might be an effective way to promote healthy behaviors among older adults.

THE RELATIONSHIP BETWEEN RECEIPT OF COLORECTAL CANCER SCREENING AND KNOWLEDGE AMONG VULNERABLE RURAL RESIDENTS

S.H. Bardach, N.E. Schoenberg, S.T. Fleming, J. Hatcher, Gerontology, University of KY, Lexington, Kentucky

Colorectal cancer (CRC) is the second leading cause of cancer-related deaths nationally and among residents of rural Appalachia. Rates of guideline-consistent CRC screening in Appalachian Kentucky are suboptimal, approximately 36%. Although not the only determinant, health behavior theory generally considers knowledge a precursor to engaging in cancer screening. This study sought to determine the relationship between CRC screening knowledge, specifically regarding recommended screening intervals and receipt of screening among rural residents of Appalachian Kentucky. Between November 20, 2009 and April 22, 2010, respondents (n=1,182) between the ages of 50 and 76 completed a telephone survey including questions on demographics, health history, and knowledge about CRC screening. While 67% of respondents indicated receiving screenings according to guidelines, they also demonstrated significant knowledge deficiencies about screening recommendations. Nearly half of respondents were unable to identify the recommended screening frequency for any of the CRC screening modalities. The seeming disconnect between high rates of screening and low level of knowledge may reflect the medical complexity of this population which requires more regular physician visits and may result in individuals being directed to screening appointments without having specific knowledge of recommended intervals. Enhanced provider efforts to educate patients and recommend screening have the potential to increase early detection and reduce cancer mortality in this underserved region.

SAFETY KNOWLEDGE AND INJURY PREVALENCE IN OLDER ADULTS WITH DIABETES

T.D. Wilson, J.H. Patrick, West Virginia University, Morgantown, West Virginia

Older adults are at significant risk of unintended injury in the home (CDC, 2010). Given the known comorbid complications, older adults with diabetes are at an especially high risk of injury. We investigated the relations among safety knowledge, home safety precautions and injury among adults with (n = 199) and without (n = 137) diabetes. These adults (58% female; mean age = 60.2 years) completed self-report measures. Results of t-tests showed that adults with diabetes reported more total injuries (M = 22.4) than adults without diabetes (M = 16.8; t(319) = 2.56, p < .05). Adults with diabetes also reported less safety knowledge and fewer home precautions. A linear regression examining the associations among knowledge, home safety, and diabetes status accounted for significant variance in the number of injuries experienced (F (2, 312) = 16.42, p < .001). However, only home safety precautions emerged as a unique predictor of injury (Beta = -.34). Our results suggest that given their lower levels of knowledge and safety precautions, vulnerability to injury among adults with diabetes might be reduced via increased use of home safety precautions.

WOMEN’S PREVENTATIVE HEALTH SCREENING AT MIDLIFE

S. Stahl, J.H. Patrick, Morgantown, West Virginia

National health objectives listed in Healthy People 2010/2020 have specifically addressed the need for increasing health screening in women. Engagement in health screening is thought to be an important first step in the utilization of future healthcare services (e.g., medical care, health promotion interventions). The primary goal of the current study was to examine middle-aged women’s engagement in ten health screens that are specifically recommended for aging women by the USDHHS (e.g., screens for breast, cervical, and colon cancer). Our subsample included 75 women between the ages of 40 and 65 years (M age = 49.14 years; SD = 4.56) who completed an online survey. Most women had insurance (public = 26.3%; private = 67.1%) and believed they could “easily” access healthcare services (86.8%). Women reported receiving an average of five health screens (SD = 1.84) and were most likely to report receiving screens for cholesterol (92.1%) and high blood pressure (85.5%), and least likely to report receiving screens for osteoporosis (30.3%) and colorectal cancer (34.2%). Interestingly, age, insurance, and access to healthcare were not significantly associated with engagement in preventative screening. When examining the eight SF-36 scales, women who reported receiving over half of the USDHHS recommended health screens were significantly less likely to experi-
SociaL anD HeaLth DIsparities among ELDers in HawaII: IMplications for HeaLth LiteraCry

Social and health disparities among elders in Hawaii: Implications for health literacy

Life expectancy in Hawaii is the longest of any US state. However, in this multiethnic state (24% Hawaiian, 24% Caucasian, 18% Japanese, 16% Filipino, 7% Chinese), a 10-year difference is seen between our longest-living (Japanese and Chinese) and shortest-living (Hawaiian) groups. This session examines reasons for continued differences and outlines work of Ha Kupuna, National Resource Center for Native Hawaiian Elders and the Center on Aging, both at the University of Hawaii at Manoa, to address disparities faced by Hawaii’s people. Data from the US Census, death records, BRFSS and the Hawaii Health Survey were compiled to examine socio-economic variables, years of productive life lost, behavioral risk and disease prevalence data for the state’s major ethnic groups. Taken together, data suggest that the disparate ethnic profiles seen among the elderly in Hawaii result from very different socio-economic influences and life courses of these groups. In later life, strategy to address these disparities can focus on health literacy. The literature defines health literacy as the degree to which individuals have the capacity to obtain, process, and understand basic health information and services needed to make appropriate health decisions. Health literacy is essential to involving elders in their care and to reducing health inequalities. Research has found that racial/ethnic populations face unique challenges related to health literacy. Recent research conducted by the UH Center on Aging examines the role of health literacy and culture in Hawaii’s aged to develop tailored approaches for optimal long-term care transitions.

LESSONS LEARNED IN DISSEMINATING AN EVIDENCE-BASED PROGRAM FOR OLDER ADULTS ON A NATIONAL SCALE

Lessons learned in disseminating an evidence-based program for older adults on a national scale

S.L. Hughes, P. Desai, R. Smith-Ray, G.M. Huber, University of Illinois at Chicago, Chicago, Illinois

Fit and Strong! is an 8-week evidence-based, turnkey program for older adults with lower extremity osteoarthritis. Currently, two collaborative efforts are underway to translate and diffuse the program. The first effort is funded by CDC and supports dissemination of the program in two areas on aging in Illinois and two in North Carolina with a minimum of 30 providers. This translation study uses Glasgow’s RE-AIM model and Greene et al.’s work on evaluation to identify facilitators and barriers to the reach, adoption, implementation and maintenance of Fit and Strong! in those states. In addition to the CDC-funded translation effort, AoA is also funding the dissemination of the program in the same two states plus Florida. The goal of the AoA effort is to enroll an additional 20 new providers to adopt the program. The evaluation of this effort includes participant pre- and posttest outcomes, fidelity checks to assess intervention adaptations and participant and instructor program evaluations. To date, 40 providers have adopted the program, 141 instructors have been trained and over 536 new participants have been enrolled in the program. On a subset of participants (n=300), baseline pre-posttest outcomes show continued statistically significant impact of the program on improved lower extremity pain and stiffness, energy/fatigue, self-efficacy for exercise with a marginal impact (p<.07) on BMI. Factors that facilitate and impede program adoption, fidelity, and sustainability will be discussed as well as adaptations made by instructors and providers.

PERFORMANCE DIFFERENCES ON OBJECTIVE ASSESSMENTS OF MEDICATION KNOWLEDGE: AN EXAMINATION OF ETHNICITY, EDUCATION, AND HEALTH

Performance differences on objective assessments of medication knowledge: An examination of ethnicity, education, and health

The present analyses examined racial differences in performance between European-American (EA) and African-American (AA) older adults within the functional domains of medication use, telephone use, financial ability, and nutrition using the Revised Observed Tasks of Daily Living assessment (OTDL-R) and the Everyday Cognition Battery knowledge domain (ECB-K). Data came from a community dwelling sample of 189 older adults with an average age of 73.08 (SD = 7.00, range = 60-94). The sample consisted of 35% AA and 45% EA. Results indicated that there were no main effects of ethnicity on overall ECB-K performance (F(2, 191) = 3.35, p = .01) but multivariate analyses revealed a significant main effect of ethnicity for domain-specific performance for the ECB-K, F(3, 191) = 3.32, p = .02. Follow-up univariate ANOVAs revealed significantly lower mean scores for AA relative to EA on the medication domain, but equivalent performance in the nutrition and finance domains. There were no main effects of ethnicity on overall OTDL-R performance (F(2, 191) = 1.04, p = .31), nor were there domain-specific performance differences. Discussion will focus on the potential role of education, health, and medication use in explaining performance differences between AA and EA within the medication domain of the ECB-K specifically.
INTERGENERATIONAL RELATIONSHIPS

OLDER FOSTER PARENTS: SUPPORTS AND RESOURCES
W. Metcalfe1, 2, G. Sanders1, 1. Path North Dakota Inc., Fargo, North Dakota
2. North Dakota State University, Fargo, North Dakota

The goal of this qualitative study was to examine the support experiences of older foster parents. Thirty-seven foster parents, age 62 and older, were interviewed about supports. The support needs of older foster parents were found to be consistent with those of foster parents in general. Older foster parents were healthy, personally flexible, and adaptable. Analysis of these interviews revealed that older foster parents experienced social workers and support groups as valuable resources. Other unique themes included: being valued and respected; education and training; support groups; and respite. Older foster parents consistently experienced their age and life experience as a unique and powerful personal support upon which to draw.

INTERGENERATIONAL TRANSFERS: A QUALITATIVE STUDY
M. Devine, M.E. Szinovacz, University of Massachusetts Boston, Boston, Massachusetts

Intergenerational transfers are an inherent part of family relationships and an important means of understanding family dynamics. Of special interest is whether and to what extent adult children’s care for parents is tied to parents’ financial transfers. Recent studies on intergenerational transfers were typically quantitative and relied on questions about the amount of time and/or money transfers. Qualitative studies are more suited to explore the conditions and intricacies of such transfers, helping to enrich theorizing. We conducted in-depth interviews with 50 caregiving adult children, including 20 sibling dyads (40 siblings) and 10 adult children from separate families. We first identified major categories of transfers and themes surrounding the exchange of transfers. These included type of transfers (e.g., small financial gifts, care for grandchildren, or deeds); distribution of transfers (e.g., equal among children, based on need); timing of transfers (e.g., past gifts, future bequests); expectations regarding transfers (e.g., should earn them, caregivers have a right to them); and agreement or disagreement among siblings about fairness of transfers. We found considerable ambiguity in responses and complexity in exchanges, e.g., when caregivers indicated that one “shouldn’t sponge off” one’s parents but at the same time accepted a house deed or when caregivers were expected to distribute some of the bequest they received to their siblings, a situation not always welcomed by the siblings. We will present the main themes emerging from our qualitative analyses and tie them to existing theories such as altruism or reciprocity.

INFLUENCE OF PARENT-CHILD RELATIONSHIP FACTORS ON SERVICE UTILIZATION BY PERSONS WITH DEMENTIA AND THEIR ADULT CHILDREN
C. Podgonski, Psychiatry, University of Rochester Medical Center, Rochester, New York

Despite the growth and efficacy of community-based programs for persons dealing with dementia, only between 36% and 50% of caregivers use supportive services. While the chronic stress of caregiving has been linked to increased health risks and acceleration of disease, interventions involving service use have yielded improvements in caregivers’ depressive symptoms, social support, stress appraisals, and delays of institutionalization. This pilot study examined whether key family relationship characteristics (affective involvement, communication, problem solving), and intergenerational factors (individuation, intimacy, intimidation) between a parent and his/her adult child caregiver are associated with adherence to physician recommendations to contact the Alzheimer’s Association following a dementia diagnosis. Parent-adult child dyads (N=21) were recruited from a university-based Memory Disorders Clinic and followed for 6 months. Parents had mild dementia (CDR<1). The parent sample had a mean age of 80.0 (SD=9.3), 13.4 (SD=3.2) years of education; 4.2 (SD=2.1) contacts per week with the identified adult child, and a mean depression score (PHQ-9) of 6.0 (SD=5.1). Adult children were on average 53.0 (SD=6.6) years of age, had 15.2 (SD=2.3) years of education, and had a mean PHQ-9 score of 4.2 (SD=5.1). Of 20 dyads 40% contacted the Alzheimer’s Association. The mean length of time between diagnosis and contact was 38.9 (range 0-268; SD=89) days. In comparison to families who did not contact the Alzheimer’s Association, those who did reported more parent-child contact hours per week, higher subjective stress burden on the Caregiver Burden Assessment, and less intergenerational intimacy as measured by the Personal Authority in the Family System Questionnaire.

THE DISENFRANCHISED: PREDICTOR OF LOW LEVELS OF PARENTAL SUPPORT AMONG ADULT CHILDREN

Most parents provide tangible and intangible support to their grown children, but some offspring may receive little parental support. This study is to identify types of intergenerational support that parents are least likely to give their adult children, and reasons underlying for absences of support. In this study, lack of support to children, referred to as disenfranchising, is defined as offspring receiving help only yearly or even less often. We proposed three complementary models (i.e., Estrangement, Self-sufficiency, parents’ characteristics) to predict low levels of 5 kinds of support. Using data from The Family Exchanges Study, we investigated middle-aged parents (aged 40 to 60, N=633) who reported how often they provided support to offspring aged 18 or over (n=1384). A total of 8% of the offspring were disenfranchised. Practical and financial supports were most likely to be absent. Multilevel models showed that low levels of positive and negative relationship quality and absence of contact between parents and offspring were predictive of disenfranchisement for both tangible and intangible support (i.e., Estrangement model). Offspring who were self-sufficient (older, married, and employed full-time) were more likely to receive low levels of tangible support, but they still received some intangible support. Parents’ characteristics were generally less predictive of disenfranchisement of any type of support. These findings suggest that intergenerational support is driven by relationship context and the need for support. By examining mechanisms on disenfranchisement, this study explores central features of parent-child dynamics, and provides empirical evidence for solidarity and contingency theories.

HOW DOES PARENT INFLUENCE ON CHANGE OF GENDER ROLE IDEOLOGY OVER THE LIFE COURSE: FOCUSED ON DIFFERENCES BETWEEN SON AND DAUGHTER
J. Min, M. Silverstein, USC, Los Angeles, California

Literature consistently shows that parental values influence children’s values. However, less is known about the stability of values over the life course and the role of gender in the process. This research examined 1) how one’s gender role ideology changes over the life course; 2) how this change or stability is sensitive to parents’ value; and 3) how this pattern differs between sons and daughters. We hypothesized that the changes of children’s egalitarianism in the transition to adulthood would be more salient to daughters, rather than sons. Using the 1971 and 2000 waves of the Longitudinal Study of Generations (LSOG), the sample consisted of 647 parent-child dyads. Structural equation modeling results showed that changes in children’s gender role ideology were sensitive to parent’s gender role ideology in the transition to adulthood ($\chi^2 =$
IS GRANDPARENTING BENEFICIAL OR DETRIMENTAL FOR ELDERLY MEXICAN AMERICANS’ PSYCHOLOGICAL WELL-BEING?
Y. Liu1, Z. Cong2, 1. Human Development and Family Studies, Texas Tech University, Lubbock, Texas, 2. Pennsylvania State University, University Park, Pennsylvania

This study examined elderly Mexican American’s grandparenting experience and its association with elder’s depression. We also took into consideration the financial support from the adult children to the elders and from the elderly parents to their adult children in the process. Based on a convenient sample of 101 elders collected in a city in west Texas in 2010, we conducted a cross-sectional analysis with multiple regression to examine how elders’ depressive symptoms were associated with their length of grandparenting experiences, financial support both from and toward their adult children, controlling for demographic characteristics. Results showed that grandparenting increased elders’ depressive symptoms, and financial support to adult children was beneficial in alleviating depression. The significant interaction between the involvement in caring for grandchildren and providing financial support to adult children suggested that older parents would experience even more depressive symptoms when they had to provide more financial support as their help with child care was called upon. The findings indicated that financial strains were important reasons for stressful grandparenting experiences.

LIVING WITH GRANDPARENTS: AN ASSESSMENT OF FAMILY STABILITY AND CHILD OUTCOMES
R.E. Bulanda, Miami University, Oxford, Ohio

Family structures of children are becoming increasingly fluid and diverse, and these family structures and transitions are increasingly involving grandparents. Estimates suggest approximately 6 million grandparents co-reside with their grandchildren in the U.S. today. Families involving grandparents living with grandchildren is assessed in the existing literature, with much of the emphasis on the outcomes for the grandparents. For example, recent studies have examined the impact of caring for grandchildren on health outcomes and marital quality of the grandparents. Fewer studies have examined the long-term influence for grandchildren who have co-resided with their grandparent(s). This is a significant weakness within the current literature, especially since co-residing with grandparents is often an adaptive strategy following instances of divorce and/or downward social mobility. This study uses data from the 1995 National Survey of Family Growth to examine how children’s family structure transitions into households with grandparents are associated with their well-being and transition into adulthood. These data are ideal for this purpose because they provide complete accounts of respondents’ family structure experiences from birth until age 18, including the presence of one or both grandparents in the household. In addition, these data allow for assessments of the timing of these family structure experiences (early childhood, middle childhood, and adolescence). The outcomes assessed in the project are all established indicators of a successful transition into adulthood and are known correlates of family instability: early age of first sex, teen birth, and high school graduation.

AFRICAN AMERICAN GRANDPARENTS AND GRANDCHILDREN: CAREGIVING RECIPROCITY ACROSS THE LIFESPAN
L.J. Ficker1, P.A. Lichtenberg2, 1. Wayne State University Merrill Palmer Skillman Institute, Detroit, Michigan, 2. Wayne State University Institute of Gerontology, Detroit, Michigan

The objective of the study was to examine patterns of involvement and caregiving between grandparents and grandchildren to determine if reciprocity of caregiving exists (e.g., is a child who is cared for by a grandparent more likely to be a source of tangible and/or emotional support as an adult). We interviewed 200 African American elders over age 55 in order to assess family structure and kinship care; past and present. The sample was 90.5% female and the average age was 70.8 years old (SD = 8.9). Almost 80% of the sample had grandchildren (n = 159) and a majority of the grandparents (72%) reported past care for a grandchild; one-third were providing childcare for young grandchildren at the time of the study. Regression analyses were conducted on 105 grandparents who have adult grandchildren living in close enough proximity for them to provide tangible support. Involvement with adult grandchildren (e.g., eating meals together, visiting) is predicted by the duration of grandparent care and how emotionally close the grandparent feels to the grandchild. In contrast, grandchildren’s tangible support of the grandparent (e.g., taking grandparent to the doctor, helping with shopping and household chores) is predicted by age of grandparent (younger = more involvement) and whether or not the grandparent ever provided childcare for a grandchild, regardless of the closeness of the relationship or duration of care.

INTERACTIONS WITH CHILDREN-IN-LAW AND ELDERS’ DEPRESSIVE SYMPTOMS IN MEXICAN AMERICAN FAMILIES
Z. Cong, Human Development and Family Studies, Texas Tech Univ, Lubbock, Texas

This study examined how relation with children-in-law influenced Mexican American elders’ depressive symptoms, and how their acculturation level and endorsement for familism affect the examined relationship. Our data was from 196 parent-child-in-law dyads from 99 elders recruited from west Texas in 2010 and 2011. Regression with robust
standard error was used to accommodate the nesting data structure. Results showed that relationships with children-in-law were significantly associated with lower level of depressive symptoms in elders. Elders with stronger familialism and less acculturation level were more affected by children-in-law’s relationship. In addition, relationships with daughters-in-law were more influential than relationships with sons-in-law on elders’ depressive symptoms. This investigation reveals the importance of incorporating children-in-law in the examination of intergenerational support in Mexican American families, where familialism sets the tone for intergenerational relationships.

THE EFFECTS OF RELATIONSHIPS WITH ADULT CHILDREN ON SUCCESSFUL AGING OF THE ELDERLY: MODERATION EFFECTS OF ATTACHMENT STYLES, MARITAL RELATIONSHIPS AND GRANDPARENTS-GRANDCHILDREN RELATIONSHIPS

Y. Jeong, J. An, Pusan National Univ., Busan, Republic of Korea

The purpose of this study was to examine the effects of relationships with adult children on successful aging and especially moderation effects of attachment styles, marital relationships, and grandparents-grandchildren relationships of the elderly. 550 elderly people over 60 years old having a spouse, non-cohabitated children and grandchildren were included. Results indicated that the effects of relationship with adult children on successful aging were different according to the attachment styles, marital relationships, and grandparents-grandchildren relationships of the elderly. The effect of relationship with adult children on successful aging was higher in case of secure attachment style of the elderly than dismissing, fearful, and preoccupied styles and better marital relationships and grandparents-grandchildren relationships of the elderly. Lastly, total paths of research model were different according to the gender of the elderly. This study explains the role of attachment styles as moderation variable of relationship with adult children on successful aging and discusses the importance of healthy degree about psychological separation with adult children. Also this study suggest the importance of marital relationship and grandparents-grandchildren relationship as alternative supporter when the elderly has relational problems with adult child.

AMBIVALENCE AND SUPPORT BETWEEN OLDER PARENTS AND ADULT CHILDREN

J.P. Lendon, M. Silverstein, Gerontology, USC, Los Angeles, California

Much of the research on intergenerational relationships examines the exchange of supportive behaviors and the emotional aspects of parent-child relationships. Additionally, research on caregiving has examined both the burden and rewards of family caregiving. However, little research as investigated the mutual interplay between having mixed feelings and exchanging support in adult parent-child relationships. A particular gap in aging families research is whether ambivalent feelings about parents reduces the likelihood of adult children providing instrumental support (such as help with chores, financial support, providing advice, etc.). Are children who feel ambivalent towards their parents more or less likely to provide instrumental support? Does providing instrumental support lead to an increase in ambivalent feelings towards parents or children? This study analyzed over 800 parent-child dyads from 1988 to 2005 with data from the Longitudinal Study of Generations. Logistic regression determined that children’s initial mixed feelings did not affect the likelihood of providing support in the future. However, dual change score models showed that increases in support provision produced increases in mixed feelings, which subsequently reduced levels of support over the 17 year time span. This research provides a direct link, as expected, between emotions and behaviors in the dynamic relationships between parents and adult children. We suggest future research on successful negotiation of ambivalent feelings to produce more positive outcomes for support exchange and caregiving.

“DO AS I SAY, NOT AS I DO”: MESSAGES FROM PARENTS TO THEIR EMERGING ADULTS ABOUT LATE-LIFE CAREGIVING

H. Igarashi¹, D.P. Coehlo², K. Hooker¹, 1. Human Development & Family Sciences, Oregon State University, Corvallis, Oregon, 2. Juniper Ridge Clinic, Bend, Oregon

How does the experience of providing care to an aging parent influence one’s own behaviors and conversations with emerging adult children about filial duty? This qualitative, exploratory study examined the experiences of middle-aged parents as they simultaneously launched their emerging adult children and engaged in caregiving duties with aging parents. This work extends previous understandings of the experiences of caregiving for two generations by exploring the impact of a more lengthy transition to adulthood. Young adults today are requiring substantial parental support (Settersten & Ray, 2010), and we explored how this may affect feelings and behaviors about the flow of support up the generational ladder (Hagestad, 1982). Six focus groups were conducted, composed of parents with children age 18-30 years, and who provided care for one or more parent (N = 29). Parents in the middle generation described the burdens and sacrifices of caring for their aging parents, yet were clear about their desire to continue to provide this care. These voluntary obligations were often commitments made with imperfect knowledge of the road that lay ahead. However, now equipped with more understanding, parents expressed a strong desire to buffer their children from the impact of their own aging. Other relevant themes included ambivalence, unanticipated care giving, proactive behaviors, conversations about aging, and engagement in the development of their young adult children. These themes reflect complex and sometime contradictory issues that are often present in intergenerational ties, and the efforts made to resolve them.

THE STRUCTURE OF INTERGENERATIONAL EXCHANGES OF MIDDLE-AGED MARRIED ADULTS AND THEIR PARENTS AND PARENTS-IN-LAW IN KOREA: LATENT CLASS ANALYSIS

K. Kim¹, S.H. Zarit², G. Han¹, 1. The Pennsylvania State University, University Park, Pennsylvania, 2. Seoul National University, Seoul, Republic of Korea

Prior studies on intergenerational exchanges have focused on support exchanges of adult children with their own parents. However, middle-aged adults, especially married adults, usually have two sets of parents, their own parents and parents of their spouse, and exchange various types of support with both of them. The current study examines the structure of support exchanges that married adults give and receive from both their parents and parents-in-law. We analyzed data from 937 married adults (aged 30s to 50s) in the study “Successful midlife development: Mental health and work/family life course in Korea and the United States.” A latent class analysis using 12 indicators (financial, instrumental, and emotional support given to and received from parents and parents-in-law) identified five latent classes of intergenerational exchanges. Three classes showed balanced patterns of exchanges between parents and parents-in-law: high exchanges, low exchanges, and giving more than receiving. The other two classes showing imbalanced patterns between parents and parents-in-law were exchanges with only own parents and exchanges with own parents but giving tangible support to parents-in-law. The two imbalanced classes showed significant gender differences in membership probabilities. Whereas men were more likely to belong to the class who exchanged support with only own parents, women were more likely to belong to the class who gave tangible support to parents-in-law, which reflects patrilineal patterns in intergenerational exchanges in Korean families. After controlling for demographics of participants.
and geographic distance from parents and parents-in-law, marital support and conflict showed significant associations with the latent class memberships.

COMMONALITIES IN THE EXPERIENCE OF LATER MOTHERHOOD: THE INFLUENCE OF IDEOLOGIES ON EMPTY NEST WOMEN
K. Feldman, Kent State University, Kent, Ohio

Norms surrounding motherhood promote intensive mothering as the most acceptable child rearing style despite possible negative implications for mothers later in life. Intensive mothering may lead to alienation as well as long-term financial dependence for women. This study uses a mixed methods approach to explore the persuasiveness of the cultural imperative of intensive mothering. Data from 339 mailed surveys reveal high levels of salience of motherhood for women after children leave home across diverse racial (27% Black; 70% White), socioeconomic (15% reported annual incomes under $30,000; 37% reported annual incomes over $60,000), and marital categories (51% married; 20% divorced or separated; 25% widowed). In fact nearly two-thirds of the sample (64%) rated the salience of motherhood at the highest level available, with no significant differences across demographic groups. Mothers’ attitudes and expectations were also remarkably similar regardless of social location. Ordinary least squares regression showed that demographic variables accounted for insignificant portions of the variance in women’s attitudes. For instance, the combination of demographic variables including age, race, marital status, income, education, and occupational prestige explained three percent of the variance in mother’s expectations about children leaving home, and six percent of the variance in attitudes about children returning home. Focus group discussions indicated that mothers continued to place children’s needs above their own, separated themselves from the responsibilities of motherhood gradually, and defined their own success in terms of their children’s achievements. Even after children leave home, the norms of intensive motherhood remain pervasive in women’s lives.

GRANDMA’S HOUSE: A SAFE PLACE TO PLAY?
D.K. Nadorff, J.H. Patrick, Psychology, West Virginia University, Morgantown, West Virginia

Today, an increasing percentage of grandparents are assuming the responsibility for raising their grandchildren (Census, 2003). The safety of these home environments is of importance, as unintentional injury is the leading cause of death across all age groups (Borse et al., 2008). A model was proposed for the prediction of custodial grandchild safety (composed of the number of hazards present in the home, and the number of injuries experienced by the child), with the predictors of gender, safety knowledge, and depressive symptoms. Our results suggest an adequate fit of the data to the model [X2 (df = 11, n = 180) = 29.06, p < .002; GFI = .956; CFI = .952; RMSEA = .096]. This model explains 14.8% of the variance in child injuries, 32.6% of the variance in safety knowledge, and 34.4% of the variance in home hazards. Several group differences based on grandparent gender were also present. Grandfathers seem to be faring more poorly; reporting less safety knowledge [t = -9.28 (1, 178), p < .000], a more hazardous home environment [t = 7.48 (1, 178), p < .000], more types of children’s injuries having occurred in the past year [t = 4.29 (1, 178), p < .000], and more major injuries having occurred in the past 5 years [t = 2.54, (1, 178), p < .05]. Our results indicate that the variance in the injuries to children being raised by their grandparents is explained by the safety of their home environment. The state of their home is in turn predicted by their depressive symptoms. Future researchers are encouraged to consider length of co-residence, and grandchild variables, such as tendency to engage in high-risk behaviors.

OLDER MOTHER-ADULT DAUGHTER DYADS: HOW TO IMPROVE HYPERTENSION MANAGEMENT TO INCREASE LIFESPAN
C. Shawler, J. Meyers, J. Edward, J. Ling, A. Calloway, K. Stinson, M. Rayens, School of Nursing, University of Louisville, Louisville, Kentucky, University of Kentucky, Lexington, Kentucky

Hypertension (HTN) is one of the top factors associated with cardiovascular disease. Women tend to have higher prevalence of HTN than men. There appears to be a positive relationship between HTN and health related quality of life (HRQOL). Purpose: Investigate the influence of quality of relationship and inner strength on outcomes of hypertension self management, heart healthy behaviors (HHB), and HRQOL over time in older mothers and adult daughters. Method: Sample: 46 dyads of mothers (age > 65; M=77) with HTN and daughters (age 40-63; M=51) with or without HTN. Measures: Autonomy Relatedness Inventory - quality of relationship; Inner Strength Questionnaire; SF-36 for HRQOL; Hill-Bone Scale - hypertension self management; AHA Live and Learn Scale for HHB. Dyadic data were analyzed using Actor-Partner Interdependence Model (APIM) a dyad-based regression to determine the effect of the mothers’ and daughters’ independent variable on own dependent variable score (actor effect) and partner’s dependent variable score (partner effect). Significant Results: (1) Actor effects for mothers and daughters with quality of relationship on self management, HRQOL and HHB; partner effects for self management strategies; daughter partner effect for HRQOL and HHB. (2) Actor and partner effects for mothers and daughters with inner strength on HRQOL and HHB; actor effect for mothers for self-management; partner effects for daughters and mothers for self management strategies. Conclusion and Discussion: Mothers’ and daughters’ quality of relationship and inner strength influenced HTN self management, HRQOL, and HHB. Findings suggest that interventions to improve cardiovascular health and HRQOL should involve dyads.

RACIAL DIFFERENCES IN LATER LIFE MARITAL DYNAMICS AND HEALTH OUTCOMES
J.R. Bulanda, Sociology & Gerontology, Miami University, Oxford, Ohio

A growing number of studies find an association between marital quality and health – particularly in later life – but very few consider whether the relationship between marital quality and health differs based on race. The relationship between marital quality and physical health may be particularly salient for African Americans, as a number of studies find that African Americans report lower marital quality and have more health problems than other race-ethnic groups. Yet, previous research also documents strong social support networks and high levels of religiosity among African Americans, suggesting sources of resiliency that might protect health despite lower ratings of marital satisfaction. This study examines potential Black-White differences in marital quality and physical health using a longitudinal, nationally representative sample of older adults from the 2006 and 2008 waves of the Health and Retirement Study (HRS). Positive and negative dimensions of marital quality at baseline are used as independent variables predicting changes in subjective health and chronic conditions over a two-year time period. The role of social support in moderating the relationship between marital quality and health is considered, as are potential mediating mechanisms such as health behaviors and health care utilization. Analyses account for the diverse family structures as well as sources of chronic stress, demographic factors, and socioeconomic status. Preliminary results show a significant relationship between positive marital support and subjective health, and suggest that this relationship operates similarly for African Americans and Whites.

ADULT CHILD SUPPORT, HEALTH AND PHYSICIAN VISITS OF MEXICAN AMERICAN ELDERS
S. Park, Z. Cong, J. Scott, Human Development & Family Studies, Texas Tech University, Lubbock, Texas

This study examined how support from adult children influenced frequencies of physicians visit for Mexican-American elders. Data were
collected from interviews with a convenient sample of 82 Mexican-American elders living in Lubbock, TX, in 2010. We used OLS regressions to predict the likelihood of elders’ utilizing physician services based on the Anderson-Newman Behavioral Model. Results showed the influences of children’s support on frequencies of physician visits depended on the type of the support—instrumental, emotional, and financial. We found significant interactions between children’s support and the functional health status of Mexican-American elders, suggesting the effects of children’s support were contextual to elders’ health status. For elders with higher level of ADL impairments, moderate or higher levels of financial support from children enabled elders to visit physicians, whereas moderate or high emotional support reduced physician visits compared to lower levels of support. For elders with higher level of IADL impairments, while receiving any hands-on support reduced elders’ physician visits, moderate or higher levels of emotional support increased frequencies of physician visits, compared to lower levels emotional support.

THE MEMORY OF THE FATHER: FAMILY STRUCTURE, CHILDHOOD FATHER LOSS, AND MIDDLE-AGED AND OLDER WOMEN’S PATERNAL RELATIONSHIPS

E.M. Krampe1, R.R. Newton2, 1. Department of Sociology, California State University, Fullerton, California. 2. Fielding Graduate University, Santa Barbara, California.

We used data from a multi-ethnic sample to study the paternal relationship of 312 female participants aged 40 and older. We examined their overall feelings about the father, childhood physical relationship with the father, and perception of their father’s involvement with them in childhood. We explored participants’ perception of maternal support for their childhood bond with father, and perception of the father-mother relationship. Findings revealed that age was negatively associated with the first three dimensions of the father-daughter bond. African Americans, Asian/Pacific Islanders, and Hispanic participants reported less positive paternal experiences than non-Hispanic whites. Co-residence with both biological parents before age 18 consistently correlated with more positive responses in the above five dimensions. Participants from separated or divorced families had the lowest ratings on all five scales; participants whose fathers died before they were 18 were the most positive about four of the five dimensions of their paternal relationships.

FAMILY CAREGIVING SYSTEM: NETWORK OF COMPLEMENTING AND COMPENSATORY ROLES AND FUNCTIONS

This paper analyses the family caregiving system for elder care recipients in Singapore from a qualitative and systemic perspective. The data emerges from a research project conducted in 2010, and funded by the Singapore government. The aim was to expand the current understanding of family caregiving, and impact on intergenerational family dynamics. The sample consisted of adult child caregivers (30), grandchildren (28) and foreign domestic workers (FDW) (15). To complement the family’s functions as well to compensate for the time they are away from home, the FDW enters the caregiving system. The findings show that grand-children and foreign domestic workers are the support to the adult children caregivers, and caregiving has both positive and negative effects. Spiritual factors and sibling support to adult child caregivers mediate the stresses experienced by the latter. The session will provide participants insights into the interplay and inter-dependency of family relationships in the caregiving system.

SESSION 995 (POSTER)

LIFE COURSE DEVELOPMENT AND HEALTH

BODY MASS INDEX IN EARLY AND LATE MIDLIFE AND COGNITIVE ABILITIES IN LATE LIFE

The aims of this study were to study the association between early and late midlife body mass index (BMI), change in BMI, and late life cognitive abilities in a dementia free sample. BMI was calculated from self-reported height and weight in early midlife (mean age 39.9 years, range 25-50) (1963 or 1973) and from assessed weight and height in late midlife (mean age 61.1 years, range 50-75). Starting in 1986 participants were assessed five times at three year intervals on a cognitive test battery in the longitudinal Swedish Adoption/Twin Study of Aging (N=657). Latent growth curve models, adjusting for pairness, showed that persons with higher BMI in early midlife had significantly lower cognitive performance across domains in late life. Moreover, obesity was significantly associated with a steeper decline in perceptual speed and non-significantly associated with steeper decline in verbal and spatial abilities. Both being overweight and overweight/obese in late life were associated with an increased risk of lower cognitive abilities across domains. However, when decline in BMI was controlled for, underweight in late midlife was no longer associated with lower cognitive ability in any domain. Further, being underweight across midlife, and weight loss between early and late midlife, were each associated with lower mean level cognitive abilities in late life (centered at age 65). In conclusion, several different weight patterns were associated with lower cognitive abilities in late life. Weight patterns may be an important clue to understand the association between weight and cognitive health in late life.

LIFESPAN TRAJECTORIES OF PSYCHOLOGICAL HEALTH AS PREDICTORS OF MORTALITY: LONGITUDINAL FINDINGS FROM THE OAKLAND GROWTH STUDY

C. Jones, J.M. Campbell, psychology, California state university, Fresno, California.

The connections between psychological and physical health illustrate holistic interactions between physiological systems, personality, and lifestyle issues (e.g., Roberts, Kuncel, Shiner, Caspi, & Goldberg, 2007). Studies that allow an examination of both psychological and physical health across the entire lifespan are particularly helpful in teasing out such interactions. The Oakland Growth Study (OGS), begun in 1929, is one such study. Here we use measures of psychological health, based on the 100-item California Q-sort (Block, 1961), available from age 14 through to age 75, to predict longevity. When lifespan trajectories of psychological health were classified via finite mixture modeling (Jones & Peskin, 2010; Nagin, 2005), three patterns emerged: Stable Low, Increasing from Low, and Increasing from Moderate. As of 2010, approximately 23% of the OGS members are believed to be still alive; date of death is available for 34%, and 43% are of unknown status. After excluding those individuals of unknown mortality status, when the association between mortality status and psychological health trajectory type was examined, a significant link was discovered (X2(4,N=72)=9.59, p=0.048). Significantly more individuals than expected who are still alive show an Increasing from Moderate pattern of psychological health. Significantly more individuals than expected who are dead show a Stable Low pattern of psychological health.
Approximately 75 years earlier, when participants were age 18, differential levels of psychological health are seen by mortality status: those still alive in 2010 were significantly more psychologically healthy in adolescence than those now dead ($F(2,55)=3.80$, $p=.028$).

EARLY LIFE ADVERSITY AND ADULT BIOLOGICAL RISK PROFILES

E.M. Friedman¹, A.S. Karlamangla², T. Seeman¹, 1. Sociology, UCLA, Los Angeles, California, 2. UCLA, Los Angeles, California

Growing evidence suggests that early environment has long-lasting effects on health and physical functioning well into old age. Evidence, for example, indicates that both socioeconomic and social circumstances in childhood are strongly associated with health outcomes well into later life. However, the biological mechanisms linking early life circumstances to later life health is less well explored. This study investigates the relationship between early life adversity on multiple biological parameters known to predict health risks and on allostatic load, a cumulative measure of physiological wear-and-tear. Allostatic load has been hypothesized to be the biological pathway through which stressful events over the life course lead to chronic disease in later life. We use data from two waves of the National Survey of Midlife Development in the United States (MIDUS) study to explore the association between reported social adversity (i.e. parental death, parental divorce, parental abuse) and socioeconomic disadvantage (i.e. on welfare, relative poverty, and parents have less than a high school degree) before age 18 and their effects on biological risk profiles in middle and later life. We find that both socioeconomic and social disadvantage in early life are significantly and positively related to cumulative allostatic load. In addition, this relationship persists for social adversity (but not socioeconomic), even after controls for current socioeconomic status. These effects are most pronounced for secondary stress systems, including inflammation, cardiovascular function, and metabolic lipids.

POSITIVELY AGING: THE LIVED EXPERIENCE OF HIV-POSITIVE BLACK WOMEN AGE 50+

M. McDoorn¹, M. Drainoni², M. Sullivan, M. Naisterter, B. Bokhour², 1. Health Policy & Management, BUSPH, Boston, Massachusetts, 2. Boston Medical Center, Boston, Massachusetts

Research is beginning to look at the experience of older adults living with HIV/AIDS and the challenge of engaging and retaining patients over their lifespan. The US Senate Special Committee on Aging estimates that by 2015 nearly 50% of persons living with HIV/AIDS will be older than age 50. Understanding the long range social, survival, and health outcome effects of this disease in an older population has not been fully explored. The study of Black women aging with HIV explores the disease and lifespan trajectory among a population that is disproportionately affected by HIV/AIDS. Qualitative inquiry in this group has mainly focused upon younger Black women, thus the impetus to explore the narratives of older Black women. The purpose of this study is to (1) explore the lifespan experience of aging Black women living with HIV/AIDS and (2) identify key facilitators or barriers to engagement and retention in HIV care among this group. We conducted in-person semi-structured interviews of 20 Black women, ages 50 and up, at an urban HIV primary care clinic. Our analysis was informed by grounded theory and narrative analysis. Preliminary key thematic areas include: stigma, discrimination, social support, positive life transformation due to HIV, coming to terms with illness, avoidance of burdening family, and motivation for the future through children/grandchildren. Our study highlights the specific needs among this growing population and the multidimensional aspects of retaining them in HIV care.

EARLY PARENT-CHILD RELATIONSHIPS AND HEALTH OUTCOMES ACROSS ADULTHOOD AN EXAMINATION OF PHYSIOLOGIC FUNCTIONING

M. Horn Mallen³, S.T. Charles⁴, J.R. Piazza⁴, 1. Human Services, CSU Fullerton, Fullerton, California, 2. UC Irvine, Irvine, California, 3. Penn State, College Park, Pennsylvania

There is a growing body of literature indicating that the quality of early parent-child relationships has strong implications for chronic physical and emotional health outcomes in adulthood. Specifically, parent-child relationships characterized by low warmth, support and nurturance is related to decreased well-being in late adulthood. More recent findings indicate that early parent-child relationship quality is also related to daily stressor exposure and reactivity in adulthood. To fully examine the interrelationships between health and stress-related outcomes across adulthood, the present study extends current findings and utilizes measures of allostatic load, or indices of physiologic wear and tear on the body due to stressor exposure. Participants in the current study included over 900 adults, aged 25-64, from the Midlife in the United States (MIDUS) survey. Retrospective measures of parent-child relationship quality during childhood and current biomarker data indicate that low mother-child and father-child relationships are related to higher levels of cholesterol and triglycerides in adulthood. Additional analyses, including gender and age, as well as other biomarker indices such as cortisol, will be presented. Findings shed light on the critical role of early childhood support and stress mechanisms across the life span.

THE EFFECTS OF EARLY LIFE HEALTH STATUS ON STATUS ATTAINMENT AND LATER LIFE HEALTH

C. Elman¹, L.A. Wray¹, J. Xi¹, 1. The University of Akron, Akron, Ohio, 2. Pennsylvania State University, State College, Pennsylvania

The correlations between status attainment and later life health remain among the most well-established in the social sciences although how these relationships emerge over the adult life course is not yet well understood. We untangle interdependencies, using all waves of the nationally representative Health and Retirement Study and a life course framework, by exploring the relationships between retrospective self-assessed health status, learning problems and risk behavior in youth and outcomes across several educational and occupational domains. Multivariate models explore how factors combine across life stages, in the production of later life health. Findings are that self-rated youth health status and self-assessed ability to learn “matter” for later life health as they differentially anchor a range of potential mediating lifetime educational and occupational outcomes. Youth health status and learning effects on adult health are further stratified by gender and race/ethnicity.

AGE-RELATED DIFFERENCES IN ANXIETY BUFFERING PROCESSES FOLLOWING MORTALITY REMINDERS

According to terror management theory (TMT; Greenberg, Pyszczynski, & Solomon, 1986), awareness of mortality contributes to a variety of human behaviors: intolerance of different others, the appeal of rigid political, religious, and consumerist ideologies, and other diverse ways people strive to give life meaning and themselves value. Based on older adults’ increasing exposure to reminders of mortality, age differences are expected to occur in response to mortality salience induction. Indeed, while younger adults show increased punitiveness toward moral transgressors, older participants become less punitive following subtle reminders of mortality (Maxfield et al., 2007). Older adults also indicated greater generative concern following reminders of death (Maxfield et al., 2011). In the present study, age differences in responses to mortality salience were assessed via an examination of language use. Older and younger adults were either reminded of mortality or an aversive control topic and were then asked to describe important past events.
or future goals. Using the Linguistic Inquiry and Word Count (Pennebaker, Francis, & Booth, 2001), a content analysis was performed. Following DeWall & Baumeister (2007), all participants, regardless of age, used more positively-oriented emotional words following reminders of death. Of those participants reminded of mortality, older adults included more references to time, while younger adults included more references to family. Results provide additional support for the existence of age-related differences in responses to mortality, suggesting that processes for buffering against existential anxiety vary across the lifespan. Results are interpreted from terror management and socioemotional selectivity theories.

THE IMPACT OF EARLY EDUCATIONAL ATTAINMENT ON MENTAL HEALTH DISPARITIES OF BLACK & WHITE WOMEN IN MIDLIFE

L. Best, Pan-African Studies & Sociology, University of Louisville, Louisville, Kentucky

Prior research has shown that adverse early life circumstances can have a negative impact on health in later life. Specifically, socioeconomic achievement processes evident in midlife are in many ways a reflection of the accumulation (or lack thereof) of resources over time. While SES has been consistently associated with depression in women, recent supports suggest that examining changes in SES over time does a better job of capturing disparities. I propose that differences in educational attainment earlier in life leads to divergent health trajectories in adult women. Using data from the National Longitudinal Surveys Young Women cohort (1968-2003), I examined the role SES at baseline (ages 14-24) and over time played in explaining differences in their depressive symptoms over a 10-year span (1993-2003) in midlife (ages 39-51). Initially I utilize growth curve analysis to patterns in SES over time. I also examine a series of multinomial logit models to investigate the predictive nature of demographic factors in explaining the relationship between education and mental health, as defined by the CES-D Depression Scale. Results show that while both black and white women experience gains in educational attainment over time, black women remain at a disadvantage throughout adulthood. These women are also more likely to report consistently higher depressive symptoms throughout midlife.

SESSION 1000 (POSTER)

LINKS BETWEEN COGNITION AND PHYSICAL OR MENTAL HEALTH

IMPACT OF INSIGHT™ TRAINING ON USEFUL FIELD OF VIEW (UFOV) PERFORMANCE

C.L. Peronto, E. Valdés, J. Alwerdh, M. Castora-Binkley, E.M. Hudak, C. Haley, J.J. Lister, J.D. Edwards, School of Aging Studies, University of South Florida, Tampa, Florida

Previous research has shown that cognitive ability, particularly Useful Field of View Test (UFOV) performance, is important for everyday functioning in older adults. The goal of the current study was to examine whether Posis Science® Insight™, a computerized cognitive training program, produced similar improvements in UFOV performance as previously observed with prior versions of speed of processing training. Additionally, those with high and low UFOV performance at baseline were compared to determine if training was most useful to those with baseline difficulties. Participants (N=64) included healthy adults ages 55 and older with an average level of 15.96 years of education who were randomized to either the Insight™ training group (n=38) or to the delayed control group (n=26). Results indicated that the participants who received Insight™ training improved their UFOV performance more than those in the control group, F(1,61) = 5.06, p = .028. No difference in improvement was seen between those with high and low baseline UFOV abilities, t(36) = -.873, p = .388. This suggests that Insight™ is a viable tool for enhancing UFOV in older adults and may be more beneficial than previous speed of processing training as both those with and without initial UFOV difficulties benefit equally.

AFFECT, DEPRESSION, AND COGNITION IN COGNITION IN THE STUDY OF TAMOXIFEN AND RALOXIFENE (CO-STAR)

Purpose: This study examined the relationship between affect/depressive symptoms and cognitive performance in Co-STAR. The sample was comprised of 1,479 non-demented, postmenopausal women (mean age=67 years) at increased risk of breast cancer. Methods: Co-STAR participants were enrolled in the National Surgical Adjuvant Breast and Bowel Project’s Study of Tamoxifen and Raloxifene (STAR) trial that examined effectiveness of raloxifene and tamoxifen for reducing invasive breast cancer risk. At each visit, women completed a standardized neuropsychological test battery (Resnick, 2004) and self-report measures of affect and depression. Data from 3 annual Co-STAR visits were included in analyses. Linear mixed models for repeated measures using likelihood ratio tests were used. Separate analyses were performed for positive affect, negative affect, and depression (adjusted for treatment group in STAR, visit number, time since STAR randomization, age, race, and education). After main effects models were constructed, separate tests for interactions were performed. Results: Higher positive affect was associated with better letter fluency (p=0.006) and category fluency (p<0.0001). Higher negative affect was associated with worse performance on global cognitive function (p<0.0001), verbal memory (p=0.002), and spatial ability (p<0.0001). Depression was negatively associated with performance for multiple cognitive tests (verbal knowledge, figural and verbal memory). Conclusion: Findings are consistent with prior research demonstrating a link between greater depression and worse cognitive performance. The most novel finding shows a positive relationship between positive affect and verbal fluency in a large, longitudinal sample, lending support to the notion that positive affect may broaden ability to think creatively and flexibly.

TRACKING THE PERFORMANCE OF NURSING HOME RESIDENTS ON THE MMSE: CAN VARIABILITY BE USED TO PREDICT A DEMENTIA DIAGNOSIS?

A. Gerstenecker, S. Shah, B.T. Mast, S. Meeks, University of Louisville, Louisville, Kentucky

Although anecdotal evidence suggests that the cognition of nursing home residents will decline at a steady-to-sharp rate after entering a long-term care facility, few studies have tracked the cognition of nursing home residents at designated intervals over the course of a year. For residents with Alzheimer’s disease (AD), average annual rates of decline on the Mini-Mental Status Exam have been reported to be 2-3 points (Aguero-Torres et al., 1998; Small et al. 1997), and this decline may be exacerbated in the latter stages of AD. The current study examined the longitudinal trajectories of cognition in 33 nursing home residents administered two to four MMSE’s over the course of a year. Contrary to expectations, an overwhelming majority (n=21, 63%) of the sample demonstrated stable performance (<3 points) across MMSE administrations. A 2-3 point rate of decline across MMSE administrations was demonstrated by only 5 residents (15%). Two demonstrated improvement (6%) and 5 residents (15%) demonstrated variable performance characterized by both 2-3 point increases and 2-3 point decreases within the same year. A dementia diagnosis did not predict which trajectory residents would follow. This suggests that cognition remains relatively stable for the majority of resident over one year but that a substantial number also show considerable variability over this
same period. Moreover, the differences in change and stability were not fully explained by the presence of dementia.

COGNITIVE FUNCTION OF CENTENARIANS AND SEMI-SUPERCENTENARIANS
Y. Gondo1, N. Hirose2, Y. Masui1, H. Inagaki2, Y. Arai1, M. Takayama1, 1. Human sciences, Osaka University, Suita, Japan, 2. Tokyo Metropolitan Institute of Gerontology, Tokyo, Japan, 3. Department of Geriatric Medicine, Keio University School of Medicine Institute of Gerontology, Tokyo, Japan

The recent prolongation of life span has led to an expansion of the oldest old population in developed countries. Simultaneously the numbers of demented elderly has also increased. Increasing prevalence of dementia with age raised a scientific question whether dementia is inevitable or not. This is not only of scientific concern but also societally, influencing the very architecture and future of society. Centenarians are a good population to begin researching dementia prevalence. To date several studies have reported on the prevalence of dementia amongst centenarians; however, the results from these studies are highly diverged (40% to 100%). This variation may be caused by sampling methodology or variation of participation age. To overcome this problem we examined dementia status of wide variation of age in one population. Hundred ninety six centenarian (100+) and 270 semi-supercenenaian (105+) were evaluated dementia status by CDR(Clinical dementia ration). Firstly, dementia prevalence was high in both 100+ (67%) and 105+ (87%). Secondly, large sex difference was observed. Dementia prevalence in women increased according to age and all participants were evaluated as demented over 109 years. In men, although number of participants was small and no more than 109 years old were participated, half of the participants were not demented. In addition, lower cognitive status women life longer than men. These results indicate dementia is inevitable only for women but not for men.

THE INTEGRATION OF HEALTH EVENTS INTO POSSIBLE SELVES: IMPLICATIONS FOR ADAPTIVE COPING STRATEGIES
M.L. Barreto, L.D. Frazier, Florida International University, Miami, Florida

This study examined the integration of personal health events and experiences (i.e., diagnosis of illness, heart attack, broken arm, etc.) into the possible selves’ repertoire and explores the potential relationship between event-related possible selves and coping. Possible selves (i.e., future self-representations) motivate individuals to adapt to new roles and circumstances throughout the lifespan. The purpose of this study was to determine whether health events become integrated into the self system in the form of possible selves, how those events and experiences shape one’s possible selves, and whether the integration of health events and experiences is positive for developmental and psychosocial outcomes such as coping and well-being. The sample was comprised of 198 participants, both men and women. Ages ranged from 18 to 85. Participants indicated the presence of health events and experiences within their possible selves, indicating integration of stress into future self-representations. The degree to which individuals conceptualize themselves in terms of these experiences relates to their ability to cope with these challenges. The integration of health events and experiences into one’s possible selves were related to stronger coping scores. Finally, the degree of integration was examined in relation to the extent of self-regulation of the possible selves and results showed that a greater integration was related to greater self-regulatory activities associated with the event-related self. This study indicates possible avenues for prevention/intervention programs that can teach people how to incorporate change and life events into their sense of self in positive ways to promote well being.

MULTIPLE TRAJECTORIES OF COGNITIVE FUNCTION AMONG ELDERLY AMERICANS: EVIDENCE FROM THE HEALTH AND RETIREMENT STUDY
X. Xu1, J. Liang2, J.M. Bennett1, W. Ye1, A.R. Quinones3, 1. University of Michigan, Ann Arbor, Michigan, 2. Oregon Health & Science University, Portland, Oregon

OBJECTIVE: To examine population heterogeneity in changes in cognitive function in old age and identify important risk and protective factors associated with distinct trajectories of cognitive function. METHODS: Data came from the 1998-2008 Health and Retirement Study involving a national sample of 9,465 Americans age 65 and older with up to 6 repeated observations spanning 11 years. Cognitive function was assessed using a reduced version Telephone Interview for Cognitive Status (TICS), a multidimensional measure containing questions on date naming, object naming, president/vice president naming, and backwards count from 20. Group-based, semi-parametric mixture models (Proc Traj) were used for data analysis. RESULTS: Five major trajectories of cognitive function were identified: (a) healthy function, (b) minimal cognitive impairment and decline, (c) low cognitive impairment with gradual decline, (d) low cognitive impairment with accelerated decline, and (e) elevated cognitive impairment with rapid decline. They accounted for 39.2%, 38.8%, 13.2%, 4.9%, and 3.9% of the sample, respectively. More advanced age, poorer self-rated health, more limitations in activities of daily living and instrumental activities of daily living, and higher depressive symptoms at baseline were associated with greater likelihood of being in the more cognitively impaired groups or experiencing more rapid cognitive decline. Blacks, Hispanics and other ethnic minorities were more likely than whites to experience trajectories of worse cognitive function. Education and household income, however, had a protective effect. CONCLUSIONS: Among elderly Americans, there exist distinct courses of changes in cognitive function over time and significant age and racial/ethnic differences in experiencing these trajectories.

THEORY OF MIND (TOM) DOES NOT PREDICT SOCIAL FUNCTIONING IN COMMUNITY-DWELLING OLDER ADULTS
S.V. Rowe, B.T. Mast, University of Louisville, Louisville, Kentucky

Social resources are instrumental to successful aging, as support from others through social interactions is theorized to provide a buffer for the stress of daily life. Theory of mind (ToM) is a social-cognitive construct that concerns the ability to attribute mental states to the self and others. Inferences have been drawn between ToM and social functioning as a result of research indicating impaired ToM performance in clinical populations characterized by marked social deficits. Some research has indicated that ToM performance may decline with age, and it has often been argued that this could impact social functioning in late life, though this has not been tested empirically. This study hypothesized that advanced ToM (the Faux Pas Test and the Eyes Test) would predict social functioning (network size, social exchanges, perceived social support, and informant report of social behaviors) in a sample of 78 community-dwelling older adults. Contrary to predictions, there were no significant relationships between ToM and social functioning in this sample. Although the importance of ToM has often by highlighted by its proposed link with social functioning, in this sample of relatively healthy older adults this link was not supported across a variety of social functioning measures. Low power and the use of a non-clinical sample may have limited the findings.

COGNITION-ENVIRONMENT INTERACTIONS IN PREDICTING PHYSICAL ACTIVITY
J.P. Ziegelmann1,2, B. Schüz1, S. Wurm1, L. Warner2, R. Schwarzer2, C. Tesch-Roemer1, 1. German Centre of Gerontology, Berlin, Germany, 2. Freie Universität Berlin, Berlin, Germany

Background. Social-cognitive theories assume a role of context factors for health behavior. However, this relation is often weakly specified and rarely examined. The two studies presented here test whether...
properties of the meso-context (districts) affect if and how health-related cognitions are translated into physical activity. Methods. Study 1 (survey, N=6,200), Study 2 (older adults, N=300). Both assessed physical activity and health-related cognitions. Context factors (GPD at district level) were examined in multilevel models for cross-level interactions. Findings. GPA affects intercepts and slopes of attitudes in predicting physical activity (B=.08, Study 1). GPA also affects intercepts and slopes of intention (B=.06) and planning (B=.11 and .07) in predicting activity in Study 2. Discussion. These findings suggest that apart from individual-level factors such as attitudes, intentions, or planning, the opportunity structure of the environment may play an important role in determining whether health-related cognitions can be translated into actual health behavior.

ACCEPTABILITY AND FEASIBILITY OF MEANINGFUL ACTIVITY PROGRAM FOR MILD COGNITIVE IMPAIRMENT COUPLES

Y. Lu, J.E. Haase. Adult Health Nursing, Indiana University School of Nursing, Indianapolis, Indiana

Persons with mild cognitive impairment (PwMCI) are at greater risk for developing Alzheimer disease, and have diminished functional ability and quality of life. Few interventions focus on helping PwMCI improve or maintain functional performance and enhance quality of life through meaningful activity engagement. The Daily Engagement in Meaningful Activity Program (DEMA) was developed based on the Model of Human Occupation and a phenomenon of patients and spouses experiences with MCI. This presentation reports findings from a pilot study that explored the acceptability and feasibility of DEMA with PwMCI and their spouse (n = 10 dyads) and examined DEMA’s impact on meaningful activity engagement (performance and satisfaction) and health-related outcomes (relationships with family member, depression, physical functioning, cognitive function, and quality of life). During six bi-weekly, 1-hour sessions delivered over 3 months, participants learned ways to work together to set and meet meaningful activity goals, and adapt to changes that might occur over time. Data were collected pre-, post-, and 3 months post-intervention. Findings on rates of consent, session completion, and questionnaire completion indicate the DEMA and study procedures were well accepted by participants. Immediate post-program measures suggest positive trends in meaningful activity engagement performance and satisfaction and relationships with family members. Positive trends at 3-month post program were found in meaningful activity engagement performance and satisfaction. Relationships with family members, depression, physical function, cognitive function, and quality of life were maintained. Based on the promising positive results, further testing of the DEMA in a 2-group randomized clinical trial is recommended.

EVERYDAY PROBLEM-SOLVING AND INSTRUMENTAL ACTIVITIES OF DAILY LIVING: SUPPORT FOR DOMAIN SPECIFICITY

K.J. Kimbler, S.A. Lacy, L.A. Ferrante. Social & Behavioral Sciences, Florida Gulf Coast University, Fort Myers, Florida

Previous research has demonstrated a relation between everyday problem-solving performance and self-reported functional ability (e.g., Allaire & Marsiske, 2002). The current study examined the relation between the Everyday Problems Test (EPT; Willis & Marsiske, 1997) and Instrumental Activities of Daily Living (IADL; Lawton & Brody, 1969) among a sample of middle-aged and older adults (N = 102). The EPT measures everyday problem-solving performance in the domains of telephone use, shopping, meal preparation, housekeeping, transportation, health, and finances. Although the domains that are included in the EPT correspond with IADLs, the EPT focuses on cognitive performance. As a result, the EPT has been found to demonstrate small to moderate sized correlations with self-report measures of IADLs (Burton, Strauss, Bunce, Hunter, & Hultsch, 2009). In the current study, EPT scores did not significantly relate to IADLs (p = .26). Although total scores were not significantly related, further analyses revealed that domain specific performance on the EPT significantly predicted self-reported functional ability within the corresponding IADL domain (p < .05). This significant relation was found for shopping, food preparation, housekeeping, transportation, and financial management. EPT scores related to shopping, food preparation, and housekeeping significantly predicted self-reported IADL status after accounting for age, verbal ability, and inductive reasoning. Results suggest that the predictive utility of the EPT in explaining variance in IADLs may be improved by using a more domain specific approach. The potential impact of measurement issues, age differences, and sample characteristics will also be discussed.

LATENT COGNITIVE PREDICTORS OF TIMED INSTRUMENTAL ACTIVITIES OF DAILY LIVING WITH OLDER ADULTS

Purpose: In this structural equation modeling study, latent variables of cognition (speed of processing, memory, and executive function) were constructed to investigate which ones were most predictive of performing tasks on the Timed Instrumental Activities of Daily Living (TIADL) test using a sample of older adults. Methods: A cross-sectional study sample included 210 community-dwelling older adults (58% male, 85% Caucasian) age 65 and older (Mage = 75). Participants were administered a battery of cognitive, physical, and psychosocial measures along with the TIADL test. Results: Using structural equation modeling, latent variables were constructed based upon the type of cognitive measures that most closely corresponded to the cognitive domain being tested. A hypothetical model was specified and then non-significant paths were trimmed. The trimmed model fit the data well (e.g., GFI = .93, RMSEA = .7). There was a relationship between age and cognitive latent variables. Conclusion: Depressive symptomatology, speed of processing, and memory predicted physical function. Physical function and memory predicted better performance on the TIADL test. Implications for further research are posited.

SLEEP PROBLEMS AND BLOOD PRESSURE: INTERACTIVE PREDICTORS OF COGNITIVE FUNCTION IN OLDER ADULTS?

R.C. Sims1, M.A. Hosey2, L. Katzel1, S.R. Waldstein2, I. Howard University, Washington, District of Columbia. 2. University of Maryland Baltimore County, Baltimore, Maryland. 3. University of Maryland School of Medicine, Baltimore, Maryland

Sleep problems are common among older adults and have been associated with deficits across a number of cognitive domains including memory, executive function, attention, processing speed, and global cognition. Sleep problems have also been associated with elevated blood pressure, another predictor of deficits in cognitive function among older adults. Previous studies have been limited in their ability to fully assess the relations between sleep problems and cognitive function due to uni-dimensional assessments of sleep quality and/or limited cognitive data. Furthermore, few studies have examined the interaction of sleep problems and blood pressure as a predictor of cognitive function. The purpose of the analysis was to examine relations among an index of sleep problems, blood pressure, and numerous domains of cognitive function. It was hypothesized that more self-reported sleep problems would predict poorer cognitive performance, particularly in the presence of higher blood pressure. Participants were 178 stroke- and dementia-free older adults [M(SD) age = 66.48 (6.83); M(SD) education = 16.26 (2.94)]. They completed the Medical Outcomes Study (MOS) Sleep Scale, several neuropsychological measures, and a health assessment. Multiple regression analyses were run, controlling for age, gender, education, depression, BMI, alcohol use, and smoking status. Results
showed no direct associations between sleep problems and any domain of cognitive function; however, an interaction between sleep problems and systolic blood pressure was identified as a predictor of visuospatial ability. Findings suggest that, for at least one domain, blood pressure may exacerbate the negative influence of sleep problems on cognitive function.

EFFECTS OF A HOLISTIC MEMORY CLINIC FOR OLDER ADULTS
L. Hyer, C. Scott, C.A. Yeager, 1. Georgia Neurosurgical Institute, Macon, Georgia, 2. Essex County Hospital Center, Institute for Mental Health Policy, Research, and Treatment, Cedar Grove, New Jersey

The core issue related to cognitive training at older ages is whether, through targeted interventions, we can affect the aging brain’s basic operating characteristics beyond the neural changes associated with just new knowledge or strategies. In effect, can training assist with the software of the cognitive system? Increasingly, training seems to assist normal adults, but its merit for older adults with age associated memory impairment (AAMI) and mild cognitive impairment (MCI) is less clear. A question also is whether training targeting working memory generalizes to better adjustment. To assist in this process, a “holistic” program for older adults was developed, encompassing cognitive or memory training, as well as other empirically-supported areas. This six-session, manualized Memory Clinic involved several cohorts of older adults (N=100) who had AAMI and MCI. At base, this intervention involved an intense focus on attention/concentration, along with mindfulness, exercise, stress reduction, socialization, and health behaviors. Interim phone calls and one booster session were added. We conducted pre and post testing on cognition (List Learning, Story Memory, Coding, Digit Span, Recall and Recognition), memory habits (Cognitive Failures Questionnaire) and attitudes, as well as function and adjustment (SF36). We also provided a measure of compliance. Results show positive changes on all measures over baseline with those related to memory reaching significance. At the beginning, we identified at-risk and successful participants; the former performed considerably worse on cognitive and affect measures than successful ones. We discuss the results in the context of cognitive training and quality of life.

SESSION 1005 (POSTER)

MEDICAL INTERVENTIONS AND SERVICE USE IN OLD AGE

OLDER ADULTS’ DENTAL CARE SERVICE UTILIZATION: A TEST OF THE BEHAVIORAL HEALTH CARE UTILIZATION MODEL
H. Lee, J.A. Burr, Gerontology, Univ. of Massachusetts Boston, Boston, Massachusetts

Oral health is consistently shown to be associated with older adults’ overall well-being. To maintain good oral health in later life, regular utilization of dental care services is strongly recommended. However, many factors mitigate the ability to attain this important type of health care. The aim of this cross-sectional study is to describe the dental health care utilization patterns of older adults by applying Andersen’s (1995) Behavioral Model of Health Care Utilization. The model includes predisposing characteristics (age, gender, race, years of education, and life satisfaction), enabling factors (income and dental care insurance), and need factors (general health status and dental health status). The utilization of dental care services is the dependent variable in this study. Data are analyzed from a special module of the 2008 Health and Retirement Study that collects detailed information on dental health, accessibility to dental care, and dental care services utilization (N=1,323). Results from the analysis show that 65.8% of respondents aged 55 and older used dental care services between 2006 and 2008. Other results show that persons higher on the SES ladder are more likely to have visited a dentist in the previous two years, and that African Americans and Hispanics are much less likely than Whites to have seen a dental health care professional. Self-reported health status and presence of a dental health condition are positively related to the likelihood of using these services. These results provide indirect support for the cumulative advantage/disadvantage hypothesis.

TRAINING-INDUCED NEURAL PLASTICITY: FUNCTIONAL CORRELATES OF A MENTALLY REHEARSED GOLF SWING
L. Bezziola,1,2, S. Mérillat, L. Jäncke1,2, 1. University of Zurich, Institute of Psychology, Neuropsychology, Zurich, Switzerland, 2. University of Zurich, International Normal Aging and Plasticity Imaging Center (INAPIC), Zurich, Switzerland

The present functional magnetic resonance imaging study aimed to improve our knowledge about training-induced neuronal adaptations in golf novices between the age of 40 and 60 years by means of a longitudinal study design. Mental motor imagery was used to study motor skill learning and the associated neural underpinnings. We were particularly interested in changes of neuro-functional recruitment patterns that can be ascribed to the golf training. Eleven golf novices participated in the present longitudinal study with two measurement timepoints. The interval between the two measurements amounted to 40 golf-training hours. Additionally, we collected data from an age- and sex-matched control group with the same inter-measurement interval as the golf group. The participants were instructed to mentally rehearse their own golf swing from a first-person perspective. We performed a repeated-measures ANOVA (i.e., flexible factorial model in SPMB) with within-subject factor time and between-subject factor group. As expected, the analyses revealed increased hemodynamic responses during the mental imagery condition in non-primary cortical motor areas, sub-cortical motor areas and parietal regions in both groups. This result is in line with previous mental imagery research showing the involvement of motor areas while mentally rehearsing a complex movement, especially in subjects with low skill level. More importantly, only the golf novice group showed changes between the two measurement timepoints. Hemodynamic responses were decreased in non-primary motor areas after the practice interval. We assume that this finding relates to the improved skill level in the golf group after the 40 training hours.

DELIRIUM INTERVENTIONS: STATE OF THE SCIENCE
C. Brown, University of North Carolina at Greensboro, Greensboro, North Carolina

Post-operative delirium affects approximately 25 % of participants over the age of 60 having major surgery with nearly 10 % continuing with long term derangement and/or subsequent institutionalization. In 2010, the National Institutes of Health had a roundtable on opportunities to advance psychiatric emergencies. Delirium was one of a selection of key emergencies where more research is deemed imperative. There is extensive and growing science regarding delirium. In a literature review utilizing the search engines PubMed and Ovid, the terms “delirium” and “interventions” yielded studies that examined the etiology, risk factors, pathological processes, clinical presentations (i.e. psychomotor subtypes) as well as interventions to ameliorate delirium. This presentation will summarize the many interventions that are derived from scientific findings about predisposing or precipitating factors associated with delirium. Intervention studies are categorized as prevention, management or treatment of delirium. The management or prevention of delirium interventions are identified as pharmacologic or non-pharmacologic. The studies that demonstrated the greatest effectiveness were multicomponent, multidisciplinary, and aimed at prevention of delirium. Pharmacological therapies carry an increased risk of death, and efficacy is inconsistent. These findings support continued interdisciplinary collaboration, systematic detection, management and follow-up.
of those at risk for delirium, beginning with pre-hospital admission assessment and extending through discharge.

**USE OF COMPLEMENTARY AND ALTERNATIVE MEDICINE FOR ARTHRITIS BY OLDER WOMEN**

Half of adults ages 50+ in the United States use complementary and alternative medicine (CAM). Women and people with chronic health conditions are more likely than others to use CAM. Women with arthritis may be particularly likely to use CAM, because conventional medicine offers limited relief. Yet little is known about CAM use for arthritis by older women. Using data from the 2007 National Health Interview Survey and its CAM supplement, we examined specific reasons why women ages 50+ said they used CAM for arthritis. Descriptive and logistic analyses accounted for the survey design, and were weighted for national representativeness. Controls included age, ethnicity, education, marital status, income, health insurance, body mass index, health behaviors, comorbidities, and region. Participants who said they had arthritis represented about 21 million women ages 50+; 17.8 million used CAM for any reason; 1.2 million used CAM specifically for arthritis. In adjusted results, women with arthritis were more likely to say they used CAM specifically for their arthritis if conventional medicine did not help (Odds Ratio, OR 5.19, 95% Confidence Interval, CI 3.19-8.44), CAM was recommended by a health care provider (OR 3.43, CI 2.22-5.31), or CAM was recommended by family or friends (OR 4.29, CI 2.76-6.66). A large number of older women use CAM for arthritis, particularly if conventional medicine does not help or if recommended by a provider, or by family or friends. Women with arthritis could particularly benefit from targeted research on risks and potential efficacy of CAM.

**AN EXAMINATION INTO THE SLEEP WORLDS OF OLDER WOMEN WHO USE BENZODIAZEPINES**

S.L. Canham, R. Rubenstein, University of Maryland, Baltimore County, Baltimore, Maryland

Sleep – its quality, quantity, and features – is a major concern of informants interviewed for a qualitative study of the experience of benzodiazepine (BZD) use in a sample of community-dwelling women (65+). The sleep worlds of informants were often a topic of conversation and sleep was identified as significant in their lives both as an entity in itself and in relation to the “day” as an experiential unit. This paper explores how informants in this study conceptualize the reasons for sleep problems, including issues related to both health and intrusive thoughts; how BZDs are related to the management of sleep problems; and what strategies women use to get to sleep when their BZDs are unable to affect sleep onset, such as environmental considerations in the home. Finally, we discuss how sleep fits into their conception of a “day” and how BZDs not only impact the sleep worlds of informants, but also the actions and feelings of informants throughout the daytime. These findings are significant in that informants appear to be attempting to find a balance between taking a dose too high, which can potentially have side effects, including dependence, and taking a dose too low, which is unhelpful in bringing about the sedating effects of a BZD.

**REDUCING THE IMPACT OF CONTINENCE DIFFICULTIES FOR OLDER ADULTS THROUGH TECHNOLOGY, TREATMENTS AND THEORY (TACT3)**

M.L. Gilhooly1, E. van den Heuvel1, F. Jowitt1, J. Bichard2, 1. Brunel Institute for Ageing Studies, Brunel University, Uxbridge, United Kingdom, 2. Royal College of Art, London, United Kingdom

Incontinence can be a precursor to social isolation, loss of self esteem and depression. The aim of this interdisciplinary project is to reduce the impact of continence difficulties and, thus, assist older people in maintaining a positive identity and good quality of life. The TACT3 project is comprised of three research workpackages: Assistive technology development: Underwear with an integrated washable wetness sensor and vibrating alert mechanism has been developed to alert continence pad users to leakage from the pad. In addition, a colour change odour detector to indicate the presence of the odour of urine at a just imperceptible level is being developed. Challenging environmental barriers to continence: Two sets of stakeholders are involved, older people with continence difficulties and toilet providers. Focus groups, workshops, interviews and photographic diaries have been conducted to identify key issues. A design tool and pictorial reference cards will be produced. Improving continence interventions and services: Patients and their carers are being interviewed twice within a 12 month interval from a community continence service, a specialist older people’s service and a generic continence clinic. Twenty Health and social care managers and 200 practitioners will be surveyed for their views. Care outcomes will be analysed from each clinic and a cost benefit analysis will be carried out. Findings from the first two years of this three year interdisciplinary project will be presented. A prototype of the vibrating underpants will be on display. This research is funded by the UK New Dynamics of Ageing Programme.

**THE ROLE OF NUTRI-EPIGENETICS AND PERSONALIZED MEDICINE IN DIETARY LIFESTYLE CHOICES IN ALZHEIMER’S DISEASE**

G.M. Pasinetti, 1. Neurology, Mt.Sinai School of Medicine, New York, New York, 2. James J Peters Veterans Affairs Medical Center, Bronx, New York

Alzheimer’s Disease (AD) has no known cure or preventative treatments. This presents an urgent need to find a means to prevent and/or delay disease onset, or to reverse the course of the disease. Unhealthy lifestyle choices are associated with obesity, dislipidemia, and hypertension, which are all risk factors for AD. Interestingly, recent personalized medicine nutri-epigenetic studies support the possibility of identifying potential “successful” responders that could benefit from changes in dietary lifestyles. In particular, certain nutritional factors may attenuate the incidence of AD dementia, and the biochemical functions and mechanistic pathways underlying the potential benefits of specific nutrients on AD dementia are currently being defined and scrutinized. Nevertheless, the reason for inconsistency of dietary lifestyles and supplementation in attenuation of cognitive decline in abnormal aging and neurodegenerative disorders is not well understood. Thus the identification of biomarkers, to predict efficacy of altered dietary lifestyles and monitor the adherence to dietary patterns will help to improve the likelihood of success of lifestyle changes in age-related disease prevention. The increased need for this approach is currently documented in the exponential demand from consumers for novel dietary recommendations for preventing and/or treating age related degenerative conditions. Collectively, this evidence supports the possibility that in the near future we might employ dietary intervention to prevent and/or treat age-related neurodegenerative disorders such as AD dementia and that novel “personalized medicine” approaches will to identify subjects that preferentially benefit from lifestyle modification. (Supported by National Institute of Health grant P01AT004511 to GMP).

**EFFECTS OF VISION EDUCATION CLASSES ON THE WELL-BEING OF OLDER ADULTS WITH MACULAR DEGENERATION**

S. Sorensen1, K. Zanibbi1, K. White1, S. Schwalm2, L. Luna2, K.C. Hopper2, 1. Psychiatry, University of Rochester School of Medicine and Dentistry, Rochester, New York, 2. Association for the Blind and Visually Impaired-Goodwill, Rochester, New York

Older adults with vision impairment are at increased risk for falls and hospitalizations; they find it more difficult to take their medications properly, and are more likely to be socially isolated. They are often
poorly informed about their eye condition and the services and devices that help maintain functioning. Attending vision education classes may improve well-being for older Age-related Macular Degeneration (AMD) patients. Older adults with AMD (N=76; 25 males, 51 females aged 62–96, mean= 83.0), attended four vision education classes addressing medical issues, orientation and mobility, in-home adaptations, and emotional adaptation to AMD. Measures included the CESD-R for depressive symptoms, the STAI for anxiety symptoms, and the Ryff Psychological Well-Being scales. Using repeated measures ANCOVA (covariates: age and gender), yielded significant changes for an overall decrease in Personal Growth (p<.001), but also an interaction (p=.001) indicating a decrease in PG in older participants and an increase in younger participants. Near-significant main and interaction effects were found for Anxiety Symptoms (p=.061): subjects 75 and older became less, whereas younger participants became more anxious after class attendance; Purpose in Life (p=.055; interaction p=.040): younger individuals increased, whereas the older individuals decreased in purpose in life. Surprisingly, main effects suggested primarily negative effects of the classes. However, interactions suggest that young individuals benefitted more with regard to personal growth and purpose in life, whereas older adults benefitted more with regard to anxiety reduction. These results need to be interpreted with caution, since the younger age group consisted of only 10 participants.

SESSION 1010 (POSTER)

MENTAL HEALTH AND WELL-BEING IN LATER LIFE

WISEDOM AND WELL-BEING ACROSS THE LIFESPAN

J. Webster1, G.J. Westerhof2, E.T. Bohlmeijer3, 1. Langara College, Vancouver, British Columbia, Canada, 2. University of Twente, Enschede, Netherlands, 3. University of Twente, Enschede, Netherlands

Considered the pinnacle of psychosocial development, and the outcome of a long, well-lived life, wisdom ostensibly confers advantages to persons who possess it. Nevertheless, the relationship among wisdom, aging, and well-being is still not fully understood. This study investigated the relationship between wisdom and several measures of well-being across the lifespan. Participants included 186 male and 326 female Dutch adults ranging in age from 17 – 92 (M = 46.46, SD = 21.37) who completed measures of wisdom (Self-Assessed Wisdom Scale, Webster, 2010), personality (NEO-FFI, Costa & McCrae, 1992), mental health (Mental Health Continuum, Keyes et al., 2008) physical health (General Health Questionnaire, Goldberg, 1978), and a balanced time perspective (Balanced Time Perspective Scale, Webster, 2011). A series of 2 (wisdom) x 3 (age) ANOVAs revealed main effects for both variables in support of hypotheses. Main study findings revealed that wisdom was unrelated to physical health but positively related to openness to experience, mental health, and a balanced time perspective. Overall, midlife adults scored higher on wisdom than either younger or older participants. Older adults scored lower on physical and mental health, openness, and the use of a balanced time perspective. The results are discussed from a lifespan perspective in which gains and losses contribute to conditions in which midlife adults show high levels of wisdom and well-being.

IDENTITY AND WELL-BEING IN PEOPLE WITH DEMENTIA

L.S. Caddell, Psychology, Bangor University, Bangor, United Kingdom

Background: Past research has concentrated on how identity is affected by the onset and progression of dementia, and the theoretical literature has often suggested that the persistence of identity would support well-being. However, there is little empirical work that actually tests this hypothesis or quantifies the relationships between identity and aspects of well-being. Method: Fifty people with early-stage dementia completed measures of identity, mood, and well-being. Measures of identity included strength of identity, importance of role identities, self-knowledge of personality and autobiographical memory. Measures of mood included anxiety and depression, and measures of well-being, included self-esteem, quality of life, and quality of relationship with a close relative. Results: Results suggest that aspects of mood well-being are influenced by aspects of identity, and that improved mood and well-being is supported by the importance of role-identities to the person with dementia, a stronger and more definite sense of identity, better autobiographical memory functioning, and superior self-knowledge of personality. Conclusion. These results support the notion that the persistence of identity is valuable for people with dementia in terms of supporting well-being, and that identity might be an appropriate target for intervention. The implications of the results will be discussed.

THE GENERATIVITY AND MENTAL HEALTH OF CHILDLESS ADULTS

K. King, Massachusetts School of Professional Psychology, Boston, Massachusetts

Children are thought to be an important source of support and fulfillment for their aging parents, and well-documented stereotypes show a common assumption that childless adults have lower mental health than parents. Further, it is often assumed that the adult developmental task of generativity is primarily achieved through the experience of parenting. This study explores whether there is support for these views by comparing childless adults to parents on measures of generativity and mental health. An online survey was completed by 98 parents, 113 voluntary childless, and 24 involuntary childless individuals. Mental health and generativity were explored through the Center for Epidemiological Studies- Depression scale, Scale of Positive and Negative Experiences, Psychological Well-Being scale, Satisfaction with Life scale, Generative Behavior Checklist, Loyola Generativity Scale, and questions about psychiatric treatment history. Results revealed few significant differences between groups. Parents scored significantly higher than the voluntary childless on psychological well-being and positive affect, and significantly higher than the involuntary childless on life satisfaction. Parents reported more treatment for psychological difficulties than both childless groups, but lower past usage of psychiatric medications. On the Loyola Generativity Scale and the Generative Behavior Checklist, parents scored significantly higher than both childless groups. The minimal significant differences between groups on measures of mental health has important clinical implications given common stereotypes suggesting otherwise. With regard to generativity, significant differences between parents and both childless groups raises important questions about the place of this developmental task in the lives of all adults.

PET OWNERSHIP AND HEALTH CORRELATES AMONG ELDERS IN THE PHILADELPHIA AREA

C. Hoffman1, A. Glicksman1, M.H. Kleban1, K.O. Clark1, 1. Planning, Philadelphia Corporation for Aging, Philadelphia, Pennsylvania, 2. Polisher Research Institute of the Abramson Center for Jewish Life, North Wales, Pennsylvania

Interest in the possible health benefits associated with companion animals continues to grow, while data on the topic remain scarce. The 2010 Public Health Management Corporation’s Community Health Survey, a representative sample of older adults age 60+ in Philadelphia and the four surrounding counties (n=3029) included a question about the presence of pets in homes of respondents. 37% of this population has at least one pet. 16% have one dog, another 12% have one cat, 4.3% have a dog and a cat and 5% have some other combination of animals. Relationships with demographic, physical health, mental health and social capital variables will be examined. Pet owners are more likely to be under age 75 (r=-.21, p>.000), not live alone (r=.13, p>.000) and...
have better self-rated health (r=.04, p>.01). Some of the findings also challenge our expectations. The discussion will examine differences between urban and suburban residents, as well as between cat and dog owners.

CHILDLESSNESS AND LIFE SATISFACTION IN LATER ADULTHOOD
M. Plikun, M.E. Blake, D. Canuana, A. Niehau, R.D. Reeves, Department of Law, Politics, and Society, University of Evansville, Evansville, Indiana

In virtually every society, the assumption is that people will reproduce. Indeed, both developmental and life course theorists have incorporated parenting into their conceptualization of normative life tasks (George, 1993; Somers, 1993). A logical assumption, therefore, would be that parental status may correlate with satisfaction throughout the life cycle. The authors of the present study are attempting to determine whether an actual relationship exists between parental status and life satisfaction and the marital relationship at mid-life and beyond. The authors consider general factors associated with life satisfaction and the quality of the marital relationship in later years, and give particular attention to differences that exist between people with and without children. Using multiple waves of the Americans' Changing Lives Study (House, 1986; 2002), the authors explore the role of children in later life satisfaction. Specifically, the questions guiding this research are: 1) Do children play a part in life satisfaction as we age?; 2) If so, what role do they play in satisfaction?; and 3) How are life satisfaction and the marital relationship different for people who do not have children? Preliminary findings suggest that life satisfaction and the marital relationship are, in fact, affected by parental status. Individuals who have been childless across the life course seem to have greater marital satisfaction and positive life satisfaction compared to individuals who have had children. Possible differences between voluntary and involuntary childlessness are discussed.

TARGETING SCARCE RESOURCES TO PROMOTE SCREENING AND BRIEF INTERVENTION PROGRAMS FOR OLDER ADULTS
C. Coogle, J.M. Hellerstein, M. Weaver, R. Whitsett, 1. Virginia Center on Aging, Virginia Commonwealth University, Richmond, Virginia, 2. Virginia Department of Alcoholic Beverage Control, Richmond, Virginia

Screening and Brief Intervention (SBI) techniques have been widely applied as a public health approach to the delivery of treatment services that address risky drinking and alcohol abuse. Now SBI has become increasingly available to older adults at risk for developing substance use disorders. In Virginia, SBI training sessions have targeted hospital-based health care providers as well as mental health service providers in community-based clinics. Trainees have included physicians and physicians in training, nurses, nurse practitioners, physician assistants, social workers and therapists (n=43). After the trainings, participants were asked about their intentions to apply the information in their professional practices and their enthusiasm about recommending the training to others in their profession. Although the professions compared did not differ with respect to their level of commitment to apply the information or level of comfort using the techniques (p>.05), our pilot investigation of this small sample revealed that physicians were less interested in promoting the SBI training among their professional colleagues (M= 4.40, SD = 0.63) than those in the other primary care disciplines or related supporting professions (M = 4.85, SD = 0.37; p < .05). Similar site differences in this respect were also found. Although it may be more challenging to promote SBI training in locations that don’t primarily provide mental health services, hospitals and other primary care settings are precisely where training may be most useful. Other results have implications for improving receptivity to training and addressing the barriers that dampen enthusiasm for SBI training.

COMPLIMENTARY AND ALTERNATIVE TREATMENTS FOR MENTAL HEALTH IN A DIVERSE NATIONALLY REPRESENTATIVE SAMPLE
C.B. Wolley, R.S. Allen, G. Kim, 1. Department of Psychology, University of Alabama, Tuscaloosa, Alabama, 2. Center for Mental Health and Aging, Tuscaloosa, Alabama

Complimentary and alternative medicine (CAM) or treatment use is increasing in the United States with an estimated 38 percent of Americans using CAM for physician health concerns. However, CAM use to treat mental health concerns among ethnic minority (e.g. Asian Americans, Hispanic/Latino/as, African Americans) or older adults is poorly understood. The current study explores CAM use in a nationally representative diverse sample. In this sample, 20.2% of the respondents reported that they had used alternative therapies for the treatment of mental health concerns. There were significant ethnic differences (χ2(3)=339.96, p<.001) and age differences (χ2 (3)=104.65, p<.001) in who utilized alternative treatments. Non-Latino Whites endorsed the highest percentage of use, compared to Asian Americans, African Americans and Latino/a Americans. A greater percentage of adults 30-44 used alternative therapies (22.2%) compared to those in young adulthood, middle adulthood, and older adulthood. There were significant differences in the types of treatments (e.g acupuncture, herbal therapy) endorsed by ethnic group and age. The most frequently endorsed treatment was prayer or spiritual practices (12%). A number of respondents endorsed utilizing multiple treatments and MANOVA suggested that both age and ethnicity predicted the number of treatments used (F (2,19728)=85.63, p<.001). The current study suggests that CAM is utilized for mental health concerns across the lifespan by a diverse group of clients; health care providers should consider possible CAM use for mental health concerns by their clients.

CHANGES IN WELL-BEING ACROSS THE LIFESPAN: A CROSS-SECTIONAL SURVEY OF YOUNG, MIDDLE-AGED, AND OLDER ADULTS
E. Karaoylas, C.S. Mackenzie, K.B. Starzyk, Psychology, University of Manitoba, Winnipeg, Manitoba, Canada

Changes in well-being across the lifespan have been poorly understood because research has not been guided by theory and has focused on either hedonic or eudaimonic well-being outcomes. The objectives of this study is to better understand age differences in hedonic and eudaimonic well-being using Ryan, Huta, and Deci’s (2008) theory. According to this theory, four factors are responsible for living a full and deeply satisfying life (eudaimonia) and experiencing pleasure and an absence of psychological pain (hedonia): (1) pursuing intrinsic goals, (2) behaving in autonomous and volitional ways, (3) living mindfully with awareness, and (4) behaving in ways that satisfy the basic psychological needs for competence, relatedness and autonomy. Participants included 90 introductory psychology students, 90 of their parents, and 90 of their grandparents. These individuals completed a battery of questionnaires measuring personal goals, aspirations, mindfulness, basic psychological needs, and multiple measures of eudaimonic (e.g., purpose in life) and hedonic (e.g., positive affect) well-being. Results indicated that age had two effects. First, there were significant mean age differences. Age was positively associated with the pursuit of intrinsic goals, autonomous behaviour, mindfulness, the basic psychological need for autonomy, and hedonic well-being. Conversely, age was negatively associated with the basic psychological need for competence and with eudaimonic well-being. Second, the relationships amongst variables varied across age. Thus, the reasons for differences in hedonic and eudaimonic well-being across the lifespan are complex and our findings shed light on reasons for inconsistencies in previous research examining the effects of age on well-being.
SESSION 1015 (POSTER)

METHODOLOGICAL ISSUES IN AGING RESEARCH

PSYCHOLOGICAL ADJUSTMENT OF OLDER ADULTS: MEASURING THE IMPACT ON AGING
S.V. Humboldt, I.P. Leal, Instituto Superior de Psicologia Aplicada (ISPA), Lisbon, Lisbon, Portugal

Aims: There has been little attention in the research literature on the relationships between psychological adjustment and aging. This research aims at examining the relationships between older adults’ psychological adjustment, and aging. Methods: The measures used to in the study were selected to assess the reliability and validity of one new instrument, Adjustment to Aging Schedule (ATAS). Measures were completed using a variety of culturally appropriate methods, including mail-outs, self-administration and interviews. For the purposes of this study, the Health Survey Questionnaire (SF-6D), one measure of cognitive functioning - the Mini-Mental State Examination (MMSE) and demographics, were included. All variables had fewer than 2% missing values and there complete data were available for 212 older adults (mean age 80.3, SD = 6.9, range 74-101)) from eight different nationalities. Exploratory factor analyses were run for data reduction and for exploring theoretical structure. Controlling for age, gender and country of origin, we assessed the level of psychological adjustment of elderly people, and its impact on aging. Results: Psychological adjustment appears to be a catalyst to attitudinal markers of maturity and internal development which in turn impact aging, across cultures. All estimates were statistically significant (p<0.01). Conclusions: This cross-cultural study illuminates links among psychological adjustment and aging in older age, warranting further study across cultures among trailer populations over time. Recommendations for future research on older adults’ psychological adjustment and clinical practice are also presented. Key Words: Aging; Older Adults; Perceived age; Psychological Adjustment; Successful aging.

SURVEYS OF THE OLDEST OLD – WHO DO THEY REPRESENT?

Surveys of the oldest old population are associated with several design issues. Place of residence and possible physical or cognitive impairments make it difficult to maintain a representative elderly study population, in cross-sectional as well as longitudinal studies. Based on a nationally representative Swedish survey of those aged 77+, incorporating over 40 years of panel data, this study aimed to identify the characteristics of the groups of elderly people that risk being under represented. We also investigated how the prevalence of different health measures – ADL, mobility and psychological problems – differed depending on study design and response rate. Compared to directly interviewed people living at home, institutionalized and proxy interviewed individuals were older, less educated and more likely to be female. They had more problems with health, mobility and ADL, and a significantly increased mortality risk. If the study had excluded the institutionalized part of the population and/or failed to use proxy interviews, the result would have been severely biased and resulted in underestimated prevalence rates for ADL, physical mobility and psychological problems. Attaining representative samples of the oldest old population is extremely challenging. However, as this sector of the population is increasing rapidly, it is crucial that we learn how to better estimate their health status and living conditions. In surveys of the oldest old, high non-response rates and/or low levels of proxy-interviews indicate a biased study population. Accurate population estimates require that individuals are represented regardless of their living conditions, education, health status and cognitive ability.

HOW ACCURATE ARE SELF-REPORTED HEIGHT, WEIGHT, AND BODY MASS INDEX AMONG COMMUNITY-DWELLING ELDERLY JAPANESE? EVIDENCE FROM A NATIONAL POPULATION-BASED STUDY
Y. Saito, V. Yong, Nihon University, Tokyo, Japan

The aim of the study is to investigate the extent of accuracy of self-reported height, weight, and derived body mass index (BMI) of elderly Japanese aged 70+; and to assess the concordance between report-based and measurement-based BMI weight categories. The 5th wave of Nihon University Japanese Longitudinal Study of Aging included questions on self-reported height and weight, and direct physical measurements of height and weight. Results indicate that self-reported values were strongly correlated with measured values. The differences in mean values were small. On average, height was over-reported by 0.93cm (SD: 2.48) for men and 1.23cm (SD: 2.84) for women. Weight was under-reported by 1.08kg (SD: 2.55) for men and 0.88kg (SD: 2.45) for women. BMI was under-estimated by 0.68kg/m2 (SD: 1.16) for men and 0.79kg/m2 (SD: 1.49) for women. As age increases, height over-reporting increased, particularly among women, but weight under-reporting decreased for women, and BMI under-estimation increased for both sexes. Weighted kappa values showed a reasonably high concordance at 0.715 and 0.670 for men and women, respectively (p<0.0001). Overweight (BMI 25.0 to 29.9) and obesity (BMI ≥ 30) prevalence rates were under-estimated, with better specificity (range: 94.4-100%) than sensitivity (range: 59.3-65.1%). We conclude that the accuracy of self-reported height and weight is reasonably high among elderly Japanese, suggesting that they can be used in epidemiological surveys. However, caution should be exercised for the oldest age group (age 85+) as the accuracy declined.

STRESS ASSESSMENT: A COMPARISON OF CHECKLIST VS. INTERVIEW - BASED SYSTEMS IN AN OLDER ADULT SAMPLE
A. Yoder1, S. Scott1, C.S. Bergeman2, S. Monroe2, 1. Clinical Psychology, University of Notre Dame, Elkhart, Indiana, 2. Georgia Institute of Technology - School of Psychology, Atlanta, Georgia

The assessment of life stress must be reliable and valid as it has potentially powerful implications for understanding physical and mental health. The prevailing approaches to life stress assessment are interview-based and checklist systems. Previous research shows these two methods differ in assessing life stress due to definitional and operational disparities. Most research on stress measurement has occurred in younger samples yet stress measurement issues in older adults are equally important. Major events such as loss of a spouse, retirement, and health crises are common problems in later life. The present study replicates previous research by McQuaid et al. (1992) comparing an interview-based measure, the Life Events and Difficulties Schedule (Brown & Harris, 1978), to a checklist measure, the Elders Life Stress Inventory (Aldwin, 1990). The current study extends previous work by focusing on older adults, using a sample of depressed outpatients (n = 16), and a matched community sample (n = 16). The two measurement systems were compared by identifying discrepancies between the events endorsed on the checklist and the events identified with the interview-based measure. The main findings replicate prior research, revealing that the two systems yield a significant number of discrepancies in number and kinds of events. Further, the interview measure predicted depressive symptoms whereas the checklist did not. Although checklist measures are appealing due to their simplicity, this study provides further evidence
for the use of interview-based measures in depression research, and importantly extends such evidence to older adult samples.

EZCURVE: AN AUTOMATED PROGRAM FOR MODELING LONGITUDINAL DATA
L.L. Lo1, S. Liu1, M. Rovine1, K. Kosloski2, 1. Pennsylvania State University, University Park, Pennsylvania, 2. University of Nebraska, Omaha, Nebraska

The growth curve model is one of the mostly widely used statistical models for longitudinal designs with repeated measures data and is particularly useful in studying the aging process for psychological and biological domains. This modeling technique can be a time consuming procedure that involves many statistical decisions regarding the shape of the curve as well as the covariance structure associated with the chosen curve. The EZcurve program uses two algorithms that automatically identify and estimate the curvature and covariance structure for growth curves. The two alternative algorithms identify models based on iterative implementations of the linear mixed effect model. The algorithms are described alongside a visual schematic that depicts the modeling process. EZcurve is designed to be easy to use, merely requiring a data set with no other commands necessary. Additionally, the program allows optional commands to allow for flexible modeling capabilities. The results of a Monte Carlo statistical simulation demonstrate the accuracy of the program in varying data conditions. A real data example shows the implementation of the program in a study of psychological burden and identity discrepancy of a sample of aging individuals. The EZcurve program is free of charge and is available on multiple statistical platforms with the intention to facilitate longitudinal research. After attending this poster, participants will be able to apply concepts of growth curve modeling as well as the algorithms implemented for identifying such models. Participants will also be able to identify suitable available algorithms for differing data conditions.

DIRECTIONALITY OF THE LONGITUDINAL RELATIONSHIP BETWEEN OBJECTIVE AND SUBJECTIVE HEALTH
G.I. Caskie1, A. Berkowitz2, J. Margrett1, 1. Education and Human Services, Lehigh Univ, Bethlehem, Pennsylvania, 2. Iowa State University, Ames, Iowa

Objective health measures have been shown to be reliable predictors of subjective health measures (e.g., self-rated health) within time; however, more information is needed about how this relationship may change over time. In addition, given Hispanic elders’ increased health risks, understanding the relationship between measures of objective and subjective health is especially important for this ethnic group. The current study uses data from Waves 1, 2, and 3 of the Hispanic EPESE, which assessed a representative sample of 3050 individuals of Mexican origin (1292 males, 1758 females) aged 65 to 99 years with an average education level of 4.85 years (SD = 3.90). Latent variables were created for objective health (OH; indicated by number of comorbid conditions, systolic blood pressure, diastolic blood pressure, standing balance test, doctor visits) and subjective health (SH; indicated by self-rated health, health and independence concerns, ADLs, IADLs). Cross-lagged structural equation models were used to examine the relative fit of four models: (1) earlier OH predicts later SH, (2) earlier SH predicts later OH, (3) a combination of both directional paths, (4) no directional paths between OH and SH. The model in which earlier SH predicts later OH had the best fit to the data; however, better SH at Wave 1 predicted poorer OH at Wave 2 (p < .001) while better SH at Wave 2 predicted better OH at Wave 3 (p < .001). Implications of these findings for understanding how the relationship between subjective and objective health measures change over time will be discussed.

SESSION 1020 (POSTER)
PAIN, HEALTH, AND SOCIAL RELATIONS

PAIN AS A MEDIATOR OF HEALTH BEHAVIORS AND ADL FUNCTIONING: A STUDY ON OLDER VIETNAMESE ADULTS

Chronic pain in older people can have adverse effects on functional capacities. The current study focuses on chronic pain in Vietnam. Vietnam has a rapidly growing population of older people, and little systematic information is available about functioning among the older population. Pain may be a significant problem due to the cumulative effects of performing physically demanding activities in daily life, chronic illness, and for some people, the lingering effects of war injuries. Frequent experience of pain is likely to lead to decreased functional capacity. The present study tests a model of the mediating role of chronic pain on activities of daily living. Drawing upon previous research in Western countries, we posited that pain mediates the effects of health behaviors and material hardship on ADL. A secondary hypothesis examined gender differences in the path from pain to ADL functioning. A representative sample of 600 adults 55 and older was recruited from Da Nang, Vietnam and surrounding rural areas. The sample was stratified by gender (50% women), age (M = 70.33), and rural/urban (50% urban) status. A structural equation model had acceptable fit indices. Based on the joint significance test, pain was found to be a significant mediator of health behaviors on ADL functioning, but not material hardship. Pain had a stronger effect on ADL for women, though it was also significant for men. These results suggest that chronic pain plays an important role in functional status. Health programs encouraging positive health behaviors should incorporate screening and treatment for chronic pain.

THE ROLE OF PAIN IN FUNCTIONAL AND MENTAL HEALTH IN OLDER VIETNAMESE
Z. Newcomer1, A.N. Leggett1, S.H. Zant1, C. Hoang2, H. Nguyen3, 1. The Pennsylvania State University, University Park, Pennsylvania, 2. The National Technical College of Medicine 2, Da Nang, Viet Nam, 3. Wake Forest University School of Medicine, Winston-Salem, North Carolina

Despite a growing older population in Vietnam, little systematic information is available on mental and functional health for planning health and social services. Today’s elders are a unique population, having experienced war and social disruption in their earlier life, as well as the daily hardships of a developing country. One consequence of these experiences may be injuries and health problems that result in chronic pain. The current study examines predictors and consequences of pain among older adults living in Da Nang, Vietnam, and surrounding rural areas. A representative sample of 600 adults 55 and older stratified by gender, age, and rural/urban was interviewed. The sample was 50% rural, 50% women, with a mean age of 70.33. Moderate to severe pain was reported by 51% of the sample. Multiple linear regressions were used to determine predictors and outcomes of pain. Among predictors, more pain was associated with being a woman, lower education levels, more material hardship, greater number of diseases and war injury. After controlling for social demographic and health factors, pain was significantly associated with depressive symptoms, worry and sleep but not functional ability. The results suggest that pain reflects the social and historical conditions in Vietnam. Low education, greater material hardship and war injury were all significant predictors of pain, and, in turn, pain had a direct impact on quality of life, as measured by depression, worry and sleep. Health officials in Vietnam should consider pain when aiming to improve mental and physical health outcomes of older adults.
DEPRESSIVE SYMPTOM CLUSTERS IN OSTEOARTHRITIS: ASSOCIATIONS WITH PAIN AND DISABILITY

There is continuing controversy over confounding somatic symptoms of depression with chronic illness and even normal aging processes. This study examines how distinct depressive symptom clusters derived from the Center for Epidemiologic Studies Depression Scale (CES-D) are differentially associated with pain and disability among older adults with knee osteoarthritis (OA). Study participants were 48 to 91 years of age (M = 76.9, SD = 9.8); 64% female, and 79.2% White. The baseline sample at Time 1 (T1) was 369; at Time 2 (T2; one year follow-up), sample size dropped to 293. Factor analysis of the CES-D using the baseline sample yielded a four factor model (depressed mood, somatic symptoms, anhedonia, and social withdrawal) that closely paralleled Radloff’s (1977) original factor structure. In baseline cross-sectional analyses regressing pain (PGC Pain Scale) on depressive symptom clusters, somatic symptoms of depression predicted pain. In parallel analyses regressing disability (AIMS-2) on depressive symptoms, somatic symptoms of depression predicted disability. In longitudinal regression analyses, somatic symptoms was the sole significant predictor of change in pain from T1 to T2. In parallel analyses of change in functional disability from T1 to T2, the somatic symptoms and anhedonia factors were significant predictors. Discussion addresses ongoing concerns over the confounding role of somatic symptoms in the association of depression with pain and disability, and the central role of anhedonia in late life depressive syndromes. PERSISTENT PAIN IN MARRIED COUPLES IN LATER LIFE
K.J. Ishler, A.L. Townsend, Mandel School of Applied Social Sciences, Case Western Reserve University, Cleveland, Ohio

Reports of persistent pain were examined in 5,386 married couples drawn from the 1998 Health and Retirement Study, a national study of adults age 50+ and their spouses. Sizeable numbers of husbands (22%) and wives (28%) reported being “often troubled by pain.” In 423 couples (8%), both spouses reported pain (“Dual-Pain,” DP). Only one spouse reported pain in 35% of couples, with more “Wife-Pain” (WP) than “Husband-Pain” (HP) couples. Neither spouse reported pain (“No-Pain,” NP) in the remaining 57% of couples. DP couples had significantly lower income and wealth than all other couples. Compared to NP spouses, DP spouses were significantly older and had less education, higher BMI, more disease conditions, more physical limitations, and higher depressive symptomatology. Similar differences were observed between DP spouses and their same-gender peers with pain in HP (or WP) couples. Additionally, DP spouses reported greater pain intensity and activity limitation. In-depth analyses of DP couples revealed that wives reported greater pain intensity, physical limitations, and depressive symptoms than husbands. Yet, DP husbands and wives’ pain intensity, physical limitation, and depressive symptom levels remained significantly correlated (ICCadj=0.10–0.32) after gender was partialled-out. Multilevel models of pain intensity also revealed similarities and differences between DP husbands and wives—e.g., more disease conditions predicted greater pain intensity in both spouses, but the impact of specific conditions varied by gender. These findings suggest that (a) pain be considered from a dyadic perspective in future research and practice, and (b) greater attention be paid to dual-pain couples.

IMPACT OF CYMBALTA IN PERIOPERATIVE SPINE PATIENTS: PAIN, DEPRESSION, AND QUALITY OF LIFE IN OLDER ADULTS
C. Scott, L. Hyer, Georgia Neurosurgical Institute, Macon, Georgia

Since its inception in the early 2000s, Cymbalta (duloxetine Hcl) has been prescribed to treat Major Depressive Disorder (MDD), generalized Anxiety Disorder (GAD), diabetic peripheral neuropathic pain, fibromyalgia, and more importantly, chronic back pain. It was soon recognized that this antidepressant had pain relief qualities, especially for fibromyalgia and patients with both pain and depression. We assessed this antidepressant agent on pain in back surgery patients who had no major depression. The participant pool consisted of people undergoing these back surgeries — lumbar microdiscectomy, lumbar decompression and fusion, or anterior cervical decompression and fusion. The study followed a controlled, double-blind model with subjects randomized to either duloxetine or placebo. All study participants (N=79) were assessed for pain, physical functioning, adjustment, and mood markers using the following clinical assessments—the BPI (Short Form), BDI-II, CIBIC-Plus, SF-36, ADCS-ADL, and the SCL-90-R. Later, cognitive measures were added (processing speed, memory, and executive functioning). Subjects were assessed a total of three times: a week prior to surgery, four weeks post surgery, and 12 weeks post surgery. Based on this early look at 79 subjects with age as a marker (< or > 55), all trends support differences in favor of Cymbalta, with preference for age. Age was not a significant factor, however. The pain scores were reduced; depressed symptoms were reduced; overall adjustment rating was improved; functioning was better; and overall quality of life was positive. Trends then reinforce the utility of Cymbalta with older adults. Further data (N=140) will provide increased power.

THE RELATION BETWEEN PAIN, PHYSICAL DISABILITY, AND DEPRESSION IN MEDICALLY FRAIL OLDER ADULTS
A. Shah, M. Piper, A. Presnell, F. Scogin, M.P. Northland, University of Alabama, Tuscaloosa, Alabama

Depression, health comorbidity, and physical functioning have an important role in the well-being of older adults. Williamson and Shaffer (2000) explain that activity restriction may mediate the relation between physical illness and depression. Earlier activity restriction models have primarily studied pain, but this theory has been extended to other health conditions (e.g. cancer). The purpose of this study was to explore how depression was related to activity restriction/ physical disability in those endorsing arthritis compared to those endorsing other physical illnesses. This study used baseline data from Project to Enrich Rural Aged Living (PEARL), which investigated the efficacy of home-delivered cognitive-behavioral therapy for 134 medically frail rural older adults age 65 and above. The Depression subscale of the Symptom Checklist 90 Revised (Derogatis, Rickels, & Rock, 1976), FAST assessment of physical functioning (Ettinger et al., 1997), and the Charlson Comorbidity Scale (Charlson, Pompeii, Alex, & Mackenzie, 1987) were assessed. Correlational analyses were conducted to evaluate the relation between physical disability and depression based on presence of arthritis. Physical functioning was significantly related to depression in older adults with arthritis (r=-.19, p=.05) and depression was not significantly related to physical disability in medically frail older adults without arthritis (r=-.04, p=.81). Descriptives of disability and depression scores by health condition will be summarized (e.g. COPD, cancer, cardiac heart failure, diabetes).

SESSION 1025 (POSTER)

SEX AND SEXUALITY IN LATER LIFE

SPIRITUALITY, IDENTITY AND SEXUALLY AGEING WELL AMONG YORUBA PEOPLE IN SOUTHWEST NIGERIA
O.M. Agunbiade, Sociology and Anthropology, Obafemi Awolowo University, Ile-Ife, Osun State, Nigeria

This study explored the realities of spirituality, identity and sexual- ity in later life among the Yoruba people in southwest Nigeria. Sixty-four vignettes based in-depth interviews and 12 focus group discussion
SEXUAL CONCERNS OF THE AGING LGBT POPULATION
K.B. Fehling, M.A. Drickamer, Yale University, New Haven, Connecticut

Human sexuality is an important determinant of quality of life throughout life. Among healthcare professionals, there’s little knowledge of how to address the sexual problems of their elder clients, especially their LGBT elder patients. This qualitative study explores issues of importance to the sexuality of the aging LGBT population. Data was collected through one-on-one digitally recorded interviews with 15 participants 60 years of age and older who identified as lesbian, gay, bisexual, or transgender. Transcripts were separately coded by members of the research team and systematically analyzed using qualitative software. Several findings paralleled results found in heterosexual aging studies: LGBT elders engaged in less genital-focused sexual behaviors, experienced decreases in sexual desire, and experienced sexual problems due to physical ailments and medications. Study participants experienced changes in their views of sexuality, most viewing sex as a more intimate and emotional act and some viewing past behaviors negatively. LGBT elders did face specific struggles that decreased satisfaction with their sexual experiences, such as small population size and past experiences with discrimination. Timing and difficulty of “coming out” influenced their willingness to discuss sexual problems with medical professionals. Most wanted the health care professional to initiate discussions. This pilot study offers several implications for future research and clinical practice. Healthcare professionals need to initiate discussions and speak to sexual issues of this population. LGBT elders who have faced discrimination or identity issues need discerning and knowledgeable providers.

ACTIVITY RESTRICTION AND WELL-BEING IN COUPLES COPING WITH OSTEOARTHRITIS: MARITAL SATISFACTION AS A BUFFER
1. Human Development and Family Studies, Penn State University, University Park, Pennsylvania, 2. Benjamin Rose Institute on Aging, Cleveland, Ohio, 3. University of Pittsburgh, Pittsburgh, Pennsylvania

Activity restriction due to osteoarthritis (OA) may negatively affect the well-being of affected patients as well as their spouse. However, the quality of the relationship between patient and spouse may also buffer this effect. We examined the association between the activity restriction and well-being of patients with OA and their spouse using the Actor Partner Interdependence Model (APIM), and also examined the moderating role of marital satisfaction. In this dyadic study, patients with OA and their spouses (N=225 dyads) independently reported on activity restriction experienced as a result of patient OA, marital satisfaction, and depressed mood. A multilevel model was used to estimate the degree to which patient and spouse reports of activity restriction were related to each partner’s depressed mood. We also examined whether marital satisfaction would moderate this association. Findings indicate that both patients and spouses reporting higher activity restriction were more likely to have depressive symptoms (actor effect). We found a significant partner effect only for spouses. That is, when patients’ activity restriction was higher, spouses also reported higher depressed mood (β=.14, p<.05). In addition, we found that marital satisfaction moderated the association between spouses’ activity restriction and their depressed mood (β=.005, p<.05). That is, higher marital satisfaction weakened the positive association between activity restriction and depressed mood among spouses of patients with OA. Findings highlight the implication of activity restriction for the well-being of patients with OA and their spouse, and the importance of marital satisfaction for the well-being of spouses.

ONLINE DATING: OLDER ADULTS’ SELF-DESCRIPTIONS AND PREFERENCES
W.K. Watson, C. Stelle, Bowling Green State University, Bowling Green, Ohio

There is a scarcity of research on dating in later life. Recently, however, we have not only begun to recognize dating for older adults as an important topic of inquiry, but we have also acknowledged that as with younger cohorts, some older adults are utilizing online dating sites to locate a potential partner. However, as with traditional dating, most of the research on online dating focuses on the experiences of younger adults. In our exploratory qualitative content analysis, we examined online personal ads from adults ages 60+ in the U.S. from two different sources – a “traditional” online dating site that markets to adults of all ages (match.com) and an online dating site specifically geared to older adults (seniorpeoplemeet.com). While we were interested in whether these individuals marketed themselves as would be expected prior to research (e.g. women advertise looks and men advertise status) we were interested in going beyond this consistent finding to explore other aspects of online dating for older adults. Results are organized around the following: 1) Descriptions of the content of online advertisements, 2) Differences and similarities in what people advertise about themselves and what they seek in a partner, 3) Differences according to the source of advertising, and 4) Gender differences in online personals of adults ages 60+. Lastly, as more adults are expected to enter later life single, we discuss how this approach to finding an intimate partner might be an increasingly relevant and useful tool for older adults and for people who work with them.

LGBT CAREGIVING: MEASURING IMPACTS OF CULTURALLY COMPETENT CURRICULUM FOR HEALTHCARE PROFESSIONALS
T. Gendron, J. White, Virginia Commonwealth University, Richmond, Virginia

According to the National Gay and Lesbian Task Force, there are currently between 1.4 and 3.8 million LGBT (Lesbian, Gay, Bisexual and Transgender) Americans over the age of 65. By 2030, this number is expected to increase to between 3.6 and 7.2 million LGBT Americans. The Department of Gerontology at Virginia Commonwealth University has identified the LGBT aging population as at-risk for receiving less-than-optimal care from healthcare professionals. In order to address healthcare needs of this unique population, the Department of Gerontology at Virginia Commonwealth University has developed and implemented a cultural competence and sensitivity training initiative on LGBT aging issues for community-based healthcare professionals and statewide healthcare organizations/associations serving older adult communities in Virginia. Survey data from over 300 participating healthcare professionals will measure the impact of the training on awareness, cultural competence, and sensitivity toward the aging LGBT popula-
ERECTILE DYSFUNCTION IN A MIDDLE-AGED TWIN COHORT

M.D. Grant, M.S. Panizzon, C.S. Moore, R. McKenzie, W.S. Kremen, C.E. Franz, H. Xian, M. Lyons. 1. Psychology, Boston University, Boston, Massachusetts. 2. University of California, San Diego, La Jolla, California. 3. Center for Behavioral Genomics, UCSD, La Jolla, California. 4. Washington University School of Medicine, St. Louis, Missouri.

Erectile Dysfunction (ED) is defined as the inability to attain and maintain an erection sufficient to permit satisfactory sexual intercourse. ED has been associated with numerous health and psychosocial factors, such as age, diabetes, hypertension, heart disease, education, and depression. The purpose of this study was to: (1) estimate the prevalence of ED during late middle-age, (2) examine genetic and environmental influences on ED, and (3) examine the association of ED with several health and psychosocial variables in a middle-aged twin cohort. Analyses included 878 sexually active participants (age range: 51-60) from the Vietnam Era Twin Study of Aging (VETSA). ED was assessed utilizing the International Index of Erectile Function (IIEF). Structural Equation Modeling (Mx) was utilized to estimate genetic and environmental influences on ED. The prevalence of ED (“minimal” to “complete/severe”) was 28.2% (n=248). In this cohort, 52.6% of the variation of ED was explained by additive genetic effects while individual-specific environmental influences explained 47.4% of the variance. Diabetes, hypertension, hypercholesterolemia, angina, and education level were associated with significant mean differences in total ED scores. Marginal associations were observed between ED and age, ethnicity, and depression. Prevalence rates of ED in this age range were consistent with the NHANES (2000) data. Chronic health conditions were strongly associated with risk of ED in late-midlife. Future research should continue to examine the underlying genetic mechanisms of ED, putative interactions among genetic influences and various environmental factors that contribute to ED risk, and the impact of ED on aging-related quality of life.

SESSION 1030 (POSTER)

COGNITION, DEPRESSION AND MENTAL HEALTH

METABOLIC DYSREGULATION AND COGNITIVE FUNCTIONING IN OLDER CAREGIVERS AND NONCAREGIVERS

A. Hemmesch, C. Mezzacappa, S.O. Stuver, T. Heeren, L. Fredman. Epidemiology, Boston University, Boston, Massachusetts.

Metabolic syndrome, defined by five indicators of metabolic dysregulation (high waist circumference, blood pressure, blood glucose, triglycerides, and low HDL cholesterol) may compromise cognitive functioning, though most studies have only investigated single indicators of metabolic dysregulation. We examined whether having more indicators of metabolic dysregulation was associated with poorer executive functioning (Trailmaking Task B-A) and delayed recall memory (Hopkins Verbal Learning Task) in older adults. Further, because caregiving-related stress may alter associations between metabolic dysregulation and cognition, we compared associations in caregivers and non-caregivers. The sample included 175 older adults (mean age = 74.45 years): 30% were caregivers; 18% had no indicators of metabolic dysregulation, 56% had 1-2, and 27% had 3-5. Caregivers were significantly more stressed than non-caregivers (mean Perceived Stress Scale: 18.40 vs 14.54, p<0.05) and had better executive functioning (mean Trails time difference: 47.31 vs 59.44 seconds, p<0.05). In multiple linear regression models, increasing metabolic dysregulation was associated with slower executive functioning (mean Trails time difference: 42.09, 57.09, and 62.72 seconds in participants with 0, 1-2, and 3-5 indicators, respectively) and diminished memory (mean recalled: 9.23, 8.99, and 8.34 words, respectively); however, these relationships were not statistically significant. The effect of increasing metabolic dysregulation on recall memory was stronger for caregivers than non-caregivers; whereas the associations for executive functioning were similar in these groups. In summary, these preliminary results support our hypothesis that metabolic dysregulation affects cognitive functioning. Prospective studies are needed to determine whether chronic metabolic dysregulation has a stronger impact on cognitive functioning over time.

PHYSICAL ACTIVITY PREDICTS COGNITIVE FUNCTION IN FIBROMYALGIA

L. Zettel-Watson, J. Chang, R. Shimizu, D.N. Rutledge, C. Jones. B.J. Cherry. 1. California State University, Fullerton; Department of Psychology, Fullerton, California. 2. University of California, Los Angeles; Department of Psychology, Los Angeles, California. 3. California State University, Fullerton; School of Nursing, Fullerton, California. 4. California State University, Fullerton; Department of Health Science, Fullerton, California.

Fibromyalgia (FM) is a chronic pain condition affecting approximately 2 to 5% of the population. FM involves widespread chronic pain, but also typically includes stiffness, fatigue, depression, mental confusion, and sleep disturbances. Physical performance decrements have been well documented among persons with FM when compared to same-aged peers. Studies suggest that individuals with FM also perform more poorly than healthy controls across a variety of cognitive domains, and recent research links physical performance to cognitive function. The purpose of the current study was to evaluate physical performance measures as predictors of cognitive function in FM. As part of a larger study on adults aged 50 years and older with and without FM, we incorporated physical performance measures to assess balance, aerobic endurance, and fast walk velocity. Cognitive assessments measured attention/executive function, processing speed, inhibition/interference, episodic memory, and problem solving. Using data from 70 people with FM (Mage = 60 years), hierarchical regressions controlling for age and symptoms revealed a number of significant relationships between physical activity and cognitive function (p < .05). Better balance was associated with better attention/executive function, better problem solving and faster processing speed. Aerobic endurance was associated with better attention/executive function and less inhibition/interference. Faster walk velocity was associated with better attention/executive function and marginally faster processing speed. Given that both increased cognitive and physical function have been associated with better performance on basic/instrumental activities of daily living, the results have important implications for maintaining independence for aging adults with FM.

SELECTIVE UNAWARENESS OF COGNITIVE IMPAIRMENT IN MILD DEMENTIA

G. Annoni, S. Umidi, P.D. Trimarchi, M. Menotti. 1. DIMEP, University of Milano-Bicocca, Monza, Italy. 2. University of Milano-Bicocca, Dep. of Psychology, Milano, Italy.

INTRODUCTION: The present study explores unawareness of cognitive impairment (anosognosia) in mild dementia (MD) patients by means of a pre-test and post-test estimation of cognitive performance. Aim of the study is to identify possible selective anosognosia for specific cognitive domains in early stage of dementia. A second aim is to estimate relationship between anosognosia and cognitive impairment seriousness. MATERIALS AND METHODS: Two groups of participants (14 MD patients vs 25 healthy controls) were tested with a set of
neuropsychological tasks. Self-estimation of performance on each cognitive task (pre-test and post-test) were collected for each participant. From the estimated and actual performance we obtained an index expressing over/underestimation of performance for each task.

RESULTS: Participants gave different estimations for the different cognitive domains. MD patients tended to underestimate their cognitive performance with respect to healthy controls. Anosognosia emerged for executive, memory, attention, naming and logic functions. Moreover, overestimation in cognitive skills increased with the decrease of MMSE scores.

CONCLUSIONS: Our results confirm the presence of selective anosognosia for specific cognitive domains in the early stage of dementia. Moreover, anosognosia tend to increase with increasing of the global cognitive impairment. Since anosognosia could determine less request of medical consultation by patients with an early stage dementia, more attention in the screening of cognitive abilities, also in the field of general practice, could help in the early diagnosis of cognitive impairment. This activity will clarify the concept of selective anosognosia for cognitive impairment highlighting its impact on early diagnosis of dementia.

OBESITY, DIABETES, AND COGNITIVE ABILITY IN YOUNG AND OLD ADULTS
N. Cherbuin1, A.A. Bielak1, D. Bunce1,2, K. Anstey1, I. Centre for Mental Health Research, Australian National University, Canberra, Australian Capital Territory, Australia, 2. Brunel University, Uxbridge, Middlesex, United Kingdom

Background: A number of studies have shown an association between obesity, and changes in cerebral structure, cognitive ability, and dementia. However, some findings suggest that the associations between obesity and cognition might vary across the lifespan, or be mediated by diabetes. Few studies have investigated the concurrent effect of obesity, diabetes and cognition in different age groups and over multiple waves of measurements. Aims: Investigate the association between obesity (Body Mass Index, BMI), diabetes and cognition in a large longitudinal study of ageing surveying three age groups (20-24, 40-44, 60-64 years at baseline) over an 8-year follow-up (n=5796). Methods: Multilevel modelling over three waves of measurement controlling for education, heart problems, hypertension, and stroke and excluding individuals with an MMSE <24. Results: In unadjusted analyses diabetes, heart problems, hypertension, and stroke and excluding individual-level modelling over three waves of measurement controlling for education, heart problems, hypertension, and stroke and excluding individuals with an MMSE <24. Variation in BMI between individuals (β = -1.331, p<.001) and variation in BMI between individuals (β = -0.428, p<.05) but not within individuals across occasions (β = -0.018, ns) were independently associated with cognitive change. However, after adjusting for covariates the BMI effect disappeared while the effect of diabetes remained strongly significant (β = -0.895, p<.01). In multivariate analyses including both BMI and diabetes, having diabetes was associated with less cognitive change (β = -0.910, p<.001) but no age-group or BMI effect was detected. Discussion: The present results indicate that in cognitively intact individuals diabetes is associated with poorer cognition. In fully controlled models BMI was not found to be associated with cognition, possibly due to the effect of BMI being mostly explained/mediated by diabetes and other health and socio-demographic variables.

A PROSPECTIVE STUDY OF COGNITIVE PERFORMANCE IN OLDER AFRICAN-AMERICAN VERSUS WHITE WOMEN
M.K. Townsend1, E. Devore2, F. Grodstein1,2, I. Channing Laboratory, Brigham and Women's Hospital, Boston, Massachusetts, 2. Harvard School of Public Health, Boston, Massachusetts

We compared cognitive performance in older African-American versus white women enrolled in a prospective cohort of female health professionals. Cognitive function was assessed in 1995-2001 among 218 African-American and 16,760 white participants, ages 70-81 years, in the Nurses' Health Study. A follow-up assessment was completed 2 years later. We used linear regression to calculate multivariable-adjusted mean differences in both initial cognitive function and cognitive decline over 2 years in African-American versus white women. After adjusting for age, education, and a wide variety of health, lifestyle, and early sociodemographic variables, we found that African-American women had significantly worse initial cognitive function and significantly faster cognitive decline than white women. Mean differences in the global composite score (averaging six cognitive tests) in African Americans versus whites were 0.32 standard units (95% CI 0.40, 0.24) for initial cognitive function and 0.13 standard units (95% CI 0.20, 0.06) for cognitive decline over 2 years. To help interpret these mean differences, they were similar in magnitude to the mean differences in global score we observe between women 8 and 4 years apart in age, respectively. In conclusion, African-American race appeared to be strongly related to worse cognitive function and faster cognitive decline in a relatively homogeneous cohort of health professionals, among whom potential confounding by health care access and consciousness is likely minimized. Further research is needed to understand the basis of the differences we observed.

THE WAIS DIGIT SPAN TEST: A SENSITIVE INDICATOR OF COGNITIVE DECLINE IN MILD COGNITIVE IMPAIRMENT
J.J. Lortie1, R. Remington1, T.B. Shea2, H. Hoffman1,1. Knox College, Galesburg, Illinois, 2. Nursing, University of Massachusetts Lowell, Lowell, Massachusetts

As part of a multi-site, placebo-controlled study of the efficacy of a vitamin formulation against Mild Cognitive Impairment (MCI), we noted that participants with MCI receiving placebo displayed a decline in performance over 6 months in both Clock-drawing test (Clox 1) and the Wais Digit Span Test, but not in any of the domains of the Dementia Rating Scale. The decline was more pronounced after 3 months for Clox 1 than for the Digit Span Test, but a similar level of decline for both tests was observed after 6 months. The respective decline in performance of individual participants on Clox 1 and the Digit Span Test correlated after 3 months, but not after 6 months. Individual performance on the Digit Span Test also did not correlate with performance on the DRS at 6 months. By contrast, individual performance on Clox 1 correlated with performance on the DRS after 6 months. These findings indicate that an individual’s performance in Clox 1 was not a predictor of performance in the Digit Span Test. Individual performance on the Digit Span Test also did not correlate with performance on the DRS at 6 months. By contrast, individual performance on Clox 1 correlated with performance on the DRS after 6 months. These findings confirm recent studies indicating that a battery of several tests is more likely to elucidate and track cognitive decline in MCI, and support the incorporation of the Wais Digit Span Test into such a battery. Supported by the Alzheimer's Association

HIGH PLASMA FOLATE AND LOW VITAMIN B12: A DOUBLE THREAT FOR THE ELDERLY
H. Sanchez1, C. Albala1, L. Marques1, L. Allen3, M. Lavados2, J. Castillo1, R. Verdugo1, R. Uauy1, 1. Nutrition and Public Health Unit, INTA, University of Chile, Santiago, Chile, 2. Department of Neurologic Sciences, Faculty of Medicine, University of Chile, Santiago, Chile, 3. USDA, ARS Western Human Nutrition Research Center, Davis, Davis, California

Aim: Investigated the relationship between plasma vitamin B-12 and folate concentrations and cognitive function. Design: Cross-sectional study in 415 community-dwelling elderly people, age 70-79 y, selected at random from primary health centres. The protocol was approved by the ethical committee of INTA. Exclusion criteria were: plasma B-12 >700 pmol/L, MMSE <19, creatinine clearance <30 mL/min, history of stroke, TSH >6.0 mIU/L, Diabetes. Low plasma B-12 was defined as ≤148 pmol/L and high folate as >46 nmol/L. Logistic regression models were used to explore the association between MMSE <25 (the 25th percentile), as the dependent variable and four combinations (low or
normal plasma B-12, and normal or elevated plasma folate using different cut-points for the latter) of serum vitamin concentrations as the independent variables. All models were controlled for sex, age, years of schooling, and depression (GDS-15 ≥5). Results: Cognitive impairment was present in 26.0%, low plasma B-12 in 46.4% and high plasma folate in 12.6%. The adjusted models showed an increased risk of cognitive impairment for the combination of low plasma B-12 and high plasma folate. The Odds Ratio for this combination was significant when plasma folate exceeded 39nmol/L, the 66th percentile (OR 3.53; 95% CI 1.04-11.99). Conclusion: These results support the previously suspected association between the combination of low plasma vitamin B12 and high plasma folate, with increased risk of cognitive impairment. (Supported by FONDECYT: #1070592).

**EFFECT OF EXCESSIVE ALCOHOL CONSUMPTION ON COGNITIVE FUNCTIONING AMONG OLDER ADULTS**

J. Lyu, S. Lee, Gerontology Institute and Department, University of Massachusetts Boston, Boston, Massachusetts

The purpose of this study was to investigate the relationship between excessive alcohol consumption and cognition among individuals aged 65 and older. The study sample was drawn from a nationally representative data set, the Health and Retirement Study (HRS) wave 7, and the final sample was subdivided into female and male groups, which consisted of 3,888 and 2,350 subjects, respectively. Two unique domains of cognition (Fluid intelligence and Crystallized intelligence) were measured by self-reported cognition survey items, and analyzed individually. The drinking status variable consisted of three categories (currently never drinks, currently a non-excessive drinker, and current or past excessive drinker); excessive drinker was defined as being a heavy drinker in any three out of the four biennial waves between 1998 and 2004, or having a problem drinking history which was measured by the CAGE instrument. Adjusted for confounding variables, a multivariate analysis showed that excessive drinking did not have a significant impact on fluid intelligence scores relative to non-excessive drinking for either women or men, but it had a significant negative association with having a high crystallized intelligence score for women. Also, relative to non-excessive drinking, currently never drinking was negatively associated with fluid intelligence and crystallized intelligence scores, but only for women. These findings suggest that there may be a curvilinear association between drinking patterns and cognition in later life, such that among some seniors, a moderate level of alcohol consumption may be associated with better cognitive functioning.

**A PROSPECTIVE STUDY OF GAIT PERFORMANCE AND SUBSEQUENT COGNITIVE DECLINE IN A GENERAL POPULATION OF OLDER JAPANESE**

Y. Taniguchi1, H. Yoshida1, Y. Fujinawa1, Y. Motohashi2, S. Shinaki1, J. Tokyo Metropolitan Institute of Gerontology, Itabashi-ku, Tokyo, Japan, 2. Akita University Graduate School of Medicine, Akita-shi, Akita, Japan

Background Gait speed is a good predictor of cognitive decline in later life. However, it is not known whether step length or step frequency is better for predicting such decline. This study aimed to compare the predictive value for cognitive decline of gait performance measures in a population of older Japanese. Methods Among 853 cognitively intact adults aged 70 years or older who participated in a baseline survey, 666 (mean age, 75.5 [SD 4.4] years; women, 59.3%) were re-evaluated at least once during the subsequent 4-year period. Cognitive performance at the baseline was assessed by Mini-Mental State Examination (MMSE), and cognitive decline was defined as a decrease of 3 points or more on the MMSE during follow-up. Results During a median follow-up of 2.7 years, 110 adults (16.5%) had cognitive decline. Among the measures of gait performance (speed, step length, and frequency), step length was the most predictive of cognitive decline. After controlling for important confounders, older men in the lowest and middle tertiles of step length at maximum speed and older women in the lowest and middle tertiles of step length at usual speed were 4.42 (95% confidence interval [CI]: 1.65-11.8), 2.17 (95%CI: 0.82-5.71), 5.76 (95%CI:2.15-15.4), and 2.44 (95%CI:0.94-6.35) times as likely to develop cognitive decline, respectively, as those of the same sex and walking speed who were in the highest tertile. Conclusions Step length was an independent predictor of cognitive decline in a general population of older adults and may be a better predictor than overall gait speed of such decline.

**A COMPARATIVE STUDY OF FACTORS RELATED TO COGNITIVE FUNCTIONING IN LATER LIFE: HEALTH AND RETIREMENT STUDY (HRS) AND KOREAN LONGITUDINAL STUDY OF AGING (KLOSA)**

J. Lyu, C. Lee, Gerontology Institute and Department, University of Massachusetts Boston, Boston, Massachusetts

Cognitive functioning in later life has been a growing concern worldwide. There have been many studies examining factors related to cognitive functioning in later life, but few studies compared these factors internationally. The purpose of this study was to compare the factors related to cognitive functioning in later life in one of the western countries (U.S.) and one of the eastern countries (Korea). The Study sample was drawn from a nationally representative data set, the Health and Retirement Study (HRS) and the Korean Longitudinal Study of Aging (KLoSA). The final sample for HRS and KLoSA consisted of 15,095 and 7,468 individuals aged 50 or over in 2008. Cognitive was measured by self-reported cognition survey items, and analyzed individually. By performing multivariate regression analysis, the results showed that age, IADL, depression are negatively associated with cognitive functioning, and higher education, better self-rated health are positively associated with cognitive functioning in both countries. However, higher income and higher net worth were positive factors related to cognition only in U.S., and ADL was a negative factor related to cognition only in Korea. The most significant difference was gender. Females in U.S. showed higher cognition than males, while females in Korea showed lower cognition than males. These observations show that factors related to cognitive functioning in later life are different from country to country. Findings provide a foundation for further research explaining this difference.

**NIGHTTIME SLEEP QUALITY AND DAYTIME SLEEPINESS PREDICT COGNITIVE IMPAIRMENT IN HEART FAILURE**

E. Byun, J. Kim, B. Riegel, University of Pennsylvania School of Nursing, Philadelphia, Pennsylvania

Background: Approximately 25–50% of persons with heart failure (HF) have cognitive impairment (CI). Both HF and CI are risk factors for mortality. Whether nighttime sleep quality and daytime sleepiness affect CI in HF patients is debated. Purpose: To examine the relationship between nighttime sleep quality, daytime sleepiness and CI in younger (<60 years) and older (≥60) adults. Methods: A sample of 272 individuals (105 younger, 167 older) with chronic HF was enrolled into a descriptive study. Patients with obvious CI on the Telephone Screen of Impaired Cognition were excluded. CI was defined as scoring >1.5 standard deviations on ≥2 of 5 neuropsychological tests of attention, memory, processing speed and crystallized cognitive ability. Nighttime sleep quality and daytime sleepiness were measured by the Pittsburgh Sleep Quality Index and the Epworth Sleepiness Scale. Multivariate logistic regression was used to test the impact of nighttime sleep quality and daytime sleepiness on CI, with adjustment for age, gender, race, education, severity of HF, depression, and comorbidity. The model was tested twice: younger then older adults. Results: Prevalence of CI was 32% in younger and 44% in older adults. In younger adults, daytime sleepiness was a significant determinant for CI (OR 1.25, 95%CI 1.09-1.42, p=0.001), whereas nighttime sleep quality (OR 1.13, 95%CI 1.01-1.25, p=0.028) and daytime sleepiness (OR 0.91,
95%CI 0.83-0.99, p=0.047) were associated with CI in older adults. Conclusions: Both nighttime sleep quality and daytime sleepiness should be assessed in adults with HF because these factors could assist in early identification of CI.

COURSE OF DEPRESSION AND MORTALITY AMONG OLDER PRIMARY CARE PATIENTS

CONTEXT: Depression is a treatable illness that disproportionally places older adults at increased risk for mortality. OBJECTIVE: We sought to examine whether there are patterns of evolving depressive symptoms among older primary care patients that are associated with increased risk for mortality. DESIGN AND SETTING: Practice-based randomized controlled trial within 20 primary care practices in New York, New York, and Philadelphia and Pittsburgh, Pennsylvania.

PARTICIPANTS: The study sample consisted of 599 adults aged 60 years and older recruited from primary care settings. Participants were identified though a two-stage, age-stratified (60-74; 75+) depression screening of randomly sampled patients. Severity of depression was assessed using the 24-item Hamilton Depression Rating Scale (HDRS). MEASUREMENTS: Longitudinal analysis via general curve mixture modeling was carried out to classify patterns of depressive symptoms across 12 months. Vital status at 5 years was ascertained via the National Death Index Plus. RESULTS: Three patterns of change in depressive symptoms over 12 months were identified: (1) persistent depressive symptoms, (2) high but declining depressive symptoms, (3) low and declining depressive symptoms. After a median follow-up of 52.0 months, 115 patients had died. Patients with persistent depressive symptoms were more likely to have died compared with patients with a course of high but declining depressive symptoms (adjusted hazard ratio 2.32, 95% confidence interval (CI) [1.15, 4.69]). CONCLUSIONS: Persistent depressive symptoms signaled increased risk of dying in older primary care patients, even after adjustment for potentially influential characteristics such as age, smoking status, and medical comorbidity.

LATE LIFE DEPRESSION AND QUALITY OF LIFE IN GERIATRIC EVALUATION AND MANAGEMENT UNIT IN TAIWAN
J. Lin1,2, Y. Chen1,3, C. Lin1,4, H. Lee1, S. Yang1,6, T. Yih-Jung1,4, M. Huang1, 1. Division of Psychiatry, Chia Yi branch, Taichung Veterans General Hospital, Chia Yi, Taiwan, 2. Division of Allergy, Immunology and Rheumatology, Taichung Veterans General Hospital, Taichung, Taiwan, 3. Center for Geriatrics and Gerontology, Taichung Veterans General Hospital, Taichung, Taiwan, 4. Department of Family Medicine, Taichung Veterans General Hospital, Taichung, Taiwan, 5. Department of Family Medicine, Taipei Veterans General Hospital, Taipei, Taiwan, 6. Department of Nursing, Taichung Veterans General Hospital, Taichung, Taiwan

Objective: Late life depression (LLD) is not a consequence of normal aging. However, high prevalence was found from ages in community to elderly inpatients. Under diagnosed and under treated cost much medical resource and increased comorbidity in biological, psychological and social areas. Depression also cause declined in quality of life (QoL) especially in elderly inpatient. This study aimed how depression in elderly inpatient affects quality of life and functional recovery on discharge in geriatric evaluation and management unit (GEMU) in Taiwan. Method: 471 elderly inpatients admitted to GEMU from 2009 to 2010 were enrolled in this study. Basic information and comprehensive geriatric assessment (CGA) was collected including activity of daily living (ADL), geriatric depression scale (GDS), mini-mental state examination (MMSE) and QoL assessed with EQ-5D/EQ-5D-VAS on discharge. Chart review was made Chalson comorbidity index. Analysis of the data with regression model was made. Results: In the elderly who was admitted to GEMU, the prevalence of depressive symptoms is 54.4%. Worse ADL and QoL on discharge were found in depressed elderly inpatients. In linear regression model, depressive symptoms accompanied with age, female gender, duration of hospital stay and rehabilitation were significant factors that affects QoL on discharge. Conclusion: High prevalence of depressive symptoms in GEMU was found. LLD should not be overlooked in the elderly inpatients. QoL and functional recovery on discharge would be impacted negatively. Since policy of tertiary medical center limited duration of hospital stay, more effort should be made for better intervention with depressed elderly inpatients.

HOSPITAL ANXIETY AND DEPRESSION SCALE FOR DEPRESSION SCREENING IN ELDERLY INPATIENTS IN A MEMORY CONSULTATION
N. Samaras, D. Samaras, Rehabilitation and Geriatrics, Hôpitaux Universitaires de Genève, Geneva, Switzerland

Background: Depression is a frequent but under diagnosed and under treated pathology in older individuals. It frequently occurs in the context of cognitive impairment. The scale used in our inpatient memory consultation for depression screening, is the Hospital Anxiety and Depression Scale (HADS). Aim of the study: Evaluate the HADS and the depression subscale (HADS-D) as a hetero-questionnaire for screening of depression in older inpatients in a memory consultation and to evaluate the influence of dementia stage on the scale’s performance. Materials and methods: We performed a retrospective study of patients evaluated by the memory specialist and the consulting psychiatrist. The score on the HADS and HADS-D were compared to the psychiatrist’s diagnosis. Results: From 721 patients evaluated, 241 were finally included in the study. Areas under curve (AUC) for depression diagnosis were well under those reported in the literature, ranging from 0.56 to 0.6 for both HADS and HADS-D. For a cut-off of 8 on the HADS-D and 11 on HADS, specificity and sensitivity were around 0.8 and 0.3, and 0.42 and 0.65 respectively with few differences between dementia stages. Conclusion: HADS is not adequate for depression screening in older inpatients in a memory consultation setting. Low performance found in our study could be related to various factors. Geriatric inpatients show an undoubtable complexity due to their multiple somatic and psychiatric comorbidities. No distinction was made between different depression syndromes. The HADS was employed as a hetero-evaluation scale, though it has never been validated as such.

FACTORS AFFECTING LEVELS OF ANXIETY AND DEPRESSION IN PATIENTS WITH COPD
H. Lee1,2, Y. Jeong1, Y. Lim1, I. Kim1, 1. Pusan National University, Yangsan, Republic of Korea, 2. University of Wisconsin, Madison, Wisconsin

Purpose: The purpose of this study was to examine the correlates of depression and anxiety in patients with Chronic Obstructive Pulmonary Disease (COPD). Method: The participants of this study were 209 patients diagnosed with COPD from 5 hospitals in South Korea. Data were collected from March 3 to October 25, 2010. The measures included were the Bristol COPD Knowledge Questionnaire, COPD Self-Efficacy Scale, BODE index estimating the severity of COPD, and Hospital Anxiety and Depression Scale. Data were analyzed with descriptive statistics, Pearson Correlation, ANOVA, and multiple regressions using SPSS WIN program. Results: About 93% of the participants were male, 85% lived with their spouses, and 63% had less than high school education. Participants who are male, live with their spouse, have more than high school education, have a job, and stopped smoking tend to report lower levels of anxiety and depression. In the multivariate approach, higher self-efficacy (β=−.39) and living with spouse (β=−.17) had statistically
significant relation to the lower level of anxiety, which explaining 25% of the variances. Higher self-efficacy ($\beta=-.42$) and knowledge level ($\beta=-.25$), lower BODE scores ($\beta=1.14$), and having jobs ($\beta=-1.13$) also significantly related to the lower level of depression, which explaining 38% of the variances in depression. Conclusion: This study suggest the clue of highly susceptible patients who prone to experience anxiety and depression and give directions for potentially efficient strategies to reduce the levels of anxiety and depression in patients with COPD. Further intervention study to increase self-efficacy in patient with COPD is warranted.

**HIGH-FUNCTIONING OLDER STROKE SURVIVORS SELF-IDENTIFY AND REPORT POST-STROKE DEPRESSIVE SYMPTOMS**

N. Klinedinst², P.C. Clark², S.B. Dunha³, 1. Dept of Epidemiology and Public Health, University of Maryland School of Medicine, Baltimore, Maryland, 2. Georgia State University, Atlanta, Georgia, 3. Emory University, Atlanta, Georgia

Post-stroke depression is difficult to diagnose and is under-treated. Stroke survivors (SS) may misinterpret depressive symptoms (DS) as signs of aging or other post-stroke sequelae and not report their symptoms to the healthcare provider (HCP). This study explored perceptions of the self-identified label and cause of DS among older SS (N= 44). SS were 3-6 months post stroke with Barthel Index mean score 87.95±16.61, mean age 68.52±8.87 years, 50% male, 55% African American, 73% college-educated. SS responded to the CES-D and a modified version (SPQ) of the Revised Illness Perception Questionnaire via one time interview. SS were instructed to answer the SPQ questions about the cluster of symptoms identified from their responses on the CES-D. The mean CES-D score was 10.80±7.40 and 25% (n=11) scored ≥16. Six percent (n=2) of SS who scored <16 and 73% of SSs who scored ≥16 on the CES-D labeled the cluster of symptoms ‘depression’. SS attributed the cause of the symptoms to ‘stroke’, ‘stress or worry’, ‘family problems’, ‘aging’, and ‘depression’. SS who labeled the symptoms ‘depression’ were significantly more likely to report the symptoms to their HCP (70%) than not (p=.03). All SS who reported the DS to the HCP (n=16) perceived the ‘stroke’ caused their DS (p<.01). Clinicians may be aided in diagnosing post-stroke depression by merely asking high-functioning and well-educated stroke survivors whether they perceive they are experiencing depression related to the stroke. The ability of lower-functioning or less-educated SS to correctly identify, interpret, and report DS merits future study.

**CONTRIBUTING FACTORS TO POOR PHYSICAL FUNCTION IN OLDER ADULTS WITH SCHIZOPHRENIA**

H. Leutwiler, B. Miller, E. Hubbard, S. Shin, A. Hasanien, S. Vinogradov, UCSF, San Francisco, California

Introduction: Adults with schizophrenia are living longer but exhibit poor physical function compared to the general population. To design targeted interventions to improve the physical function of this vulnerable population, we must identify the factors that contribute to poor physical function. Some contributing factors are known, including lower socioeconomic status, iatrogenic effects of medication, and health care disparities. The associations between neurocognition, psychiatric symptomatology, and physical function of older adults with schizophrenia have not been adequately explored. We present preliminary finding of an ongoing study to examine the associations between neurocognitive function, schizophrenia symptoms, and physical function. Methods: A cross sectional study in 50 older adults with schizophrenia that assessed neurocognitive function with the Matrics Consensus Cognitive Battery, schizophrenia symptoms with the Positive and Negative Syndrome Scale, and physical function with the SF-12 and the Timed Get Up and Go Test. Bivariate correlations were used to evaluate the associations. Results: To date, 15 participants have completed the study. Preliminary analyses reveal that poorer self rated physical function is associated with higher number and severity of total (r=-.47) and negative (r=-.59) schizophrenia symptoms. Higher scores on attention/vigilance (r=.55) and executive function (r=.44) tests are associated with better physical function. Conclusions: Our findings provide insight to the contributing factors in functional decline among older adults with schizophrenia. The data will inform the design of lifestyle interventions that may promote physical function and neurocognition and simultaneously alleviate psychiatric symptoms for older adults with schizophrenia.

**ASSESSMENT OF BIPOLAR DISORDER IN THE ELDERLY: THE GERI-BD APPROACH**

Introduction: Literature describing elders with bipolar disorder remains limited. The NIH GERI-BD study determines outcome of mood stabilizer treatment in elders diagnosed with bipolar disorder (BD) participating in a 9-week, randomized controlled trial. Methods: Instrument selection was informed by the clinical population, study design and tolerability of assessments. Additionally, selection was guided by experience in young adult BD patients, geriatric unipolar depression, and open studies in geriatric bipolar patients. Results: As a study of treatment of bipolar disorder the domains of assessment include diagnosis (Structured Clinical Interview for DSM-IV-TR), treatment history (Bipolar Treatment History Form) and mood symptoms (Young Mania Rating Scale [YMRS], Hamilton Depression Rating Scale [HDRS], Montgomery Asberg Depression Rating Scale). Given the aged population being studied measures of cognition (Mini-Mental State Examination and Dementia Rating Scale), medical co-morbidity (Cumulative Illness Rating Scale), functioning (World Health Organization Disability Assessment Schedule), quality of life (SF-12 Health Survey) and tolerability of study medication (Semi-Structured Interview For The UK Side Effects Rating Scale) are of particular importance. In our sample (N=100) the mean age was 69 years (S.D. = 7.13); 50% (N= 50) were female, 9% were African American, and 9% Hispanic. YMRS score of 26.4 (S.D. = 6.7) and 24-item HDRS score of 9.6 (S.D. = 6.8). Conclusion: This battery of assessments balances clinical and practical considerations and scientific needs. The baseline data is being used to examine the characteristics of this understudied patient subgroup.

**PSYCHOSOCIAL FUNCTIONING AND HEALTH STATUS AS INFLUENCES ON SELF-ASSESSMENT OF HEALTH**

N. Galdona¹, E. Urdaneta¹, C. Martinez-Taboada¹, J. Yanguas², 1. R+D, Fundación Ingema, San Sebastian, Spain, 2. Universidad del País Vasco. Facultad de Psicología, San Sebastian, Guipúzcoa, Spain

Self-Assessment of Health (SAH) has long intrigued researchers in Gerontology because it is an important predictor of a number of future Health Outcomes, such as Mortality, Health Care Utilization (Nybo, Petersen, & Gaist, 2003) and Medication Intake (Fulop, Strain, & Stetin, 2003). SAH is associated both to Health Status-related measures and to Psychosocial measures such as Personality Traits (Chapman, Duberstein & Lyness, 2007) or Social Support (Bisconti & Bergeman, 2002). The goal of the current study is to increase the understanding of the information included in Elderly People’s SAH judgments by assessing the contribution of various factors related to Physical and Psychosocial functioning. A sample of 102 people, aged 66-80 with a mean age of 71, took part in this study. SAH was measured using a single item of the SF-36 scale, which assesses participants’ Perceived Health Status: “In general, would you say your health is excellent, very good, good, fair or poor? Effect was evaluated by the PANAS, Personality Traits by the NEO-FFI, Social Support by the DUKE UNC-11 questionnaire.
and Satisfaction with Life by SWLS. Finally, measures of Health Status like Medication Intake, Charlson Comorbidity Index and the Number of Doctor Visits were obtained. A statistically significant difference was found in Positive Affect (Z=−2.28, p<0.05), Satisfaction with Life (Z=−2.97, p<0.01), Neurotic trait (Z=−2.54, p<0.05) and Medication Intake (Z=−2.06, p<0.05) depending on the positive or negative SAH. These finding show the importance of paying attention to measures of Physical Health and Psychosocial criteria when analyzing Elderly People’s Health.

FACTORS ASSOCIATED WITH BURNOUT IN THE PROVISION OF CARE BY MIGRANT CAREGIVERS

In the last two decades Spain has witnessed a significant increase in the share of population from non-European Union origin. Their employment choices are mainly limited to low-qualified jobs, such as caregiving for elderly people. These carers are non-trained, face extra demands from the care recipient’s family based on their disadvantaged position and thus engage themselves in long working hours. Many of them show symptoms of Burnout Syndrome. 42 Latin-American Migrant carers, aged 23–65, were interviewed. All of them were caring for community-dwelling elderly dependant people in Spain. Socio-demographic characteristics, Depression, Self-Reported Health and Burnout were measured with standardized scales. Pearson correlation coefficient was used to analyze the relationship between Burnout Syndrome and its consequences in Migrant carers Well Being. Results show a positive relationship between Emotional Exhaustion (r=0.639; p=0.000) and Depersonalization (r=0.725; p=0.000), whereas a negative association was found between Depression and Personal Accomplishment (r=−0.601; p=0.000). With regard to Self-Reported Health, this was negatively associated with Emotional Exhaustion (r=−0.533; p=0.000) and Depersonalization (r=−0.353; p=0.025). Conversely, Personal Accomplishment correlated positively (r=0.542; p=0.000) with higher Perceived Health. The negative consequences of burnout in Migrant carers of elderly people were observed. Caregivers showing higher levels of Burnout presented greater Depression and poorer Self-Reported Health. These results are preliminary and innovative in the study of the consequences of care provision to the elderly by migrant carers.

CHRONIC HEALTH CONDITIONS AND PSYCHOLOGICAL WELL-BEING: BARRIERS TO HEALTH CARE UTILIZATION AMONG OLDER ADULTS IN CALIFORNIA
M. Aydin, I. Padilla-Frausto, D. Grant, UCLA Center for Health Policy Research, Los Angeles, California

This study examines the impact of psychological well-being on delay of care for chronic health conditions among the 55+ population in California. Data from the adult 2009 California Health Interview Survey are utilized (N=47,614). All chronic conditions were based on self-reports of ever diagnosed by a health care professional. Psychological well-being is captured using severe psychological distress (SPD) and a one-item measure for suicide ideation anytime in the past. Delay or forgoing medical care needed in the past year served as the outcome measure. Results show increased rates of delay among those with SPD, self-reported high blood pressure (36.0%; CI: 23.4-48.6) and heart disease (17.4%; CI: 10.7-24.2) compared to older adults without SPD and with one of these chronic conditions (8.3%; CI: 7.2-9.3 and 7.8%; CI: 6.4-9.1, respectively). Approximately 29% (CI: 15.5-43.6) of adults with diabetes and serious suicidal thoughts report delay of health care, compared to only 7.5% (CI: 6.1-8.9) with diabetes but no suicide ideation. Having both SPD and suicide ideation significantly increases rates of delay in seeking care among those with diabetes (35.8%; CI: 19.5-52.1) compared to adults with diabetes but no SPD or suicidal thoughts (7.2%; CI: 6.1-8.9). Findings suggest that poor psychological health may serve as a barrier to health care utilization regardless of need among the chronically ill in California. Multivariate analyses are needed to investigate the link between these chronic physical and mental health conditions and the role of demographic characteristics in the likelihood of delaying necessary care among the elderly.

SESSION 1035 (POSTER)
DISABILITY, FALLS, AND MOBILITY

GUIDANCE-BASED INTERVENTION ON PHYSICAL RESTRAINT REDUCTION IN NURSING HOMES: A CLUSTER-RCT [ISRCTN34978419]
G. Meyer¹, A. Gerlach¹, A. Haul¹, S. Kopke², 1. Nursing Science, University of Witten/Herdecke, Witten, North Rhein-Westfalia, Germany, 2. University of Hamburg, Hamburg, Hamburg, Germany

Introduction: Physical restraints (PR) are common in German nursing homes. Center prevalence is variable. We investigated whether a guidance-based intervention could reduce PR use and center variation. Methods and materials: In two regions in Germany, 49 nursing homes were approached, 36 reported PR prevalence of >20% and agreed to participate. Clusters were block-randomized and externally allocated to the intervention group (IG, n=18) and control group (CG, n=18). IG received the guidance, 1.5-hour education for all nurses, brochures for legal guardians and residents’ relatives, a one-day workshop for nominated nurses, 3-months counseling. CG received brief information on PR. Primary outcome were residents with >1 PR after 6 months and secondary outcomes number of PR, falls, fractures, psychotropic medication, costs. Nurses’ knowledge and self-efficacy was assessed after education. Nominated nurses were interviewed after 6 months. Results: At baseline 3701 (IG: 1917, CG: 1784) and after 6 months 3670 (IG: 1868, CG: 1802) residents were analyzed as they were seen at least once by blinded external investigators directly observing PR. In the IG PR prevalence decreased from 31.5% at baseline to 22.6% after 6 months compared to 30.6% and 29.1% in the CG (ARR 6.5%, Cluster-adjusted 95%(CI 0.6-12.4; p=0.032). All PR decreased. Falls and fractures did not significantly differ between study groups. Center variance was still pronounced. Other outcomes are awaiting analysis. Conclusion: The intervention safely reduced PR in nursing homes. Currently conducted process evaluation may offer understanding of facilitators and barriers of the interventions’ implementation. Funding: German Ministry of Education and Research

ETHNIC DIFFERENCE IN PERFORMANCE-BASED MEASURES OF BASIC AND INSTRUMENTAL ACTIVITIES OF DAILY LIVING
S.E. Espinoza¹,², H.P. Hazuda¹, 1. University of Texas Health Science Center at San Antonio, San Antonio, Texas, 2. South Texas Veterans Healthcare System, San Antonio, Texas

Introduction: Previous studies have reported that disability prevalence is higher in Mexican American (MA) compared with European American (EA) older adults. Lower socioeconomic status (SES) and higher diabetes prevalence in MAs may explain this disparity. Because most studies relied on self-report measures, we examined ethnic differences in performance-based measures of disability, with attention to SES and diabetes as possible explanatory factors for any observed differences. Methods: Subjects were a community-dwelling cohort of 727 older (65+ years) MAs and EAs who participated in the San Antonio Longitudinal Study of Aging (SALSA) baseline examination. ADL and IADL disability were assessed with the SALSA Structured Assessment of Independent Living Skills; higher scores indicated greater disability. Analysis of covariance was used to examine ethnic differences, adjusting for socio demographic factors (age, sex, income, education) and diabetes. Results: MAs had lower education and income, but higher prevalence of diabetes compared with EAs. Both ADL and IADL disability scores were higher for MAs (23.2 vs. 18.3, p<0.0001; 57.9 vs. 42.6).
A. Mirelman

OBJECTIVES: To evaluate definitions and prevalence of disability, its association with mortality, and differences among gender, racial, and ethnic groups in older community-dwelling adults. METHODS: A systematic review of observational population-based studies published in English. Pooled prevalence of disability was calculated with random effects model. RESULTS: We identified 62 studies examining disability in community-dwelling older adults. Five reported gender differences and three reported racial/ethnic differences. Disability was defined as having difficulty or requiring help with basic (BADL) or instrumental (IADL) activities of daily living and categorized as any, moderate, severe, or by individual activities. The pooled prevalence (%) by definition were: any BADL (9.6), moderate BADL (16.1), severe BADL (6.5), walking (7.2), bathing (6.6), dressing/hygiene (4.5), toileting (3.1), transferring (2.9), eating (1.9), any IADL (17.8), moderate IADL (21.3), severe IADL (6.2), transportation (54.3), housekeeping (35.8), shopping (17.3), finances (14.1), meal preparation (13.2), telephoning (4.2), and medication management (3.8). In general, women had higher prevalence of disability than men, but disabled men were more likely to die. When compared to older people without disability, those with BADL disabilities were at higher risk for death (OR range 1.9-86.8) than those with IADL disabilities (OR range 1.5-6.6). The prevalence of any BADL disability was highest in African Americans (13.6), American Indians (11.6), Hispanic Americans (11.0), and lowest in Caucasians (8.1). Few studies reported gender, race or ethnic differences in death rates or how individual disabilities influence mortality CONCLUSIONS: Disability is prevalent and associated with increased mortality. More research is needed to determine the impact individual disabilities have on mortality and to identify gender, racial, and ethnic disparities so targeted prevention efforts can be developed and implemented.

SYSTEMATIC REVIEW OF DISABILITY DEFINITIONS, PREVALENCE AND ASSOCIATION WITH MORTALITY IN COMMUNITY-DWELLING OLDER ADULTS

K. Talley1, T.A. Shamiyan2, J.T. Pacala1, R. Kane2, 1. School of Nursing, University of Minnesota, Minneapolis, Minnesota, 2. School of Public Health, University of Minnesota, Minneapolis, Minnesota, 3. Medical School, University of Minnesota, Minneapolis, Minnesota

The prevalence of any BADL disability was calculated with random effects model. RESULTS: We identified 62 studies examining disability in community-dwelling older adults. Five reported gender differences and three reported racial/ethnic differences. Disability was defined as having difficulty or requiring help with basic (BADL) or instrumental (IADL) activities of daily living and categorized as any, moderate, severe, or by individual activities. The pooled prevalence (%) by definition were: any BADL (9.6), moderate BADL (16.1), severe BADL (6.5), walking (7.2), bathing (6.6), dressing/hygiene (4.5), toileting (3.1), transferring (2.9), eating (1.9), any IADL (17.8), moderate IADL (21.3), severe IADL (6.2), transportation (54.3), housekeeping (35.8), shopping (17.3), finances (14.1), meal preparation (13.2), telephoning (4.2), and medication management (3.8). In general, women had higher prevalence of disability than men, but disabled men were more likely to die. When compared to older people without disability, those with BADL disabilities were at higher risk for death (OR range 1.9-86.8) than those with IADL disabilities (OR range 1.5-6.6). The prevalence of any BADL disability was highest in African Americans (13.6), American Indians (11.6), Hispanic Americans (11.0), and lowest in Caucasians (8.1). Few studies reported gender, race or ethnic differences in death rates or how individual disabilities influence mortality CONCLUSIONS: Disability is prevalent and associated with increased mortality. More research is needed to determine the impact individual disabilities have on mortality and to identify gender, racial, and ethnic disparities so targeted prevention efforts can be developed and implemented.

POTENTIAL UTILITY OF USING A BODY-WORN SENSOR IN THE COMMUNITY-SETTING TO AUGMENT THE ASSESSMENT OF MOBILITY IN COHORT STUDIES OF AGING

A. Mirelman1, A. Weiss2, A. Buchman3, D.A. Bennett1, J. Hausdorff1, 1. I. Tel Aviv Sourasky Medical Center, Tel Aviv, Israel, 2. Tel Aviv University, Tel Aviv; Israel, 3. Rush University Medical Center, Chicago, Illinois

Objective: Community-based cohort studies of aging have generally relied on simple measures (e.g., timed walk) to quantify gait and mobility. We hypothesized that more precise spatial-temporal measures of gait derived from a body-worn sensor (accelerometer on the belt) could enhance standard gait testing in participants’ homes. Methods: 50 participants of the Rush Memory and Aging Project, a community-based cohort study (mean age 84.3±4.8 yrs, 67% female), were studied. Gait speed was determined from the time to walk 8 feet (averaged over two walks). During this walk, subjects wore a small, light-weight 3-D accelerometer on their lower back. The signal from the accelerometer was used to derive measures of step-to-step variability (e.g., step and stride regularity, step symmetry, the height of dominant frequency). We stratified the participants based the presence or absence of mobility disability (MD) using the Rosow-Breslau scale of mobility disability and compared their gait measures. Results: Gait speed was slower among those with MD (No MD=0.55±0.21 m/s vs. Yes MD=0.66±0.16 m/s), but this failed to achieve statistical significance (p=0.065). In contrast, the groups differed with respect to step regularity (p=0.021), stride regularity (p=0.028), step symmetry (p=0.05), and height of the dominant frequency in the anterior-posterior direction (p=0.05). Conclusion: While standard measures of gait speed did not differ, accelerometer-derived measures of gait showed that older subjects with mobility disability walked with less step-to-step consistency and increased variability. Accelerometer-derived measures may augment standard gait testing and enhance the identification of older persons with mobility impairments in the community-setting. Supported by National Institute on Aging grants R01AG17917 and R01AG24480.

QUANTIFYING FALL RISK DUE TO COGNITIVE IMPAIRMENT IN OLDER ADULTS: A SYSTEMATIC REVIEW AND META-ANALYSIS

M. Montero-Odasso1, S.W. Muir1, K. Gopaul1, 1. Medicine, Division of Geriatric Medicine, University of Western Ontario, London, Ontario, Canada, 2. Parkwood Hospital, London, Ontario, Canada, 3. Lawson Research Institute, London, Ontario, Canada

Objectives: To evaluate and summarize the evidence linking cognitive impairment to falls in older adults, including a determination of which tests and cognitive domains are highly associated with fall risk. Methods: Systematic review and meta-analysis. Articles in MEDLINE, EMBASE, PsycINFO (1988 – 2010) and bibliographies of retrieved papers were searched. Adults (age ≥ 60) in a prospective cohort study, at least 1 year duration, and not specific to a single disease-defined population. Two authors independently extracted data, including study characteristics, quality assessment, and outcomes. Fixed effects meta-analysis was performed and I2 statistic was used to quantify heterogeneity. Results: Twenty-seven studies met the inclusion criteria. Thirteen methods were used to assess cognition. Summary risk estimates for community-dwelling older adults were: any fall, OR=1.32 (95% confidence interval (CI) = 1.18-1.49; I2=74.3%), a serious fall injury, RR=2.33 (CI=1.61-3.36; I2=5.9%) and a fracture, RR=1.78 (CI=1.34-2.37; I2=0.0%). In the institution-dwelling population, the summary risk estimate for any fall was OR=1.88 (CI=1.54-2.30; I2=46.9%). Impairment of global cognitive function was not sufficient to identify an increased risk. Executive function impairment, even subtle deficits in healthy older adults, was consistently associated with an increased fall risk up to 3 times the odds of falling. Conclusions: Cognitive impairment imparts a moderate increased fall risk in community and institution-dwelling older adults. Importantly, measures of global cognitive status should not be used in isolation to quantify risk. Impairment of executive function was consistently associated with an increased fall risk and should be a routine part of a falls risk assessment in older adults.

A CONFIRMATORY PATH ANALYSIS RELATING PHYSICAL FUNCTIONS AND PAIN TO FALLS IN ELDERLY ADULTS

B. Dai1, C. Giuliani3, 1. Allied Health Sciences, UNC Chapel Hill, Chapel Hill, North Carolina, 2. Human Movement Science, Chapel Hill, North Carolina

Introduction: Falls in elderly adults are a major health problem. Poor physical function has been associated with falls, but more discrete cause-effect relationships are not well understood. Methods: Data from 888 subjects (556 men, 67 ± 8.5 yrs) included measurements for: strength (30 second chair rise and arm curl); balance (single leg stand, tandem stand, and 360 degree turn); flexibility (lower and upper body); endurance (normalized scores for 2 min step or 6 min walk tests). Time up and go test (TUG) was also tested. Falls during the previous year and
current pain were recorded. Structural equation modeling included 11 observed variables and 4 latent variables (strength, flexibility, balance, and impaired mobility). Impaired mobility (IM) was modeled as a function of strength, flexibility, balance, endurance, and pain. Fall and TUG were modeled as a function of IM. Results: The model demonstrated good fit ($\chi^2=45.03$, DF $=30$, p $=0.04$, CFI=1.0, RMSEA=0.02). Balance and IM contributed highest to falls with standardized total effects (STE) of 0.38 and -0.31 respectively. Balance (STE=-1.23) contributed mostly to IM, when flexibility (STE=-0.21) and pain (STE=-0.06) significantly contributed to IM. IM had a STE of 0.97 on TUG. Conclusion: Balance was the most important factor for determining mobility and falls and should be considered a priority in fall screening and prevention programs. As expected the TUG is a good functional screening tool for mobility and fall risk.

MOBILITY, FALLS, AND MEDICATION USE IN OLDER ADULTS SEEN AT A GERIATRIC ASSESSMENT CLINIC

C. Sadowski1, A. Marin2, R. Tsuyuki2,4, P. Priest2, M. Hervas-Malo4, 1. Faculty of Pharmacy, University of Alberta, Edmonton, Alberta, Canada, 2. University of Alberta Faculty of Medicine & Dentistry, Edmonton, Alberta, Canada

Background: Older adults often have multiple risk factors for falls. The most modifiable falls risk is medication. Objective: To describe the rates of falls among older adults, and the relationship to medications. Methods: A retrospective chart review was conducted through the interdisciplinary seniors clinic at the Misericordia Community Hospital, Edmonton, Alberta. Patients were seen in the clinic in 2006 or 2007, age 65 years or older, and admitted from a community living setting were included. The data was abstracted by a research assistant, entered into an Excel database, and analyzed by SPSS 15.0. Results: A total of 224 patients were included, with 142 (63%) female, mean age 80 (SD 7). A total of 74 (33%) were referred to the clinic for assessment of falls/mobility concerns, while only 18 (8%) had documented mobility problems. After assessment 110 (49%) were found to have a problem with falls, and another 57 (25%) had other mobility concerns. For 110 patients with a history of falls, they were on the following medications: cholinesterase inhibitors (17, 16%), antipsychotics (15, 14%), tricyclic antidepressants (12, 11%), selective serotonin reuptake inhibitors (27, 25%), benzodiazepine (20, 18%), zopiclone (18, 16%), NSAID (22, 20%), opioid (20, 18%), anticholinergic for overactive bladder (6, 6%). Conclusions: Although few patients were referred for falls assessment, 110 (49%) were found to have a problem with falls, and another 57 (25%) had other mobility concerns. For 110 patients with a history of falls, they were on the following medications: cholinesterase inhibitors (17, 16%), antipsychotics (15, 14%), tricyclic antidepressants (12, 11%), selective serotonin reuptake inhibitors (27, 25%), benzodiazepine (20, 18%), zopiclone (18, 16%), NSAID (22, 20%), opioid (20, 18%), anticholinergic for overactive bladder (6, 6%).

RISK FACTORS RELATED TO DISABILITY IN OLDER ADULTS: ARTHRITIS, OBESITY AND PHYSICAL ACTIVITY

B. Manrique-Espinoza, A. Salinas, K. Moreno-Tamayo, M. Tellez-Rojo Solis, National Institute of Public Health, Cuernavaca, Morelos, Mexico

Objective: To estimate the effect of arthritis, obesity and physical activity on the incidence of functional dependence in Mexican poor older adults. Methods: Longitudinal study of older adults (aged 65 to 74) participating in the impact evaluation study of the social pension program 70 y más (2007-2009). For the study we selected the group of older adults who had no functional dependence (FD) at baseline. We evaluated the presence of arthritis by self-report of medical diagnosis and associated symptoms, with weight and height measurements were calculated body mass index (BMI), and we used the short version of the International Physical Activity Questionnaire to assess physical activity. At follow-up we assessed the onset of FD when the elderly reported needing help to make at least one activity of daily life (ADL). The analytical sample was 2,123 elderly. We used a logistic regression model adjusted for baseline characteristics. Results. After 16 months of follow up, the incidence of FD was 10.5%. The elderly without a diagnosis of arthritis but with symptoms of arthritis and elderly diagnosed with arthritis and symptoms showed higher risk of FD (OR=1.79, p<0.01 and OR=1.72, p<0.05, respectively) compared with older adults undiagnosed and without symptoms. Older adults with BMI<30 had higher risk of FD (OR=1.46, p <0.10). Vigorous physical activity was a protective factor on the occurrence of FD (OR=0.61, p <0.10). Conclusions. Arthritis and obesity are chronic conditions that are associated significantly with the development of disability while vigorous physical activity reduces the risk of developing disability in a sample of Mexican older people.

ASSOCIATION BETWEEN CHANGES IN PHYSICAL AND COGNITIVE FUNCTIONS IN ELDERLY INSTITUTIONAL RESIDENTS

T. Komatsu1, F. Togo2, H. Park3, T. Mitan1, 1. School of Health Science, Department of Physical Therapy, Tokyo University of Technology, Komatsu, Tokyo, Japan, 2. Health Administration and Psychosocial Factor Research Group National Institute of Occupational Safety and Health, Japan, Kawasaki, Japan, 3. Tokyo Metropolitan Institute of Gerontology, Tokyo, Japan, Itabashi, Japan, 4. Watanabe Hospital, Kashiwa, Japan

Relationship between physical and cognitive functions in elderly institutional residents with moderate to severe cognitive dysfunction in unclear. The aim of this study was to investigate cognitive and physical functions in elderly institutional residents. Subjects were 22 elderly institutional residents (age 83.9 ± 2.35 years) with cognitive impairment (MMSE < 24 points) at baseline. All subjects were able to walk independently or with the help of a walking aid. Changes in the ability of walk and the paralysis of the limbs were not observed during this study. Cognitive function was assessed by MMSE. Physical function was assessed by Barthel Index, hand grip strength, and walking at maximum and normal speed (speed and number of steps). These items were measured at the baseline and six months later. During this study, group or individual therapeutic exercise was conducted by physical therapists about two times per week in average. MMSE scores decreased in 9 subjects (reduced MMSE) and did not decrease in 13 subjects (non-reduced MMSE). The number of steps during walking at maximum speed increased in the group of subjects with reduced MMSE (p <0.05), but did not increase in the group of subjects with non-reduced MMSE. Hand grip strength and maximum and normal walking speed decreased significantly (p <0.05) at 6 months compared with baseline only in the group of subjects with reduced MMSE. Our results showed that physical function decreased only in the group of subjects with reduced MMSE, suggesting that cognitive decline might cause physically frail. For elderly with cognitive impairment, additional exercise and/or other intervention programs might be needed to maintain and improve physical function.

COMBINED COGNITIVE AND FITNESS TRAINING DIMINISHES BALANCE VARIABILITY IN OLDER ADULTS

S.A. Fraser1, K.K. Vadaga2, N. Berryman3, 1. Université de Québec à Montréal and Institut de gériatrie de Montréal, Montréal, Quebec, Canada, 2. Concordia University, Montréal, Quebec, Canada, 3. Institut de gériatrie de Montréal, Montréal, Quebec, Canada, 4. Université de Montréal, Montréal, Quebec, Canada

Background: Recent research has supported the use of a cognitive computerized dual-task to improve balance control in a sample of healthy older adults. However, in this intervention study, participants who received cognitive training were compared to a passive control group. This raises the possibility that global treatment effects could have influenced the results. Methods: The current longitudinal study was designed to compare the effect of different types of training on several cognitive and physical measures, while controlling for possible treatment effects. Participants were randomly assigned to one of the following training groups: (1) cognitive and aerobic; (2) cognitive and stretching; (3)
OLDER ADULTS
MODERATE-VIGOROUS PHYSICAL ACTIVITY MAY BE
non-diabetics. This pilot data will form the basis for additional studies
impairment, higher levels of pain, and worse SAH when compared to
SAH than non-diabetes. CONCLUSIONS: In this small sample of older
patients with diabetes and 37 without, mean age 74, completed the study. 30% of all par-
ticipants reported shoulder pain. Diabetics reported significantly worse
function and more pain with shoulder maneuvers, and overall worse
SAH than non-diabetes. CONCLUSIONS: In this small sample of older
adults, the majority of measures suggested that diabetics have higher
impairment, higher levels of pain, and worse SAH when compared to
non-diabetics. This pilot data will form the basis for additional studies
using larger populations to learn more about this condition and test
potential interventions to improve function and quality of life.

SHOULDER SYMPTOMS AND FUNCTION IN DIABETIC
AND NON-DIABETIC GERIATRIC PATIENTS
D. Abbott, E.A. Burns, A.K. Rosenthal, Medical College of Wisconsin, Milwaukee, Wisconsin
BACKGROUND: Chronic painful tendon disorders are a common
problem in diabetics and are linked to reduced quality of life. This study
compared frequency of shoulder problems and relationship to daily func-
tion in diabetic vs. non-diabetic older veterans. We hypothesized that
diabetics report higher rates of upper shoulder pain, greater functional
impairment and worse quality of life. METHODS: Patients aged > 60
attending a Primary Care Clinic at the Zablocki VAMC, Milwaukee, WI, from 7/10-8/10 were recruited. Potential participants were
approached at check-in, and if agreeable, were further screened for exclu-
sion criteria then underwent informed consent. Data collected included
demographics, medical history, and current medications. Participants
answered questions on shoulder pain and self-assessed health (SAH).
Function was assessed with the Stanford Modified Health Assessment
Questionnaire (MHAQ). Shoulder mobility and pain was assessed with
a standard series of arm maneuvers. RESULTS: 30 patients with dia-
etes and 37 without, mean age 74, completed the study. 30% of all par-
ticipants reported shoulder pain. Diabetics reported significantly worse
function and more pain with shoulder maneuvers, and overall worse
SAH than non-diabetes. CONCLUSIONS: In this small sample of older
adults, the majority of measures suggested that diabetics have higher
impairment, higher levels of pain, and worse SAH when compared to
non-diabetics. This pilot data will form the basis for additional studies
using larger populations to learn more about this condition and test
potential interventions to improve function and quality of life.

MODERATE-VIGOROUS PHYSICAL ACTIVITY MAY BE
NEEDED TO MAINTAIN PHYSICAL FUNCTION IN
OLDER ADULTS
S.A. Foulis, R. Larsen, D. Callahan, J. Kent-Braun, University of
Massachusetts- Amherst, Amherst, Massachusetts
Habitual physical activity (PA) level affects multiple physiological
processes, including those responsible for maintenance of mobility and
physical function in old age. Lower moderate-vigorous PA (MVPA), as
observed in older adults, may have significant negative consequences.
Currently, recommendations exist for PA in the elderly; however, the
dose (intensity and duration) of PA required to maintain mobility has
not been established. The purpose of this study is to investigate the rela-
tionship between objectively-measured PA and physical function in older
adults. Fifty-six older adults (65-85 yrs), ranging in PA level from those
with mobility impairments to runners, were accelerometers to measure
habitual PA over the course of one week. Using established cutpoints,
total minutes of PA, time spent in low-intensity PA, and time in MVPA
were determined. Each participant also completed 3 measures of phys-
ical function: 10 chair rises, 8-stair ascent, and 8-stair descent. MVPA
ranged from 0.25-91 minutes/day. Linear regression analyses revealed
no association between total or low-intensity PA and any measure of
physical function (p>0.08). In contrast, higher MVPA time was associated
with better physical function (r=0.48, p<0.01). Bilinear regression
analyses revealed critical thresholds for adequate physical function at
8-11 minutes/day of MVPA (p<0.01). These results suggest that MVPA
may be a necessary component of daily activity in order to maintain
physical function in aging adults. More research is needed to establish
the minimum recommended daily PA dose for maintaining mobility in
older men and women.

WHY DON’T OLDER PEOPLE PARTICIPATE IN FALL
PREVENTION PROGRAMS?
S. McMahon, L. Talley, J.F. Wyman, 1. Arizona State University,
Phoenix, Arizona, 2. University of Minnesota, Minneapolis, Minnesota
PURPOSE: Despite decades of research on effective fall prevent-
ion methods, fall-related injury and death rates are increasing. Under-
standing how individual, interpersonal, community, and environmen-
tal factors influence older peoples’ views about falls, and their
prevention, may expand the scope and reach of fall prevention efforts.
The purpose of this review was to examine older peoples’ perspectives
on falls and their prevention within a social ecological framework
(Stokols, 1996). Research questions included: 1) What are the per-
spectives of older people regarding their own fall risk; 2) What do older
people view as barriers and facilitators for participating in fall preven-
tion programs? METHODS: A systematic literature review was con-
ducted of qualitative and quantitative studies published in English
between 2005-2010. Eligible studies examined community-dwelling
older peoples’ perspectives of fall risk or fall prevention strategies. Study
quality was appraised with standardized checklists. Thematic analysis
and group discussions were conducted until there was consensus on
themes and social ecological levels. RESULTS: Nineteen of 118 stud-
ies were eligible. Participants (age range 60-90) lived in 10 countries.
Most studies had moderate quality ratings. Themes related to older peo-
lies’ perspectives of fall risk (fear of vulnerability, maintaining auton-
omy and independence, and interpreting risk) and views of fall pre-
vention (participant/program characteristics, relevance and preference,
maintaining autonomy and independence, and support and access) ap-
peared at individual, interpersonal, organizational, and community
levels. CONCLUSIONS: Examining older peoples’ perspectives about
fall risk and prevention within a social ecological framework identi-
fied several multilevel factors to consider when designing and improv-
ing fall prevention efforts.

DEPRESSION AND FALLS AMONG COMMUNITY-
DWELLING ELDERLY: THE MOBILIZE BOSTON STUDY
L. Quach1,2, F.M. Yang1,3, E. Netown, R.N. Jones1,4, J.A. Burr1,
L. Lipsitz1,2,4, 1. Institute for Aging Research, Hebrew SeniorLife,
Boston, Massachusetts, 2. Harvard Medical School, Boston, Massachusetts, 3. University of Massachusetts Boston, Boston,
Massachusetts, 4. Division of Gerontology, Beth Israel Deaconess
Medical Center, Boston, Massachusetts
Falls are a major public health problem for the elderly, while depres-
sion is commonly associated with falls among older adults. The mech-
anism underlying the relationship between depression and falls is unclear.
The aim of this study is to examine the effects of cognitive function
and antidepressant use on the relationship between falls and depression.
The study used secondary data from the “Maintenance of Balance, Inde-
pendent living. Intellect and Zest in the Elderly” (MOBILIZE) Boston
study, which is a population-based longitudinal study (n=765). Falls
were captured prospectively from September 2005 through April 2010.
Depression was assessed with a modification of the Center for Epi-
demiologic Studies Depression-Revised scale variable and standard-
ized using latent variable modeling, with a mean of 51 (± 10 standard
deivation) at baseline. Linear regression was used to estimate the assoc-
iation between depression and the potential mediators. Negative bino-
mial regression was performed to estimate the change in the coeffi-
cient for depression with and without executive function or
line dancing may be an effective intervention but further work with larger sample is needed.

CHANGE TRAJECTORIES OF CHRONIC DISEASE, DISABILITY AND DEPRESSION OF A CHINESE ELDERLY POPULATION: AUTOREGRESSIVE GROWTH CURVE MODELLING

H. Chi1, C. Chen1, J. Mullan1, D. Griffith1, T. Lan2,4, I. Kreis1, M. Huang1, I. Kaohsiung Medical University, Kaohsiung, Taiwan, 2. National Health Research Institutes, Miaoli, Taiwan, 3. University of Wollongong, Wollongong, New South Wales, Australia, 4. National Yang-Ming University, Taipei, Taiwan

This study explores change trajectories of chronic disease, disability and depression when the effects of contextual and other structural factors are simultaneously considered. This study adopted a prospective, closed cohort study design. The cohort includes 1260 older adults participating in the 1994 Multidimensional Functional Assessment Questionnaire survey in Kaohsiung City, Taiwan. Five follow-up interviews were conducted in 1996, 1998, 2000, 2002 and 2004. The study investigated changes of status in three health domains at six time points during 1994-2004, controlling for baseline demographic characteristics. Functional status was assessed using 27 items of chronic disease, six Activities of Daily Living and six Instrumental Activities of Daily Living, and 15-items from the Short Psychiatric Evaluation Schedule. Multivariate latent growth modelling was applied to all available data and complete data set. The results show strong change trajectories among the three health domains, with initial poor health status (i.e. existence and level of chronic disease and disability) predictive of further problems across health domains. Continue growth of chronic disease had a significant impact on the development of disability and depression. Furthermore, the initial status of chronic disease and depression had a significant impact on the beginning of depressive symptoms at the early stage. Our results demonstrate that clinicians should carefully evaluate depressive symptoms in person with the new onset of chronic disease and disability.

PAIN, AUTONOMY AND MOBILITY IN GERMAN NURSING HOMES RESIDENTS

S. Kalinowski1, M. Kölzsch2, I. Wulff1, R. Kreutz2, D. Draeger1, 1. Charité—Universitätsmedizin Berlin, Institute for Medical Sociology, Berlin, Germany, 2. Charité—Universitätsmedizin Berlin, Institute of Clinical Pharmacology and Toxicology, Berlin, Germany

Background: Pain is one of the most important syndromes in the elderly population, particularly in nursing home residents (NHR). Despite a growing interest in this topic, pain prevalence, treatment and associated factors are widely unknown. Objective: The purpose was to evaluate pain prevalence, treatment and associations of pain with autonomy and mobility in NHR. Methods: We conducted a cross-sectional study in a random sample of NHR from nursing homes in Berlin and Brandenburg, Germany. Data were collected by interviews with NHR, assessments (Barthel Index, Timed “up & go”-Test, Hertz Perceived Enactment of Autonomy Scale) and by analysis of nursing records. Furthermore, institutional parameters were collected by questionnaire. Results: Overall 560 NHR (age: 81 ± 11 years, 61 % women) from 40 nursing homes were included in our study. Half of the residents suffered from pain. Quality and appropriateness of pain medication, according to the Pain Medication Appropriateness Scale, was insufficient. Furthermore, increased perceived autonomy corresponded with increasing independence in performing activities of daily living (p<0.001) as well as with absence of pain (p=0.041). NHR with pain showed significantly lower levels of functional mobility than persons without pain (p<0.001). Besides, there was a lack of individually adapted training programs to promote mobility. Conclusion: We identified deficits regarding adequate pain treatment in German NHR. Our results show that NHR with pain are disadvantaged in terms of mobility and self-determination. Accord-

Vestibular Dysfunction and gait speed in older individuals

M. Davalos-Bichara, M. Zuniga, J.P. Carey, M.C. Schubert, J.D. Walston, J. Hughes, Y. Agrawal, Johns Hopkins Medical Institutions, Baltimore, Maryland

Background: Gait speed reflects function in several organ systems and has been shown to strongly predict survival in older individuals. The inner ear vestibular system is known to play an integral role in balance control and locomotion. Our objectives were: 1) to evaluate vestibular function in older individuals, and 2) to determine the contribution of vestibular function to gait speed in this population. Methods: Community-dwelling participants age ≥70 years underwent two clinical tests of vestibular function: 1) right and left head impulse testing (HIT; a positive test indicates right or left horizontal semicircular canal dysfunction), 2) the modified Romberg test (mRT; a positive test suggests difficulty integrating vestibular information), as well as gait speed measurement on a 4-meter walkway. Results: We enrolled 20 participants; 55% were female and the mean age was 76.7 years (SD 4.4). Thirty-five and thirty percent of subjects had abnormal right and left HITs respectively; individuals with a positive right HIT were also more likely to have a positive left-sided HIT (p=0.0072). Mean (SD) gait speeds were lower in subjects with positive vs. negative HITs (right 0.90(0.2) vs. 1.4(0.4) m/s; p=0.0053; left: 1.1(0.7) vs. 1.3(0.3) m/s; p=0.3060.) In addition, gait speeds in subjects with a positive mRT (60% of participants) were lower than those with a negative mRT (1.0(0.3) vs. 1.6(0.4) m/s; p=0.0037). Conclusions: A significant proportion of older individuals have evidence of vestibular dysfunction, which is associated with a reduction in gait speed. Further quantitative vestibular testing and assessment of fall risk are in progress.

Effects of line dancing on physical performance in older adults with mobility difficulty

C. Bennett2,3, B.L. Roberts2, 1. University of West Florida, Pensacola, Florida, 2. University of Florida, Gainesville, Florida

Older adults with decreased mobility are at a greater risk for disability. Exercise can reduce the risk of disability. Dance is a popular form of exercise and line dancing allows older adults the freedom to dance at their own pace without a partner. The purpose of this pilot was to examine the effects of 8-week line dancing on physical performance and health in older adults with mobility difficulty (difficulty walking 1/4 mile and climbing one flight of stairs). Nine females, 1 male ranged in age from 66-87 years (mean=73). Subjects were randomly assigned to a control group (no contact) or dance group. The control group continued their usual daily activities. The dance group participated in 30 minute line dance sessions, twice a week for 8 weeks taught by an experienced line dancing instructor. The dances progressed from easy to more difficult. From pretest to posttest, the dance group had reduced times for tandem balance (-2.3%), one leg standing balance (-74%), 4 meter walk (-15.4%), and five chair stands (-12%). The control group had increases in times for tandem balance (+27%), one leg standing balance (+36%), 4 meter walk (+2.3%), and five chair stands (+8.5%). For pain, the control group reported experiencing more pain at posttest (35.7%) than the dance group (14.3%). These findings suggest that
During the past 25 years there has been a debate over “generational equity” that has focused on the sharing the benefits and burdens associated with government social problems such as Social Security and Medicare. Since the early 1990s there has been a related debate, largely among economists, about the relative merits of “generational accounting” as a way of dealing with generational (more specifically age cohort) differences in tax burdens, particularly those linked to such programs as Social Security and Medicare. In our analysis we seek to integrate these two literatures with a focus on describing, assessing, and reframing generational accounting. We present the generational accounting model and how it relates to the broader generational equity debate; we discuss the advantages of this model as outlined by its proponents; we present some of the major criticisms of the model made by other economists; and we outline some ways in which a reframing of the model would potentially make it of use to a broader range of scholars, researchers, and policy analysts, particularly to non-economists. Social programs that can be linked to projected lifetime imbalances in intergenerational taxes are understood by proponents of generational accounting as demonstrating that they are generationally inequitable. The reframing of GA that we outline seeks to consider how proposed changes in these policies would affect intra generational equity. To examine intra generational equity we must consider the different effects on different groups based on such factors as income, race, ethnicity, immigration status, and gender.

FACTORS ASSOCIATED WITH PURCHASING LONG TERM CARE INSURANCE
S. Reynolds1, H. Meng2, N.S. Park2, B. Lee1, K. Hyer1, 1. School of Aging Studies, University of South Florida, Tampa, Florida, 2. USF School of Social Work, Tampa, Florida, 3. USF Mental Health, Law, & Policy, Tampa, Florida

Most older adults agree that Long Term Care Insurance (LTCI) is a desirable product, but few actually buy it, raising the question of what individual factors drive LTCI consumer purchasing behavior. In this study, we use six waves of the Health & Retirement Study (HRS: 1998-2008) to estimate the likelihood of having purchased LTCI in the population age 50 and older (N=19,904). Predictor variables include sociodemographic, health, lifestyle, and health insurance factors. Findings indicate that characteristics most likely to predict having LTCI are: female gender, higher education, higher income and/or wealth, reporting fair/poor health, abstaining from alcohol, engaging in vigorous activity, and having Medicare or Employer-provided insurance. Characteristics of those least likely to have LTCI are: Hispanic origin, lower education, and receipt of Medicaid. Interestingly, ADL difficulties were not predictive of having LTCI; this finding may indicate that those who most need long term care are not buying LTCI. Further studies should include disability trajectories, social resources, cognition, and interactions of ADL difficulties with other covariates in predicting LTCI purchasing behavior. Given current and future strains on the funding of long term care, policy makers and the insurance industry must have comprehensive consumer information to maximize the ability to fund long term care in creative and entrepreneurial ways.

UNINSURED U.S. OLDER ADULTS AGED 65 OR OLDER: WHO ARE THEY?

Objective: Despite greater devastating effects of being uninsured among older adults aged 65 or older, few studies focused on this age group due to almost universal coverage of Medicare. This study describes health care needs, expenditures, out-of-pocket (OOP) financial burden, and attitudes toward medical care and health insurance of older uninsured individuals. Older adults covered by both Medicare and private insurance consist of a comparison group. Methods: The pooled 2000-2007 Medical Expenditure Panel Survey was analyzed (N=27,738). The SHAPES model was used to account for the complex sampling design. Results: About 0.4% of U.S. older adults were uninsured all year (95% CI=0.29%-0.47%), while 41.4% had both Medicare and private insurance for whole year. Interestingly, older adults without insurance were more likely to agree that they did not need health insurance (18% vs. 4%), health insurance was not worth the cost (32% vs. 14%), and they were more likely to take risks than others (30% vs. 14%). A logistic regression model indicates that the uninsured were more likely to be late-life immigrant, younger, low income, African American, Hispanic, and had a lower number of chronic conditions. After controlling for predisposing, need, and enabling factors, the uninsured displayed lower total and OOP medical expenditures. However, their OOP financial burden, expressed by the percentage of income spent on OOP medical expenditures, was much greater among the uninsured (54% vs. 11%). Conclusion: Even though the number is small, uninsured older adults should receive further attention from policy makers, practitioners, and scholars.

PREDICTING LONG STAYS AMONG PERSONS NEWLY ADMITTED TO RI NURSING HOMES USING MDS ASSESSMENT DATA
S.M. Allen, P.L. Gozalo, B. Steinman, Community Health, Brown University, Providence, Rhode Island

Rebalancing states’ long term care (LTC) systems by developing better access to community-based LTC services is an important policy goal intended to reduce LTC costs and respond to older persons’ preferences to remain in the community. We investigated the predictors of long stay status using RI Nursing Home (NH) MDS Admission Assessment data merged to RI Medicaid claims for the year 2008. New admissions to a Rhode Island NH with at least one Medicaid NH claim in 2008 comprised our analytic sample (n=2159). Long stay status was defined as remaining in the NH 90 days post admission or later. Among new admits in 2008, 1,039 (48.1%) were long stay using this definition. We modeled long stay status using logistic regression. Our model included demographic characteristics (age, gender, race, education), cognitive and ADL impairment level, NH admission from the community or hospital, social support characteristics, and individuals’ preference to return to the community. Persons age >75 (OR= 2.1; CI=1.6,2.8) and with impaired cognitive status (OR=1.7; CI=1.3,2.3) were significantly more likely than persons age 65-74 and with intact cognition to become long stay NH residents. Persons who were black (OR=5.6; CI=.32,.98), had support to return to the community (OR=.57; CI=.42,77), and who preferred to return to the community (OR=.55; CI=.40,.75) were less likely to become long stay than their peers. ADL status at admission did not predict long stay status. Implications for the need for effective NH transition programs for residents who do not require a NH level of care are discussed.

AT THE CROSSROADS OF PROFITABILITY AND SECURITY: CURRENT ISSUES AND SUGGESTIONS ON AGE FRIENDLY INDUSTRIAL POLICY AND ELDERLY CARE POLICY IN OECD COUNTRIES
B. Hwang, Pusan National University, Busan, Republic of Korea

This study examines and contrasts the development processes among OECD countries of Age Friendly industrial policy and Elderly Care Policy and argues that some OECD countries have addressed challenges
of aging society according to the political economy of profitability, while others with regard to rather security and equity. This Study also argues, based on the results of in-depth key informant interviews with a variety of stakeholders, that the different behaviors and attitudes of people in OECD countries toward senior citizens are due in large part to their perception of each own government’s contradictory ideas about Age Friendly industrial policy and Elderly Care policy.

THE BENEFITS TO MEDICARE BENEFICIARIES OF PERSONALIZED ASSISTANCE WITH PART D OPEN ENROLLMENT
M. Rose, L.S. Noelker, Katz Policy Institute, Benjamin Rose Institute on Aging, Cleveland, Ohio

The annual review of Medicare Part D prescription drug coverage is a continuing challenge for beneficiaries. With literally hundreds of plans to choose from, during each open enrollment period, beneficiaries consider a multitude of variables. These include whether their plan will continue to be available, the formulary will cover all of their current prescriptions, and the cost is affordable, as well as possible prior authorization before medications are covered and step therapy. These considerations require that beneficiaries understand how to use Medicare’s web-based Plan Finder tool, or work with the plan, physician, pharmacist or Medicare in order to get answers and make decisions. As a result, beneficiaries commonly express reluctance to change plans, even when it is in their best economic interest to do so. A free service staffed by a benefits specialist at the non-profit Benjamin Rose Institute on Aging’s Medicare and Benefits Enrollment Center is available to help beneficiaries understand the Medicare Part D program and evaluate personalized options. During the 2010 open enrollment period, 107 clients received assistance in evaluating their current Part D plan and determining whether a change would be to their advantage. Almost 2/3 (70%) of them did so; for 80%, the reason given was to lower costs. The median annual cost savings for clients who changed plans was $234; the maximum exceeded $4,100. Policy recommendations to reduce the complexity and improve the outcomes of this process include limiting the number of plans and requiring open formularies covering all drugs.

SOME SUGGESTIONS ABOUT THE SOUTH KOREA WELFARE POLICY TOWARD THE AGED POPULATION
Y. Son, Elderly Care Management, Catholic University of Pusan, Busan, Republic of Korea

The current paper examined the changing nature of South Korea welfare policy toward the elderly population’s long-term care system. South Korea, coupled with the rapid increase in the oldest population, has launched the 5th public long-term care insurance in 2008, primarily financed by the working population. Since then, the structure of long-term care system has been reorganized; programs and services provided by the public have been noticeably increased. There was not only a large number of increase in nursing facilities, but also a newly established manpower called aged care workers were trained and now needed. There was not only a large number of increase in nursing facilities, but also a newly established manpower called aged care workers were trained and now needed.

OHIO’S UNDER 60 NURSING HOME RESIDENTS: ARE NURSING HOMES PREPARED FOR YOUNGER RESIDENT WITH SEVERE MENTAL ILLNESS?
I.M. Nelson, Scripps Gerontology Center, Oxford, Ohio

Similar to the national trend, the number of residents under age 60 residing in Ohio’s nursing homes has grown. Fueling this growth is an increased number of residents diagnosed with mental illness. This study attempts to develop a clearer profile of these residents and to look closer at how well prepared nursing homes are to meet the needs of this younger population. The Minimum Data Set (MDS) and a statewide survey addressing nursing home characteristics such as size, employee ratios, culture change, and mental health staffing and training are utilized. Of the nursing home residents under 60 actively residing in a nursing home between April 2009 and June 2009 (N=7,300), 1 in 5 were classified as having a severe mental illness (SMI) such as Major Depression, Schizophrenia, or Bipolar disease. Of those with SMI, 6% had no activities of daily living impairments. Less than 3% received any type of psychological therapy with a larger percentage receiving medications. The results from the statewide survey show that nearly no nursing homes had psychologists or psychiatrists on staff. The majority of psychiatrists or psychologists who were contracted provided less than 10 hours of service per month. Finally, less than half of all direct care workers such as RNs and STNAs are given training related to resident mental health concerns, aggressive patients, or procedures for psychiatric emergencies. Additional findings and further discussion about the implications of a growing younger resident population with psychiatric problems on nursing home care will be presented.

PREDICTING OUT-OF-POCKET CAREGIVING EXPENSES USING THE 2009 CALIFORNIA HEALTH INTERVIEW SURVEY
G. Boyer, Ederly Care Management, Catholic University of Pusan, Busan, Republic of Korea

Given the growing American elderly population and the inclusion of the CLASS Act in the Patient Protection and Affordable Care Act, scholars will continue to study the costs of long-term care. For the first time, The 2009 California Health Interview Survey inquired about informal caregiving, including out-of-pocket spending related to the care of family members, neighbors, and friends. This study sought to identify what predicts these out-of-pocket expenses in California. A cross-sectional, ordered logit regression was performed, using income to predict out-of-pocket expenses controlling for additional socio-demographic factors. A preliminary analysis of expenditures for long-term caregiving presents several interesting findings. First, income and hours worked per week were positively associated with out of pocket spending. In fact, caregivers with higher incomes were predicted to spend up to $1000 in the past month on caregiving. The number of hours worked per week was a positive predictor for all levels of expenditures. Married caregivers were more likely than never-married caregivers to have any out-of-pocket expenditures. Similarly, in comparison to women, male caregivers have a higher likelihood of having any expenditures. However, race/ethnicity, and physical health factors were not significantly associated with any level of expenditure. These preliminary results suggest that income, work obligations, gender, and marital status affect the out-of-pocket long-term care expenditures. More research is needed to elucidate the drivers of informal caregiving expenses and examine whether the health care reform’s CLASS Act will substitute or supplement caregivers’ spending.

DISCHARGE PLANNING WITH OLDER ADULTS IN MINNESOTA HOSPITALS
C.K. Eaton, 1. Winona State University, Winona, Minnesota, 2. University of Minnesota, St. Paul, Minnesota

In 2008, over 200,000 people age 65 and older were discharged from hospitals in Minnesota. Many seniors leave hospitals with on-going care needs whether they return to home with services or temporarily or permanently relocate for post-acute care. Most of the literature in this area was conducted over 25 years ago, before health maintenance organizations, diagnosis related groups, and home and community based care initiatives. Thus, little is known about how hospitals currently conduct discharge planning and who is responsible for this task at a time when older adults are leaving the hospital with complex health needs and after shorter stays. This presentation identifies the current state of discharge planning in an entire state; delineating discharge planning with seniors.
HOUSING, SERVICES, AND SOCIAL SUPPORT

A QUALITY IMPROVEMENT INTERVENTION TO IMPROVE PAIN ASSESSMENT AND MANAGEMENT IN THE NURSING HOME SETTING
J.E. Rydell1,2, C. Mueller1. 1. Nursing, Concordia College, Moorhead, MN, Minnesota, 2. University of Minnesota, Minneapolis, Minnesota

Pain is undertreated in nursing home settings with rates of undertreatment estimated 49% to 84%. A quality improvement project, designed to improve pain assessment and management of residents, was implemented to improve pain management outcomes and foster utilization of hospice services. Project methods were developed and implemented by a quality improvement team comprising licensed and non-licensed nursing staff. The team implemented and evaluated a pain assessment and management process, with implementation of a flowsheet to facilitate resident pain assessment on a “per shift” basis. Education was provided to nursing staff to enhance pain assessment and management processes. The target Effectiveness Ratio was 1.00. The intervention resulted in an increase in documentation of pain in nurses’ focus notes and nursing narrative sections of resident records. However, documentation of pain management follow-up did not increase. The percent of residents experiencing moderate to severe pain decreased from 7.0% pre-intervention to 3.9% one month and 6.4% two months post-intervention (Effectiveness Ratio 1.10 and 0.21, respectively). Utilization of hospice services did not increase one and two months post-intervention (Effectiveness Ratio 0.0), but increased to 100% (4 deaths/4 on hospice: Effectiveness Ratio 1.0) three months post-intervention. The utilization of a quality improvement team to implement strategies for improving pain assessment and management outcomes and utilization of hospice services may be beneficial when outcomes are measured long-term.

THE EXPERIENCE OF HOME FOR OLDER ADULTS: AN INTEGRATED INQUIRY
M. Thornton, University of Colorado College of Nursing, Denver, Colorado

The home environment represents the center of individual and family life throughout the lifespan and is commonly overlooked as an influential factor in the human experience of health/illness. This experience appears to be especially important for older adults who transition across environments as they age. The purpose of this integrated inquiry was to examine the human experience of home for older adults, to more fully develop this experience in the context of nursing, gerontology, and human science. The physical characteristics of the environment and influences on health/illness can and have been examined within the domain of natural science, proposing the need for a human science perspective to further explore the experience of home for later relation to health/illness. As a potential moderator of the health/illness experience, the experience of home for older adults is important to nursing practice and development of strategies to ease transitions and structure supportive environments. Carper’s Patterns of Knowing were used as a framework for this inquiry, employing multiple forms of knowledge. Results of the inquiry showed the human experience of home to be that of comfort, intimacy, connectedness, and security. While knowledge exists related to the meaning of home, the actual experience of home has yet to be explicitly described for older adults. Disciplines beyond the social sciences must become aware of the importance of this phenomenon, and nursing should engage in further exploration. Additional forms of focused inquiry and measurement are needed to further explore the experience of home in relation to health/illness.

EXPANDING THE RELATIONSHIP BETWEEN ASSISTED LIVING AND PACE
M. McNabney, P. Kohli, B. Leff, A.I. Arbaje, Johns Hopkins University, Baltimore, Maryland

The purpose of this study was to evaluate how assisted living (AL) is utilized by the Program of All-Inclusive Care for the Elderly (PACE). Because the main objective of PACE is to provide cost-effective, coordinated care for aging patients in a community-based setting, we evaluated this relationship by conducting three focus groups of staff members at one PACE site. These included: 1. clinical staff (nurses, therapists), 2. administrative/social work staff, and 3. direct care aides/drivers. Discussion focused on how PACE utilizes AL in the care of older adults, including the perceived advantages and disadvantages. The demographics of the focus group participants were: mean age 50.3 years; 91% women, 78% white. After transcribing the focus groups discussions, we categorized staff perspectives. Analysis of the transcripts indicate that patient-related factors that led to AL usage included: 1) increased medical and daily care needs; 2) short-stay rehab and respite needs; 3) need for supervision or concern for safety at home; and 4) insufficient support from caregivers. The program-related factors were 1) inability to coordinate care in home setting (especially if associated with recurrent or unnecessary hospital use); and 2) cost-effectiveness of care (compared to NH and hospital). These findings indicate that many factors influence the decision to utilize AL within PACE. To better define this relationship, chart reviews are also being conducted to collect information about the medical conditions, disabilities, and living situations of the participants to identify major themes centered around patient- and program-related factors related to AL usage.

NURSE EMPOWERMENT IN NURSING HOMES: THE CRUCIAL ROLE OF THE DIRECTOR OF NURSING
A. Rao, School of Nursing, University of Pennsylvania, Philadelphia, Pennsylvania

This poster summarizes a systematic review of the literature to illustrate the role of nursing home (NH) directors of nursing (DONs) in fostering empowerment among licensed nurses. Literature from the disciplines of nursing, management, and women’s studies is synthesized to outline the concept of empowerment and highlight its significance within nursing, while summarizing the manner in which nursing leadership influences nurse empowerment. The major findings of this review suggest that nurse empowerment is important because it is associated with a variety of improved nurse outcomes, greater consistency of care, and increased patient satisfaction. Further, several studies demonstrate that nurse leaders’ management practices play a critical role in shaping nurse perceptions of empowerment, but that their capacity for fostering empowerment is highly context dependent. Most of these studies have been conducted with Registered Nurses in acute care settings. Because NHs differ from acute care both structurally and demographically, the generalizability of these findings to the NH setting is questionable. In NHs, DONs are the leaders responsible for providing the positive management that can potentially empower nurses, yet the contextual dynamics impacting their capacity for effectiveness remain largely unexplored. Further research explicitly examining nurse empowerment in NHs is, therefore, needed to build knowledge about how to
better equip DONs to deal with challenges unique to their care environment. Ultimately, this knowledge can help DONs to more effectively provide empowering leadership to nurses who will, in turn, be better able to exercise their professional power to care for their residents.

**LINKING OLDER PERSONS TO COMMUNITY SUPPORT SERVICES: A CASE STUDY OF PRIMARY CARE PROVIDERS**

J. Ploeg, M. Denton, B. Hutchison, J. Tindale, C. McAiney, A. Moore, K. Brazil, J. Pledgerleith, School of Nursing, McMaster University, Hamilton, Ontario, Canada, 2. University of Guelph, Guelph, Ontario, Canada

Community Support Services (CSSs) assist older adults to maintain their quality of life and ‘age in place.’ Research indicates that older adults know little about CSSs and that they identify their primary care providers as key sources of information about such services. This research used a qualitative multiple-case design to assess how primary care physicians and the interprofessional health care providers (IHCPS) in their practices link older adults to CSSs. Face-to-face interviews were conducted with primary care physicians and IHCPS working in four different models of primary health care within Ontario, Canada. A total of 43 interviews were conducted (physicians = 23; IHCPS = 20). Findings indicate that primary care physicians know relatively little about CSSs and when available, turn to other professionals within their practice to link older adults to services. IHCPS usually have greater awareness of CSSs than physicians. Physicians and IHCPS working in multidisciplinary team models of primary care described a reliance on the expertise within the team to make linkages while physicians working in solo or small group practices faced greater challenges in making these linkages. IHCPS use a comprehensive process of assessment of needs, identifying support services, prioritizing service needs, sharing information with patients, assessing acceptability of services to patients, negotiating a plan with patients, working as a health care team, connecting with community agencies, and following up, in order to link older adults to an appropriate CSS. Strategies and resources that could improve the linkage of older adults to appropriate CSSs were identified.

**MEDICAL INSTABILITY, DELIRIUM, DEPRESSION AND PARTICIPATION IN REHABILITATION AMONG OLDER ADULTS IN POST-ACUTE CARE**

S.E. Hardy, Geriatrics, University of Pittsburgh School of Medicine, Pittsburgh, Pennsylvania

Older adults in post-acute care must participate in rehabilitation to maximize the chance of functional recovery. Discharge from the hospital “quicker and sicker” may limit the ability of patients to participate in therapy. We examine the association of medical instability, delirium, and depressive symptoms with participation in therapy among 90 previously community-dwelling older adults admitted to skilled nursing facilities for post acute care. Respiratory instability was defined as a new requirement for supplemental oxygen or hypoxia with rest or activity. Cardiac instability was defined as abnormal blood pressure or pulse or orthostatic changes. Symptoms, assessed at rest and with simple activities, included fatigue, chest pain, other pain, and dizziness. Participants had mean ± SD age of 82.2±8; 79% were female and 84% were non-Hispanic White. 22 participants (24%) were classified as having no, poor, or fair participation by therapists (versus good, very good, or excellent). Poor participation was significantly associated with delirium (23% vs. 6%, p=0.04) and greater ADL dependence (mean 5.2 vs. 4.2 of 7 ADLs, p=0.046). There were no significant differences between poor and good participants in age (83 vs. 81, p=0.26), female sex (86% vs. 76%, p=0.37), white race (86% vs. 84%, p=0.84), cognitive impairment (68% vs. 74%, p=0.63), depressive symptoms (5% vs. 10%, p=0.40), cardiac instability (23% vs. 19%, p=0.71), respiratory instability (23% vs. 15%, p=0.38), or symptom instability (86% vs. 78%, p=0.39). Poor rehabilitation participation may mediate the relationship between delirium and poor functional outcomes.

**SAFER CARE FOR OLDER PERSONS (IN RESIDENTIAL ENVIRONMENTS) PROTOCOLS: IMPROVING RESIDENT CARE AND QUALITY OF LIFE FOR STAFF IN NURSING HOMES – A PROJECT COMBINING QUALITY IMPROVEMENT AND RESEARCH**

SCOPE is a two-year proof of principle study (2010-2012) funded by Health Canada, being carried out in seven nursing homes in western Canada. It includes an education and support intervention for direct caregivers to improve the safety and quality of care delivery. We hypothesize that this intervention will improve not only the care provided to residents but also the quality of work-life for direct caregivers. The one year quality improvement (QI) intervention includes tools adapted from the Institute for Healthcare Improvement’s Breakthrough Series: Collaborative Model and Canada’s Safer Healthcare Now! improvement campaign. Local improvement teams in each nursing home (1-2 per facility) are led by healthcare aides (non-regulated caregivers) and focus on the management of one of three topic areas: pain, skin care, or resident behavior. These areas for intervention were chosen by managers and caregivers in the sector through a Delphi-like process. Critical elements of the program include local measurement, virtual and face-to-face learning sessions involving change management, QI methods and clinical expertise, ongoing virtual and in person support, and social networking. Quality of work-life is being measured using standard instruments before, during and one year following the intervention. In this session, we report on the progress of the teams in improving care processes at the 6 month mark and show that over ½ of the teams have made substantial progress toward attaining their improvement goals.

**COORDINATING CARE FOR FALLS VIA EMERGENCY RESPONDERS**

E. Phelan, H. Meischke, B. Stubbs, C. Fahrenbruch, J. Herbert, A. Imperial, I. U of Washington, School of Medicine, Seattle, Washington, 2. Emergency Medical Services (EMS) Division, Public Health – Seattle & King County, Seattle, Washington, 3. U of Washington, School of Public Health, Seattle, Washington, 4. Public Health - Seattle & King County, Seattle, Washington

**Background** Falls account for a substantial portion of 9-1-1 calls, but few studies have examined the potential for an emergency medical system role in fall prevention. We tested the feasibility and effectiveness of an emergency medical technician (EMT)-delivered, at-scene intervention to link elders calling 9-1-1 for a fall with fall prevention programs in their community. **Methods** The intervention consisted of a brief public health message about the preventability of falls and written program information left at scene. Data sources included 9-1-1 reports, telephone interviews with intervention district fallers and sociodemographically comparable faller controls, and in-person interviews with intervention district EMTs. Interviews elicited faller recall and perceptions of the intervention, EMT perceptions of intervention feasibility, and resultant referrals. **Results** Fifteen percent of 9-1-1 calls during the intervention were for senior falls. The intervention was delivered to 49% of fallers. Their mean age (N=111) was 81±8 years; 77% were women, 40% had annual incomes under $20K, and 39% lived alone. Thirty-three percent reported that an EMT had discussed falls and fall prevention (vs. 11% of controls, P<0.05); 86% reported that the information was useful. Six percent reported having made an appointment with a fall prevention program (vs. 3% of controls). EMTs reported that the intervention was worthwhile and did not add substantially to their workload. **Conclusions** A brief, at-scene intervention is feasible and acceptable to fallers and EMTs. Although it activates only a small
percent to seek out a fall prevention program, the public health impact of this low-cost strategy may be substantial.

FACTORS AFFECTING ATTITUDES OF COMMUNITY-DWELLING OLDER ADULTS TOWARD LONG-TERM CARE UTILIZATIONS

Y. Lim, J. Yoo, Department of Nursing, Yonsei University Wonju College of Medicine, Wonju, Kanwon-do, Republic of Korea

The purpose of the study was to determine factors affecting attitudes of community dwelling Korean older adults toward long-term care utilizations. A total of 222 community dwelling Korean older adults over 60 year old were surveyed to choose home care or nursing home care with hypothetical situations including hip fracture and severe dementia. A logistic regression analysis was used to identify variables that affected attitudes of long-term care utilizations among older adults. In case of hip fracture, gender (OR=2.16, p=.024) was factor of nursing home care utilizations, indicating that odds that older women would prefer nursing home care if they have hip fracture, as long as they can afford it, were 2.16 times greater than the odds that older men would prefer nursing home utilization. In case of severe dementia, also, gender (OR=2.09, p=.032) was factor of nursing home care utilizations, indicating that odds that older women would prefer nursing home care if they have severe dementia, in order not to be a burden for caregivers were 2.09 times greater than the odds that older men would do that. Age, education, economic state, living arrangement, cardiac disease, endocrine disease, and musculoskeletal disease were not a significant factor to affect attitudes of older adults toward long-term care utilizations with hypothetical situations including hip fracture and severe dementia. Implications of these findings for further research and application to health care professionals are discussed.

CARE PREFERENCES OF ELDERLY WOMEN AND MEN IN GERMANY

A. Kuhlemeier, S. Blueher, D. Draeger, Medizinische Soziologie, Charité Berlin, Berlin, Germany

Background: In Germany the current percentage of residential care is relatively low. Seeing the demographic change and the assumed change of values with regard to the willingness of loved ones to take over care the question comes up in which way care is provided in the future. Objective: The aim of the study was to find out the individual expectations and orientations of elderly men and women with regard to high-quality care. Method: A random sample of 20,000 participants (>40 years) was obtained among the insurants of 4 different private nursing care insurances. 6,218 insurants replied to the questionnaire, which corresponds to a response of over 31 %. Results: In case of need for help dwelling care by relatives – assisted by nursing services – is clearly preferred by nearly 80 % of all respondents. The aim for autonomy and living in a familiar ambiance are the most dominant motives to prefer dwelling care. Moreover there are widely spread expectations that loved ones have to take over care as far as possible. 55 % of all respondents and even 64 % of family caregivers clearly refused the statement “care by the loved ones is no longer contemporary”. Residential care on the other hand is preferred in case of dementia or if the loved ones have to take over care as far as possible. 55 % of all respondents and even 64 % of family caregivers clearly refused the statement “care by the loved ones is no longer contemporary”. Residential care on the other hand is preferred in case of dementia or if the loved ones are exessive burdened. Conclusion: The results show that expectations and orientations with regard to high-quality care are – in medium-term – expected to be relatively persistent. These expectations are strongly connected with the preference of dwelling care.

MEASURING PERSON-CENTERED CARE IN LONG TERM CARE: INSTRUMENT DEVELOPMENT

D. Porock1,2, Y. Chang1, J. Li1, 1. School of Nursing, University at Buffalo, Buffalo, New York, 2. University of Nottingham, Nottingham, United Kingdom

Background: Person-centered care (PCC) is a philosophical approach where the autonomy and personhood of the elder is central to daily care and activities in long-term care (LTC). PCC places the emphasis on seeing the elder as an individual: who they are, their needs, history, personal preferences, passions, interests, culture, routines, and relationships. Currently there are no comprehensive measures of PCC quality. Purpose: To develop three comprehensive, psychometrically sound instruments for measuring the quality of person-centered care from the perspectives of 1. LTC residents; 2. their family; and 3 the staff who care for them. Methods: Two stage development. 1. Literature review, focus groups and content validity testing were used to develop items for the three questionnaires 2. Psychometric testing. Participants in both stages were residents, families and staff from LTC facilities in Western New York. Qualitative methods were used to analyze focus group data and identify domains and items for the surveys. Content validity followed Lynn’s method. Reliability and construct validity testing were utilized with the pilot study data. Results: We expect a total 300 participants in the psychometric testing, 100 each from residents, family members and staff. The instruments showed satisfactory psychometric properties which warrant further development and use for research and quality monitoring. Conclusion: These newly developed instruments provide a starting place for measuring PCC which is more comprehensive in capturing all the relevant domains. However, a larger sample is needed along with predictive validity testing to determine the usefulness of these instruments in LTC research and practice.

INDEPENDENCE AND DEPENDENCE: THE PERSPECTIVES OF OLDER TAIWANESE WITH PHYSICAL DISABILITIES

L. Chang1, J. Wang2, 1. National Cheng-Kung University, Tainan, Taiwan, 2. Chung Jung Christian University, Tainan, Taiwan

Objectives. Independence and dependence has long served as an important indicator of health and needs for social services for older adults with disabilities. There is limited understanding of how older adults with disabilities conceptualize Independence/dependence in Taiwan. The study explored the meanings of Independence/dependence from their perspectives. Qualitative Methods. 18 older Taiwanese with physical disabilities were recruited from three out-patient rehabilitation clinics and participated in one or two taped in-depth interviews. 26.5-hour of participant observation of their daily routines were completed, including 20-hour of videotape. Interviews were transcribed in verbatim, video tapes reviewed and described in extensive field notes. Transcripts were analyzed with thematic analysis, with the assistance of Atlas.ti 5.5 software. Results. Three themes emerged from the narratives. (1) Independence/dependence was an elusive concept, evidenced by the participants’ difficulties in articulating definitions. (2) Difficulty in rating independence/dependence. Self-rated level of independence varied, primarily conditioned upon interpersonal contexts. (3) Dilemma of “striving for independence.” Despite regaining independence as the proclaimed goal of rehabilitation, the primacy of rehabilitation in daily routines, and diligent attendance in daily rehabilitation sessions that aimed at motor recovery, most participants showed a lack of interests and exertion in independently completing daily tasks outside of rehabilitation. Results: Of “striving for independence.” Despite regaining independence as the proclaimed goal of rehabilitation, the primacy of rehabilitation in daily routines, and diligent attendance in daily rehabilitation sessions that aimed at motor recovery, most participants showed a lack of interests and exertion in independently completing daily tasks outside of rehabilitation clinics, and considered the need for assistance as legitimate. Conclusions. The findings reveal a gap between independence defined in health and social services and the perceptions of older adults, and between the concerted efforts of doing rehabilitation and the lassitude for practicing independence in daily lives.

DEVELOPMENT AND EVALUATION OF A MODIFIED HOSPITAL ELDER LIFE PROGRAM

C. Chen, National Taiwan University, Taipei, Taiwan

Background: Older hospitalized patients often experience geriatric syndromes that may be prevented using complex interventions.
For example, the Hospital Elder Life Program (HELP) was shown to be successful, but sites with limited resources might find the HELP costly. Thus, modifying the HELP to include only key nursing components might prove more cost-effective. Objectives: To develop and evaluate a modified HELP intervention derived from a conceptual model of shared geriatric-risk factors. Method: The modified HELP intervention was developed and evaluated based on the United Kingdom Medical Research Council’s evaluation framework. According to this framework, the modified HELP was based on a conceptual model of shared risk factors and literature analysis. The HELP’s feasibility, efficacy, and components were evaluated between August 2007 and April 2009 in a pre-and post-intervention pilot trial. Participants were 179 patients enrolled as the control (n=77) and intervention (n=102) groups. Results: The modified HELP intervention targeting three shared risk factors (cognitive, functional, and nutritional status) was successfully implemented on a surgical ward. The average 7-day inpatient intervention for older patients undergoing common elective, abdominal surgical procedures substantially reduced the rates of eight common geriatric syndromes: delirium, functional dependence, malnutrition, weight loss, depression, incontinence, pressure ulcers, chewing difficulty, swallowing difficulty, and sleep disturbance. Conclusions: Theses findings suggest that revising care to target three shared risk factors significantly reduces the development of eight common geriatric syndromes and continued development of the HELP is indicated. Thus, the next logical step in testing its effectiveness and long-term benefit is a randomized controlled trial.

HOSPITAL-RELATED QUALITY OF CARE IMPROVEMENTS ASSOCIATED WITH A HIGH RISK CASE MANAGEMENT PILOT PROGRAM FOR MEDICARE MEMBERS WITH MEDIGAP COVERAGE

Research Objective: Estimate the relationship between participation in a High Risk Case Management (HRCM) program and inpatient hospital-related quality of care for Medicare beneficiaries with an AARP® Medicare Supplement (i.e. Medigap) plan insured by UnitedHealthcare Insurance Company or UnitedHealthcare Insurance Company of New York. Study Design: In-home and telephone HRCM services were provided by nurses and social workers to improve care coordination for those with multiple chronic conditions. Propensity-score-weighted regression analyses were used to estimate associations between HRCM participation and three inpatient, hospital-related quality of care metrics: having one or more visits with a doctor within 15 days of a hospital discharge, fewer readmissions within 30 days of a hospital discharge, and lower average inpatient hospital expenditures. Population Studied: Sample members resided in five pilot states. Those who qualified for the program had Hierarchical Condition Category scores greater than 3.74. 676 members voluntarily participated in the program. 5,654 similar members were used for comparison. Results: After adjusting for demographic and health status differences, HRCM participants were significantly (3.7%, p=0.05) more likely to have an office visit within 15 days of a hospital discharge, significantly less likely (28.1%, p=0.07) to have a hospital readmission within 30 days of hospital discharge, and averaged significantly fewer inpatient hospital expenditures per month ($37.28, p=0.01). In addition, almost all members (98%) were satisfied with the program. Conclusions: This is the first known HRCM program designed for Medigap members. It was associated with high member satisfaction and better hospital-related quality of care in its first year.

TITLE: DIET QUALITY AND SOCIAL SUPPORT: FACTORS ASSOCIATED WITH SERUM CAROTENOID CONCENTRATIONS AMONG OLDER DISABLED WOMEN (THE WOMEN’S HEALTH AND AGING STUDY)

PURPOSE: This study investigated the relationship between social support, including instrumental support, emotional support, social interaction, social space, and family networks, and diet quality, as indicated by serum carotenoid levels. DESIGN AND METHODS: The sample consisted of participants in the Women’s Health and Aging Study with longitudinal carotenoid data (n=325). We performed regression analyses on baseline indicators of social support—and on change in social support—to determine whether baseline level or change in levels of social support predict change in serum carotenoid levels over 2 years. To determine whether or not regression to the mean was driving these results, we performed an analysis that included baseline and change levels of social support indicators. RESULTS: At baseline, the frequency of leaving one’s home was associated with a decrease in carotenoid levels. Leaving one’s home more frequently predicted an increase in carotenoid levels and attending fewer activities predicted a decrease in carotenoid levels. However, increased telephone use predicted a decrease in carotenoids. IMPLICATIONS: In older, community-resident disabled women, baseline levels of social support did not consistently predict diet quality. However, change in social support predicted both positive and negative change in nutritional status and thus provides supportive evidence that social activity and family interaction may play meaningful roles in the maintenance of nutritional status of functionally compromised older women. Further research is necessary to more fully understand the impact of multiple forms of social supports on the nutritional status of older adults.

UTILIZATION OF COMMUNITY POTENTIAL FOR DISASTER DAMAGE REDUCTION AND RECOVERY

K. Kitagawa, T. Nagai, M. Tahara, H. Ok, B. Pyon, 1. Culture & Education, Saga University, Saga, Japan. 2. Mokwon University, Daejeon, Democratic People’s Republic of Korea

Japan’s biggest recorded earthquake in north-east coast had hit on Mar.11, 2011. Previous years, disasters were frequent in Japan such as 20.1% of natural disasters in the world occur in Japan, and the related damage accounts for 11.9% of that in the world. Volunteer disaster-prevention activities by community residents are being seen as a new type of social activism in Japan, from a viewpoint of enhancing local disaster prevention capabilities. The number of community fire brigades which have long been important providers of disaster prevention, is decreasing, and there are now less than 900,000 members all over Japan. Moreover, the members are aging, potentially becoming the target of relief activities themselves during disasters, considering that 60% of disaster victims in Japan are elderly. We studied relief operations by social welfare facilities. In our research, we found that 64.1% of long-term care insurance facilities and 51.0% of facilities for the disabled were prepared to accept evacuee from the community. It is expected that they will be evacuation centers during disasters. We conducted qualitative studies with the co-operation of staff of community support centers, and clarified that care manager has the capacity to provide medical care, insurance, nursing services and social rehabilitation of elderly people after disasters. By 2010, 99.1% of municipalities in Japan had created evacuation plans for those who require nursing care. Two thirds of municipalities are now making individual plans for such residents. Municipalities are preparing disaster prevention plans which take advantage of the power of community.
THE RETURN ON INVESTMENT ASSOCIATED WITH A HIGH RISK CASE MANAGEMENT PILOT PROGRAM FOR MEDICARE BENEFICIARIES WITH MEDIGAP COVERAGE
K. Hawkins1, R.J. Ozminkowski1,2, G.R. Bhattari3, W. Wang1, P. Parker2, C. Barnowski2, R.J. Migliori2, C.S. Yeh1, 1. Analytics and Data Management, Ingenix, Ann Arbor, Michigan, 2. UnitedHealth Group, Minnetonka, Minnesota, 3. AARP Services Inc., Washington, District of Columbia

Research Objective: Estimate the return on investment (ROI) associated with participation in a pilot High Risk Case Management (HRCM) program for Medicare beneficiaries with an AARP® Medicare Supplement (i.e. Medigap) plan insured by UnitedHealthcare Insurance Company or UnitedHealthcare Insurance Company of New York. Study Design: In-home and telephone HRCM services were provided by nurses and social workers to improve care coordination for those with multiple chronic conditions. Propensity-score-weighted multiple regression analyses were used in a difference-in-difference framework to estimate savings in total healthcare expenditures per engaged participant per month that were associated with program participation. ROI was estimated as monthly savings divided by monthly costs of the program.

Population Studied: Those who qualified for the program resided in five pilot states with Hierarchical Condition Category scores greater than 3.74. 676 members voluntarily participated in the program. 5,654 similar insureds were used for comparison. Results: The ROI showed favorable savings ($2.18 per dollar spent on the program). These savings primarily accrued to Medicare, which paid about 84% of total healthcare expenditures. To a lesser extent savings accrued to the Medigap payer and to members, who paid 7% and 9% of total expenditures, respectively. Almost all members (98%) were satisfied with the program. Conclusions: This is the first known HRCM program designed solely for Medigap members. While its ROI estimate was not statistically significant (p=0.65) in the first year, these results are encouraging for a pilot program. As the program continues to expand, continued member satisfaction and statistically significant results are anticipated.

COST-COMPARISON OF PACE VISION SERVICE BASED ON SITE OF CARE
A. Diller, K.D. Frick, M. McNabney, Johns Hopkins, Baltimore, Maryland

Background: The Program of All-inclusive Care for the Elderly (PACE) is a full-risk, capitated model of care for nursing-home eligible older adults, accountable for achieving maximal independence and health for enrollees. Between FY09 and FY10, the Johns Hopkins PACE center transitioned from out-sourced vision services to providing in-house, weekly vision care through an optometrist and mobile clinic. This study evaluates the effects of changes in site-of-care on resource utilization. Methods: Evaluation of direct costs and service provision was performed as a secondary data analysis of claims data submitted with a primary diagnosis for an ophthalmologic condition between the 1 year pre- and the 1 year post-transition in services. Results: There was a decrease in total expenditures for vision services delivered in FY09 and FY10 from $140,919 to $84,140. Notably, more patients received care in FY10 (119) than in FY09 (78) and a higher total number of procedures were performed (721 in FY10 versus 610 in FY09). Conclusions: Despite a 40% reduction in vision care expenditures associated with internalizing specialty services, 53% more patients accessed care and 18% more procedures were performed. Moving primary vision services to the PACE site may enhance access, resulting in greater patient utilization and more comprehensive patient care. Additionally, point-of-care collaboration between PACE managers and non-affiliated health professionals may foster an environment for greater efficiency with less expensive, and perhaps less medically inappropriate, care for this frail, elderly population. We plan to evaluate the impact of these services on vision outcomes in the future.

SESSION 1050 (POSTER)

EDUCATION AND TRAINING PROGRAMS

FACTORs ASSOCIATED WITH HEALTH SERVICES ADMINISTRATION STUDENTS’ INTEREST IN LONG-TERM CARE
A. Temple, J.M. Thompson, Health Sciences, James Madison University, Harrisonburg, Virginia

With the aging of the population, there will be an increased demand for health administrators in long-term care (LTC) settings. This study explored factors related to interest in careers in LTC among 68 undergraduate health services administration students at one mid-Atlantic state university. Students completed an online survey that contained items relating to demographics, completion of gerontology coursework, experience in LTC settings, frequency and quality of contact with older adults, perceptions of the career field, attitudes towards aging, and interest in LTC. Multiple linear regression was used to examine factors associated with interest in a career in LTC administration upon graduation. Of the students surveyed, 32% expressed interest working in LTC administration. Volunteer or work-related experience in LTC settings (beta=0.20, p<.05), quality of contact with unrelated older adults (beta=0.28, p<.05), satisfaction working with the elderly (beta=0.29, p<.05), and confidence in the ability to work in LTC (beta=0.39, p<.01) were all positively associated with interest in LTC administration. These findings suggest that educational programs should incorporate opportunities for experience in LTC settings and tailor coursework to foster confidence in the field to increase the number of students in LTC administration.

TRAINING PROGRAM IN AGING RESEARCH FOR SOCIAL WORK FACULTY: A FOLLOW-UP STUDY
C.M. Mehrotra, Psychology, The College of St. Scholastica, Duluth, Minnesota

With support provided by NIH and the Hartford Foundation we have offered a training program to expand the pool of social work faculty engaged in aging research. Program design includes an initial summer institute, ongoing consultation, a mid year meeting, and a follow-up institute. Our past presentations at GSA annual meetings have focused on the program design, its content, intended outcomes, and formative evaluation. This poster reports the results of a follow-up evaluation we conducted in June 2010 to assess program outcomes. Key findings: More than 95 percent of the participants have incorporated recent advances in their courses; 82 percent have engaged students in conducting aging research; 88 percent have used their skills and knowledge from the training program in writing grant applications; and more than 70 percent have given presentations at national and regional conferences. In addition, more than 60 percent have received funds exceeding a total of eight million dollars to conduct aging research. Analysis of their grant applications indicates that a number of these projects focus on aging in ethnic minority populations. Furthermore, grant support has been provided by a large variety of funding agencies. This not only indicates widespread interest in aging research, but also shows recognition of untapped potential of social work faculty to contribute to aging research and generate useful knowledge in new ways. The poster presentation would also include lessons learned in conducting the training activities. This information may be useful to colleagues interested in designing research training programs in other disciplines.

OLDER STUDENTS IN MSW PROGRAMS: RE-TOOLING FOR WORK

Purpose: To enhance knowledge of pathways that led adults 40 years of age or older to obtain a graduate degree in social work (MSW) and
to gain insight into their experiences in the program as well as the job market afterward. Methods: Inclusion criteria included age (40+ years) and participation in the MSW program from 1999 to 2009. Sixty-one alums were contacted and 60 (98%) participated in telephone interviews. Results: On average, respondents were 45 years of age when they returned for the MSW. Most were female (85%) and Caucasian (60%). Prior to the MSW, most (58%) respondents had been in the for-profit sector and most (57%) switched into the non-profit sector after the MSW. Volunteering and caregiving were pathways that led to the MSW and 72% reported having a ‘pivotal moment’ that led them to seek an MSW. Push-factors included lack of meaning in their work while pull-factors included the people-centric nature of the MSW, social work as a suitable post-retirement career, and human service agencies mandating the MSW. Most believed age was an asset in the program and in their job search (58%). Twenty-one percent reported age discrimination. Most reported their post-MSW job was more satisfying than their pre-MSW job and that they were better able to contribute to society. Implications: This MSW program was pivotal in re-tooling baby boomer’s skills and knowledge to advance or launch their careers. Next steps involve developing strategies to recruit and support older students in MSW programs.

UNDERGRADUATE PERCEPTIONS OF WORKING WITH OLDER PEOPLE: IMPLICATIONS FOR THE NURSING PROFESSION

C. Neville, R. Dickie, School of Nursing and Midwifery, The University of Queensland, Ipswich, Queensland, Australia

Recent literature suggests that nursing students are reluctant to seek employment with older people upon completion of baccalaureate programs. This has implications in regard to recruiting a high quality gerontological workforce. Therefore it is imperative to gain a better understanding of the factors that influence nursing students’ perceptions of older people. This understanding is relevant for nursing education curriculum developers and healthcare employers. This three year (2008-2010) longitudinal investigation was undertaken in an Australian University. Data was collected annually using the Perception of Working with Older People Scale (Nolan et al, 2001). This scale assesses perceptions of working with older people in general, one’s personal disposition towards or intention to work with older people and ones’ perceptions of the consequences of working with older people. Results (n = 205) indicated that younger students and students who have no experience with older people have more positive perceptions. However, female students, those who have worked with older people prior to their nursing education, those who currently work with older people and students in first year compared to second and third year students have significantly more positive perceptions. Currently there is a gerontological nurse shortage and there is no indication this situation will improve any time in the future. The study reinforces that the important association between perceptions of older people and the type of exposure to older people during the undergraduate curriculum warrants more attention if graduate nurses are to seek employment in this challenging and rapidly expanding clinical area.

GAPS IN WORKFORCE EDUCATION AND TRAINING: WHAT WE CAN LEARN FROM NEW YORK STATE

B.P. Horowitz1, R. Maiden1, J.L. Howe1, 1. York College-CUNY, Jamaica, New York, 2. Alfred University, Alfred, New York, 3. Mount Sinai School of Medicine, New York, New York

On March 23, 2010 President Obama signed the Patient Protection and Affordable Care Act into law with the goal of health care security for Americans. Currently over 35 million Americans have Medicare, 36 million Medicaid. By 2030 it is estimated there will over 70 million Americans 65 years or older; the number of adults 85 or older is projected to reach 8.9 million. New York State (NYS) ranks third in the nation in the number of older adults. While older adults are often healthy into advanced age, advanced age is associated with greater risk for chronic illness and disability, often requiring health and human service services to address complex health and social needs. The question looms: How will these providers be adequately trained? This paper provides findings from a NYS study that sought to identify concerns and offers recommendations on workforce education/training challenges in gerontology/geriatrics. Data was obtained from a statewide sample of executive level personnel, gerontologists, providers of services, older adults, and other stakeholders (N=355). Key themes identified through content analysis included need for education on aging in agencies serving older adults, education on human development and disability, and more opportunities for training/education for providers. Lack of funding was identified as a significant barrier to employee education as well as a lack of consensus among employers, universities, government agencies and providers on what education programs should be offered. We will make recommendations about strategies to close training gaps which will be generalizable to states with similar demographics.

PARTNERING WITH OLDER ADULTS: USING NURSING STUDENTS’ REFLECTIVE JOURNALS TO IDENTIFY LEARNING

S. Davies1,2, A. Reitmaier1, L. Smith1, 1. Nursing, Winona State University, Winona, Minnesota, 2. University of Sheffield, Sheffield, United Kingdom

The benefits of intergenerational contact between old and young adults have been demonstrated; yet nursing programs have underexplored the potential of these relationships for enhancing student learning. This paper presents data from student reflective journals to evaluate an undergraduate course in gerontological nursing. The sixteen-week course aims to create positive learning experiences by involving older adults as partners in student learning. Elders are recruited to receive bi-weekly visits from a designated student in order to share aspects of their life and experiences with them. Students work with the older adults to develop health promotion projects that will benefit the whole community in which the older adult lives. They write reflective journals based upon their conversations with each older adult as a method of evaluating their learning. A data matrix was initially developed from a consideration of thirty journals. A further fifty journals were then mapped onto these categories, which were refined and adjusted. Journals were completed during 2010. Three major themes were identified representing the impact of interactions between the students and the older adults on student learning: discovering connections (making links with evidence and viewing the person holistically, adapting our thinking (becoming aware and being challenged, building intergenerational relationships (recognizing the value in spending time with older adult and the potential for mutual learning. The presentation will elaborate on these themes to illuminate the processes through which student nurses apply theoretical learning. The findings have relevance for nurse educators, student nurses, older adults and gerontological practitioners.

HEALTH CARE DECISION MAKING: EVALUATION OF INTERPROFESSIONAL ETHICS TRAINING AND POLICY ISSUES

M.E. Morrisey, Graduate School of Social Service, Fordham University, White Plains, New York

Health care decision making is an important area of policy making for older adults today as it concerns critical issues such as advance care planning, self-determination, conversations with family members, health care agents and health care professionals, caregiving, and multidimensional aspects of health and well-being. The complexity of laws and policies that affect health care decision making for older adults and shifting paradigms in policy point to the urgent need for ethics training for social workers and all health care professionals working with older adults in diverse practice settings. There is little data available on the evaluation of ethics training for health care professionals and ethics committee members working in health care settings and the impact of such train-
implications of these trends. The presentation also addresses how these trends look at the effects of declining home values and how it may affect long-term care choices. The presentation draws on data from the Health and Retirement Study (1998-2008), this study takes into account the changing circumstances of the elderly. For many elders, the period after age 65 is a time of rapid and considerable changes in the areas of income, health and functioning, as well as living situations. As such, this study extends the current literature by exploring the longitudinal processes leading to eventual take-up of benefits among the aged. Methodologically, the research relies on event history analysis of data from the Health and Retirement Study spanning the years 1996-2006 to explain both the timing of transition to eligibility and participation status, as well as the role of life events (i.e., changes in health, functioning, and expected benefit levels) on the take-up decision. Life table analysis yields a cumulative, twelve-year take-up rate of ~36% among those eligible, and a cumulative, twelve-year eligibility rate of ~25% among those at risk. Meanwhile, hazard models reveal that changes in health and functioning over time in addition to changes in the expected benefit significantly influence the participation decision.

**HOME EQUITY AND LONG-TERM CARE FINANCE AFTER THE CRASH**

D.L. Redfoot, AARP Public Policy Institute, Washington, District of Columbia

A substantial body of research indicates that many older homeowners use their home equity as an insurance policy for crises in retirement years—especially to finance long-term care needs. With so many people treating home equity as a self-insurance policy, this presentation looks at the effects of declining home values and how it may affect long-term care choices. The presentation draws on data from the Health and Retirement Survey and other more recent sources to discuss the policy implications of these trends. The presentation also addresses how these trends may play out differently for different segments of the older population by race/ethnicity, gender, and marital status.

**AGE COHORT AND GENDER DIFFERENCES IN WORK TRANSITIONS**

F. Tang, Y. Lee, University of Pittsburgh, Pittsburgh, Pennsylvania

With potential reductions in retirement income sources and possible cutbacks in Medicare and Medicaid, many older Americans have to choose a longer work life, experience phased-out connections to the workplace, and follow different pathways to complete retirement. Using data from the Health and Retirement Study (1998-2008), this study...
examines stage sequential change over time in transition from full-time employment to complete retirement and investigates age cohort and gender differences in the transition process toward retirement. Latent transition analysis revealed four distinct statuses: the fully-retired, partially-retired, full-time work, and part-time work. Among 5,531 adults reporting full-time work hours in 1998, 67% remained in the full-time work status in 2000. From 2000 to 2004, 51% remained there, 27% transitioned to the fully-retired, 12% to part-time work, and 10% to the partially-retired status. From 2004 to 2008, 47% remained in full-time work status while 29% transitioned to fully retired, 13% to part-time work, and 10% to partially-retired status. Age cohort and gender differences were identified in the status prevalence and transition probabilities. For example, early baby boomers (born 1946-1953) were most likely to transition to partially-retired status; whereas the silent cohort (born 1936-1945) were most likely to transition to the fully-retired, and the long civic cohort (born 1926-1935) most likely to transition to part-time work status. Women were more likely than men to remain in full-time work status at older age. Findings have implications for changes in workforce practices and public policies to adjust for retirement transition among older workers.

SENIOR ECONOMIC INSECURITY ON THE RISE
T. Meschede, L. A. Sullivan, Heller School, Brandeis University, Waltham, Massachusetts

Not only did dramatic changes in the retirement landscape increase financial risks for seniors, the recent recession added more financial challenges for individuals approaching or living in retirement. This study documents the impacts of the recession on the economic fragility of seniors by depicting trends between 2004, 2006, and 2008 utilizing key measures of economic security such as housing and health expenses, home equity, and assets. Using Consumer Expenditure Survey and Health and Retirement Study data, analyses indicate that the overall financial risk has increased significantly (p<0.001) between 2004 and 2008. Analyses of the major sources of increased risk point to housing expenses, rising expenses relative to budgets, and a decrease in assets. For example, while 41.7 percent of senior households were spending 30 percent or more of their income on housing expenses in 2004, meeting the Department of Housing and Urban Development (HUD) definition of burdened by housing expenses, the proportion at risk rose to 47.0 percent in 2008. The percent spending no more than 20 percent of income on housing fell three percent during this time to 33.5 percent. For African-American and Latino seniors, who overall have lower retirement benefits and savings, the future is especially bleak. Preliminary analyses point to seniors of color at particular financial risk during retirement. This paper discusses policy solutions to enhance existing programs for seniors and support asset development for adults of all ages to better prepare them for their retirement years.

HOUSING WEALTH OF THE BABY BOOM GENERATION
S. Neufeld, Wayne State University, Detroit, Michigan

Introduction: Historically, the largest component of household wealth in the U.S., aside from Social Security, has been home equity. However, the increase in mortgage debt over several decades, coupled with the decline in housing prices after 2006 has reduced housing wealth substantially. This has particular significance for the baby boom generation, who are nearing retirement age. Methods: We use data from the Survey of Consumer Finances reports from 1989 to 2007 and calibrated to the Federal Flow of Funds (FoF) data published quarterly by the Federal Reserve Bank. We address the questions: To what extent has boomer housing wealth been reduced? Can boomers still count on their home equity to help fund their retirements? Findings: Since 2006 the value of all housing stock owned by the baby boom generation has declined by about $2.2T to $7.9T. Mortgage debt however remains at $4.7T, about the same as in 2007. The housing crash has, thus, exacerbated the long-term trend in declining home equity: the equity of households aged 55-64 (aged 45-54) in 1989 was 81% (70%) on average, but has now dwindled to only 50% (35%). Thus, the average boomer household’s housing wealth is roughly $125K today, only modestly more than their $112K annual income, quite insufficient to fund retirement at the levels they might desire. Discussion: Boomer households remain highly leveraged and their home equity is at historic lows. Mortgage debt will take many years to pay down, which has significant implications for boomer labor force participation in their later years.

SESSION 1060 (POSTER)

HEALTH AND SERVICE CONSIDERATIONS AMONG DIVERSE AND SPECIAL POPULATIONS

GROWING OLD IN JAPAN: EXPERIENCES AND NEEDS OF ETHNIC CHINESE ELDERS OF YOKOHAMA CHINATOWN
L. Sun, L. Chen1, 1. School of Social Work, Kwansei Gakuin University School of Human Welfare Studies, Nishinomiya, Japan, 2. Kwansei Gakuin University School of Human Welfare Studies Dept. of Social Organization Development, Nishinomiya, Japan

BACKGROUND: The issues related to ethnic and racial minorities aging in Japan has been mostly overlooked by the aging network including government, social service providers, and researchers. Today, only 1.74% of foreigners living in Japan, but this population has been growing in recent years. As for persons who were 65 years and older, there were 79,098 persons (6% of total foreign population). This does not include persons who naturalized as Japanese citizens, for example, the 500 Chinese persons who have naturalized as Japanese citizens annually. The increase in the ethnic and racial minorities demands the investigation of their needs in a country that is far behind in providing access and services catering to a diverse user group. This study is the first study, to the authors’ knowledge, on examining the needs of ethnic Chinese older adults living in Japan. METHODS: Qualitative interviews were conducted in Mandarin Chinese, Cantonese dialect, and/ or Japanese by the authors with older adults of Chinese ancestry living in Yokohama, Japan - home of the largest Chinatown in Japan. Older adults were identified through local Chinese organizations. Open-ended questions were prepared focusing on their history and culture, as well as their thoughts on their identity. In particular, questions about their thoughts on growing old in Japan and their current needs were asked. Interviews were recorded and transcribed for analysis. Coding was done by the authors. RESULTS: 11 older adults (6 females, 5 males) agreed to be interviewed. Ages ranged from 64 to 90 years old. The majority were naturalized as Japanese citizens, however, many were not receiving pension due to lack of contribution history and health insurance. Although past the retirement age, the majority of men continued to work and all of them were involved in some kind of community volunteer activities and hobby groups. Health and long-term care issues were not a dominant part of the interviews, but rather, all of them referred to the need for healthy older adults to participate in society and find meaning in old age. IMPLICATIONS: Overall, their needs were not so different from the needs of ethnic Japanese, with some serious exceptions including lack of pension and health insurance. The unexpected gains from post-war Japan as the victors of the war have seemed to have compensated for much of their pre-war discrimination, and allowed them to thrive financially and socially to this day. Moreover, Chinatown - as a community - and
their strong familial bonds have served as the foundations of their survival as well. This research was funded by Nissay Foundation.

IMPLEMENTING THE NATIONAL RESOURCE CENTER ON LGBT AGING: RESULTS FROM A BASELINE SURVEY

The National Resource Center on LGBT Aging (NRC) is the country’s first and only technical assistance resource center aimed at improving the quality of services and supports for lesbian, gay, bisexual and transgender (LGBT) elders. Established in 2010 through a three-year grant from the U.S. Administration on Aging, the NRC provides training, technical assistance and educational resources to aging service providers, LGBT organizations and LGBT older adults. The NRC is led by Services & Advocacy for GLBT Elders (SAGE), in partnership with ten organizations nationwide representing service providers, professional associations, and universities to carry out the following goals: improve the services that aging service providers and LGBT service providers offer to LGBT elders by educating them about the population’s particular needs; and to increase long-term planning and knowledge among LGBT elders. In the first year of its implementation, the NRC conducted a nationwide baseline web-based survey of LGBT service providers, older adult service providers, and older adults (N = 1,732). The purpose of the survey was to determine resource needs among these stakeholders. This paper presents descriptive results of the survey, including bivariate analyses comparing stakeholder needs. Preliminary findings suggest that both LGBT-focused and older adult service organizations lack policies sensitive to the needs of LGBT elders. Results also show significant differences in resource needs among different age groups and income levels of respondents. Detailed results will be presented along with implications to future policy and research to meet the needs of this vulnerable underserved population will be discussed.

SOCIAL INTEGRATION, HEALTH, AND MENTAL HEALTH AMONG ASIAN INDIAN, CHINESE AND KOREAN IMMIGRANT ELDERS

Research has established the relationship between social integration and health, yet little research has focused on older Asian Americans. This study applies social integration and social exchange theories to examine the effects of family relationships and social exchanges on health, and mental health. The study data were derived from the Asian American Elders in New York City Study, a population-based survey of Asian Americans over 65. The study sample was restricted to 259 Chinese, Indian, and Korean elders. The Geriatric Depression Scale and the general health item from the MOS were selected as dependent variables for multivariate linear regression models. The mean age was 72.6 (SD=6.3). Indian elders were younger than Chinese and Korean elders. Koreans had the lowest mean GDS scores. Indian elders were in poor health and received and provided more care than elders from the other ethnic groups. Multivariate regression models showed that compared to Indian elders, Korean elders report higher levels of depression and are in worse health. Secondly, when the elder is able to provide care to their child’s family, they reported lower levels of depression. Conversely, when the elder receives care from their child, they rate their health more poorly. The differences in overall health and mental health function are reflective of the diversity among the Asian racial category. Furthermore, while being socially integrated is important, the type of connection matters. Implications for researchers and practitioners who work with Asian American elders will be discussed.

HEALTH RELATED QUALITY OF LIFE: THE ROLE OF RACE AND ENGLISH PROFICIENCY FOR OLDER IMMIGRANTS

Race has frequently been discussed as an influence of HRQOL, while language’s role has enjoyed limited attention. Using data from the 2003 and 2005 California Health Interview Survey, this study examines the relationship between social determinants of HRQOL in older immigrants. Data for foreign-born respondents 65 and older was used. Race was categorized using the UCLA Center for Health Policy Research definitions of race. Mixed race respondents were excluded from the study sample to ensure proper classification. The study included 2,575 immigrant Latino, Asians and Whites. Multivariate logistic regression models were tested for the four outcomes of HRQOL. The results show the central role of English proficiency on the health of older immigrants. Elders who spoke well or only spoke English were more likely to be in good health than those who spoke English poorly. In terms of limited days, those who spoke well or only spoke English were less likely to report more limited physical days and overall limited days than elders who spoke English poorly. While more Latino and Asian elders were in poor health compared to non-Hispanic Whites, the racial/ethnic differences were not observed once other factors were controlled. In terms of limited days, Asian elders were less likely to report more limited physical days and overall limited days than non-Hispanic White elders. The findings raise questions about the role of English proficiency on health among older immigrants. Implications for gerontological research and practice older immigrants will be discussed.

TYPES OF DISABILITY AND LIVING ARRANGEMENTS AMONG ASIAN INDIAN, CHINESE, FILIPINO, JAPANESE, KOREAN, AND VIETNAMESE OLDER ADULTS IN THE UNITED STATES

S. Lee, Gerontology, Univ. of Massachusetts Boston, Boston, Massachusetts

The purpose of this study is to explore how type of disability shapes living arrangements among older Asian adults in the United States. Given the paucity of research on Asian ethnic group variations based on marital status, this study analyzes singles and couples separately. This study compares six Asian ethnic groups (Asian Indian, Chinese, Filipino, Japanese, Korean, and Vietnamese) as a majority of older Asians are from one of these six countries. The data are drawn from the U.S. Census 2000 5% Public Use Microdata Sample (PUMS). The findings for singles show that the effect of being limited only on ADL is not significant for any of the specific groups except for Chinese, where the odds of living alone are 67% greater than among the non-disabled. The effect of being limited on both IADL and ADL is statistically significant for Asian Indian, Filipino, Korean, and Vietnamese, where the odds of living alone are 1.74 – 2.58 times higher than among the non-disabled. The findings for couples show that the effect of one or both spouses being limited on ADL is statistically significant for Chinese, Japanese, and Korean couples. The likelihood of living alone decreases by 40% and 53% respectively for Japanese and Korean couples than among the non-disabled, however, the likelihood of living alone increases by 30% for Chinese couples. It is important to be aware of the Asian ethnic group variations in their living arrangements and to promote well-being of the disabled Asian older adults especially those who live alone.

LONG-TERM CARE AMONG OLDER MEXICAN AMERICANS: THE CONSTRAINTS OF CULTURE

K.C. Prickett, J.L. Angel, Sociology, The University of Texas at Austin, Austin, Texas, 2. The Population Research Center, Austin, Texas, 3. The LBJ School of Public Affairs, Austin, Texas

Purpose. This study addresses long-term care issues facing Mexican-American families in later life. Although the family is central to
Mexican-American identity and culture, Mexican Americans are living longer and with more serious health problems. Consequently, options in elder care often conflict with family traditions. Methods. Using the Hispanic-Established Populations for Epidemiologic Studies of the Elderly and nursing home data provided by the Department of Health and Human Services, this research examines the impact of functional incapacity on living arrangements for elderly, unmarried Mexican American men and women. Results. A greater percent of those living with family experience at least one ADL disability compared to those living alone (46.5% versus 34.3%, respectively). In addition, of those living alone and with an ADL disability, a greater proportion is likely to be very impoverished ($10,000 or less) than those living with family and with an ADL disability (67.2% versus 40.4%). Regression analyses reveal a lack of income mitigates the likelihood of living with family for those with an ADL disability. Finally, nursing home availability has little effect on informal care arrangements once Medicaid is taken into account. Discussion. These findings suggest that despite a cultural preference for family-based long-term care, disability and income interact in ways that constrain and enable these care options. Participants at this presentation will learn how income and disability can influence long-term care decisions among Mexican-American families. In addition, participants will be informed regarding implications for long-term care policy development.

USE OF AND UNMET NEEDS FOR HOME AND COMMUNITY-BASED SERVICES BY FRAIL, OLDER KOREAN AMERICANS AND THEIR CAREGIVERS

B.L. Casado, S.E. Lee
1. University of Maryland, School of Social Work, Baltimore, Maryland, 2. San Jose State University, School of Social Work, San Jose, California

PURPOSE: With changing demographics, the older population in the United States is becoming increasingly diverse. Yet the literature is limited regarding the need for home- and community-based services (HCBS) in older ethnic minority populations. This study explored the needs for these services among older Korean Americans (KA). DESIGN & METHODS: Data were drawn from a cross-sectional survey study of caregivers of frail older KA (N = 146). It examined the utilization and the reasons for non-use of eight types of HCBS programs (respite, adult day care, personal care, home health, housekeeping, home-delivered meals, transportation, and support group). Guided by the health behavioral model, the predictors of unmet needs for these services were explored. RESULTS: The utilization of HCBS among KA was low. Reasons for non-use varied across service type, but respondents often reported non-necessity, lack of awareness, and care-recipient refusal. Predictors of unmet need for HCBS also varied by types of service and included caregiver gender, relationship, care-recipient cognitive impairment, caregiver burden, caregiving hours, Medicaid coverage, and caregiver service-use efficacy. IMPLICATIONS: This study demonstrated the need to outreach the KA community and collaboratively explore innovative ways to modify and expand existing HCBS programs for older KA and their caregivers.

BLACK AND WHITE OLDER COUPLES: INTERDEPENDENCIES IN DISABILITY, PERSONAL RESOURCES, AND WELL-BEING

E.M. Dunbar, J. Smith, B. Ingersoll-Dayton

The prevalence of functional limitations, physical disability and cognitive impairment in the population over age 50 represents a major challenge for society and older individuals. Physical disability is a risk factor for depression and lower emotional well-being in later life, especially as individuals begin to progressively require increased assistance to remain living in the community. Disability within the marital or cohabiting relationship also presents a challenge to older adults as the daily stressors of one partner can influence the well-being of his or her spouse. Few studies have examined couple and partner differences in the co-occurrence of disability, personal resources, depression and well-being. We do this using data from a nationally representative sample of older couples aged 50 and over who participated in the 2008 wave of the Health and Retirement Study (HRS: White Couples, N=2,002; Black Couples, N=222). We use repeated measures ANOVA to identify differences between Black and White couples on various demographic, control, functional limitation, cognitive and well-being measures. Preliminary analyses suggest that there are statistically significant differences between Black and White couples in age, education, memory, total functional limitations and depression. In follow-up analyses we conduct intra-class correlations (Kenny et al, 2006) to quantify the degree of interdependence within Black and White couples. Our findings speak to the importance of considering the differences in degree of interdependence between Black and White older couples and how these differences can inform couple-level interventions.

SESSION 1065 (POSTER)

IMPROVING NURSING HOME QUALITY

BEYOND THE EDGE OF CHAOS: TURNOVER CO-VARIATION, DIRECTOR OF NURSING LEADERSHIP, AND CARE QUALITY IN A NURSING HOME

S.R. Hunt, K. Corazzini, J. Barroso, R.A. Anderson, School of Nursing, Duke University, Durham, North Carolina

More than one third of nursing homes’ directors of nursing (DON) leave their positions annually; importantly, this turnover often co-occurs with turnover at all levels of management and direct care staff (AHCA, 2008). The purpose of this study is to describe the structural and relational processes of turnover co-variation and its impact on quality of clinical leadership and resident care outcomes. This case study is a secondary analysis (N=97 staff in 1 nursing home) of data drawn from a larger, comparative case study of nursing management practices, and matched with CMS quality measures and survey deficiencies. During the 6-month data collection period, this nursing home experienced greater than national average turnover in DONs (N=4) and other levels of staff. Using data coded in the parent study as leadership and turnover, open coding techniques using Atlas.ti were used to answer the study aims; new codes were validated by agreement with two researchers from the original study. Text chunks were sorted and analyzed for themes using matrices (Crabtree and Miller, 1999). Turnover co-variation emerged from relational processes and eroded structural supports necessary for high quality care. Emergent themes of how turnover co-variation weakened DON clinical leadership included (a) pre-hire contextual conditions, (b) insufficient resources and (d) exit conditions. Relational process interventions and enhanced structural supports during turnover crises are critical for successful enactment of the DON role, nursing home workforce stabilization and quality care.

DEVELOPMENT OF A TOOLKIT TO IMPROVE COMMUNICATION ENVIRONMENTS IN LONG TERM CARE SETTINGS

J.A. Sanford, M. Calkins, J. Brush, C. Bruce, 1. CATEA, GA Tech, Atlanta, Georgia, 2. I.D.E.A.S., Inc., Kirtland, Ohio

Despite increasing evidence that the environment in long term care (LTC) facilities can either positively or negatively impact communication of residents with dementia, clinicians lack the tools to assess and modify these settings to support communication. This paper reports the results of a study with 59 LTC clinicians to evaluate the effectiveness of a new Communication Toolkit that was developed to help therapists and other clinicians identify physical barriers and make recommenda-

The Gerontological Society of America
CULTURE CHANGE: A NON-PHARMACOLOGICAL APPROACH TO TREATING ELDER AGITATION

O.R. Burack, A. Weiner, J. Reinhardt, Research, Jewish Home Lifecare, New York, New York

Agitation, including inappropriate verbal and physical behavior, is prevalent among nursing home residents. Culture change with its person-centered care approach provides a potential nonpharmacological method to reducing agitated behaviors. The purpose of the present study was to examine the impact of a culture change initiative on the frequency of agitated behaviors among nursing home residents. Seven long-term-care communities across a three campus nursing home system served as pilot communities for a culture change intervention designed to transform the nursing home from a traditional hospital-model of care to a person centered model of care. Six comparison communities were matched to the experimental communities and continued to function with the traditional nursing home organizational structure and departmental hierarchy. Data were collected at baseline prior to the culture change initiative and again two years later. 101 residents participated in the study at both time points (experimental n=50, comparison n=51). Each resident’s primary day certified nursing assistant completed the Cohen-Mansfield Agitation Inventory, examining three types of agitation: aggressive, physically non-aggressive, and verbally agitated behaviors. After controlling for ADL functioning and ethnicity, a significant condition by time interaction was found for aggressive and physically non-aggressive behaviors. The comparison group displayed a significant increase in agitation over time compared to an average decline for the culture change group. A trend with the same pattern was found for verbally agitated behaviors. These findings indicate culture change can and should be explored as a nonpharmacological approach to reducing agitation in residents with varying levels of dementia.

THE MORE THINGS CHANGE, THE MORE THEY STAY THE SAME: FAMILY SATISFACTION IN OHIO NURSING HOMES FROM 2001 TO 2010

J. Staker, Scripps Gerontology Center, Oxford, Ohio

In 2001, Ohio was the first state to collect statewide nursing home family and resident satisfaction data for public reporting. Since that year, family data have been collected 5 times: 2001, 2001, 2006, 2008, and 2010. The first year (2001) only 69% of Ohio nursing homes participated. In 2010, this proportion grew to 97% of Ohio’s 961 facilities. Over 115,000 residents’ families and friends have responded to the nursing home family satisfaction survey. During this decade, multiple changes have occurred in Ohio’s nursing home industry, including a shift to younger residents, increasing numbers of short-stay residents, a new emphasis on nursing home culture change and person-centered care and the inclusion of family satisfaction scores in Ohio’s Medicaid reimbursement formula. Despite these shifts in the industry as a whole, statewide family satisfaction scores in some areas are intractable, while other changes suggest things may be getting worse, not better, in some aspects of nursing home life. For example, satisfaction with several aspects of the admission process has declined; while scores related to areas of resident choice that should have improved due to culture change have remained much the same. This presentation will highlight aspects of stability and change in family satisfaction statewide, as well as among individual facilities. Where possible, facility data from Ohio’s Biennial Survey of Long-Term Care Facilities will be combined with satisfaction data to examine the characteristics of facilities where change has and has not occurred.

CHARACTERISTICS OF NURSING HOME SOCIAL WORKERS WHO REPORT THRIVING AT WORK

M. Bern-Klug, J. Liu, University of Iowa, Iowa City, Iowa

While most research about nursing home workers focuses on the challenges of the setting and issues related to turn-over, we were interested in the factors related to reports of thriving at work. The concept of “thriving” according to Spreitzer et al’s, “Social Embeddedness of Thriving at Work” model includes the experiences of vitality and learning. Using an adaptation of their model, we used data from a nationally representative survey of 928 full-time nursing home social service directors to test the applicability of the model for this population. Results indicate that the model explains about 30% of the variation. Measures representing decision-making discretion, a climate of trust and respect, broad information sharing, and role consistency were statistically significant, as was the perception of salary (although the actual salary was not). Findings suggest that changes in job structures can increase the job satisfaction and sense of thriving among nursing home social workers.

SINGING, BINGO, PRIMP AND POLISH: CONSIDERING MALE RESIDENTS IN NURSING HOME ACTIVITIES

B. Buron, T. Killian, Nursing, University of Arkansas, Fayetteville, Arkansas

Although it is well-documented that there are substantively more female than male residents in nursing homes, male residents consistently comprise approximately 30% of the population. Several studies have suggested that the nursing home experience may be less satisfactory for males compared to females, possibly related to a lack of activities interesting to male residents. Therefore, the purpose of this preliminary study was to describe activities provided by Activity Directors (ADs) using gender as a framework to interpret and evaluate those activities. Fifty-one AD’s employed in Arkansas nursing homes provided qualitative and quantitative data. All were female, ranged in age from 20 to 64 years old (mean = 41.6 years), and worked in their facility between 0 and 18 years (mean = 3.5 years). ADs were asked to describe the most common activities provided, the number of male/female resident participants in those activities, and their opinions about whether the activities were more interesting to males/females, or equally interesting to both, as well as several other questions. Male participation rates were substantially lower, with 44% of females and 36% of males participating in the most common activity provided (e.g. BINGO, religious services, and singing/music). Of these activities, 44% of ADs perceived them as more interesting to females, 2% more interesting to males, and 53% equally interesting to both. Furthermore, compared to female residents, a substantial gap existed between AD’s perceived ideal activities for males and the activities they actually provided for them. This paper expands on these findings and discusses implications.

THE RELATIONSHIPS AMONG PATIENT SAFETY CULTURE, PROCESSES OF CARE, AND RESIDENT FALLS IN NURSING HOMES

Studies have shown that patient safety culture, defined as the outcome of a concerted organizational effort to move towards safety, is
poorly developed in nursing homes (NHs) and therefore, residents of nursing homes may be at risk of harm. Using the Revised Version of Donabedian’s Structure-Process-Outcome (SPO) Model, this study examines the relationships among top management’s ratings of NH patient safety culture, safe processes of care, and resident outcomes. Using directors of nursing and NH administrators’ responses from a nationally representative sample of 3559 NHs on the Agency for Healthcare Research and Quality 2008 Nursing Home Survey on Patient Safety Culture, the Online Survey Certification and Reporting Database, and the Minimum Data Set, we examine if the patient safety culture of NHs is related to processes of care (restraint use and catheterization) and patient safety outcomes (falls). Using hierarchical generalized linear models, we find that higher ratings of patient safety culture were significantly related to lower prevalence of physical restraints (est. = -.003; p < .001) and resident falls (est = -.001; p < .05). Furthermore, poorer processes of care (catheterization and restraint use) were related to negative patient safety outcomes when controlling for structural characteristics and patient safety culture (est = .109, p < .001; est = .573, p < .001, respectively). These findings hopefully will contribute to the development of a patient safety culture in NHs and promote improvements in health care that can be measured by processes of care and resident outcomes.

ASSESSING RCFE LICENSES: CAN THE CONSUMER OF LONG-TERM CARE RELY ON CALIFORNIA’S RCFE LICENSES TO BE ACCURATE?
C.M. Murphy1, C.L. Selder1, 1. San Diego State University, San Diego, California, 2. Consumer Advocates for RCFE Reform, San Diego, California

Purpose: This study assessed the accuracy of the RCFE License in 348 RCFE public files located in the offices of Community Care Licensing Division (CCLD), California Department of Social Services (DSS) for the Residential Care Facility for the Elderly (RCFE), to determine how compliance CCLD is in its obligation to maintain reliable authorizing documents (i.e. licenses). Methods: This ten-year retrospective descriptive study reviewed 348 public files of licensed RCFEs in California. Files obtained through California Public Records Act requests were reviewed; data corresponding to following defined parameters as they pertained to the license were collected—(status with the state, authorized capacity, and authorization to provide various long-term care services). Data was analyzed in aggregate and by facility size (i.e. bed capacity). For LLCs, LLPs, NFPs and Corp data (existence and legal status) was verified using California’s Secretary of State’s (CASOS) Business Search portal. Findings: 59.4% of licenses did not have documentation in the file to support the abilities authorized on the license. 12% (18/149) of the legal entities (LLC/LLPs, NFPs and Corporations) were disqualified to do business in the state, yet each was currently licensed by CCLD. Implications: RCFE licenses should represent “proof” of what services the licensee is authorized by the state to provide. The state, as regulator, has a duty to be competent and the public has the right to rely on the correctness of a state-issued license. There are also state laws that bar some facilities from operating, and yet they are still licensed by CCLD. The finding that 12% of the licensees are disqualified to do business in the state, and yet are operating going concerns, is illegal and CCLD is liable for licensing them. The consumer may question the level of due diligence demonstrated by CCLD in continuing to renew license of licensees no longer qualified to do business in California. Final implication of this finding is the possible undermining of CCLD’s regulatory ability. Continue to do business when disqualified by state, then all other regulatory actions taken by CCLD may be called into question as well.

A CONSIDERATION OF FACTORS THAT MAY INFLUENCE CHANGE IN ALABAMA NURSING HOMES
L. Jacobs, A. Snow, Psychology, University of Alabama, Tuscaloosa, Alabama

The current state of traditional nursing homes, which is designed to resemble an acute care model, is in need of change. Fortunately, a movement known as culture change is progressing and expanding in nursing homes. Culture change is a movement directed towards flattening the internal structural, allowing more autonomy for residents and staff, enhancing the environment, and improving the quality of care of residents. The purpose of this study was to identify factors that are related to adopting culture change in Alabama. Three categories of nursing home features were examined: structural factors, market factors, and administrator influence. Additionally, administrators’ perceptions of barriers to implementation were explored. A standardized survey was used to collect administrator self-report information about their facility and attitudes regarding culture change. Structural and market factor information was obtained from public websites. Seventy-seven nursing homes participated, and the majority of administrators reported they were familiar with culture change, yet culture change principles only “somewhat” described their nursing home. Nursing homes with a lower Medicaid census were more likely to implement culture change practices, F(4, 61) = 2.887, p < .03, np2 = .16. Nursing homes situated in counties with a higher median income and more older adults were also more likely to implement these practices, F(4, 57) = 2.94, p = .028, np2 = .17, and F(4, 57) = 2.97, p = .027, np2 = .17, respectively. Barriers to implementation were residents’ ability to engage, staff resistance to change, lack of resources, and regulations/survey process impediments.

NEIGHBORHOOD POVERTY AS A PREDICTOR OF LOW CMS FIVE-STAR QUALITY RATINGS
D.A. Dunn, Y. Zheng, Gerontology, University Of Kentucky, Georgetown, Kentucky

The authors examined the relationships between Center for Medicaid and Medicare Services (CMS) Five-Star Quality Rating System (QRS) and neighborhood poverty levels in order to test the hypothesis that higher neighborhood poverty levels would be associated with a lower CMS quality rating for the categories; overall; staffing; quality; and health. Data values were from the CMS Nursing Home Compare website filtered to identify LTC facilities located within a twenty-five mile radius of a medium sized Midwest metropolitan neighborhood (n=65). Neighborhood poverty levels were obtained from the US Census Bureau 2000. Ordinal logistic regression models were used to estimate an average effect (odds ratio) of neighborhood poverty levels as they related to the awarded CMS QRS star. Poverty was associated with the odds of being given a lower rating in the categories of: overall, quality, health and staffing. There was a significant finding for poverty as a predictor variable for low staffing ratings. Staffing showed that as the poverty unit moved from lower to higher levels of poverty there was 5.7 times greater odds of being given a lower star rating (p = .0179). Non profit ownership was associated with higher staffing quality ratings than profit ownership (p = .0003) in areas of high poverty versus low poverty. Further research and investigation into the states with mandatory patient-staff ratios and CMS staffing rating as it relates to neighborhood poverty should be explored to advance legislation in this field.

IMPROVING QUALITY OF LIFE IN NURSING HOMES: FROM INNOVATION TO IMPLEMENTATION
H.B. Degenholtz, A.L. Resnick, N. Bulger, University of Pittsburgh, Pittsburgh, Pennsylvania

The recent introduction of Version 3.0 of the Nursing Home Minimum Data Set (MDS 3.0) and the changes to the nursing home inspection system (survey and certification) have increased attention to resident quality of life (QOL). However, nursing home operators face a lack of practical tools for assessing and improving resident (QOL). We pre-
vously developed and demonstrated the efficacy of an assessment and care planning system for improving resident QOL: the Quality of Life Structured Resident Interview and Care Plan (QOL.SRI/CP). The key elements of the QOL.SRI/CP are the generation of quarterly quantitative QOL scores that can be used to track individual and facility level change, and qualitative data that drive feasible, concise QOL related care plan tasks. Residents are shown to experience improvements in QOL over 90 days. We have developed an organizational-level program to disseminate the QOL.SRI/CP. The materials have been produced in a format that is compatible with the MDS 3.0 and are available for download at http://www.improvingqol.pitt.edu, facilitating adoption and minimizing the training necessary. The implementation model involves commitment from top management, staff training and iterative implementation. We tested our training and implementation materials with four facilities and conducted three large group training sessions using a train-the-trainer model. This approach is compatible with a range of quality improvement techniques. Results show that facilities that staff are able to incorporate the additional QOL questions into their routine with limited additional time commitment.

THE INFLUENCE OF CONSISTENT RESIDENT ASSIGNMENT ON NURSING HOME DEFICIENCY CITATIONS

The association of consistent resident assignment of Nurse Aides (NAs) with quality of care and quality of life of nursing home residents is examined (using five groups of deficiency citations). Data used came from a survey of nursing home administrators, the Online Survey Certification and Reporting data, and the Area Resource File. The information including consistent resident assignment and staffing variables of Registered Nurses, Licensed Practical Nurses, and NAs were measured in 2007, and come from 3,941 facilities. Negative binomial regression and multivariate logistic regression models were used. An average of 68% of nursing homes in this sample reported using consisted resident assignment. However, the actual level of NA consistent resident assignment used varied substantially. Only 28% of nursing homes using NA consistent resident assignment did so at the often recommended level of 85% (or more). In the multivariate analyses, Quality of Life deficiency citations (Resident), Quality of Life deficiency citations (Staffing), Quality of Life deficiency citations (Facility), and Quality of Care deficiency citations were significantly (p<.01) lower in facilities with the highest levels of consistent NA resident assignment. Few significant findings were found in nursing homes using lower levels of consistent resident assignment. Consistent resident assignment has developed as a preferred practice in nursing homes based on little empirical evidence. The findings presented here provide some justification for the use of this staffing practice for NAs.

DIETARY SERVICE RELATED NURSING HOME DEFICIENCIES

K.M. Smith, K.S. Thomas, K. Hyer, H. Meng, University of South Florida, Tampa, Florida

Dietary services play an integral role in the health and quality of life for nursing home residents. This exploratory study examines the relationship between the number of dieticians and food service workers and dietary service deficiencies in nursing homes. Data from the Online Survey Certification and Reporting database was used to examine the relationship among dieticians and food service workers and dietary service related deficiency citations for 15,370 free-standing nursing homes during 2008. Using a generalized estimating equation approach to account for clustering at the state level, we estimated the relationship between dieticians and food service workers and facilities’ dietary service related deficiency scores – calculated using the Centers for Medicare and Medicaid Services’ Nursing Home Compare Five-Star Quality Rating System which accounts for the complexity of the scope and severity of the citations. Our results indicate that within facilities with at least one full time dietician, the number of dieticians (est=-.082, p=.046) and the number of food service workers (est=-.002, p=.013) was predictive of lower dietary service related deficiency scores after controlling for for-profit status, chain membership, total beds, occupancy, and percent private pay. With a large sample size and advanced methods, we have found a relationship between dieticians and food service workers and nursing home quality as measured by dietary service related deficiencies. The findings from this study signify the need for further research on dietary services in nursing homes, dietary related deficiency citations and the impact on residents’ clinical and quality of life outcomes.

SESSION 1070 (POSTER)

MEASURES AND METHODS

EXAMINING THE RELATIONSHIP BETWEEN A MINIMUM DATA SET COMPOSITE QUALITY INDICATOR AND THE ARTIFACTS OF CULTURE CHANGE TOOL

J.L. Sullivan1,2, M. Shwartz1,2, M. Gerena-Melia1, D. Berlowitz1,3, J. Burgess1,3, 1. Center for Organization Leadership and Management Research, VA Boston Healthcare System, Boston, Massachusetts, 2. Center for Health Quality, Outcomes & Economic Research, Bedford, Massachusetts, 3. Boston University, Boston, Massachusetts

It is increasingly important to understand the extent to which CC initiatives are associated with improvement in quality given the high adoption rate of CC principles in NHs. We use a Bayesian hierarchical model to estimate the latent construct “culture change” as represented by the Artifacts of CC Tool and to analyze the relationship of the latent construct to the composite measure developed from the individual MDS QIs. We also adjust for case mix through RUGs scores. For this study, 107 VA NHs were included that had at least one-third long-stay residents and had at least 10 residents as the denominator for those MDS QIs for which most residents were eligible. In the Bayesian hierarchical model, the Artifacts Latent Score has a mean of .166 and a SD of .90. The model indicates that 1 SD increase in the Artifacts Latent Score is associated with a .18 SD decrease in the MDS-Based Quality Score. This translates into about 3.8 fewer adverse events per 1,000 residents. The correlation between the adjusted Artifacts Latent Score (adjusted for RUGs) and the Quality Score is .18 (95% credible interval -.25 to -.10). There is clear evidence of an association between CC activities and MDS clinical outcomes, but results are not that strong. Further research needs to test if variations in NH care processes and policies may be driving the facilities doing better on the Artifacts Tool and the MDS measures compared to those that do poorly.

MAKING NURSING HOME QUALITY MEASURES MORE UNDERSTANDABLE

T. Lewis1,2, R. Kane3,4, M. Woll3, C. Mueller1, B. Dowd2, D. Radosевич2, 1. MN Department of Human Services, St. Paul, Minnesota, 2. University of Minnesota - School of Public Health, Minneapolis, Minnesota, 3. Columbia University, New York, New York, 4. University of Minnesota - School of Nursing, Minneapolis, Minnesota

Informing consumers about quality can affect consumer and provider behavior. For ten years, the University of Minnesota (UMN) and the Minnesota Department of Human Services (DHIS) have generated a comprehensive set of 24 case-mix adjusted nursing home quality measures derived from the Minimum Data Set as part of Minnesota’s Nursing Home Report Card website. Consumers and providers can now get a weighted total score or individual reports of each measure. Our goal is to make these measures more useful to end users. After eliminating potentially collinear measures and those with low response rates, we
conducted a series of exploratory factor analyses, arriving at a stable result comprising 17 QIs present on 12,490 residents for the second quarter of 2006. The result included six discrete care area factors (Continence; Physical Functioning; Infections; Mood/Behavior; Pain/Inactivity; and Accidents). We determined the reliability of these results by recreating them for the fourth quarter of 2007, and verified their structure through a confirmatory factor analysis. The factors explained 53% of the variance and showed acceptable independence, with the average difference in absolute factor loadings equaling 0.6 and only two loading pairs showing a difference of 0.2. These results suggest that nursing home care outcomes can be streamlined to improve the use of QI information for consumers, providers and policymakers.

USEFULNESS OF THE RESPONSE TREE IN SCALES MEASURING SYMPTOMS IN OLDER INPATIENTS

M. Fox, S. Sidani, D. Steiner, K.S. McGilton, C. Grady, J. Nursing, Faculty of Health, York University, Toronto, Ontario, Canada. 2. Ryerson University, Toronto, Ontario, Canada. 3. University of Toronto, Toronto, Ontario, Canada. 4. Toronto Rehabilitation Institute, Toronto, Ontario, Canada. 5. Baycrest, Toronto, Ontario, Canada

Applying a response tree to standardized self-report scales has been recommended to improve older adults’ comprehension and reduce burden while maintaining standardization of the interview. However, public opinion researchers have posed several potential utility, validity, and reliability limitations of the response tree which have not been examined in the clinical setting. OBJECTIVES: This study evaluated if applying a response tree to 3 scales measuring symptoms altered their psychometric properties and utility, and if there were any utility age group differences. METHODS: Both formats (original and response tree) of 3 scales (Insomnia Severity Index, the Fatigue and Orthostatic Intolerance Scales) were administered to a sample of 43 younger (aged 30-35) and 43 older (aged 65+) in-patients of a rehabilitation facility. RESULTS: The response tree had no effect on: the scales’ psychometric properties and utility, and if there were any utility age group differences.

COMMUNITY-BASED PARTICIPATORY RESEARCH APPROACH TO ASSESS THE HEALTH NEEDS OF CHINESE OLDER ADULTS

Background: Chinese aging population are increasing rapidly, yet very little is known about health and aging in US Chinese populations. The objective of this study is to examine the cultural views of healthy aging, knowledge and barriers to services, and perception on health sciences research among community-dwelling Chinese older adults in Chicago’s Chinatown. Methods: This qualitative study is guided by the Precedent-Process conceptual model with community-based participatory research design. Data analysis is based on eight focus group interviews with Chinese older adults (age 60+) (N=78). We used a grounded theory framework to systematically guide the thematic structure of our data. Results: Findings show participants described cultural conception of health in terms of physical function, psychological well-being, social support and cognitive function. The availability, affordability, and cultural barriers towards health care services were major negative enabling factors that inhibit participants from fulfilling health needs. Perception and knowledge of health sciences research were also discussed. Conclusion: This study has implications for the delivery of culturally appropriate health care services to the Chinese aging population.

MEASURING TRANSCENDENCE AMONG CHINESE OLDER ADULTS – A SPIRITUAL APPROACH

V. Lou, C. Chan, L. Kong, Tung Wah Group of Hospitals, Hong Kong, Hong Kong. 2. University of Hong Kong, Hong Kong. 3. School of Nursing, The University of Hong Kong, Hong Kong

Objectives. Spiritual care is one of the key elements of the holistic care perspective. In our previous studies, we reflected that spirituality among Chinese older adults should be understood in a context of non-religious lifestyle. This study aims to validate the spirituality measure, Transcendence Scale for Chinese Elders (TSCE). Method. The draft version of TSCE was developed based on focus groups, in-depth interviews and a Delphi process. Together with other standardized measures, including World Health Organization Quality of Life measures (WHO-QoL), Purpose in Life (PIL), and Positive and Negative Affect Scale (PNAS), the 16-items, 5-point TSCE draft was administered to 825 older adults in Hong Kong and Shanghai. Results. Face and content validity of TSCE were established during a Delphi process. Confirmatory factor analysis identified a six-item, one-factor model that showed satisfactory model fit indexes (SRMR=.036, C-CFI=.953, R-RMSEA=.063).

The internal consistency reliability of the 6-item TSCE was satisfactory as indicated by Chronbach’s alpha of .70. TSCE also showed satisfactory criterion-related validity as indicated by having moderate correlation with PNAS (r=.47), Purpose in Life (r=.35), and psychological well-being as measured by WHOQoL (r=.35). Conclusion. TSCE was developed to measure transcendence among Chinese older adults’ spirituality. Results of the present study showed that TSCE was a reliable and valid measure that assesses transcendence among the Chinese older population in which the social cultural context is featured by non-religious, relationship-oriented and interdependent self-construct. Implications for how to enhance spirituality among Chinese older adults will be discussed.

CROSS-CULTURAL COMPARABILITY OF THE MOS-SOCCIAL SUPPORT SCALE BETWEEN WHITE NON-HISPANIC & KOREAN-AMERICAN OLDER ADULTS

H. Jeon, Boston College, Chestnut Hill, Massachusetts

This study examined the equivalence of factor structure of an abbreviated version (10 out of 20 original) of Medical Outcomes Study-Social Support Survey (MOS-SSS) between community dwelling White non-Hispanic and Korean-American older adults. The MOS-SSS was designed to measure self-perceived adequacy of functional social support among patients with chronic illness. Data came from the Korean-American Elderly: Social Support and Long Term Care (1994). The data included 221 Korean immigrants and 201 White non-Hispanic groups, aged 65 and older from Southern California. Explanatory Factor Analysis, Internal Consistency Reliability Analysis and Confirmatory Factor Analysis were used to examine cultural comparability of the scale’s psychometric properties. Result showed that the abbreviated 10 items MOS-SSS scale had similar consistency reliability between two racial groups (cronbach’s α for White non-Hispanic was .92 and Korean-American was .956). However, the scale did not have the same factor structure when compared between White non-Hispanic and Korean-American older adults (White non-Hispanic group had 2 factors while Korean-American had 1). It is suggested that the MOS-SSS scale should not be used in comparing mean differences of social support between elderly Koreans and non-Hispanic White elderly research between two ethnic groups. Differences in factor structures and psychometric properties might reveal cultural differences in the manifestation of social support across cultures.
REEVALUATING THE ROLE OF SOCIAL WORK IN THE COMPREHENSIVE GERIATRIC ASSESSMENT
R.L. Abney, D. Racz, Geriatrics Center Social Work, University of Michigan Health Systems, Ann Arbor, Michigan

The University of Michigan Geriatrics Center Clinics offers multidisciplinary primary and specialty care in an outpatient medical setting. Social Work has been an integral part of this service delivery, providing full psychosocial assessments for all primary care patients. Growing patient numbers, increasing complexity of patient care coordination, rising costs, and space constraints have made it necessary to ask whether this model remains the most effective use of valuable social work time and resources. Since 2008, the social work team conducted a series of pilot studies to develop and test a screening tool to identify which patients have immediate and emerging social work needs that require a full psychosocial assessment on the first appointment; others received streamlined medical assessments only. A follow up study, added brief social work visits as options to new intakes. 86% of all new patients received the full social work intake (N=188); a randomized chart audit confirmed that almost ¼ of these new intakes resulted in SW follow up at or prior to return visit; thereby validating the use of full psychosocial assessments. 14% of all new patients with a brief social work assessment (N=31), following appropriate pre-screening and scheduled by patients themselves, were served appropriately by a brief assessment. While these efforts support the current practice of full assessment for all new primary care patients, the team continues to experiment with variations and updates to the social work model to ensure best practice and quality of care for geriatric patients.

STRUCTURAL VALIDITY OF THE CENTER FOR EPIDEMIOLOGIC STUDIES DEPRESSION SCALE IN BLACK AND WHITE CUSTODIAL GRANDMOTHERS
G.C. Smith, P.A. Palmieri, B. Hall, LifeSpan Development, Kent State University, Kent, Ohio, 2. Summa Health System, Akron, Ohio, 3. Medical University of South Carolina, Charleston, South Carolina

We investigated the measurement equivalence of the 20-item Center for Epidemiologic Studies Depression Scale (CES-D Radloff, 1977) across race in a sample of Black (n = 366) and White (n = 367) custodial grandmothers. Confirmatory factor analyses of the proposed four CES-D factors were conducted using the WLSMV estimator for ordinal data in MPlus version 6.1 (Muthen & Muthen, 2010). Four latent models were tested. The first model specified all items as loading on one depression factor. The next model separated the four reverse coded items into a separate methods factor. The third model we tested was a three factor model with the same methods factor and an interpersonal problems factor. Compared to these models, the original four factor CES-D model with correlated Depressed Affect, Somatic Complaints, Wellbeing, and Interpersonal Problems proposed by Radloff (1977) evidenced the best fit to data from both the Black and White samples. Furthermore, these four factors showed differential patterns of association with external variables, supporting the construct validity of the factor solution. For example, and as expected, Somatic Complaints correlated higher with self-reported physical health than did the other three CES-D factors. Tests of configural, threshold, and metric invariance indicated that the four factor model performed relatively similarly in both samples. All but four of the CES-D items were invariant across the two groups. The results of this investigation lend further support for the use of the CES-D in racially diverse caregiver samples. [Funded by NIMH R01 066851-02]

BUILDING A REGISTRY OF RESEARCH VOLUNTEERS AMONG OLDER URBAN AFRICAN AMERICANS
L.A. Chadiha, O.G. Washington, P.A. Lichtenberg, C.R. Green, K.L. Daniels, J. Jackson, University of Michigan, Ann Arbor, Michigan, 2. Wayne State University, Detroit, Michigan

Purpose of the study: An emerging strategy for increasing public participation in health research is volunteer registries. Using a community-based participatory research framework, we describe recruitment processes and outcomes in building a research volunteer registry of older urban African Americans. The specific research question examined retrospectively was: How does a community outreach partnership between older residents and academic researchers of the Healthier Black Elder Center facilitate recruitment of older urban African Americans for a research volunteer registry? Design and Methods: We adapted program evaluation methods for conducting a process evaluation to understanding and articulating the processes involved in enrolling older urban African Americans in a volunteer health registry. We used the logic model for clarifying how community outreach health education activities supported development of a research volunteer registry of older urban African Americans. Results: Paralleling the seven years in which an annual health reception was held, enrollees in a research volunteer registry increased from 102 to 1273 enrollees, representing more than a 10-fold increase. The percentage change in enrollees between any given years was 82% for 2004, 53% for 2005, 15% for 2006, 143% for 2007, 14% for 2008, and 40% for 2009. Implications: Targeted outreach to under-represented groups to build a registry of volunteers for health research may be a promising strategy for addressing recruitment disparities in African Americans’ research participation.

ARE RESEARCHERS AND POTENTIAL PROXIES AS COMFORTABLE WITH PROXY CONSENT FOR DEMENTIA RESEARCH?
M. Dubois, J.E. Graham, G. Bravo, S. Wildeman, C. Cohen, Sciences de la santé communautaire, Université de Sherbrooke, Sherbrooke, Quebec, Canada, 2. Research Center on Aging, Sherbrooke, Quebec, Canada, 3. Dálhousie University, Halifax, Nova Scotia, Canada, 4. University of Toronto, Toronto, Ontario, Canada, 5. Sunnybrook Health Sciences Centre, Toronto, Ontario, Canada

OBJECTIVE: In dementia research, potential participants often lack the capacity to provide informed consent. Who, if anyone, can then provide this consent and does it depend on the risk-benefit profile of the study? We investigated and compared the views of two highly concerned groups: researchers in aging and potential proxies, namely informal caregivers of cognitively-impaired older adults. METHODS: A postal survey was completed by 177 researchers and 384 informal caregivers from Canada. They were presented with scenarios involving four types of proxies (non-assigned, designated in a healthcare advance directive with or without instructions specific to research, and court-appointed). A fifth scenario asked the respondent to imagine him/herself unable to make decisions with no one assigned to make these decisions. Given a series of risk-benefit profiles, respondents indicated whether they were comfortable with proxy consent to research for each scenario. RESULTS: Less than 2% of the respondents felt proxy consent should never be allowed. For research involving little or no risk and potential personal benefits, over 90% felt comfortable with substitute consent by a designated or court-appointed proxy while more than 80% would allow a non-assigned proxy. For studies involving serious risks with potentially greater personal benefits, informal caregivers were less comfortable with consent from any type of proxy (all ps<0.01). CONCLUSIONS: For both informal caregivers and researchers, comfort depended far more on risk-benefit profile associated with the research scenario than with type of proxy. A large majority were comfortable with consent from any type of proxy for low-risk research.

COMPARING RISK PERCEPTIONS IN DEMENTIA RESEARCH ACROSS FIVE STAKEHOLDER GROUPS
G. Bravo, S. Germain, M. Dubois, J.E. Graham, C. Cohen, S. Wildeman, 1. Research Centre on Aging, University Of Sherbrooke, Sherbrooke, Quebec, Canada, 2. Dalhousie University, Halifax, Nova Scotia, Canada, 3. University of Toronto, Toronto, Ontario, Canada

Research, conducted mainly in the field of environmental and technological hazards, has found risk perceptions to vary greatly between
laypersons and experts, as well as within these groups. Objectives: To compare risk perceptions, in the specific context of a dementia drug trial, across 5 stakeholder groups and explore personal characteristics, beyond group membership, associated with risk perceptions. Methods: A postal survey involving 2,060 Canadians belonging to one of the following groups: community-dwelling older adults, informal caregivers of cognitively impaired persons, physicians, researchers in aging, and REB members. Survey participants were given 8 short risk descriptions and asked to categorize the level of risk on a scale ranging from “No risk” to “Serious risk”. Examples of risk descriptions: “The medicine may trigger anxiety in 15% of patients” and “There is a 1% possibility of death among patients taking the medicine”. Results: Risk assessments differ across groups on all descriptions (p<.0001). Further testing revealed 3 clusters of respondents: one comprising older adults and caregivers, another combining researchers and REB members, and a third limited to physicians. Age, sex, disposition toward research, and the role of side effects in substitute decision-making predicted risk perceptions among older adults and caregivers. The latter variable was the only factor linked to risk perceptions among members of the second cluster. No factors were found to influence the perception of risk among physicians. Conclusion: The observed variability in risk perceptions underscores the importance of involving representatives of all stakeholder groups in REBs, including older adults and informal caregivers.

HISTORY AND THEORY OF DECISION-MAKING CAPACITY ASSESSMENT
M. Henry, University of Utah, Salt Lake City, Utah

Older adults with cognitive impairment who are able to exercise control over their lives are more likely to report better quality of life, health outcomes, and other measures of well being than those with less control. Yet the legal standards approach to treatment decision-making capacity often categorically excludes older adults with cognitive impairment from decisions about their medical treatment. This research reviewed the origins of the legal standards approach, beginning with law journal articles in the 1940s that addressed the capacity to enter into a contract and make a will, to the work of Roth, Meisel, and Lidz, published in 1977, to the MacArthur Treatment Capacity Study conducted by Applebaum, Grisso, Berg, and other colleagues, and the research that has followed the 1996 publication of the MacArthur Capacity Assessment Tools. This research considered assumptions of the legal standards approach and explored the legal, ethical, and practical implications of using statutes and case law as the basis for the construct of treatment decision-making capacity. The research suggests that the legal standards approach clarifies legal relationships between providers and patients by providing a standard, but this clarity comes at the expense of older adults with cognitive impairment who wish to remain involved in decisions about their care. More research is needed to support a new view of treatment decision-making capacity that de-emphasizes dichotomous judgments, balances ethical imperatives, and by doing so, supports the inclusion of older adults with cognitive impairment in their treatment decisions to the greatest degree possible.

VALIDITY OF A COMBINED FUNCTIONAL STATUS SCALE IN PREDICTING LONG-TERM NURSING HOME STAY
M. Castora-Binkley, H. Meng, K. Hyer, Department of Aging Studies, University of South Florida, Tampa, Florida

Planning and delivery of long-term supportive services for older adults requires simple yet accurate measures of the demand for care. Recent evidence suggests that the traditional activities of daily living (ADL) and instrumental activities of daily living (IADL) are age biased when used separately and the combined ADL/IADL scale is age-neutral and more sensitive to change. This study tests the validity of the combined ADL/IADL scale in predicting long-term nursing home stay in a nationally representative sample of community-dwelling U.S. adults age 65+. We used data from the Health and Retirement Survey to investigate whether the combined ADL/IADL is predictive of long-term nursing home stay after controlling for demographic, physical health, cognition, and other covariates during a 10-year period. The sample consisted of 4,309 older adults in 1998 (baseline). 43% of the sample died during a follow-up period, 8% had at least one long-term nursing home stay. Multivariate logistic regression models were used to compare the performance of the combined scale compared to that of the two separate scales. We found that neither ADLs (p = .09) nor IADLs (p = .68) were significant in predicting long-term nursing home stay, in part due to collinearity; however, the combined scale remained a significant independent predictor of long-term nursing home stay (Odds Ratio = 1.06, 95% Confidence Interval 1.004 – 1.112). These findings highlight the usefulness of a combined measure of functional status in predicting long-term nursing home use and assists policymakers and service providers in better identifying those at-risk for nursing home care.

SESSION 1075 (SYMPOSIUM)

IS LIFESPAN REGULATED?
Chair: S. Olshansky, Univ of IL-Chicago Rm 2440, Chicago, Illinois

The development of a unified conceptual framework for the field of biogerontology has been impeded by undefined terminology. Nowhere is this more evident than in the terms aging, lifespan, longevity and their underlying biology. Because Robert Butler made a career of bringing clarity and understanding to the fields of geriatric medicine and biogerontology it is only fitting that a Presidential Symposium be dedicated as a tribute in the Biological Sciences Section to Dr. Butler in an attempt to define these major phenomena in order to place them in a context where the genetic components of longevity are distinguished from the stochastic process of aging. Specifically, speakers will discuss these phenomena within the framework of life history theory.

LIFESPAN: WHAT IS IT & WHY DOES IT EXIST?
B.A. Carnes, Geriatric Medicine, Univ of Oklahoma Health Sciences Center, Oklahoma City, Oklahoma

Lifespan is a term whose meaning overlaps with other terms like “duration of life” and “longevity.” It has also been applied to species. As such, it describes both individual and population concepts of time. Further, its extension has been used as proof that an anti-aging intervention (e.g., caloric restriction) was successful. Thus, lifespan has also been linked to aging itself. However, lifespan appears to be many things. Is it regulated and, if so, does it apply to all the lifespan concepts? The presentation will partition the generic “lifespan” term into a non-overlapping set of more specific terms that describe biologically meaningful spans of time. In so doing, the presentation hopes to add clarity to a concept that has been chosen as the organizing theme for this year’s conference.

WHY SURVIVE? DEFINING QUALITY OF LIFE IN OLD AGE
R. Binstock, Case Western Reserve University, Cleveland, Ohio

In the 1960s two opposing individualistic theories defined “successful aging” as (1) “the acceptance and desire for a process of disengagement from active life,” or (2) “the maintenance as far and as long as possible of the activities and attitudes of middle age.” Robert Butler’s 1975 book, Why Survive?, emphasized the influence of social conditions in shaping quality of life in old age. Rowe and Kahn selected both individual and socio-cultural objective factors for distinguishing between successful and “usual aging” in the 1980s and 1990s in terms of (1) low probability of disease and disease-related disability, (2) high cognitive and physical functional capacity, and (3) active engagement with life. In 2010, Pruchno et al. developed research on subjective measures of successful aging. Definitions of quality of life in old age will continually change and be enriched as medicine, culture, and social institutions evolve.
SESSION 1080 (PAPER)

DIVERGENT RESPONSES TO STRESS AND TRAUMA IN LATER LIFE

USE OF SLEEPING MEDICATION AND SLEEP QUALITY IN LATER LIFE

S. Aher, S. Venn, Sociology, University of Surrey, Guildford, United Kingdom

Background: Sleep problems and use of sleeping medication increase with advancing age, yet both lead to greater likelihood of falls and confusion. It is therefore important to understand ways to reduce sleep problems and use of sleeping medication in later life. Methods: Complementary data from a large-scale survey and qualitative interviews are analysed. The British Understanding Society survey (2009) is analysed to examine how social and health factors influence use of sleeping medication age >65 (n=3131). Qualitative interviews with 62 older people (average age 75) in SE England with clinically poor sleep (PSQI >5) is analysed to understand older people’s use (or non-use) of sleeping medication. Results: Use of sleeping medicines increases with age, especially for women; over age 85, 25% of women and 15% of men take medicines to help them sleep 3 or more times a week. Logistic regression analysis shows that older people with poorer health and in socially disadvantaged circumstances are higher users of sleeping medication. Qualitative interviews show that most older people do not consider seeing their doctor for help with their sleep, partly because they fear being prescribed sleeping medication. Conclusions: Older people with poor sleep were reticent to seek professional help for their sleep problems and generally against taking sleeping medication. There is a need to raise awareness of alternative, non-pharmacological, solutions to poor sleep for older people. 1 The SonnIA project is funded by the New Dynamics of Ageing initiative, supported by AHRC, BBSRC, ESRC, ESRC and MRC (RES-339-25-0009).

FACTORs ASSOCIATED WITH RESILIENCY AMONG OLDER ADULTS LIVING WITH HIV

D.J. Brennan,1 C.A. Emler,2 S. Brennenstuhl,1 S. Rueda,F. Ibanez-Carrasco1, S.B. Rourke1,1, S. Karapita1, I. University of Toronto, Toronto, Ontario, Canada, 2. University of Washington, Tacoma, Washington, USA, 3. University of Hawaii, Manoa, Honolulu, Hawaii, USA, 4. Casey House, Toronto, Ontario, Canada

BACKGROUND: Though older people living with HIV/AIDS (PHAs) face a myriad of physical and mental health challenges, resiliencies of this population are rarely examined. This study sought to understand mental health quality of life differences based on sexual orientation and gender among older PHAs living in Ontario. METHODS: This cross-sectional study analyzed data from PHAs who participated in the Ontario Cohort Study, a community-governed, multi-site study that collects clinical and socio-behavioural information. The present study analyzed data from 383 participants (age 50+) who completed an assessment battery between September, 2007 and March, 2010. Logistic regression analysis shows that older people with poorer health and in socially disadvantaged circumstances are higher users of sleeping medication. Qualitative interviews show that most older people do not consider seeing their doctor for help with their sleep, partly because they fear being prescribed sleeping medication. Conclusions: Older people with poor sleep were reticent to seek professional help for their sleep problems and generally against taking sleeping medication. There is a need to raise awareness of alternative, non-pharmacological, solutions to poor sleep for older people. 1 The SonnIA project is funded by the New Dynamics of Ageing initiative, supported by AHRC, BBSRC, ESRC, ESRC and MRC (RES-339-25-0009).

USE OF SLEEPING MEDICATION AND SLEEP QUALITY IN LATER LIFE

S. Aher, S. Venn, Sociology, University of Surrey, Guildford, United Kingdom

LONG-TERM INFLUENCES OF TRAUMA ON ATTACHMENT-RELATED ANXIETY AND AVOIDANCE AND RELATIONAL SATISFACTION IN AGING MEN

C.E. Franz2, M. Lyons3, M.D. Grant1, R. McKenzie4, M.S. Panizzon5, A. Ramundo5, A. Shahroudi3, W.S. Kremen2.1, Psychiatry, University of California San Diego, La Jolla, California, USA, 2. Boston University, Boston, Massachusetts

Exposure to traumatic events resulting in post-traumatic stress disorder (PTSD) is known to have consequences for psychosocial functioning. We examined the long-term influence of PTSD on relational outcomes up to 30–40 years post-onset in late middle-aged men. Participants were 1237 individual male twins in the Vietnam Era Twin Study of Aging (VETSA). When participants were an average age of 42, PTSD diagnoses were determined by the Diagnostic Interview Schedule; 7% (N=86) were diagnosed with PTSD. Average onset age was 23.8 years old (range 12–40 years). As part of the VETSA—at average age 55—participants completed the Experiences in Close Relationships (attachment style) scale, Center for Epidemiologic Studies Depression scale, MPQ stress-reaction (anxiety) scale, and life satisfaction measures for marriage, children, and best friend. Non-twin analyses were performed using mixed models adjusting for family as a random effect. At age 55, having an earlier diagnosis of PTSD was associated with significantly higher levels of avoidant attachment, depressive symptoms, and anxiety as well as lower levels of satisfaction with friends and marriages. Findings from discordant twin analyses in monozygotic pairs in which only one twin had PTSD suggest that the avoidant attachment difference was due to environmental influences rather than genetic influences. In summary, earlier life exposure to traumatic events resulting in PTSD affected relational outcomes 30–40 years later in middle-aged men. Such long-term trauma-related effects are important since emotional detachment and other forms of ill-being have been found to be causally related to poorer health outcomes in older adults.

DIVERGENT RESPONSES TO STRESS AND TRAUMA IN LATER LIFE

USE OF SLEEPING MEDICATION AND SLEEP QUALITY IN LATER LIFE

S. Aher, S. Venn, Sociology, University of Surrey, Guildford, United Kingdom

Background: Sleep problems and use of sleeping medication increase with advancing age, yet both lead to greater likelihood of falls and confusion. LONG-TERM INFLUENCES OF TRAUMA ON ATTACHMENT-RELATED ANXIETY AND AVOIDANCE AND RELATIONAL SATISFACTION IN AGING MEN

C.E. Franz2, M. Lyons3, M.D. Grant1, R. McKenzie4, M.S. Panizzon5, A. Ramundo5, A. Shahroudi3, W.S. Kremen2.1, Psychiatry, University of California San Diego, La Jolla, California, USA, 2. Boston University, Boston, Massachusetts

Exposure to traumatic events resulting in post-traumatic stress disorder (PTSD) is known to have consequences for psychosocial functioning. We examined the long-term influence of PTSD on relational outcomes up to 30–40 years post-onset in late middle-aged men. Participants were 1237 individual male twins in the Vietnam Era Twin Study of Aging (VETSA). When participants were an average age of 42, PTSD diagnoses were determined by the Diagnostic Interview Schedule; 7% (N=86) were diagnosed with PTSD. Average onset age was 23.8 years old (range 12–40 years). As part of the VETSA—at average age 55—participants completed the Experiences in Close Relationships (attachment style) scale, Center for Epidemiologic Studies Depression scale, MPQ stress-reaction (anxiety) scale, and life satisfaction measures for marriage, children, and best friend. Non-twin analyses were performed using mixed models adjusting for family as a random effect. At age 55, having an earlier diagnosis of PTSD was associated with significantly higher levels of avoidant attachment, depressive symptoms, and anxiety as well as lower levels of satisfaction with friends and marriages. Findings from discordant twin analyses in monozygotic pairs in which only one twin had PTSD suggest that the avoidant attachment difference was due to environmental influences rather than genetic influences. In summary, earlier life exposure to traumatic events resulting in PTSD affected relational outcomes 30–40 years later in middle-aged men. Such long-term trauma-related effects are important since emotional detachment and other forms of ill-being have been found to be causally related to poorer health outcomes in older adults.
Benzodiazepines (BZDs) are an important coping tool in the management of sleep and anxiety problems in older women and have been recognized as such in the literature. However, while the negative implications of BZD use, including higher incidence of falls and hip fractures and potential dependence, have been highlighted, the positive impact these medications have in the lives of older women users has been downplayed.

Regardless of the length of time spent caregiving, these caregivers’ experiences of caregiving have been greatly shaped by their BZD usage as these medications are used as a mechanism of support, particularly as it relates to the control of emotions. For instance, reports suggest that BZDs are needed for their ability to calm caregivers in times of particular strain or when they are having difficulty sleeping. The implications of these findings are significant in that the majority of long-term care (LTC) is provided informally by family and friends, with spousal caregivers often the default carer. Understanding the value women place on the use of these medications for the management of their daily lives can help in planning how to best support those who make up the foundation of LTC and who save the formal system billions in dollars.

SESSION 1085 (PAPER)

EFFECTS OF HEALTH AND SOCIAL BEHAVIOR ON COGNITIVE FUNCTIONING

HYPERTENSION IS ASSOCIATED WITH IMPAIRED RECOGNITION OF FACE-NAME ASSOCIATIONS BY OLDER ADULTS

A.R. Bender, N. Raz, Wayne State University Institute of Gerontology, Detroit, Michigan

Older adults perform worse than their younger counterparts on tests of episodic memory. Greater age differences are frequently observed for associations between items than for recognition of individual items. However, in most extant studies, age-prevalent vascular risk factors such as hypertension are not taken into account. As those risk factors may exert deleterious effects on memory, it is important to gauge their influence on age memory declines. In sample of 141 older adults (50 to 77 years; mean age = 61.1, sd = 7.9 years), we assessed recognition of faces, names, and their pairings. Participants studied lists of face-name pairs, followed by two item and two associative recognition tests employing a 2 alternative, forced-choice paradigm. Although greater age was associated with poorer memory, participants with diagnosed hypertension recognized fewer associations than normotensive participants; no difference was observed for item recognition. There was no differential age effect on item and association recognition. The findings indicate that reported differential effects of age on associative memory may represent a confounding effect of age-related elevation in vascular risk.

ASSOCIATION BETWEEN SMOKING HISTORY AND COGNITIVE DECLINE IN THE WHITEHALL II STUDY

S. Sabia1, A. Elbaz2, A. Dugravot1, J. Head1, M. Shipley1, G. Hagger-Johnson1, M. Kivimaki2, A. Singh-Manoux3, 1. Department of Epidemiology & Public Health, University College London, London, United Kingdom, 2. Inserm, U708, F-75013, Paris, France, 3. UPMC Univ Paris 6, F-75005, Paris, France, 4. INSERM U1018, F-94807 Villejuif Cedex, France

OBJECTIVE: We examined the association between smoking history and decline in multiple domains of cognition between midlife and early old age. METHODS: Data are from 5099 men and 2137 women, mean age 56 years (standard deviation=6) at the start of cognitive testing (Phase 5 of the Whitehall II cohort study, 1997-1999). Smoking history was assessed over a 25-year period (Phases 1 (1965-1988) to 9 (2007-2009)). Five cognitive tests were assessed three times over 10 years (Phases 5, 7 (2002-2004) and 9) and converted to T-scores to compute scores in memory, vocabulary, and executive function. All five tests were combined to yield a global cognitive score. Linear mixed models were used to assess the association between smoking history and 10-year cognitive decline. RESULTS: In men, faster decline in global cognition (mean difference between the change of current versus never smokers=-0.96 (-1.51; -0.40) and executive function (-1.13 (-1.75; -0.51)) was observed among current smokers at Phase 5 compared to never smokers. Cognitive decline among those who continued to smoke until the end of the study was even faster. Recent ex-smokers also had greater decline in executive function (-0.82 (-1.43; -0.20)) while the decline in long term ex-smokers no different to the never smokers. No association between smoking and cognitive decline was found in women. CONCLUSION: Our results show that compared to never smokers, middle-aged male smokers experience faster cognitive decline in global cognition and executive function. Ten years after smoking cessation no residual adverse effect of smoking on cognitive decline was found.

COGNITION AND BLOOD PRESSURE IN OLD AGE: REPORT FROM TWO SWEDISH POPULATION-BASED LONGITUDINAL STUDIES

V. Thorvaldsson1, T. Svensson2, B. Johansson1, 1. Department of Psychology, University of Gothenburg, Gothenburg, Sweden, 2. Lund University, Lund, Sweden

Hypertension in midlife has in previous studies been associated with increased risk of cognitive impairment and dementia in old age. The association between blood pressure in old age and cognitive function is however less clear. Several studies do though suggest that both hypertension and hypotension in old age is associated with cognitive impairment. In this paper we evaluate associations between levels and changes in blood pressure and cognitive function using data from two Swedish population-based longitudinal aging studies. First, the Gothenburg H70 study (n=382) which includes 12 repeated assessments of blood pressure and cognitive function from age 70 over 30 years or until death, and second, the Lund 80+ study (n=212) including repeated annual assessments of blood pressure and cognitive function from age 80 over 20 years or until death. The main findings provide support of the hypothesis of an inverted U shaped association between blood pressure in old age and cognitive function. That is, both hypertension and hypotension are associated with cognitive impairment and increased risk of dementia in old age. The potential modeling approaches and mechanisms behind the associations are discussed.

APOE-E4 AND VASCULAR HEALTH RISK FACTORS ON DOMAIN-SPECIFIC COGNITION

A. Revell1, K. Schae2, 1. Department of Psychology, UMASS Dartmouth, North Dartmouth, Massachusetts, 2. University of Washington, Seattle, Washington

The patterns of cardiovascular health and genetic risk factors in the detection of cognitive impairment are under investigation by many, though identifying which risks are present by cognitive domain is less clear. In a sample of 450 community-dwelling older adults (mean age=72.21, SD age =7.92, range 59-93) from the Seattle Longitudinal Study (SLS), we investigated whether older adults genotyped for Apolipoprotein E epsilon 4 (APOE-e4) without e4 alleles (n=334) and those with one or more APOE-e4 alleles (n=116) showed significant factor mean level differences in memory recall, perceptual speed, and verbal reasoning factors (based on measures from the SLS neuropsychological battery; Schae, 2005), and further whether these cognitive domains were predicted by years smoking, heart disease presence, or...
Body Mass Index (BMI). Full-information, multiple-group, structural equation models in Mplus (Muthen & Muthen, 1998-2008) indicated that individuals with one or more APOE-e4 alleles had significantly lower mean levels of performance on the memory recall domain and lower mean BMI. The model met commonly used criteria for acceptable fit (CFI=93; RMSEA=.07), and all indicators were statistically significant (p < .05). Presence of other vascular and non-vascular factors should be investigated to provide supplementary support across similar cognitive measures from other longitudinal studies.

SESSION 1090 (PAPER)

LIFESTYLE, HEALTH, AND MORTALITY

A LIFESTYLE INTERVENTION TO REDUCE DIABETES RISK IN MINORITY AND LOWER-SOCIOECONOMIC STATUS ADULTS

A. Stewart1, A. Kanaya1, J. Santoyo-Olsson1, S. Gregorich1, M. Grossman1, T. Moore2, 1. University of California San Francisco, San Francisco, California, 2. City of Berkeley Department of Parks, Recreation and Waterfront, Berkeley, California

Intensive lifestyle interventions lower diabetes incidence in large clinical trials. Translating such interventions into real world settings is thus a major priority. We report on the effectiveness of a low-intensity lifestyle intervention (Live Well, Be Well) to improve clinical and behavioral diabetes risk factors in lower-socioeconomic status (SES) and ethnic minority adults. Through an academic-public health department partnership, community-dwelling adults at risk for developing diabetes were randomized to a 1-year individualized lifestyle program or wait-list control group. The program was delivered in Spanish and English by health department counselors and promoted increased physical activity and improved diet through primarily telephone counseling with 2 in-person sessions, and 5 group workshops. Primary outcomes (6 and 12 months) were fasting glucose, triglycerides, HDL- and LDL-cholesterol, weight, waist circumference, and systolic blood pressure. Secondary outcomes included diet, physical activity, and health-related quality of life. The sample (N=230) averaged 56 years of age (range 25-91) and was 73% women, 27% Spanish-speaking, and 80% ethnic minority. Study retention was 92%. At 6 months, the intervention group lost 2 pounds more than controls (P=.03) and had greater triglyceride reduction (difference 23 mg/dL, P=.02). The intervention group consumed 7.1 fewer grams of fat per day (P=.04), ate more fruits and vegetables (P=.01), had greater psychological well-being (P=.05), and had greater improvement in self-rated health (P=.05) than controls. Although modest, the observed improvement in several important risk factors is encouraging because of the substantial challenges in designing effective community-based translational interventions for lower-SES and minority communities.

LIFESTYLE EFFECTS ON MORBIDITY AND MORTALITY IN US ELDERLY POPULATION

I. Akushevich1, J. Kravchenko1, S.V. Ukraintseva1, K.G. Arbee1, A.I. Yashin1, 1. Center for Population Health and Aging, Duke University, Durham, North Carolina, 2. Duke Cancer Institute, Duke University, Durham, North Carolina

Most of aging-related diseases are associated with multiple behavioral factors which are potentially modifiable. Large-scale population-based studies can be used to quantify the effects of characteristics of lifestyle, functional status, and comorbidities (self-reported) on risk of aging-related morbidity and attributed to chronic diseases mortality. Measured in the National Long Term Care Survey (NLTCS) characteristics were grouped in fourteen groups (such as daily living activities, physical activities, smoking, alcohol consumption, social activities, self-reported comorbidity, health insurance, etc.) and tested for associations with morbidity and mortality risk. Physical activity, tobacco consumption, comorbidity, demographic characteristics, and health insurance and medical care providers were significant contributors to changes of chronic disease incidence and mortality risk. Resulting from this analysis, the “portraits” of groups at higher cancer risk were obtained based on NLTCS variables and constructed from these variables aggregated indices: e.g., smoking and pulmonary comorbidity were strongly associated with lung cancer incidence risk, and comorbidity and BMI were associated with colon cancer risk. Several types of the effects of second variables were identified: confoundings, candidate mediators, independent predictors, and overlapping predictors. We concluded, that measured characteristics representing a spectrum of characteristics of elderly life (behavioral risk factors, physical activities, morbidity, etc.) analyzed both individually and grouped in related clusters, significantly affect risks in the U.S. elderly. The most influential of the potentially preventable risk factors can be detected using approaches discussed in this report and applied to further deeper analyses, including other data sets with detailed risk factors description.

ACHIEVING HEALTHY AGING: THE IMPACT OF LIFESTYLE FACTORS ON LONGEVITY AND HEALTH IN LATER LIFE

J.E. Byles1, A. Dobson1, 1. Faculty of Health, The University of Newcastle, Newcastle, New South Wales, Australia, 2. The University of Queensland, Brisbane, Queensland, Australia

Healthy ageing is a policy imperative for ageing populations. Ideally, current and future populations of older people will not only live longer, but with limited physical disability and reduced need for services. Health promotion across the life course is thought to be a critical step in achieving this goal of healthy ageing. In this presentation, we examine late life lifestyle factors associated with healthy ageing among 12431 women in the Australian Longitudinal Study on Women’s Health. The women were aged 70-75 years when the study began in 1996, and have contributed information on their health behaviours and wellbeing across five data points (1996, 1999, 2002, 2005, 2008). The findings emphasise the importance of health behaviours for establishing and maintaining good health well into late life. Smoking is associated with reduced life expectancy and reduced healthy life expectancy even among those in excellent health at the commencement of the study; quitting smoking continues to be of benefit even at advanced older age. Moderate consumption of alcohol is associated with reduced mortality, and improved health related quality of life. There is a U-shaped relationship between BMI and mortality, with lowest mortality in the overweight BMI range. Physical Activity is strongly associated with longevity and wellbeing, and protects against negative health effects of higher BMI levels. The presentation will provide participants with precise estimates of the impact of health promotion activities in later life, and the importance of these activities in older age.

EFFECTS OF EARLY LIFE EXPOSURES, MIGRATION TO THE US AND ADULT LIFESTYLE ON THE HEALTH OF OLDER ADULT PUERTORICANS

M. McCrae, 1. Sociology/Center for Demography & Ecology, University of Wisconsin-Madison, Madison, Wisconsin

This paper examines how adverse early life experiences of cohorts born during the early 20th century in Puerto Rico are shaping their health at older adult ages and how migration to the US in later life and adult lifestyle might have compounded these early life effects. Rapid mortality decline in infants and children due to massive public health interventions and medical technology in the late 1920s-early 1940s in Puerto Rico produced cohorts whose health at older ages is potentially more heavily influenced by poor early life exposures compared with earlier cohorts. Many migrated to the US during adulthood. Using data from the Puerto Rico Elderly Health Conditions (PREHCO) study (n=4291) and aggregate historical data, multivariate models examine early life conditions (season of birth, birthplace, IMR, childhood health, knee
height, mother and father SES, parental health, contextual variables at the municipality level) and their effects on older adult health (heart disease, diabetes, functionality and mortality) across four groups of older adult Puerto Ricans according to age (born prior to the late 1920s and after) and birthplace (rural/urban) and according to their migration to the US while controlling also for adult SES, obesity and lifestyle factors (smoking, drinking, diet, exercise). Findings: some effects of poor early life exposures on older adult health are much stronger for those who migrated, lived and/or worked in the US before returning to Puerto Rico at older ages. I discuss possible interpretations for these results (selection, early life and adult environment and lifestyle) in the paper.

IS AGE SEGREGATION THE BEST ALTERNATIVE FOR OLDER AMERICANS LIVING ALONE?
E. Portacolone, UCSF, Berkeley, California
In 2006 more than a third of all Americans over 75, five million of them, lived on their own. Thanks to the ‘longevity revolution’ and to the desire to live at home rather than in an institution the number of older one-head household will increase. Living alone in older age can be a deliberate choice or the product of events beyond control. Death or institutionalization of a significant other, lack of family, the reluctance to be a burden, the desire for a feeling of belonging, or a history of living alone for years are all inroads to this path. More than one year of ethnographic fieldwork among 43 San Franciscans over 75 living alone led to the contention that older adults living alone in buildings for seniors tend to express less worries and feel less lonely than those living in apartments and houses next to neighbors of all ages. The paper reflect on the conditions of possibility that makes segregation by age an appealing alternative sought even by radical activists for social justice. The reflection will reveal how ageism, individualism, and fragmented public services make living in houses for seniors an attractive practice. The reflection will reveal how ageism, individualism, and fragmented public services make living in houses for seniors an attractive practice.

SESSION 1095 (PAPER)

SEX, INTIMACY, AND MARITAL RELATIONSHIPS

EXPLORING THE RELATIONSHIP BETWEEN FREQUENCY OF SEXUAL ACTIVITY AND HAPPINESS AMONG OLDER MARRIED AMERICANS
A. Jackson, Physical Therapy, Florida A & M University, Tallahassee, Florida
The purpose of this study is two-fold: (1) to examine the correlation between frequency of sexual activity and general happiness among married older Americans and (2) to examine the correlation between frequency of sexual activity and marital happiness among older married Americans. This study employed quantitative data drawn from the 2004-2008 General Social Surveys. The sample included all married respondents 65 years of age and older with valid responses for the dependent, independent, and control variables. Both bivariate cross-tabulations and binary logistic regression analyses were conducted. As expected, the data support a positive association between sexual activity and general happiness in the married older sample (p < 0.05). Also, as expected, the data support a positive association between frequency of sexual activity and marital happiness (p < 0.05). Even with the introduction of control variables, frequency of sexual activity was found to be a significant predictor of both general and marital happiness (p < 0.05). This study suggests that sexual activity does indeed contribute the happiness and well-being of married couples in later life. It is necessary to examine and explore this relationship in order to better understand the factors contributing to quality of life in this population. Further exploring the physiological, psychological, and sociological constraints on older Americans’ participation sexual activities will help in developing and organizing specific sexual health interventions for couples in this growing segment of our population.

THE MEANING OF SEXUAL PERFORMANCE AMONG MEN WITH AND WITHOUT ERECTILE DYSFUNCTION
E.H. Thompson, K. Barnes, Sociology & Anthropology, College of the Holy Cross, Worcester, Massachusetts
Abstract Body (Required; Limit 250 words): Has direct-to-consumer advertising of erectile dysfunction medication affected men’s sexual performance expectations? This study investigated to what extent adult men were willing to endorse the ‘sex for life’ expectations evident within both traditional masculinity and direct-to-consumer erectile dysfunction (ED) advertising. Method: A convenience sample (N=132) of men from New England age 50 and older (M age = 59.8) examined the sexual performance expectations among men with and without erectile dysfunction. Findings: Two new measures — a 5-item Men’s Sexual Performance Attitudes (MSPA) and a 7-item Late Life Sexual Performance Expectations (LLSPE) — revealed that adult men disavowed sexual performance was a defining feature of their masculinity, and there was no difference in attitude among men with and without erectile dysfunction. However, the group of men with erectile dysfunction and using oral ED medication were much more wary to disparage the maxim that erectile dysfunction equaled troubled masculinity. Unlike the other mid-to-late life men, this group seemed willing to accept the argument that erectile dysfunction was a marker of troubled masculinity. Their peers strongly rejected this principle. Discussion: The ways that mature men perceive sexual functioning is discussed in terms of their partnered sexuality, the way endorsing a traditional masculinity ideology encourages use of oral ED medication, and how physicians and other clinicians might manage men’s sexual competency worries.

THEORIZING INTIMACY ACROSS THE LIFE COURSE: A MODEL OF THE INTIMATE SELF
B. McCann1, K. Allen2, 1. University of Louisiana Monroe, Monroe, Louisiana, 2. Virginia Tech, Blacksburg, Virginia
One important lifestyle factor that affects the aging process is close, personal relationships. Typically intimacy is conceptualized only as an interpersonal process, however social research suggests that intimacy may be a more complex construct. In this theoretical paper we propose a three-part model of the intimate self which brings together interpersonal processes and socio-structural processes. The model we propose has grown out of our research on intimacy and family in midlife and later life. Moreover, we integrated concepts from three theoretical perspectives: life course theory, feminist theory, and social constructionist theory. The model is composed of three nested triangles; each triangle is made up of one concept from each of the three theories. The outermost triangle, Collective Intimacy, is most distal and represents the influence of larger cultural norms and historic changes. The middle triangle—Relational Intimacy—focuses on older adults’ place within and among families and social networks. Finally, the innermost triangle, Personal Intimacy, represents the ways in which particular individuals operate within cohort and generational time and make sense of that experience. In summary, we present a more holistic model of an important lifestyle factor, intimacy, which may be useful to researchers and practitioners working in gerontology.

IS MARRIAGE BETTER THE SECOND TIME AROUND? COMPARING FIRST MARRIAGES AND REMARRIAGES AFTER MID-LIFE
T.M. Cooney, L.A. Snyder, C.M. Prouls, Human Development & Family Studies, University of Missouri, Columbia, Missouri
One-fourth of married persons today are in remarriages (22.7% of marrieds 65 and older) and the percent of remarried persons 65 and older will increase with the aging of the Baby Boom cohort. Marriage appears to offer important benefits in later life, with married persons generally reporting better health and well-being than non-married peers, though these associations vary some by gender. Evidence also suggests that, above and beyond marital status, marital quality positively affects well-
being. Missing in most discussions of mid- to later-life marriage, however, is a distinction between persons in first marriages and remarriages. With a growing share of the older population occupying a remarried status, it is increasingly important to consider the quality of these unions. This study uses data from the National Social Life, Health and Aging Project (NSHAP) to compare marriage and remarriage quality for persons ages 57 to 85. The sample consists of 712 men and 529 women in first marriages and 355 men and 203 women in remarriages. Controlling for group differences in age, race, health, spousal health and SES, we find no differences in men’s reports of marital quality in first and higher order unions. However, remarried women report more positive marital experiences than women in first marriages. They report significantly greater emotional and physical satisfaction with their marriages, more free time spent with spouse, and less marital strain. We discuss potential implications of these findings for later life well-being of future cohorts of elderly.

WIDENING THE SOCIAL CONTEXT OF DISABLEMENT: THE IMPORTANCE OF MARITAL AND NONMARITAL RELATIONSHIPS FOR LONELINESS

D.F. Warner, S. Adams, Case Western Reserve University, Cleveland, Ohio

Disability occurs within a web of interpersonal relationships that provide psychosocial resources to and/or place demands on older adults. Grounded in the stress process and life course perspectives, we examined the social context of disablement by examining the influence of marital quality and social support from family and friends on the association between physical disability and loneliness among married older adults. Using data from the nationally representative National Social Life, Health, and Aging Project (NSHAP), we found that the association between functional limitations and higher levels of loneliness was partially accounted for by the fact that, while supportive non-spousal relations are associated with fewer feelings of loneliness, functional limitations were associated with less supportive non-spousal relationships. Positive marital quality moderated the association between functional limitations and loneliness, as older disabled adults in marriages with greater positive attributes were effectively buffered from the negative consequences of functional impairment for loneliness. By contrast, the association between functional limitations and loneliness was exacerbated for older disabled adults in marriages with fewer positive attributes. However, we found no evidence that supportive non-spousal relations compensate for the elevated loneliness among older disabled adults in low-quality marriages. This pattern of associations was similar for women and men. The findings demonstrate the importance of considering the wider social context of disablement. Although both marital and nonmarital relationships are important for feelings of loneliness, our findings indicate that when confronted with a stressor such as disability it is the quality of the marital relationship that alone matters.

SESSION 1100 (SYMPOSIUM)

COMMUNITY-BASED THERAPEUTIC INTERVENTIONS FOR EARLY-STAGE DEMENTIA: OUTCOMES AND SCOPE

Chair: S.C. Burgener, Biobehavioral Health Nursing, University of Illinois College of Nursing, Urbana, Illinois
Co-Chair: L. Buettner, University of North Carolina Department of Therapeutic Recreation, Greensboro, North Carolina
Discussant: K.C. Buckwalter, The University of Iowa College of Nursing, Iowa City, Iowa

Increasingly, the extant research has described positive outcomes from non-pharmacological therapies for persons with early-stage dementia (PwD), including positive effects on cognitive functioning. Traditionally there has been less attention given to the benefits of non-pharmacological therapies compared to pharmacological treatments. Concomitantly, no consensus has been reached regarding the most effective components of non-pharmacological therapies or optimal target outcomes. Because of this gap in the research literature, further study is needed to identify (1) effective components of non-pharmacological therapies, (2) outcomes impacted by individual or multi-modal treatments, and (3) optimal structures for community-based interventions. This symposium includes four presentations that illustrate a variety of non-pharmacological interventions impacting on relevant outcomes of PwD. The research has been conducted by and developed from a range of disciplinary perspectives. The first presenter (Burgener; recreational therapy) will describe the effects of a cognitive training intervention on apathy outcomes. The second presenter (Morhardt; social work) will illustrate the outcomes from an improvisational acting intervention. The third presenter (Yu; nursing) will describe the effects of a 6-month aerobic exercise intervention on cognitive outcomes. The final presenter (Burgener; nursing) will describe the cognitive and psychological outcomes from a multi-modal intervention, including cognitive, creative, and exercise components. Each presentation will include descriptions of specific interventions, outcome measures, positive effects for PwD, and approaches to offering the intervention in a community setting.

MAINTAINING COGNITION USING AEROBIC EXERCISE IN ALZHEIMER’S DISEASE

F. Yu1, N.W. Nelson1, K. Savik1, M. Dysken2, J.F. Wyman1, 1. School of Nursing, University of Minnesota, Minneapolis, Minnesota, 2. Minneapolis Veterans Affairs Medical Center, Minneapolis, Minnesota, 3. St Thomas University, Minneapolis, Minnesota

Aerobic exercise could be potentially effective for delaying cognitive decline via biologically sound mechanisms in the >25 million individuals with Alzheimer’s disease (AD). However, few studies have tested the effect of sole aerobic exercise on cognition in AD. This pilot study used a one-group repeated-measures design to examine the change in cognition from aerobic exercise in older adults with AD. Eight of 11 enrolled participants (mean age 81.4 ± 5.38 years) completed 6 months of individualized, supervised, moderate intensity cycling three times a week. Cognition was measured using the AD Assessment Scale, Mini-Mental State Examination, Trail Making Tests, Executive Interview-25, Stroop test, and Controlled Oral Word Association Test at baseline, 3 and 6 months. The results show that there are no significant changes in any measures. We conclude that this study provides preliminary evidence suggesting that older adults with AD might be able to delay cognitive decline from aerobic exercise.

MENTALLY STIMULATING ACTIVITIES FOR APATHY IN EARLY STAGE AD

L.L. Buettner1, S. Fitzsimmons1, K. Sink2, 1. UNCG, Greensboro, North Carolina, 2. Wake Forest Baptist Medical Center, Winston Salem, North Carolina

We studied changes in apathy among 77 community dwelling older persons with mild memory loss in a randomized clinical trial comparing two non-pharmacological interventions over four weeks. The study used a pre-post design with randomization by site to avoid contamination and diffusion of effect. Interventions were offered twice weekly after baseline evaluations were completed. The treatment group received classroom style mentally stimulating activities (MSAs) while the control group received a structured early stage social support (SS) group. The results showed the MSA group had significantly lower levels of apathy (p<.001) and significantly lower symptoms of depression (p<.001). While both groups improved in quality of life, the MSA group was significantly better (p=.02) than the SS group. The project shows promising results in that the MSA intervention may provide a much needed method of reducing apathy and depressive symptoms, while motivating participation and increasing quality of life.
THE MEMORY ENSEMBLE: AN IMPROVISATIONAL THEATRE INTERVENTION FOR PERSONS WITH EARLY STAGE DEMENTIA

This study’s purpose is to test an intervention to support the strengths and abilities of persons with early stage dementia (ESG). A partnership was formed between a National Institute on Aging Alzheimer’s Disease Center (ADC) and a theatre ensemble to create an improvisational intervention for persons with ESG. A 7-week curriculum was developed. Six community dwelling participants enrolled in a pilot program of seven 90-minute sessions. Field notes were documented and a pre/post-test of Quality of Life (QOL) was administered. Written evaluations were obtained. Field notes were analyzed thematically and pre/post testing revealed a slight improvement in QOL. Subjects found the intervention mentally stimulating, were better able to accept their diagnosis and cope with cognitive changes, and felt less isolated and alone. These results show promise for further development and refinement of an improvisational theatre intervention for persons with ESG.

A COMMUNITY-BASED INTERVENTION FOR PERSONS WITH EARLY-STAGE DEMENTIA: EFFECTS ON COGNITION AND DEPRESSIVE SYMPTOMS

S.C. Burgener, R. Mathy, Biobehavioral Health Nursing, University of Illinois College of Nursing, Urbana, Illinois

Non-pharmacological interventions initiated early in dementia have the potential to improve outcomes, including cognitive and emotional functioning. Multimodal interventions provide a variety of stimuli, affecting neuronal activity and responses through varying mechanisms. The purpose of this pre/post-test study was to test the effectiveness of a community-based, multimodal intervention on cognitive and depressive outcomes of persons with early-stage dementia (PwD). The intervention consists of cognitive, creative, social, and exercise (TaiChi) activities, offered 4 hours/day, 1-2 days/week. Seventeen participants (mean age = 76.9) comprised the sample, with data being collected at baseline and one-year following initial participation. Findings reveal stability in cognitive functioning, with Mini Mental State Examination scores varying from 26.12 at baseline to 27.83 at one year. Geriatric Depression Scale scores were also stable, being 2.14 at baseline and 2.0 at year one. Findings support a trend toward positive effects for early-stage PwD from participation in the multimodal intervention.

SESSION 1105 (SYMPOSIUM)

CONNECTING OLDER ADULTS WITH THE COMMUNITY: APPLICATIONS OF COMPUTER TECHNOLOGY

Chair: M.S. Heinz, Human Development and Family Studies, Iowa State University, Ames, Iowa

Discussant: J. Coughlin, Massachusetts Institute of Technology, Cambridge, Massachusetts

There are many benefits of technology to older adults such as increased independence and connectedness. Barriers to using technology are also noted, particularly as they relate to usability aspects of products and older adults’ attitudes about technology. The purpose of this symposium is to report first results from a two-phase study of computer applications that assist older adults to connect to the community. In the first phase of the study, three focus groups were conducted regarding their perceptions and usage of technology. Based on the focus group discussion, two computer prototypes (i.e., check-in monitor and daily health diary) were developed in order to meet three key needs older adults identified in the focus groups: concern about safety, health, and social connectedness. Skype was also used with older adults in order to address the concern over lack of social connectedness. Eight older adults living in an independent-living community tested the computer prototypes over a ten-day period. A follow-up focus group was conducted after participants completed the ten-day testing period. Older adult perceptions regarding the usability of the prototypes will be shared and discussed (e.g., usefulness, enjoyment). After attending this symposium, participants will have an understanding of older adults’ perceptions and current uses of technology and learn about older adult reactions to testing out new computer prototypes. The symposium will include older adults’ reactions to computer scientists coming into their homes to install equipment, usability of the computer prototypes, and perceptions of Skype before and after using the technology.

OLDER ADULTS AND PERCEPTIONS OF TECHNOLOGY

Changes and advancements in technology have the potential to benefit older adults by promoting independence and increased ability to age in place. However, older adults are less likely to adopt new technology unless they see benefits to themselves. This study assessed perceptions of thirty older adults in the Midwest concerning technology via three separate focus groups (i.e., independent living community, a rural community, and exercise program participants) with a particular focus on oldest-old and rural individuals. The focus group questions included items such as what technology older adults currently used, desired improvements in technology, and the greatest challenges participants were facing or would face. Five themes emerged from all three focus groups: technology barriers, transportation needs, help and assistance, self-monitoring, and gaming. After attending this session, participants will understand older adult perceptions, current uses of technology, and implications for technology designers and service providers who work with older adults.

THE COMPUTER DOESN’T BITE YOU! FOCUS GROUP DISCUSSION ON COMPUTER USE AMONG OLDER ADULTS

J. Cho, P. Martin, H. Yang, J. Wong, Iowa State Univ, Ames, Iowa

Computers and technology are necessities for everyday life in the 21st century regardless of age. Specifically, using technology has become a main component of work, education, communication, entertainment, and health care. In the current study, we used a computer program to check the health status of eight residents in an independent living community over a ten-day period. Participants initially expressed low confidence in their ability to use a computer. Pre- and post-focus group sessions were administered to assess attitudes toward technology. Results showed older adults learned and were confident about computers and usage of checking health status on computers, and recommended using an on-line health status check as an alternative to a regular office visit. The results of this study highlight the effects of technology, how technology improves the quality of life and promotes healthy and independent living among aging populations.

OLDER ADULTS AND NEWER TECHNOLOGIES: CHALLENGES AND STRATEGIES

N. Kelly, Iowa State University, Johnston, Iowa

Computers and related technologies are becoming ubiquitous. Their use is increasingly necessary to fully engage in various facets of daily life, and such innovations hold great promise for improving the lives of older adults. But technology development is traditionally oriented to the young; it does not take into account the sensory and cognitive effects of aging. Thus, obstacles exist in the products themselves. Another barrier to adoption may be older adults’ negative attitudes toward newer technology. However, research has shown that such attitudinal issues are less prevalent than stereotypes suggest. For example, previous research noted that older adults are quite open to adopting new tech-
Although computers offer an opportunity to enhance the lives of older adults, use is relatively low compared to other age groups. Barriers, such as lack of confidence and health issues, are obstacles preventing computer use. This study reports on results from a focus-group discussion that examined the attitudes of eight older adults in an independent living community following a ten-day period of using Skype. Results noted several barriers that participants overcame while taking part in this study, including trust issues surrounding a computer camera in their home and privacy issues concerning how they appeared to others during Skype sessions. Positive perceptions residents noted were: it was “fun” for them and their families, useful as a “check-in” device, and helpful as a way to increase self-confidence in “today’s technology.” Likewise, participants wished to continue Skype after the study ended. The results of our study suggest that adults can overcome technology barriers.

FAMILY INVOLVEMENT IN DEMENTIA CARE – AN INTERCONTINENTAL OVERVIEW

Chair: J. Gräske, Alice Salomon University of Applied Sciences, Berlin, Germany
Co-Chair: E. van Rossum, Maastricht University, Maastricht, Netherlands
Discussant: B. Resnick, University of Maryland, Baltimore, Maryland

Care for Persons with Dementia Requires a Person-Centered Approach. Family Involvement Serves to an Individualization of Care Provided to Residents, and Improves Residents Quality of Life. Family Member’s Participation in Dementia Care is Possible in Various Ways and Helps Residents Staying Involved in Every Day Life. This Symposium Aims to Provide an Overview of Selected Ways of Family Involvement and the Impact on Residents’ Health-Related Outcomes. Each Presenter Will Discuss Current Approaches to Improve Dementia Care All Over the World. Everyday Life as well as Dementia Care in Special Circumstances are Included in the Symposium. Results of Family Involvement in Meaningful Activities, Decision Making, and Sexuality Will be Presented. The First Presenter shall Evaluate the Impact of Family Involvement from Residents Perspective Using Self-Rated Quality of Life Instruments, using data from a longitudinal German study (n=104). The Second Presenter Addresses Results from a U.S Study Using 205 dyads of Care Givers and Care Recipients with Dementia in an Early Stage on the Decision Making Process in Every Day Life. The Third Presenter Focuses on Differences in Family Involvement in Meaningful Activities Between Traditional Nursing Homes and Small-Scale Living Facilities, including 206 Family Caregivers and 259 People With Moderate to Severe Dementia in the Netherlands. The Final Presentation Discusses an Imported though Neglected Area of Sexual Expression of People With Dementia in Long-Term care and Specifically Addresses Family’s Perspective. The Presentations Show, that Family Involvement is Essential for Residents to Improve Their Everyday Life and Private Needs.

FAMILY INVOLVEMENT IN GERMAN SHARED-HOUSING ARRANGEMENTS – A LONGITUDINAL STUDY

J. Gräske, K. Wolf-Ostermann, Alice Salomon University of Applied Sciences, Berlin, Germany

Background: Family Involvement in Dementia Care is Considered to Be Beneficial to Persons With Dementia. Shared-housing Arrangements (SHA) are a New Approach in Dementia Care in Germany. Family Involvement is a Core Aim in This Setting. Empirical Findings of Frequency and Applied Tasks Are Lacking yet as well as the Impact on Residents Outcomes. Method: We Conducted a Longitudinal Study to Assess Family Involvement and the Impact on Residents Quality of Life (QUALIDEM) and Challenging Behavior (CMAI). Results: We Included 104 Residents (Mostly Female, 79.0 Years) of 36 SHA. Family Members of 60% of all Residents are Involved in Dementia Care. Predominantly, They are Involved in Reading out and Taking Their Relatives for a Walk. Residents with Family Involvement Have a Higher QoL and Less Challenging Behaviors than People Without. Conclusion: Family Involvement is Not as Present as Postulated. We can Confirm, that It Is Beneficial for Residents of SHA.

FAMILY INVOLVEMENT IN DEMENTIA CARE: SMALL-SCALE LIVING FACILITIES AND TRADITIONAL NURSING HOMES COMPARED

H. Verbeek, S.M. Zwakhalen, E. Van Rossum, G.I. Kempen, J. Hamers, Maastricht University, CAPHRI School for Public Health and Primary Care, Department of Health Care and Nursing Science, Maastricht, Netherlands

This Study Compared Involvement of Family Caregivers in Care for People with Dementia Living in Two Different Settings: Traditional Nursing Homes (TNH) and Small-scale Living Facilities (SSLF). Involvement With Care Was Assessed in 206 Family Caregivers (106 in SSLF and 100 in TNH) During 1 Year (Baseline Assessment and Follow-ups After 6 and 12 Months). Family Caregivers Were Most Often Involved in Sitting, Chatting and Walking With Residents. Only Small Differences Were Identified Between The Two Settings: Family Caregivers in SSLF Were More Engaged in Helping Others and Assisting With Household Chores. No Significant Effects Were Found for Frequency and Duration of Visits and Number of Activities During Visiting. Our Results Indicate That Involvement With Care is Not Different for Family Caregivers in SSLF Compared with TNH, Although Small Differences Between Type of Activities Emerged.

CARE RECIPIENT AND FAMILY CAREGIVER PERCEPTIONS OF EVERYDAY CARE IN EARLY-STAGE DEMENTIA: THE EFFECT OF INCONGRUENCE ON QUALITY OF LIFE

H. Moon, A.L. Townsend, C.J. Whittatch, 1. case western reserve university, Cleveland, Ohio, 2. Benjamin Rose Institute, Cleveland, Ohio

Few studies have examined the differences between care recipients (CRs) with early-stage dementia and family caregivers (CGs) in their perspectives about CRs’ daily care, and the effect on CGs’ and CRs’ quality of life (QoL). This study examines differences between CR and CG reports about: 1) CR involvement in decision making about daily care, 2) CR values and preferences about social relations, and 3) the effect of these differences on CG and CR QoL. Within 205 care dyads (i.e., CRs with early-stage dementia and CGs). CGs rated CRs’ involvement in decision making as significantly lower than CRs. CGs also reported that CRs valued maintaining social relations significantly less than CRs reported. Multilevel analysis revealed that there was a significant effect of incongruence on values and preferences on CGs’ and CRs’ QOL. Discussion will focus on the implications of the findings for developing strategies for improving CR and CG QoL.
DAD WOULD NEVER HAVE DONE THAT!: OLDER PEOPLE’S EXPRESSION OF THEIR SEXUALITY IN LONG TERM CARE
M. Bauer, R. Nay, D. Fetherstonhaugh, L. McAuliffe, La Trobe University, Bundoora, Victoria, Australia

The sexual needs and wellbeing of older people living in residential aged care remains a significant challenge, receives scant attention in practice and is easily dismissed. As guardians and informal carers, family play an important role in residential aged care facilities; however they can also be one of the hurdles to the acknowledgement of residents’ sexuality and residents being unable to express their sexual needs. Many family members find it difficult to accept that sexual expression may still be important for the older person in an aged care facility, particularly when dementia is involved. This paper will present research findings from a project which involved interviews and focus groups with resident’s family members in two Australian states on the issue of sexuality and older people living in residential aged care. Research findings underscore the need for policy, information and education.

SESSION 1115 (SYMPOSIUM)

IMPLEMENTATION OF LOW VISION INTERVENTIONS FOR OLDER ADULTS: CHALLENGES AND REWARDS
Chair: G. Zijlstra, Maastricht University, CAPHRI School for Public Health and Primary Care, Maastricht, Netherlands
Co-Chair: V. Cimarolli, Jewish Home Lifecare, Research Institute on Aging, New York, New York
Discussant: A. Horowitz, Fordham University, Graduate School of Social Service, New York, New York

Low vision is a common age-related chronic condition associated with increased functional disability, depression, loneliness, mobility problems, falls, mortality risk, and reduced quality of life. Vision rehabilitation centers offer services for older people with low vision that focus on improving vision-related functioning to promote independence and psychosocial well-being. However, there is a lack of research documenting development and implementation issues (e.g., enrolment challenges) of such interventions as well as their potential effectiveness in alleviating the negative effects of vision loss. The aim of the symposium is to present new data - from studies conducted in the US, Germany, and the Netherlands - on the development and/or evaluation of low vision interventions targeting older adults in various settings and to discuss implementation challenges and rewards. First, data on the impact of vision loss on physical rehabilitation use and outcomes in elderly sub-acute care patients along with implications for the design of low vision interventions will be presented. The second paper will focus on the outcomes of a qualitative process evaluation discussing implementation challenges of a psychosocial consultation program. The third presenter will report on a RCT that tested the acceptability of identification cane training by partially-sighted older adults and their mobility instructors. The final two presentations will give results from two problem-solving therapy trials focusing on their implementation challenges and efficacy in reducing depression and improving vision function. Our discussant will facilitate a discussion on-site.

THE IMPACT OF VISION LOSS ON SUB-ACUTE REHABILITATION USE AND OUTCOMES: INTERVENTION OPPORTUNITIES

This study investigated the effects of vision impairment on occupational therapy utilization and outcomes of 100 elders receiving sub-acute rehabilitation in a nursing home setting. Understanding vision loss in this context is important to ensure effective use of physical rehabilitation and to achieve optimal patient outcomes. We assessed both subjective (self-rated difficulties in performing activities of daily living) and objective (visual acuity and contrast sensitivity) vision impairment impact. Regression analyses indicate that controlling for socio-demographic, health, and social support variables, decreased contrast sensitivity was a significant predictor of fewer occupational therapy minutes used and decreased visual acuity functioned as a significant predictor of higher functional dependency at discharge. Results underscore the importance of the development of low vision rehabilitation interventions that can be delivered in conjunction with traditional sub-acute physical rehabilitation. Specific intervention opportunities, such as low vision self-management programs will be discussed.

CHALLENGES OF A PSYCHOSOCIAL COUNSELLING PROGRAM FOR VISUALLY IMPAIRED ELDERLY: FINDINGS FROM QUALITATIVE PROCESS EVALUATION
I. Himmelsbach, F. Oswald, S. Driebold, F. Esch, K. Metzler, J. Nagel, 1. Interdisciplinary Ageing Research, Goethe University, Frankfurt, Germany, 2. Foundation for the Blind and Visually Impaired, Frankfurt, Germany, 3. Blindenstudienanstalt/German Institute for the Blind (blista), Marburg, Germany

Three aims are central for development and evaluation of this program: Understanding visual impairment as challenge for psychosocial counselling, replacing segmented interventions by an integrative concept and striving for permanent continuation of the program. The project encompasses two phases: Phase 1 (month 1-18) emphasizes concept development and qualitative evaluation, whereas phase 2 (month 19-36) focuses on quantitative outcome evaluation of the final concept. Conceptual and empirical findings of phase 1 are drawn from qualitative analyses of expert and client interviews, as well as counselling records and are presented on three levels: A) the central categories, e.g. vision and age specific contents of consultation, or the interrelation of potential needs versus subjective evaluation of the intervention from clients’ and experts’ perspectives. B) the final concept achieved by subsequent concept optimization based on the emerging categories. C) the set of outcome concepts and related quantitative measures for qualitative analyses in phase 2.

ACCEPTABILITY OF AN ORIENTATION AND MOBILITY TRAINING IN IDENTIFICATION CANE USE: OUTCOMES OF AN RCT
G. Zijlstra, J. Ballemans, G.I. Kempen, Maastricht University, CAPHRI School for Public Health and Primary Care, Maastricht, Netherlands

Vision rehabilitation services generally lack standardized intervention protocols and scientific knowledge about the effects of their services. In an RCT the effects and acceptability of a newly developed standardized orientation and mobility (O&M) training for identification cane use were compared to usual care, i.e. the regular training. Data on the acceptability was collected from 29 O&M-trainers and 68 partially-sighted older adults. Participants of the standardized training rated the overall training slightly higher than participants of the regular training; trainers of the standardized training were less positive about the overall training than their counterparts of the regular training. According to the trainers of both groups O&M-skills were only partly achieved in about 38% of the participants; about 52% of the participants of both groups reported that the trainings contributed to their mobility needs. The standardized O&M-training is feasible; yet, essential components of the standardized training were likely not or insufficiently applied.
OUTCOMES OF A DEPRESSION FOCUSED PROBLEM-SOLVING THERAPY TRIAL FOR OLDER ADULTS WITH VISION LOSS

Depression is a major health problem strongly associated with disability among older adults, and affecting about one-third of those with age-related vision loss. This study describes a randomized trial comparing Problem Solving Treatment (PST) to a Social Contact intervention for 42 visually impaired older adults with subthreshold or mild major depression. While recruitment was difficult, those who did participate in the therapy completed their treatment schedule, and had very positive feedback. Identified problems for elders in the PST group were related to issues in daily living likely made harder due to vision disability (socialization, household maintenance, transportation issues). Data on depression diagnosis and symptoms were collected at baseline, 11-weeks later (following intervention), and 3 months post intervention. Preliminary results showed a significant decrease in depressive symptoms over time in both groups. Recruitment challenges and solutions are discussed as well as issues relating to acceptance and adherence to the treatment program.

EFFECTIVENESS OF PROBLEM-SOLVING TREATMENT VERSUS SUPPORTIVE THERAPY IN IMPROVING VISION FUNCTION IN AMD
R. Casten, B.W. Rovner, B. Leiby. Thomas Jefferson University, Philadelphia, Pennsylvania

This randomized controlled trial tested the efficacy of Problem Solving Treatment to improve vision-related function in patients with AMD. Control subjects received Supportive Therapy (ST), an attention control treatment. Subjects were assessed at baseline and at 3 and 6 months (masked to treatment assignment). Both groups received 6 in-home treatment sessions. The primary outcome was Targeted Vision Function (TVF), which is the average difficulty rating of vision goals that are meaningful to subjects. The secondary outcomes were the NEI-VFQ subscale scores of: near activities, distance activities, social function, meaningful to subjects. The secondary outcomes were the NEI-VFQ subscale scores of: near activities, distance activities, social function, meaningful to subjects. Preliminary results showed a significant decrease in depressive symptoms over time in both groups. Recruitment challenges and solutions are discussed as well as issues relating to acceptance and adherence to the treatment program.

SESSION 1120 (SYMPOSIUM)

INTERSECTIONAL PERSPECTIVES ON AGE RELATIONS: RECENT RESEARCH AND CHALLENGES
Chair: C. Krekula, Dept of Social Studies, Karlstad University, Karlstad, Sweden
Co-Chair: N. King, Virginia Tech, Virginia, Virginia
Discussant: T. Calasanti, Virginia Tech, Virginia, Virginia

Globalisation and demands for equality have drawn attention to diversity in ageing; yet most conference presentations on global age relations have appeared in contexts that provided little sustained attention. The five papers in this symposium contribute a more thorough accounting of age relations. With comments by a discussant, they provide empirical support for compatible theories of intersections of inequities of age, class, and gender. Each identifies a research frontier and the challenges associated with the study of particular dimensions of age relations. Krekula’s research shows how policies of “gender mainstreaming” affect age relations. Nilsson’s analysis of self-reports of old rural men with no immediate family shows how codes of masculinity shape their old age and confrontations with death. King’s study of the discourse of gerontological Social Work shows how age relations structure applications of professional empowerment to women and men. Pietilä and Ojala’s study of male factory workers shows how codes of manhood also shape their approaches to medical care as they age. Finally, Clarke, Korotchenko, and Bennett’s study of chronically ill shows how gender and class intersect with age relations to shape strategies of self care. As a whole, these presentations demonstrate the variety of challenges facing intersectional research and the possibility of developing coherent theory from multiple studies.

DISCOURSES IN CONFLICT OR ACCORD? ON STRATEGIES FOR AGE AND/OR GENDER BASED EQUALITY
C. Krekula, Dept of Social Studies, Karlstad University, Karlstad, Sweden

Gender mainstreaming has been defined as a strategy which aims to bring about gender equality. The concept emphasizes that we must bear in mind the different consequences that legislation and action plans can have for women and men. Since the concept was first proposed in 1985, the vocabulary has been broadly adopted internationally. However, there are various levels of implementation and progress. In both the political and academic debates the differences are substantial, for example with respect to the formulation of goals and how other bases for inequality are addressed. In this paper, I discuss the strategy from an intersectional perspective by way of analysing how gender equality and age based equality interact. By referring to qualitative data I shed light on how different applications of gender mainstreaming can both maintain and challenge asymmetrical age relations. In so doing, theoretical tensions and research frameworks will be reconsidered.

AGEING AND MASCULINITY IN THE RURAL
M. Nilsson, Karlstad University, Karlstad, Sweden

The rural context has consequences for the ways that gender structures the lives of people throughout the life course, both materially and socially. Norms of masculinity remain strong in rural areas where there is less room for deviations than in urban areas. This is not least connected to the scarcity of meeting places, and above all to that of alternative spaces. Men in rural areas who have remained unmarried throughout their lives and live without a partner tend to live in the areas where they were born. The identity and ways of living of unmarried men is often tied to the places where they live, but it is also connected to notions of heterosexuality and coyness. In this paper I explore the ways that unmarried and childless older men talk about relationships and childlessness in relation to norms of masculinity and heterosexuality, notions of ageing, growing old and approaching death.

GERONTOLOGICAL “EMPOWERMENT” AND THE IMPUTATION OF ACTION TO OLD WOMEN AND MEN
N. King, Virginia Tech, Blacksburg, Virginia

To social gerontologists, “empowerment” appears to mean discrepancy and causal force, or the self-perception of having them. This research bears upon social gerontologists’ discussions, in their academic journals, of this concept and suggests what functions they serve for that professional group. The journal articles (from four mainstream journals in the field) studied here often urge that old people should enjoy greater empowerment, and that gerontologists should help to bring this about with their research and advocacy. This essay combines content analysis and constructivist theory to suggest why. It argues that those imputations of empowerment express affiliation with an oppressed group, affirm professionals’ entitlement to intervene on their behalves, and justify those interventions by framing them as the actions of clients.

ACTING AGE IN THE CONTEXT OF HEALTH
I. Pietiä, H. Ojala. 1. School of Health Sciences, University of Tampere, Tampere, Finland, 2. University of Tampere, School of Social Sciences and Humanities, Tampere, Finland

This paper focuses on the intersections of age, gender and class in interpretations of the aging of middle-aged working-class men. It is
based on interview data in which Finnish industrial workers are interviewed about health. Based on the theoretical implications of intersectionality, the paper provides an empirical analysis of how categorizations of age and conceptualizations of aging are tightly interwoven with gender and class in interviews. The middle-aged interviewees base their interpretations of the aging self on negotiating their position between the categories of the ‘young’ and ‘old’. Both these groups are labeled with rather negative characteristics regarding the irresponsibility for health among the young and impaired functional ability of the old, which conflicts with the working-class expectations regarding masculinity and femininity. The findings suggest that studying how people ‘act age’ requires consideration of the respects in which aging is an age-specific and gendered process shaped by class-based values and ideals.

‘THE DOCTORS CAN ONLY DO SO MUCH, THE REST IS UP TO YOU’: SELF CARE STRATEGIES AMONG OLDER ADULTS WITH MULTIPLE CHRONIC CONDITIONS
L.C. Hurd Clarke, A. Korotchenko, E.V. Bennett, School of Human Kinetics, University of British Columbia, Vancouver, British Columbia, Canada

The majority of older adults will experience at least one chronic condition in later life and the average number of chronic conditions has been found to increase with age. This paper focuses on the self-care strategies employed by 35 older adults (aged 75+) who had a range of three to 14 chronic conditions (average of six). The analysis of our data revealed four broad categories of self-care: a) adherence to medical interventions (including conventional and alternative medicine); b) care of the body through diet, exercise, rest/sleep, and appearance work; c) engagement or non-engagement with social and community support resources; and d) use of psychological and spiritual strategies. We discuss the gendered and social class patterns among the self-care strategies employed by our participants in light of the literature on age relations, gender, and help-seeking behaviour as well as in terms of extant social discourses pertaining to healthism and health promotion.

SESSION 1125 (SYMPOSIUM)

PREVALENCE OF LIFESTYLE BEHAVIORS IN OLDER ADULTS WITH CANCER
Chair: T. Cadet, Simmons College, Boston, Massachusetts
Co-Chair: K. Bellizzi, University of Connecticut, Storrs, Connecticut
Discussant: H.I. Cohen, Duke University, Durham, North Carolina

Understanding lifestyle behaviors among older adults with cancer is a critical step to develop and target interventions aimed at decreasing morbidity, mortality, and improving quality of life in this rapidly growing population. This symposium, co-sponsored by the Research on Cancer and Aging Interest Group and Emerging Scholars and Professional Organization (ESPO) will examine the prevalence of cancer screening, exercise, diet, and smoking among older adults with cancer. Using data from the National Health Interview Survey, the first presentation will describe the high screening rates occurring in racially diverse adults over the age of 75, and the extent to which physicians are continuing to recommend screening to this group. The second presentation will explore these screening practices in more detail by examining patterns of utilization, factors associated with utilization, and the relationship between utilization and breast cancer outcomes from the Breast Cancer Treatment Effectiveness in Older Women study. The third presentation will focus on demographic antecedents and quality of life correlates of health promotion efforts with particular attention to the greater propensity of older women compared to older men to adopt positive lifestyle changes, such as exercise and healthy eating following a cancer diagnosis. The final presentation will examine smoking concordance among older lung and colorectal cancer survivors and their caregivers and its impact on mental and physical quality of life indicators using data from the Cancer Care Outcomes and Research Surveil-

The Gerontological Society of America

STILL SCREENING AFTER ALL THESE YEARS: PREVALENCE OF CANCER SCREENING IN OLDER RACIALLY DIVERSE ADULTS
K. Bellizzi, E. Breslau, H.I. Cohen, Duke University, Durham, North Carolina
National Cancer Institute, Bethesda, Maryland

While early detection of cancer through screening programs has led to a substantial decline in mortality and morbidity in the population, less attention has been given to segments of the population where screening may not be appropriate, such as older adults with limited life expectancy. Data were analyzed from the 2005 and 2008 National Health Interview Survey. Screening behaviors were examined according to the United States Preventive Services Task Force recommendations for breast, cervical, colorectal and prostate cancer screening. Among adults aged 75-79, the percentage screened was colorectal (57%), breast (62%) cervical (53%) and prostate cancer (56%). Among the 80 plus age group, rates of screening ranged from a low of 38% for cervical cancer screening to a high of 50% for breast cancer screening. Over 50% physicians continue to recommend screening to adults over the age of 75 despite the ambiguity of recommendations for this group.

MAMMOGRAPHY SCREENING AMONG OLDER BREAST CANCER SURVIVORS
R.A. Silliman, T. Field, T. Lash, M. Fox, 1. Boston University Medical Center, Boston, Massachusetts, 2. University of Massachusetts Medical School, Worcester, Massachusetts

Breast cancer survivors are at risk for recurrence and second primaries in the contralateral breast. Although surveillance mammography is known to be underused, factors associated with underuse are poorly understood. Further, although there are no clinical trial data that demonstrate its effectiveness in relation to breast cancer mortality, annual surveillance mammography is recommended. Taking advantage of a cohort study of 1859 older women (65+) diagnosed with stage I or II breast cancer in six integrated health care delivery systems, we ascertained patient and health care system factors associated with surveillance mammography use and estimated the effect of surveillance mammograms on the rate of breast cancer mortality. Women at higher risk of recurrence were less likely to receive annual mammograms while those with visits to either breast cancer surgeons or oncologists were more likely. Each additional surveillance mammography was associated with a decrease in the odds of breast cancer mortality.

SELF-CARE AND HEALTHY LIFESTYLES IN A COMMUNITY SAMPLE OF ELDERLY CANCER SURVIVORS
E. Kahana, B. Kahana, D. Kulle, J. Li, L. Lovegreen, J. Brown, 1. Case Western Reserve University, Cleveland, Ohio, 2. Cleveland State University, Cleveland, Ohio

This study explored self care and adoption of healthy lifestyle behaviors among 174 community dwelling cancer survivors (mean age 80.6). Self care activities included seeking health information primarily through print media (36.8%). Patient initiative was also considered in terms of use of non-traditional treatments and enrollment in clinical trials. Only a small minority utilized alternative care, or clinical trials. Patients reported strong physician support for non-traditional treatments. Psycho-social interventions, including Internet based support groups or mental health services, were infrequently relied on. Engaging in healthy lifestyle behaviors was a more frequent adaptation in this group. Among those not already committed to smoking avoidance, healthy diets and exercise prior to cancer diagnosis, nearly one out of five began healthy practices after diagnosis. Women were significantly more likely than men to start exercise and healthy diets. Findings underscore the will-

CANCER PATIENT-CAREGIVER DYADS AND QUALITY OF LIFE: MENTAL HEALTH GOING DOWN IN SMOKE?
J. Rowland, Division of Cancer Control and Population Sciences, National Cancer Institute, Bethesda, Maryland

Cancer poses enormous stress not only on the patient diagnosed, but also on his or her caregiver. Distress may be heightened when members of this dyad are mismatched on smoking status (one smokes, but the other does not). Smoking concordance and patient and caregiver mental and physical quality of life were analyzed in a large sample of lung and colorectal patient-caregiver dyads (N = 472) drawn from the national multi-site Cancer Care Outcomes Research and Surveillance (CanCORS) and the CanCORS Caregiver studies; the majority of the cancer patients were older than 65 (53.1%). While dyad smoking was less strongly associated with physical well-being, smoking by one or both members of the dyad was associated with worse mental health than for members of non-smoking dyads. Results highlight the importance of assessing smoking in both cancer patients and their caregivers and referring to appropriate smoking cessation and psychosocial services as needed.

SESSION 1130 (SYMPOSIUM)

SUICIDE IN LATE LIFE: PROXIMAL AND DISTAL RISK FACTORS
Chair: J.J. Gregg, Psychology, West Virginia University, Morgantown, West Virginia
Co-Chair: P. Bamonti, Psychology, West Virginia University, Morgantown, West Virginia
Discussant: Y. Conwell, University of Rochester School of Medicine, Rochester, New York

Although older adults (ages 65+) only comprise 12.6% of the general population, they account for 15.7% of all suicides (American Association of Suicidology, 2010). The objective of this symposium is to highlight cutting edge research on proximal and distal risk factors of suicide in late life using innovative methodologies and analytic strategies. The first portion of the presentations will examine the applicability of the Interpersonal Theory of Suicide to older adults. According to this theory, both thwarted belongingness and perceived burdensomeness are predictors of suicidal behavior (Joiner, 2005; Van Orden et al., 2010). First, Dr. Kim Van Orden will present a study examining the relation between perceived burdensomeness, thwarted belongingness, and death by suicide in older adults utilizing a psychological autopsy study. Next, Meghan Marty will present research on the validity of a measure of perceived burdensomeness and thwarted belongingness among community dwelling older adults. Dr. Alisa O’Riley will then examine the relation between personality traits, familial distress, and perceived burdensomeness in treatment seeking older adults. This symposium will also address other potential risk factors for suicidal behavior. Sarra Nazem will present research using survival analysis in a population-based sample evaluating headache as a risk factor for death by suicide. Lastly, Dr. Mark Kaplan will present research using a national sample to examine differences in method of suicide in older adult males. This symposium will increase awareness of important factors associated with suicide in late life that have implications for future research, assessment, and practice.
association between headaches and suicide. The present study examined the relation between headaches and suicide in the population-based Swedish Twin Registry. Participants included 42,928 individuals who responded to a mailed questionnaire in 1967 or 1973. Poisson regression was used to estimate risk of suicide associated with headache over a period of up to 36 years. The relation between headaches and suicide was moderated by gender, \( \chi^2(1) = 9.01, p < .01 \); women who experienced headaches were twice as likely to die by suicide as women who did not experience headaches, IRR: 2.01 (95% CI 1.22, 3.31). Headaches were not associated with increased risk for suicide in men, IRR: 0.62 (95% CI 0.34, 1.15). Findings support the conclusion that headaches are associated with suicide in women but not in men.

**CHARACTERISTICS OF OLDER MALE SUICIDE DECEDENTS USING DIFFERENT METHODS**

M.S. Kaplan¹, B. McFarland², N. Huguet¹. 1. Portland State University, Portland, Oregon. 2. Oregon Health & Science University, Portland, Oregon

Suicide is a leading cause of death in older adulthood, and most older men who die of suicide do so with firearms. This paper examines the differences in characteristics of older male suicide decedents using different suicide methods. Data were obtained from the 2003 to 2008 National Violent Death Reporting System restricted access database. Using logistic regression, a model was developed to differentiate older male suicide decedents who used firearms (n = 4290) from those who used other suicide methods (n = 1067). The results show that the presence of a health problem at the time of death was one of the best predictors of firearm suicide. Place of suicide and veteran status further increased likelihood of firearm use. Suicides occurring in mostly rural counties and in the South were significantly more likely to involve firearms. We conclude with a discussion of the implications for suicide researchers, clinicians, and policymakers.

**SESSION 1135 (SYMPOSIUM)**

**BODY COMPOSITION AND HIP FRACTURE**

Chair: D. Alley, University of Maryland, Baltimore, Maryland
Co-Chair: D. Orwig, University of Maryland, Baltimore, Maryland
Discussant: D.P. Kiel, Hebrew SeniorLife, Boston, Massachusetts

The relationships between body composition and hip fracture are complex: both fat and lean mass may be related to risk of fracture and to fracture recovery, but hip fracture also affects body composition. Additionally, secular trends in obesity have resulted in large shifts in the body composition of recent cohorts of older adults, and it is unknown how these changes are related to risk of fracture or the characteristics of hip fracture patients. The presentations in this symposium address important aspects of the association between fat, muscle, and bone in influencing the risk of hip fracture and the process of hip fracture recovery. Lloyd and colleagues examine the association between body mass index (BMI) and bone mineral density in a recent sample of older adults, allowing for a re-examination of this relationship in an era of widespread obesity. Yerges and colleagues document an increase in BMI allowing for a re-examination of this relationship in an era of widespread obesity. Yerges and colleagues document an increase in BMI

**SHORT-TERM CHANGES IN BODY COMPOSITION AFTER HIP FRACTURE**

C. D’Adamo¹, W. Hawkes¹, R.R. Miller¹, M. Hochberg¹, J. Yu-Yahiro², J. Magaziner¹. 1. University of Maryland School of Medicine, Baltimore, Maryland. 2. Union Memorial Hospital, Baltimore, Maryland

Deleterious changes in body composition contribute to the persistent decline in physical function during the year after hip fracture. However, little is known about short-term changes in post-fracture body composition as no studies have examined changes prior to two-month follow-up visits. Thus, the goal of this study was to determine whether short-term changes in body composition occur after hip fracture. Measures of body composition (total body mass, lean body mass, fat mass, and hip bone mineral density) were assessed at 3 day, 10 day, and 2 month post-fracture visits in 155 female hip fracture patients from the third cohort of the Baltimore Hip Studies. Longitudinal analysis of post-fracture body composition was conducted using mixed models. Decreases in total body and lean mass were shown to occur from 3 to 10 days (p < 0.05), reflecting the need for increased vigilance and therapeutic intervention shortly after hip fracture.

**LEAN MASS AND THE RISK OF HIP FRACTURE IN OLDER ADULTS: THE FRAMINGHAM STUDY**

R.R. McLean¹,¹, M.T. Hannan¹,², S.D. Berry¹,¹, K. Broe¹, X. Zhang¹, L. Cupples¹, D.P. Kiel¹,². 1. Hebrew SeniorLife Institute for Aging Research, Boston, Massachusetts. 2. Harvard Medical School, Boston, Massachusetts. 3. Boston University School of Public Health Biostatistics Dept, Boston, Massachusetts

Reduced muscle mass is associated with poor functioning in older adults, yet little is known on its relation with hip fracture. We examined whether baseline leg and total lean mass, measured via DXA, predicted hip fracture risk among elderly men and women of the Framingham Heart Study, hypothesizing that lower lean mass is associated with higher hip fracture risk. The 306 men and 541 women (mean age 78 yrs at baseline) experienced 20 and 74 hip fractures, respectively, over a median follow-up of 9.8 yrs. While lean mass did not predict hip fracture risk among men, in women each kg increase in leg and total lean mass was associated with a 30% and 13% increased risk for hip fracture, respectively (Ps<0.01). Our unexpected findings in older women may reflect that those with greater lean mass are more active and thus have a greater opportunity to fall and fracture.

**BODY MASS INDEX AND BONE MINERAL DENSITY IN ADULTS OVER 50: RESULTS FROM NHANES 2005-2008**

J. Lloyd¹, D. Alley¹, W. Hawkes¹, S.R. Waldstein¹, M. Hochberg¹, D. Orwig¹. 1. Epidemiology and Preventive Medicine/Gerontology, University of Maryland, Baltimore, Maryland. 2. University of Maryland, Baltimore County, Baltimore, Maryland

Although previous studies have reported a positive relationship between body mass index (BMI) and bone mineral density (BMD), this relationship hasn’t been examined in more recent cohorts. Using data from the National Health and Nutrition Examination Survey (2005-2008), we examined the association between BMI and low BMD and osteoporosis (defined as ≥1 SD and ≥2.5 SD below young, sex-specific mean, respectively). There were 3,801 adults ≥50 years (mean 63 years), predominately female (51.75%), white (83.52%), and overweight or obese (72%), with a mean femoral neck BMD of 0.78 gm/cm² (SD=0.14). Both overweight and obese persons had significantly lower odds of low BMD (OR=0.21, CI: 0.13-0.34; and OR=0.10, 95% CI: 0.05, 0.22, respectively) and osteoporosis (OR=0.19, 95% CI: 0.08, 0.44; and OR=0.21, 95% CI: 0.08, 0.59, respectively). Gender and race were not significant effect modifiers. Results demonstrate the strong positive association between BMI and BMD, consistent with prior research.
TRENDS IN BODY MASS INDEX AMONG HIP FRACTURE CASES: DATA FROM THE BALTIMORE HIP STUDIES
L. Yerges-Armstrong, D. Alley, J. Lloyd, W. Hawkes, D. Orwig, J. Magaziner, University of Maryland, Baltimore, Maryland

The prevalence of overweight and obesity is rising among older Americans, but less is known about trends among individuals who fracture. We utilized data from the Baltimore Hip Studies (BHS), a series of prospective cohort studies of hip fracture outcomes in older community-dwelling participants from the Baltimore area, to compare body mass index (BMI) at the time of hospitalization for hip fracture in three BHS cohorts with similar eligibility criteria. For women, the average BMI was 22.1 for the cohort initiating enrollment in 1990, 22.7 for the cohort initiated in 1992 and 25.0 for the cohort initiated in 2006. For men, data were only available in two cohorts (1990 and 2006). The average BMI was 23.4 for men in the cohort initiated in 1990 compared to 25.4 for men in the 2006 cohort. These observations could indicate that the archetype of the “thin, frail” hip fracture patient may be changing.

SARCOPENIA AND FUNCTIONAL RECOVERY AFTER A HIP FRACTURE
N. Chiles, D. Alley, W. Hawkes, D. Orwig, University of Maryland, Baltimore, Baltimore, Maryland

Adequate muscle mass may be important in hip fracture recovery. This study assessed the impact of sarcopenia 2 months after a hip fracture on physical performance 6 months post-fracture. Data from 109 female patients admitted to two Baltimore-area hospitals from 1992-1995 were analyzed. Sarcopenia classification was based on DXA-measured appendicular lean mass normalized for height and coded according to Baumgartner’s definition (≤5.45kg/m² for women). Physical performance was measured by the Lower Extremity Gain Scale (LEGS, range: 0-36). Only 62 participants (56.9%) were sarcopenic at 2 months post-fracture. Mean LEGS score at 6 months was 23.7 (SD 8.3). There was little association between sarcopenia at 2 months and physical performance 6 months post-fracture. Our findings indicate that sarcopenia may not be predictive of functional recovery after hip fracture.

SESSION 1140 (SYMPOSIUM)

BUILDING ACADEMIC GERIATRIC NURSING CAPACITY ALUMNI RESEARCH: EXPANDING THE LIFESPAN FOR DIVERSE POPULATIONS
Chair: C.E. Rogers, Arizona State University, Mesa, Arizona
Discussant: C.E. Rogers, Arizona State University, Mesa, Arizona

Because the lifespan of older adults is predicted to increase in the next 20 years both in number and diversity, changes that accompany aging are expected to be hallmarked by an anticipated 20% increase in older adults with disabilities. Given these predicted changes, the need for empirical testing and application of culturally relevant, theory based research to promote healthy lifestyle behaviors targeting disability reduction is critical. The purpose of this symposium is to report the findings of theory based research in promoting healthy behaviors for older adults in different settings. The objectives are to report a) culturally relevant influences on healthy behaviors, b) barriers to participating in healthy behaviors for specific populations of older adults, c) findings from effective, theory based intervention research, and d) a discussion of how these approaches advance the science for improving health outcomes for older adults across the lifespan. Approaches to improving health outcomes in older adults will overarch the framework of this symposium with 4 research reports. Rogers et al. discusses the relationship between positive spiritual beliefs and healthy behaviors for older adults using a model of healthy aging. Chu reports how post-immigration lifestyle changes increase the risk for chronic disease among Vietnamese American older adults; Purath reports the effect of a theory driven primary care intervention on increasing physical function among sedentary older adults, and Yao describes the application of a Positive Emotion Motivated Tai Chi model to improve health outcomes using a dyadic approach for caregivers and patients with Alzheimer’s disease.

BENEFITS FOR DEMENTIA CAREGIVERS PARTICIPATING IN A CAREGIVER-ASSISTED TAI CHI INTERVENTION

This presentation reports the benefits of a Caregiver-Assisted Tai Chi (CATC) fall risks reduction program on participating caregivers. CATC is a dyadic approach in which a person with Alzheimer’s disease (AD) undergoes an adapted Tai Chi exercise program together with his/her family caregiver, with a goal to enhance AD participation and adherence. Caregiver outcomes were measured using Timed Up and Go (TUG), unipedal stance time (UST), CES-D and Zarit Burden Scale. Linear Mixed Model analyses showed improvement in TUG (p<.002) and UST (p<.007)post-intervention, controlling for age. These improvements are more obvious than improvements accrued in AD patients (p<.001). CES-D 10 and ZBS were correlated (rsbaseline=0.84; r4 week=0.76; r16 week=0.82; p<0.0001) and reductions in both scores were observed from baseline to post-intervention (NS, p>.05). The CATC approach may be a practical model in improving health and quality of life for both the AD and their family caregivers.

USE OF A THEORY-DRIVEN INTERVENTION TO INCREASE PHYSICAL ACTIVITY AND FITNESS IN OLDER ADULTS
J. Purath1, C. Keller2, 1. College of Nursing, Washington State University, Spokane, Washington, 2. Arizona State University, Phoenix, Arizona

This paper describes results of a randomized controlled trial to promote physical activity (PA) among 72 community-dwelling older adults. The theory-driven primary care intervention uses physical fitness test results as a basis for mutual goal-setting to increase PA and improve physical fitness. We hypothesized that intervention participants will significantly 1) increase PA and fitness and 2) increase self-efficacy and decrease barriers for physical activity. Intervention participants increased weekly frequency of PA (p<3.2; p<0.05) and improved upper (F=4.03; p<0.05) and lower body strength (F=4.34; p<0.05). Moderate PA, and other fitness outcomes were not significantly improved. Barriers and self-efficacy did not mediate PA or fitness. Income and education moderated PA.

SPIRITUAL BELIEFS ACROSS THE LIFESPAN AND HEALTHY LIFESTYLE BEHAVIORS
C.E. Rogers, C. Keller, L.K. Larkey, Arizona State University, Mesa, Arizona

Rowe and Kahns’ revised model of healthy aging was used to explore the relationship between spiritual beliefs and healthy behaviors for older adults. To advance this theory, a synthesis of the literature was completed to evaluate the strength of the research reporting the the antecedents and consequences of positive spiritual beliefs among older adults. Antecedents to positive spiritual beliefs include previous religious/spiritual experiences, gender, cultural beliefs, onset of illness, and loss of family and friends. Consequences of positive spirituality include better psychological outcomes, adapting to loss and chronic disease, and participating in healthy behaviors. Spiritual beliefs increased with age across demographics (gender and cultural, racial, and ethnic groups) and were associated with health outcomes for older adults. Findings from this synthesis provide evidence that interventions designed to promote positive spirituality while increasing healthy lifestyle behaviors may reduce the risk of chronic disease for older adults regardless of demographic background.
LIFESTYLE CHANGES THAT IMPACT HEALTH STATUS OF VIETNAMESE AMERICAN ELDERS IN THE 21ST CENTURY

N. Chu, University of OklahomaHSC College of Nursing, Oklahoma City, Oklahoma

Minorities were roughly 1/3 of the U.S. population in 2008 and are expected to become the majority by mid 21st century. There is a growing need for health professionals to provide cross-cultural care to very diverse populations. This presentation focuses on lifestyle changes among Vietnamese American elders and recommendations to achieve healthy aging. An ethnographic study of N=57 participants (27 elders ages 60 and over, 11 middle aged adults and 19 community leaders and providers) focused on the health needs of Vietnamese elders in a mid-sized U.S. city. The study was guided by the Andersen and Newman utilization framework. The interview data revealed the elders were at risk for one or more chronic conditions. Common lifestyle changes after arrival in America included a sedentary lifestyle, consuming more meat and fatty diets. Language barriers, low health literacy, and lack of transportation were major barriers to access preventive and health services.

SESSION 1145 (SYMPOSIUM)

FAMILIES HIGHLY CLUSTERED FOR EXCEPTIONAL LONGEVITY: THE LONG LIFE FAMILY STUDY

Chair: T.T. Perls, Medicine & Geriatrics, Boston University School of Medicine, Boston, Massachusetts

Discussant: W. Rossi, National Institute on Aging, Bethesda, Maryland

The Long Life Family Study (LLFS) is a National Institute on Aging-funded effort to determine non-genetic and genetic factors that predispose members of long lived families to exceptional survival. As the LLFS prepares for its genetic studies, its investigators have been investigating numerous phenotypic features of its 539 families and 4,953 family members and offspring spousal controls. The LLFS subjects are linked to their records in US Censuses of 1910, 1920 or 1930. Preliminary analysis of these data indicate that farm background, living in a two-parent household, and having immigrant parents predict survival to advanced age. The Danish component of the LLFS is accessing the Danish government’s vital and health statistics and cancer registries to study cancer rates amongst LLFS subjects and population-based controls. Telomere length plays key roles in both aging and cancer and in a third study we find that telomere length predictably declines with age and might also be a biomarker of healthy aging. In a fourth study, a healthy aging index consisting of pulse pressure, forced vital capacity, creatinine, mini-mental status, and fasting glucose demonstrated a heritability of 0.57. In our fifth study, LLFS probands have been noted to have disease free survival that is comparable to a centenarian sample and participants of the LLFS not only have lower disease prevalence but they also delay the age of onset to very old ages.

HEALTH-SPAN IN PARTICIPANTS OF THE LLFS

T.T. Perls1, P. Sebastian2, N. Solovief2, 1. Medicine & Geriatrics, Boston University School of Medicine, Boston, Massachusetts, 2. Boston University School of Public Health, Boston, Massachusetts

The Long Life Family Study (LLFS) is an international study that recruited 547 families who have several members reaching very old ages. An initial description of health and functions of family members showed that the prevalence of several age-related disease in probands and their siblings tend to be less common than in other cohorts as the Framingham Heart Study (FHS), and is comparable to the New England Centenarian Study (NECS). We expand this analysis to describe the distribution of disease free survival of LLFS participants that include the first completed follow up, and we compare it to disease free survival of subjects from the NECS and the FHS. The analysis shows that LLFS probands have disease free survival that is comparable to centenarians from the NECS for several age-related disease and suggests that participants of the LLFS not only have lower disease prevalence but also delay their onset to very old ages.

EARLY LIFE PREDICTORS OF SURVIVAL TO EXTREME OLD AGE IN THE LONG LIFE FAMILY STUDY

As evidence regarding effects of early life conditions on adult health has mounted, increased attention is being paid to the cumulative influence of social origins on health throughout the life course. Early environment, including parents’ socioeconomic status, family composition, and farm residence, have exhibited significant associations with health and mortality in later life. This paper investigates whether child- hood social and economic circumstances predict survival to age 85+ in the Long Life Family Study. The LLFS subjects are linked to their records in US Censuses of 1910, 1920 or 1930. A control group, matched on age, race, and state of residence, is drawn from Census Public Use samples for the same censuses. Comparable early life characteristics are available from the census files for both LLFS subjects and the controls. Our preliminary results indicate that farm background, living in a two-parent household, and having immigrant parents predict survival to an advanced age.

TELOMERE SHORTENING IN A BIGENERATIONAL COHORT

L.S. Honig1, M. Kang2, T. LLFS Study Group2, 1. Taub Institute/ Sergievsky Ctr, Columbia University, New York, New York, 2. Washington University School of Medicine, St. Louis, Missouri

Chromosomal telomeres shorten with successive cell division. Shorter telomere length (TL) in leukocyte DNA is associated with biological aging: it has been reported to be associated with mortality and with disorders of aging including dementia. We are analyzing TL in the LLFS study, a cohort of 4,953 persons from the Northeastern USA and Denmark, which includes 539 persons with exceptional longevity (>90 years) and their children. We find that in this cohort, there is no significant difference, using regression analysis in mean TL between men and women, or in spread of TL (variance as percentage of the mean), in different age strata. But across the sample, TL is ~8% shorter for each additional year of age. TL may be a biomarker of biological age, and the family based structure of the LLFS study should through use of genetic analyses, allow detection of human genetic determinants of variations in TL.

CANCER AND LONGEVITY – IS THERE A TRADE-OFF? CANCER OCCURRENCE IN LONG LIVED FAMILIES IN DENMARK

K. Christensen, Danish Aging Research Center, University of Southern Denmark, Odense C, Denmark

Animal models have suggested a complex interaction between cancer risk and longevity indicating a trade-off where low cancer risk is associated with accelerating aging phenotypes and, vice versa, that longevity potential comes with the cost of increased cancer risk. The data for humans are sparse and conflicting. Here we study 76 Danish families (1268 individuals) in the Long Life Family Study (LLFS) and similar Danish families identified through population register searches – a total of 10,139 individuals. The hypothesis is that longevity is positively associated with cancer risk in offspring and siblings of long-lived individuals compared to their spouses and the background population. Cancer diagnosed in Denmark since 1943 is available through the Danish Cancer Registry. If longevity is positively associated with cancer risk in first degree relatives, this would help explain the low
HERITABILITY OF A HEALTHY AGING INDEX IN THE LONG LIFE FAMILY STUDY

Epidemiology and Division of Geriatric Medicine, University of Pittsburgh, Graduate School of Public Health and School of Medicine, Pittsburgh, Pennsylvania. 2. University of Pittsburgh, Graduate School of Public Health, Pittsburgh, Pennsylvania

Longevity is characterized by better health at younger ages. Health is challenging to assess across generations, since most middle-aged adults are free of disease or disability. The Long Life Family Study (LLFS) assessed health in long-lived sibships (n=1453, mean age 90.5) and their adult children (n=2411, mean age 60.5). We constructed a healthy aging index using multiple physiologic measures. Based on a previously published index, pulse pressure, forced vital capacity, creatinine, mini-mental status, and fasting glucose were scored as 0, 1, or 2 using approximate tertiles. Scores were summed from 0-10. Initial heritability was 0.2, but rose to 0.57 with optimization of weights (which weighted glucose higher than other traits). These findings support further evaluation of the genetic and environmental factors contributing to this phenotype of healthy aging.

SESSION 1150 (SYMPOSIUM)

NEW DYNAMICS OF NUTRITION

Chair. A. Walker, Sociological Studies, University of Sheffield, Sheffield, United Kingdom

The complex relationship between nutrition and ageing requires increased understanding of the individual, social and environmental contexts in which people live. Multidisciplinary approaches to nutrition and ageing provide a means of exploring key issues and developing new tools and models for intervening to prevent malnutrition and related conditions, such as sarcopenia, obesity, and frailty, to improve the lives of older people. This symposium presents three projects illustrating multidisciplinary approaches across different aspects of nutrition in the lives of older people: migration and transnational nutrition, malnutrition in hospitals and developing new ways to measure nutritional status. These projects are part of the New Dynamics of Ageing Programme, a UK-based research initiative bringing together researchers from diverse disciplines to develop practical policy and implementation guidance and novel scientific, technological and design responses to improve quality of life as people age. The MINA project is addressing ageing, migration, and nutrition across two generations of Bangladeshi women who are socially disadvantaged, have poorer health status, and face complex challenges of ageing, poverty, racism, and social exclusion. Mappmal is developing a novel prototype for a new food provision service for vulnerable older hospital patients that considers all stages of the food journey, from production to consumption (i.e. products, people, places and procedures). The NANA project is developing novel technology to provide holistic assessment of nutritional status along with cognition, physical function and mental health. The focus of the symposium is on describing experiences of multidisciplinary approaches and their implications for research, practice and policy.

MIGRATION, NUTRITION AND AGEING ACROSS THE LIFECOURSE IN BANGLADESHI FAMILIES: PROJECT MINA

J.L. Thompson, J. Merrell, B. Bogin, M. Heinrich, P. Meier, V. Garaj; 1. Centre for Exercise, Nutrition and Health Sciences, University of Bristol, Bristol, United Kingdom, 2. Swansea University, Swansea, United Kingdom, 3. Loughborough University, Loughborough, United Kingdom, 4. University of London School of Pharmacy, London, United Kingdom, 5. University of Sheffield, Sheffield, United Kingdom, 6. Brunel University, London, United Kingdom

UK Bangladeshi experience substantially poorer health than the general population. The impact of migration on food-related behaviors, ageing, health, functional status, inter-generational and transnational social networks and exchange of foods and nutrition information is not well understood in Bangladeshi women. This presentation will include results from a mixed methods study of Migration, Nutrition and Ageing Across the Lifecourse in Bangladeshi Families (MINA); participants included 37 Bangladeshi women (aged 45+) who migrated to the UK, 37 of their adult daughters (aged 18-35) and 22 mother-daughter pairs of similar age living in Bangladesh. UK mothers and daughters were more obese and less likely to follow the cooking practices of their mothers than women in Bangladesh. UK mothers had lower physical function than Bangladeshi mothers. All groups consumed below current recommendations for fruit and vegetables. Social support differed transnationally and between generations, and frequent transnational exchange of nutrition information and foods was identified.

MAPPMAL: MULTIDISCIPLINARY APPROACH TO DEVELOP A PROTOTYPE FOR THE PREVENTION OF MALNUTRITION IN OLDER PEOPLE

P. Moynihan, Institute for Ageing and Health, Newcastle University, Newcastle, United Kingdom

Approximately 60% of older people are at risk of malnutrition whilst in hospital, increasing complications and reducing quality of life. The objective of the ‘mappmal’ project is to design a new service prototype for food provision for older people in hospital with the long term aim of preventing malnutrition. A comprehensive ethnographic study of current practice with respect to hospital food provision for older patients informed a series of key service principles and concepts for food provision, from which the new service prototype is being designed in a user participative study. mappmal is engaging with key end users (food providers, caterers, dietitians, nurses, doctors, occupational therapists, speech therapists, carers, older people) at all stages of development of the new prototype by conducting workshops, focus groups and interviews. This will inform on the feasibility and acceptability of the new system, its workability and potential integration in real life.

NANA: NOVEL ASSESSMENT OF NUTRITION AND AGEING

A.J. Astell, T.D. Adlam, F. Hwang, E.A. Williams; 1. Psychology, University of St. Andrews, St. Andrews, United Kingdom, 2. Bath Institute of Medical Engineering, Bath, United Kingdom, 3. University of Reading, Reading, United Kingdom, 4. University of Sheffield, Sheffield, United Kingdom

NANA is a three-year research project developing novel technology to improve data collection about nutritional status and integrate this with current information about physical function, cognitive function and mental health. The aim is to identify individuals at risk of under-nourishment and frailty and improve targeting of interventions by taking a holistic view of the person and the context in which they live. This multi-disciplinary program brings together skills and expertise in Psychology, Nutrition, Engineering and Human Computer interaction to improve measurement tools across nutrition, cognition, physical and mental health and increase understanding of the way these domains interact. The findings should inform strategies to prevent physical and
mental decline in aging and improve medical treatment and social provision for older people. NANA has potential for commercial development primarily for use with older people but also for use with other groups in the population that would benefit from comprehensive holistic assessment.

SESSION 1155 (SYMPOSIUM)

OPTIMIZING PHYSICAL ACTIVITY IN INSTITUTIONAL SETTINGS
Chair: E. Galik, University of Maryland, Baltimore, Maryland
Discussant: C.J. Brown, University of Alabama, Birmingham, Alabama

The majority of older adults, regardless of living situation or setting, do not meet public health guidelines for physical activity. The level of physical activity for those who are institutionalized is particularly low, and these individuals are often not even performing their own functional activities (e.g., bathing and dressing). Moreover, a decline in function over time is noted across all institutional settings with those in ALs declining at a rate similar to that found in nursing home samples. Moreover, the activity that is performed by these individuals is mainly of very low intensity and in a seated position. To identify the barriers and facilitators and optimize function and physical activity in these settings it is useful to consider a comprehensive social ecological approach. The social ecological approach considers intrapersonal, interpersonal, environmental and policy factors. Intrapersonal factors include the underlying physical status and capability of the individual, mood, pain, fear, apathy, motivation and resilience. Interpersonal factors include social supports and effective interventions are guided by social cognitive theory. Environmental factors consider the impact of the physical environment (e.g., are there clear and pleasant walking areas) and the fit between the person and the environment. Lastly, policy reflects the rules and regulations within the setting that can increase or decrease access to opportunities for physical activity and reinforce such activity. Using this theoretical framework, this session will address how to optimize physical activity across all these settings and among special populations such as those moderate to severe cognitive impairment.

SUCCESSFULLY INCREASING PHYSICAL ACTIVITY AND MAINTAINING FUNCTION IN ASSISTED LIVING SETTINGS USING A FUNCTION FOCUSED CARE PHILOSOPHY
B. Resnick, University of Maryland, Baltimore, Maryland

Function Focused Care in Assisted Living (FFC-AL) is theoretically based on a social ecological model and social cognitive theory and is implemented using four components: (I) Environment and Policy Assessments; (II) Education; (III) Developing Function Focused Goals; and (IV) Mentoring and Motivating. FFC-AL was tested in a randomized controlled trial including 171 residents and 96 direct care workers (DCWs) from four assisted living communities. Control sites were exposed to FFC-Education only. DCWs in treatment sites provided more FFC by 12 months than those in the control sites. Residents in treatment sites demonstrated less decline in function, a greater percentage returned to ambulatory status, and they spent more time in moderate level physical activity at 4 months and had more counts of activity at 12 months compared to residents in control sites. Using a function focused approach in AL prevents some of the persistent functional decline commonly noted in these settings.

INNOVATIVE APPROACHES TO INCREASING PHYSICAL ACTIVITY AMONG OLDER ADULTS WITH MODERATE TO SEVERE COGNITIVE IMPAIRMENT IN NURSING HOMES
E. Galik, B. Resnick, School of Nursing, University of Maryland, Ellicott City, Maryland

Nursing home (NH) residents with moderate to severe cognitive impairment are sedentary with limited opportunities to engage in physical and functional activities in part due to custodial care environments that focus on task completion during care activities. The purpose of this study was to explore and identify successful intervention strategies that facilitated a Function Focused Care approach among NH residents with moderate to severe cognitive impairment. A qualitative study using focus group methodology and case reports was utilized. A sample of 80 nursing assistants in 4 nursing homes were recruited into the study. Intervention strategies were merged in 5 different themes which included motivating communication, “knowing what makes the resident move,” magnified sensory stimulation, adapting environments to promote physical activity, and changing institutional policies to promote physical activity.

FUNCTION-FOCUSED CARE IN ACUTE CARE SETTINGS: IS IT VIALBLE FOR OLDER ADULTS?
M. Boltz, New York University College of Nursing, New York, New York

Functional decline is a common complication of hospital stays for older adults. A descriptive analysis of 162 medical patients age 70 and above in two urban settings showed that older adults did not return to baseline function at discharge. Physical activity (measured by actigraphy) and engagement in activities of daily living was very limited; however function-focused care interactions with nurses as well as current physical capability were associated with less decline in physical function. Furthermore, nurse perception of physical capability was congruent with the Physical Capability Scale (ICC 772, p= .0001). Findings suggest that the nurse plays a pivotal role in evaluating, planning and implementing intervention to prevent functional decline in hospitalized older adults.

SESSION 1160 (SYMPOSIUM)

THE ASSOCIATION OF RACIAL EXPERIENCES AND PERCEPTIONS WITH THE SENSE OF CONTROL, HEALTH OUTCOMES, AND NEIGHBORHOOD CHARACTERISTICS IN THE AFRICAN AMERICAN HEALTH (AAH) STUDY
Chair: F. Wolinsky, Health Management and Policy, University of Iowa, Iowa City, Iowa
Discussant: K.E. Whitfield, Duke University, Durham, North Carolina

At baseline, AAH included 998 men and women who were 49-65 years old, lived either in a poor inner-city area or the near northwest suburbs of St. Louis, Missouri. Identification of the cohort began with a complete enumeration of all housing units in the two target areas, followed by random multistage cluster sampling, resulting in a probability based sample fully representative of the two areas. The AAH participants have been shown to be substantially more socioeconomically and health disadvantaged than their counterparts interviewed at the same time in nationally representative studies. Other than age, inclusion criteria were self-reported black or African American race and MMSE scores > 16. Detailed baseline in-home evaluations were conducted in 2000-2001, with a 76% response rate. Brief telephone follow-up interviews were conducted at 1, 2, and 4 years post-baseline. At 3 years post-baseline, in-home evaluations were once again conducted. Detailed telephone follow-ups were conducted at 7 years post-baseline. At the 9-year follow-up in 2010, in-home evaluations were again conducted, and a rich battery of racial
experiences and perceptions were added to the protocol, including measures of school segregation during grades 1-12, racial consciousness, perceived discrimination, feeling responsible for the African American community, and resilience. This symposium showcases the important associations of those factors with the sense of control, blood pressure, peak expiratory flow, chair stands, normal gait speed, grip strength, balance, and neighborhood characteristics. Racial experiences and perceptions need to be considered to fully understand health outcomes and address health disparities in African Americans.

SCHOOL SEGREGATION AND THE SENSE OF CONTROL IN THE AFRICAN AMERICAN HEALTH COHORT: AN UNINTENDED CONSEQUENCE OF DESEGREGATION

F. Wolinsky\textsuperscript{1}, D.K. Miller\textsuperscript{2}, T. Malmstrom\textsuperscript{3}, P. Miller\textsuperscript{4}, E. Andresen\textsuperscript{5}, M. Schootman\textsuperscript{5}, 1. Health Management and Policy, University of Iowa, Iowa City, Iowa, 2. Indiana University, Indianapolis, Indiana, 3. Washington University, St. Louis, Missouri, 4. Saint Louis University, St. Louis, Missouri, 5. University of Florida, Gainesville, Florida

We examined the relationship between experiencing segregated schools during grades 1-12 and the current sense of control among the 566 AAH participants re-interviewed in 2010. We estimated the crude relationship using multiple linear regression, and serially adjusted for traditional covariates (age, gender, marital status, education, employment, income, and health), racial perceptions (racial consciousness, feeling responsible for the African American community, and perceived discrimination), and resilience. Propensity score re-weighting adjusted for potential attrition bias. After adjustment, experiencing segregated schools for at least half of grades 1-12 was associated with higher sense of control scores (standardized effect size = 0.285, p < 0.001). Attending desegregated schools was associated with lower sense of control scores, and not having been discriminated against or antagonized at school.

ASSOCIATIONS OF PERCEIVED DISCRIMINATION WITH BLOOD PRESSURE, PEAK FLOW, CHAIR STANDS, GAIT SPEED, GRIP STRENGTH, AND BALANCE IN THE AFRICAN AMERICAN HEALTH COHORT

D.K. Miller\textsuperscript{2}, T. Malmstrom\textsuperscript{3}, M. Schootman\textsuperscript{5}, E. Andresen\textsuperscript{5}, P. Miller\textsuperscript{4}, F. Wolinsky\textsuperscript{1}, 1. Health Management and Policy, University of Iowa, Iowa City, Iowa, 2. Indiana University, Indianapolis, Indiana, 3. Washington University, St. Louis, Missouri, 4. Saint Louis University, St. Louis, Missouri, 5. University of Florida, Gainesville, Florida

We examined the relationship between perceived discrimination and blood pressure, peak expiratory flow, chair stands, normal gait speed, grip strength, and balance among the 566 AAH participants re-interviewed in 2010. We estimated the relationships using multiple linear regression analyses, serially adjusted for demographic and economic factors, health status, psychological factors, and racial perceptions. Propensity score re-weighting adjusted for potential attrition bias. After adjustment for all of the covariates, participants reporting the highest (top 40\%) levels of perceived discrimination had statistically significantly higher systolic (5.82 mm Hg) and diastolic (3.89 mm Hg) blood pressure. They also had statistically significantly better balance, holding the tandem stand eyes open, tandem stand eyes closed, and one-leg stand for 4.24, 3.15, and 2.77 seconds (respectively) longer than participants who experienced lower levels of perceived discrimination. No significant associations were found between perceived discrimination and the other measures in adjusted analyses.

NEIGHBORHOOD CHARACTERISTICS, PERCEIVED DISCRIMINATION, AND RESILIENCE IN THE AFRICAN AMERICAN HEALTH COHORT

T. Malmstrom\textsuperscript{3}, M. Schootman\textsuperscript{5}, E. Andresen\textsuperscript{5}, P. Miller\textsuperscript{4}, D.K. Miller\textsuperscript{2}, F. Wolinsky\textsuperscript{1}, 1. Health Management and Policy, University of Iowa, Iowa City, Iowa, 2. Indiana University, Indianapolis, Indiana, 3. Washington University, St. Louis, Missouri, 4. Saint Louis University, St. Louis, Missouri, 5. University of Florida, Gainesville, Florida

We examined the relationship between three neighborhood characteristics—living in the inner city, observer assessment of the block where the participant lived, and the participant’s perception of their neighborhood safety—and perceived discrimination and resilience among the 566 AAH participants re-interviewed in 2010. We estimated the relationships using multiple linear regression analysis, first unadjusted, and then adjusted for demographic and economic factors, psychological factors, and health status. Propensity score re-weighting adjusted for potential attrition bias. Blocks with the worst quartile of observed conditions were statistically significantly associated with higher levels of perceived discrimination, while living in the inner city was associated with less perceived discrimination, although these relationships were not significant after adjustment. Blocks with the worst quartile of observed conditions were also significantly associated with higher levels of resilience, while living in the inner city was associated with less resilience, although these relationships were not statistically significant after adjustment.

SESSION 1165 (SYMPOSIUM)

VA GRECC SYMPOSIUM: LIFESTYLE MODIFICATION AND SUCCESSFUL COGNITIVE AGING

Chair: J.M. Gaziano, VA Boston Healthcare System, Boston, Massachusetts, Brigham and Women’s Hospital, Boston, Massachusetts, Harvard Medical School, Boston, Massachusetts

As the population ages increasing numbers of individuals are living with cognitive impairment. Successful cognitive aging is a priority for the VA as well as the broader aging population. In this session we will discuss a number of issues in the exploration of modifiable lifestyle factors that are related to cognitive health and impairment. A prevention paradigm, in contrast to a treatment paradigm, will be used as a conceptual framework. Methodologic issues in the assessment of early cognitive impairment will be discussed, and the utility of simple screening tools will be summarized. We will also explore population research methods that are used to relate modifiable risk factors with cognitive health. In particular, new national resources that are being developed will be summarized such as the Million Veteran Program. We will explore what longitudinal studies tell us about the relationship between specific lifestyle factors and Alzheimer’s Disease. We will also discuss the role lifestyle factors play in the loss of executive function. This symposium will point to the potential for modification of various factors in the maintenance of cognitive health.

CEREBROVASCULAR RISK, DECISION MAKING, AND THE BRAIN: A CRITICAL CONNECTION TO THE MAINTENANCE OF HEALTH IN OLDER ADULTS

Risk factors for cerebrovascular disease, such as hyperglycemia, hypertension, and hyperlipidemia, are generally felt to cause nonspecific atherosclerosis. In the brain, these risk factors may cause more specific deficits leading to specific cognitive deficits. This presentation will review recent data on the effects of cerebrovascular risk factors on specific brain regions. Blood glucose, cholesterol and blood pressure affect the central nervous system in very specific patterns, while converging on those structures critical for decision making and the cognitive virtualization of future events and consequences. It will be argued that
these neural effects play a role in medication adherence and efforts to mitigate cerebrovascular risk in older adults.

COGNITIVE THEN FUNCTIONAL IMPAIRMENT OR VISA VERSA: THE CLOCK IN THE BOX EXPERIENCE

J.L. Rudolph1, L.J. Grande1, R. McGlinchey2, J.G. Chester2, W. Milberg1, J. Geriatric Research, Education, and Clinical Center, VA Boston Healthcare System, Boston, Massachusetts, 2. Albert Einstein College of Medicine, New York, New York

Cognitive function is inter-twined with independent function. The objective of this symposium is to continue the discussion of which comes first: cognitive impairment or functional impairment. Using the Clock-in-the-Box, a 2-minute screening test of executive function and working memory, this symposium will discuss the relationship of these cognitive domains and function using data from three cohort studies: a) outpatient clinic patients with high cardiovascular risk, b) cardiotho-

executive function and working memory subscales of the Clock-in-

the-Box, we will explore which domain correlates with modifiable cardi-

risk factors, as well as, subsequent independent function. Future studies and clinical quality improvement can utilize cognitive screen-

ing instruments, such as the Clock-in-the-Box. Future studies will test this combination in transgenic models of AD to combine with pharmacological therapy have not been tested. Our experi-

mental studies will test this combination in transgenic models of AD to further explore the potential added benefits of lifestyle interventions in patients with AD.

COGNITIVE ACTIVITY AND REDUCED RISK FOR COGNITIVE DECLINE AND ALZHEIMER’S DISEASE: TRUTH OR MYTH?

A. Atri1,2,3, M. Mitchell1,2,3, 1. GRECC, VA Boston Medical Center, Bedford, Massachusetts, 2. Department of Neurology, Massachusetts General Hospital, Boston, Massachusetts, 3. Harvard Medical School, Boston, Massachusetts

Large-scale studies have found associations between the engage-

ment in intellectually demanding activities and cognitive performance in later life. This has suggested that cognitive activity may protect against the cognitive changes seen in normal aging and possibly also against Alzheimer’s disease and other dementing conditions. Additionally, the concepts of “Cognitive and Brain Reserve” have been proposed to explain data that high education and intelligence may buffer the effects or delay onset of dementia symptoms. We will first review the results of several of these studies and discuss the role of cognitive reserve. Next, we will discuss methodological issues in the measurement of cognitive activity and reserve and how these limitations may undermine the exist-

ing evidence purporting beneficial effects. Finally, we will discuss pos-

sible solutions for these limitations and directions for future longitudinal collaborative studies to address these important issues in cognitive aging and dementia research.

SESSION 1170 (PAPER)

CIVIC ENGAGEMENT

A LEGAL ANALYSIS OF “CIVIC ENGAGEMENT”: SIGNIFICANCE, IMPLICATIONS, AND OPPORTUNITIES

C.J. Overby, J. Hinterlong, Social Work, Virginia Commonwealth University, Richmond, Virginia

The Edward M. Kennedy Serve America Act and Congress’ reau-

thorization of the Older Americans Act of 1965 defines the term “civic engagement” within the legal realm, and has implications for research, policy, and practice. The definition should be read in conjunction with the functions of the Assistant Secretary for Aging, that delineate the responsibilities of the federal government according to the updated agenda concerning the civic engagement of older adults. This paper highlights the possibilities for policy makers and agencies given the legal definition and its accompanying responsibilities. There are possible opportunities related to the academic and policy goals of conducting meaningful research in the field of aging, and also to issues of facilitating access to programs that will promote the civic engagement of older adults. Concerning civic engagement, the Assistant Secretary is charged with its encouragement, the development of a national strategy for older adults, and the development of cost-effective community-capacity building initiatives involving older individuals. This paper explores what is possible for meeting and modeling the several “Func-

tions of Assistant Secretary,” by proposing the use of transferrable educational awards and other non-cash incentives in volunteer- and employment-training programs like the Senior Community Service and Employment Program [SCSEP]. This paper describes recent public policy developments that pertain to issues of access to, and incentives designed for the increased involvement in, civic engagement opportunities by older adults. After attending this session, participants will be able to better understand and apply the legal definition of “civic engagement” to aging-related initiatives.

SOCIAL INCLUSION OF OLDER PEOPLE THROUGH VOLUNTEERING

G. Naegle, A. Ehlers, M. Reichert, Institute of Gerontology at the TU Dortmund, Dortmund, Germany

In Europe, Social Integration Of Older People Is an Issue Of Grow-

ing Importance. Due To Demo-graphic and Societal Changes, Their Risk Of Being Socially Excluded Is Rising. The Paper Is Going To Present the Results Of the Project “Measures for Social Inclusion Of the Elderly” (Funded By the European Foundation For the Improve-

ment Of Living and Working Conditions) Which Aims At Answer-

ing the Question Whether the Risk Of Social Exclusion Of Older Peo-

ple Can Be Fought By Encourag-ing Them To Become Volunteers. The Paper Deals With the Conditions Under Which the Involvement Of Vulnerable Older People As Volunteers Can Succeed. Although Country-Specific Conditions As Well As Individual Differences Of Volunteers Have To Be Taken Into Account, Promoting and Impeding Factors for the Inclusion Of Older People Can Be Identified. Since Ageing Is Characterised By Heterogeneity and the Risk Of So-cial Exclusion Cannot Be Examined Apart From Country-Specific Con-

ditions, the Project Looked For Examples Of Best Practice From 10 European Member States: Denmark, Finland, France, Germany, Hun-

gary, Italy, Latvia, Poland, the Netherlands and United Kingdom. Good Practice Of Measures To Promote Social Inclusion Of Older People Through Volunteering As Well As Information About Na-tional Frame-

work Conditions Were Collected. Three Case Studies Per Country Were
VOLUNTEERING: PATHWAY TO INCREASED SOCIAL AND CIVIC ENGAGEMENT
N. Morrow-Howell, S. McCrary, Y. Lee, Washington University, St. Louis, Missouri

PURPOSE. Research on outcomes of volunteering in later life focuses on health of volunteers, in contrast to research on youth, where focus is on effects of volunteering on life trajectories and subsequent behaviors. The purpose of this paper is to examine the effects of volunteering on subsequent social and civic activity of older volunteers. Further, we explore the extent to which attitudes/actions in the arena of public education are affected by volunteer experience in public schools. METHODS. Data derive from a longitudinal study of older adults who volunteered for the Experience Corps (EC) program in Fall of 2006 and 2007. Telephone interviews were conducted with 338 volunteers in Fall, 2010 to capture work, education, civic and community activities undertaken subsequent to joining EC. FINDINGS. Since joining the EC program, 17% of respondents started a job, 53% started another volunteer experience, 40% started a community activity, and 38% took an education course program. Respondents reported that involvement in EC related to subsequent activity by: making a connection; increasing motivation/confidence; increasing skills/knowledge; and increasing the desire to do things outside of the home. Further, 85% reported that their experience in the EC program changed their attitude toward public education and that they are much more likely to speak out about and vote on educational issues. IMPLICATIONS: The lack of focus on volunteering in later life as a pathway may reflect ageism, and civic engagement can be viewed as a means as well as an end, as it is in young people.

CIVIC ENGAGEMENT, VOLUNTEERING AND PUBLIC SERVICES: EXPLORING THE ROLE OF OLDER PEOPLE IN THE THIRD SECTOR IN THE CONTEXT OF THE UK BIG SOCIETY AGENDA
R. Means, S. Evans, University of the West of England, Bristol, United Kingdom

The UK Coalition Government has received wide publicity for its emphasis upon ‘the Big Society’. This ambitious agenda has been linked to major public expenditure cutbacks by reducing quangos and central and local bureaucracies and relying on the capacity of communities to meet their own needs through a mixture of volunteering and locally based third sector provision. Our paper outlines the centrality of older people to this agenda, both as consumers of support and as key providers of voluntary effort through civic engagement. The current debate is explored within an historical context, analysing the changing role of volunteers and the third sector in the social care of older people since World War Two. The authors argue that previous efforts to place voluntary effort and the third sector at the centre of support for older people in the UK have failed. We present evidence of the challenges that remain if the new ‘Big Society’ initiative is to work, drawing on an evaluation of a prevention project in south west England. Despite a strong desire amongst older people’s organisations to take part in developing and delivering services, they struggled to collaborate with statutory agencies due to a lack of the necessary infrastructure and resources and differences in cultures of working. This paper highlights the implications of ‘the Big Society’ debate for an ageing population and explores the practical challenges that need to be addressed if it is to have a positive impact upon the lives of older people.

Ensuring Financial Security in Retirement

FROM PUBLIC PENSION PRIVATIZATION BACK TO UNIVERSAL PUBLIC PENSIONS: THE CASE OF ARGENTINA
S. Boulé, R. Elea-de Filipis, J. Université du Havre, La Havre, France. 2. Univ. of Mass. Boston, Boston, Massachusetts

In 2008 the Argentine government ended its 14 year experiment in privatization of old age pensions and moved toward a universal public pension with a minimum guaranteed benefit. Firstly, under privatization a contribution to one’s pension fund was voluntary; individuals with low wages, high risk of unemployment, or discontinuous labor force attachment decided that their economic interest was to keep income for immediate expenditure. The result was that the private system was under-funded. The situation worsened with the economic crisis of 2001-2002 when more than half of the participants (N=11,700,000) were no longer paying their contribution. There remained only 4,800,000 contributors. Without a guaranteed benefit many believed that entry into this system was like a lottery. Secondly, many people were going to be facing very serious poverty in old age without any pension income. The very thing that universalism was to prevent, widespread and serious poverty in old age, was now happening. From 2005 to 2007 the Social Security system was pushed to provide “private” pensions to help persons who had not contributed. Among these were many women. Under privatization individuals who had a weak attachment to the labor force became at greater risk of extreme poverty in old age. A large number of these were women, but they also included men who were self employed and working in small enterprises as well as those with a work disability. Data are from the Argentine Institute of Social Security (ANSES) and Administration of funds for retirement and pensions (AFJP).

MULTILEVEL ANALYSIS OF OLD-AGE PENSION POLICY AND OLDER ADULTS’ LIFE SATISFACTION
E. Calvo, UDP, Santiago, Chile

This study assesses the influence of old-age pension policy on older adults’ life satisfaction, and examines factors that shape this relationship. It theorizes that two distinct dimensions capture variation in the type of pension policy: individualization of risk (as opposed to risk pooling) and redistribution of resources (that is, poverty prevention through income redistribution mechanisms such as non-contributory pensions). To empirically evaluate the presence of these two dimensions and to assess their influence of life satisfaction among older adults, this study analyzes data for 126,560 adults age 45 and over living in 91 countries over the period 1981-2008. Using principal component factor analysis, it finds support for the two-dimensional model of pension policy. Next, using three-level hierarchical linear regression, this study assesses the effects of pension policy individualization and redistribution on life satisfaction, generating three additional major findings. First, life satisfaction comes with redistribution. Second, the relationship between pension policy and life satisfaction is contingent on the macro-social context. Specifically, life satisfaction outcomes are better when individualization takes place in more affluent societies than in contexts of material scarcity and when redistribution takes place in the context of traditional cultures as opposed to secular-rational cultures. A third finding is that governmental commitment to social security (i.e., government expenditures on social security as a percentage of total government expenditures) substantially improves the life satisfaction outcomes of individualization. Findings from this study are used to integrate and advance theory on comparative public policy and the larger macro-social context shaping subjective well-being.
EXIT THIS WAY: SOCIAL AND FINANCIAL IMPLICATIONS OF DIFFERENT DOORS TO “OFF-SCHEDULE” RETIREMENT

Planning for retirement presumes at least some ability to determine its timing, although arguably the most effective retirement plans account for a range of dates and scenarios. What happens when retirement occurs “off schedule,” that is, when the exit from work is significantly later or earlier than planned? Researchers at MetLife’s Mature Market Institute and Miami University’s Scripps Gerontology Center studied people approaching retirement or recently retired, conducting fifty long interviews with couples and individuals (n=79) and surveying a nationally representative sample (n=1007). The aim of the study was to explore how individuals and families think and make decisions about retirement, especially in the face of the unexpected. According to study findings, among the unexpected experiences on the path toward retirement were surprises about its timing, often with significant social and financial implications. Most of the individuals and couples interviewed had experienced or expected to experience off-schedule retirement; they described these experiences in detail. Of the 1007 people surveyed, over one-fourth (27%) had experienced or expected to experience a significantly off-schedule retirement, 19% later and 8% earlier than anticipated. The study found that the reasons for exits from work are varied and distinctive and go beyond a simple push-pull framework. We conceptualize these distinctions in terms of doors to retirement, for example, revolving doors, Dutch doors, automatic doors, trap doors, locked doors, and escape hatches, as a means of articulating the contributing factors and social and financial implications related to off-schedule retirement. Implications for research, policy and practice are identified.

INCREASING THE ELECTION OF SPOUSAL BENEFITS IN STATE PENSION PLANS
E.A. Bruce1, L.A. Martin2, 1. Gerontology Institute, Univ. of Massachusetts Boston, Boston, Massachusetts, 2. Gerontology Department, Univ. of Massachusetts Boston, Boston, Massachusetts

Increasing the election of spousal benefits in the private and public pension systems is one approach to reduce women’s low level of income in retirement. This paper examines two changes in spousal benefit election policy in the Massachusetts state pension system to assess the policies’ impact on retirees’ election of a joint and survivor annuity (J&SA) benefit. Similar to the public sector, a state worker can receive his/her benefit as a single life annuity or J&SA. Unlike the private sector, Massachusetts’s public sector workers do not need their spouse’s consent to elect a single life annuity. The state passed two laws which affected the election process. A 1988 law provided that a worker’s J&SA benefit, which was less than their single life annuity benefit, would increase to the level of a single life annuity if the spouse pre-deceased the worker, (a pop-up provision). The second law in 2004 changed the actuarial calculation such that the J&SA’s value was equal to the single life annuity if the spouse pre-deceased the worker. We examined the number of current retirees who had elected a J&SA before and after each amendment and found no change in the rate of election with the pop-up provision but a significant increase in the election of J&SA with the actuarial change. Women make up 83.5% of the beneficiaries of the actuarial change. The paper discusses these and other policy options for increasing spousal benefit elections.

SESSION 1180 (PAPER)
INTERNATIONAL ISSUES IN LONG TERM CARE POLICY
TAIWAN’S PUBLIC LONG TERM CARE INSURANCE PLAN
P. Nadash, Y. Shih, Gerontology, University of Massachusetts, Boston, Boston, Massachusetts

Since its peaceful transition to democracy (from a military dictatorship) in 1987, Taiwan has moved systematically toward the provision of a full range of social insurance protections, aimed at ensuring baseline security for its citizens: retirement security, universal health care, and, most recently, protection against the cost of long term care (LTC). The new public LTC insurance plan, to be introduced in 2013, offers coverage for citizens of all ages and disabilities. The proposed legislation finances services through contributions from employees and employers, as well as from general revenue. The legislation is supported by another piece of legislation, The LTC Services Act, which provides a badly needed overhaul of existing regulation in the LTC services sector. Together, these laws aim to support the growth of a community-based service infrastructure and the continuing and traditional role of families in providing LTC. They also address the need to develop a reliable workforce for LTC: currently, there is an overreliance on foreign workers, who comprise 86% of the LTC workforce. Using data collected through key informant interviews of stakeholders and policy makers, as well as source documents, this paper describes the shape of the reform, key factors in its development, and the policy implications of the reform, setting them in the context of other countries’ efforts as well as comparative social policy theory. Taiwan’s decisions with respect to how it structures its LTC insurance contrast significantly with the choices made in the United States when designing its public LTC Insurance, the CLASS Act.

THE ROLE OF THE PUBLIC SECTOR IN A PLAN FOR LONG-TERM CARE INSURANCE IN TAIWAN
C. Chou, S. Lin, B. Chang, Chinese Culture University, Taipei, Taiwan

Population aging has become one of the critical issues in modern societies. By year 2010, the older population in Taiwan reached 2.49 million, or 10.74% of the total population. The number is estimated to reach 5.36 million (22.5%) in 2028. A long-term care (LTC) insurance policy has yet to pass the legislature in Taiwan. This study aimed at analyzing the LTC insurance policy in Germany and Japan and developing strategies for policy formation. We investigated the following elements in both countries: 1) the structure of the existing health care policy; and 2) the roles of the public sector in the health care insurance system. We proposed a solution to promote and implement LTC insurance based on the political and economic conditions and social insurance systems in Taiwan. The models of public long-term care insurance can be categorized as tax-financed, independent, and under/with health care insurance. Two major conclusions emerged based on the analysis for the organization of the public sector. First, we suggest that the Taiwan government should integrate diverse but loosely structured administrative systems. The LTC insurance and the national health care insurance should be independent of each other but closely connected. Second, we suggest that the central and local government in Taiwan should work together, while the central government lead the policy promotion and implementation at the initial stage with assistance from the local government.

CARE OR CASH? TAIWAN’S LONG-TERM CARE IN CROSSROADS
P. Wang, National Taipei University, New Taipei, Taiwan

Prior studies that explored the policymaking of a welfare program tend to investigate retrospectively the institutional history of a policy.
Rarely have we seen analyses examining the articulation of ongoing or prospective forces that are to shape the debates of a policy. A case in point is the inclusion of a “cash-for-care” option in Taiwan’s long-term care program. The cash-for-care (in addition or as against to the in-kind service) option in long-term care programs (LTC) serves as a unique analytical tool to decipher the making of both policy and knowledge. This study aims to examine the ways in which debates on care or cash have been staged. It was conducted in 2010 and 2011, using both qualitative and quantitative methods. The findings indicate first a discourse analysis of the ways in which Taiwanese government and non-government sectors deployed the cash-benefit option in LTC. Second, a survey research that investigated service users’ motives and willingness to accept the cash-for-care benefits in LTC. Findings reveal that: (1) Few current in-kind service users will opt out for the cash-for-care option. (2) One fifth of the users preferred being allotted more service hours rather than being given cash benefits instead. (3) Moderately and severely disabled respondents tended to be more vocal than their mildly disabled counterparts. What they demanded is again services rather than cash. Program-design problems were thus identified and policy implications discussed.

INVESTIGATING THE DEMAND AND SUPPLY OF SOCIAL CARE IN THE UK
M. Evandrou1,2, J.C. Falkingham1, A. Vlachantoni1,2, 1. University of Southampton - Centre for Research on Ageing, Southampton, United Kingdom, 2. University of Southampton - ESRC Centre for Population Change, Southampton, United Kingdom

The UK’s population is ageing and, given that older people are the major users of health and social care services, this presents a major challenge for policymakers. As well as increasing the demand for care, population ageing is affecting the supply of care professionals, as the health workforce itself ages. This paper presents preliminary results from the project on the Care Life Cycle, funded by the Engineering and Physical Sciences Research Council of the UK, which brings together social scientists, including demographers, gerontologists and social policy experts, with complexity scientists. The project is aimed at modelling the demand for and supply of different kinds of social support to older people, including state, private and informal support. Demand-side factors include, for example, morbidity patterns and patterns of family formation and dissolution at the individual level, and rising wealth at the societal level. Supply-side factors include the demographic patterns of the health and social care workforce, as well as migration patterns of professionals working in this field. The paper addresses key questions facing policymakers in the UK today, regarding the short- and medium-term organisation of care provision, as well as the long-term tactical and strategic constraints on policy making in this area. In addition, the paper uses data from the English Longitudinal Study of Ageing (2002, Wave 1) in order to explore the relative importance of demographic, health and socio-economic determinants for the receipt of different kinds of care by people aged 50 and over.

SESSION 1185 (SYMPOSIUM)

INNOVATIVE TRANSPORTATION RESOURCES TO FACILITATE COMMUNITY PARTICIPATION
Chair: A. Dickerson, Occupational Therapy, East Carolina University, Greenville, North Carolina
Co-Chair: S. Classen, University of Florida, Gainesville, Florida

Discussion: M. Leary, National Center for Senior Transportation, Washington, District of Columbia

Transportation is a basic need for all people and is linked to independence and quality of life. Unfortunately, when elders must give up driving and the responsibility falls on family members who may or may not be willing to assist with the elders’ transportation needs. Assistance for medical transportation may be available, but individuals with cognitive deficits or mobility issues need more than just transit help. Additionally, it is clear that quality of life is impacted if older adults cannot attend social events, leisure activities, church services, and continue in community activities. This symposium will highlight innovative resources that may be sued to address the transportation needs of older adults. These include discussions on the following topics. Travel trainers were interviewed about services in South Florida. Perceived safety issues and unfamiliarity with public transportation may be mitigated with travel trainers. A new database has gone live via the Florida Senior Services Resources website. The characteristics of the website, known data on users, and satisfaction via surveys will be highlighted. A door-through-door program in Boston was evaluated and results will be discussed for the disadvantaged population the volunteers serve. The STARS program that works for pairing seniors with transportation networks will be highlighted. A Transportation Resource Guide for professionals was developed in North Carolina, but is a template for other professionals to use on line as a resource for their clients. It would be described.

THE TRANSPORTATION RESOURCE GUIDE FOR THERAPISTS
A. Dickerson, Occupational Therapy, East Carolina University, Greenville, North Carolina

When the older adult gives up the keys, family members ensure they get to physician appointments or other essentials places. However, there are other trips that are important to the individual. Although there may be information in one’s community, it is often not easily accessible for the elder or caregiver or coordinated through one source. The Transportation Resource Guide was developed by therapists to be used with their clients. The purpose of the Guide is to provide practitioners with a clear algorithm that will help their clients understand why it is unsafe for them to continue driving and to provide them with alternative modes of transportation that will be specific for that client based on their needs. The guide has been drafted, based on multiple interviews with clients, therapists, and transportation experts.

INNOVATIVE ALTERNATIVE TRANSPORTATION WEBSITE FOR OLDER ADULTS
S. Classen, Univ of Florida-Geological Sci, Gainesville, Florida

Depression, social isolation and early nursing home admissions, are risk factors for those who have stopped driving and are “left” without alternative transportation options. The needs of older adults are greater than just “having” access to alternative transportation as they require accessible, affordable, adaptable, and acceptable transportation options which must include a “family of services”. The University of Florida’s Institute for Mobility, Activity and Participation created, with the Florida Department of Transportation, a database offering over 700 transportation options, across Florida’s 67 counties. This database has now gone “live” via the Florida Senior Services Resource Center website and provide access to elders to a variety of transportation services (e.g. fixed-flexible route schedules) including a range of service options (door through door via pick-up and drop-off). This presentation will highlight the characteristics of this web-site, and make the known data on end-user search behaviors and satisfaction collected via surveys.

BLURRING THE LINE BETWEEN TRANSPORTATION AND HEALTH CARE: DOOR-THROUGH-DOOR MEDICAL ESCORT SERVICES
L.A. Martin, 1. Gerontology, Univ. of Massachusetts Boston, Boston, Massachusetts, 2. FriendshipWorks, Inc., Boston, Massachusetts

Transportation is recognized as a major barrier to accessing health care. Solutions such as door-through-door escort services increase our options by addressing additional physical, emotional, and navigational needs. This report presents an evaluation of one Boston-based door-through-door program and its effectiveness in addressing challenges.
TRAVEL TRAINING TO INCREASE SENIOR MOBILITY
D.P. McCarthy, Florida International University, Miami, Florida

Background: Seniors are infrequent users of public transportation and are unlikely to transition to its use when they stop driving. Travel training, individualized instruction on the use of public transportation, may mitigate the negative consequences associated with driving cessation. Methods: Travel trainers were recruited to answer questions regarding provision of services to seniors. Results: All respondents (n=27) reported providing services for seniors. Other groups served included people with disabilities, students, and those referred from other agencies. Most of those receiving services were current paratransit users while many drove themselves in private automobiles. Major obstacles for seniors’ use of public transportation were fear/safety issues or were related to walking/falling, crossing streets and other environmental concerns. Conclusion: Perceived safety issues and unfamiliarity with the use of public transportation may prevent many seniors from transitioning to its use after driving cessation. Travel training may increase users’ confidence and lead to increased community mobility.

STARS PROGRAM: LINKING SENIORS WITH SUPPLEMENTAL TRANSPORTATION PROGRAMS
H. Kerschner, Beverly Foundation, Albuquerque, New Mexico

The Beverly Foundation’s mission is to foster new ideas and options to enhance mobility and transportation for older adults through research activities, community outreach and technical assistance products. One of the key partnership projects has been the STAR Search and STAR award program, which honors the best transportation programs that provide services to older adults. This presentation will describe how data for the STARS is updated as well as the new method of linking people with over 1,000 Supplemental Transportation Programs (STP) for seniors on the STP map which will soon be on the their website.

SESSION 1190 (SYMPOSIUM)

POLICY SERIES: SOCIAL SECURITY—YOU FIX IT!
Co-Chairs: J. Rother, AARP, Washington, District of Columbia

This hands-on session, sponsored by AARP and the GSA Public Policy Committee, will involve you in a fun and informative exercise to find solutions to the long term solvency of Social Security. Session chair John Rother, Vice President of Policy, Strategy and International Relations at AARP, will provide a review of the program, its financing problem, and the leading proposals for eliminating the shortfall. Mr. Rother will then take you through an interactive exercise to come up with your own solutions for “fixing” Social Security.

SESSION 1195 (SYMPOSIUM)

SMALL-HOUSE NURSING HOMES: FINDINGS AND FUTURES
Chair: R.A. Kane, Health Policy and Management, University of Minnesota School of Public Health, Minneapolis, Minnesota

Small-scale self-contained houses licensed as nursing homes (NHs) have become visible recently, partly because of the success and replication of Green House ® NHs, a trademarked small-house NH model. This Symposium presents facility-level and system level research on small-house NHs, with an emphasis on dementia. We present findings from a longitudinal study in 3 separate Avalon-by-Otterbein small-house NF complexes in Ohio (15 houses total) to explore the experiences of persons with Alzheimer’s disease integrated into 10-person houses. Rosalie Kane presents data on outcomes for residents and perceptions of staff based on interviews and MDS data. Tetyana Shippee presents quantitative and qualitative data on family perspectives based on family telephone interviews. Most AD residents were accommodated through various stages of dementia until their deaths and the small-house environment helped preserve function, social and family relationships, and quality of life. Challenges arose when residents exhibited behavior problems, suggesting training needs for frontline workers and needs for closer integration of CNAs with health care goals. Family feedback was enthusiastic, though some were concerned that a philosophy of resident autonomy may offer “too much choice” to confused residents. Lois Cutler presents comparative information about dementia care and other features in 55 operational 55 small-house NH programs, including 22 GHs, and 18 innovative neighborhood style NHs that have developed normalized small-scale living within large NHs. Finally Terry Lum presents information about preparation for and implementation of small-house models in 6 Asian countries.

FAMILY PERSPECTIVES ON DEMENTIA CARE IN SMALL-HOUSE NURSING HOMES
T.P. Shippee, R.A. Kane, L. Peterson, L. Cutler, Health Policy and Management, University of Minnesota, 420 Delaware St. SE, MMC 729, Minnesota

Family perspectives on dementia care in small-house NHs were gathered through detailed family interviews at two points in time. Family members were highly enthusiastic, citing the advantages of the private space, the homey atmosphere, and their own involvement. Most frequent concerns expressed by family were that organized activity was insufficient, and that some residents had “too much choice” over their routines, which they deemed inappropriate for a person with dementia. Family members of residents with dementia in traditional settings (including those who had opted not to move residents to small houses) also rated their satisfaction highly, suggesting that some family may be reluctant to try a new model. Some families in the traditional settings stated that their relatives were too far advanced in the disease to be in a small house, even while others equally disabled had moved to the small houses and had maintained or even regained function.
SMALL HOUSE NURSING HOMES FOR FRAIL ELDERS IN ASIAN COUNTRIES?
T.Y. Lum, 1. University of Minnesota, St. Paul, Minnesota, 2. The University of Hong Kong, Hong Kong, Hong Kong

While the idea of small group home for elders with functional or cognitive impairments fits well in the family oriented Asian cultures, policy makers and stake holders in Asian countries have just started examining small group home as an alternative to traditional nursing home for frail elders. Using data from published records and interviews with stake holders, this paper examines the preparation and implementation of small group home for frail elders in six Asian countries and cities, including China, Hong Kong, Taiwan, Japan, Korea and Singapore. We found that Asian countries and cities have different levels of readiness to adopt small group home as an option for elderly who need residential care, with Japan as the leader among all Asian countries. We will also discuss the potential impacts of the small group home movement in long term care in Asia.

VARIATION IN SMALL-HOUSE NURSING HOMES IN THE UNITED STATES: TOWARDS A TYPOLOGY AND THE DEMENTIA CONNECTION
L. Cutler, R.A. Kane, C. Henning-Smith, Division of Health Policy & Management, School of Public Health, University of Minnesota, Minneapolis, Minnesota

Using a snowball process, we identified 45 operating small-house NHs in the United States, including 21 defined as Green House ® projects and 24 others meeting an expanded definition, including: self-contained building for no more than 18 residents; private rooms and baths; frontline staff dedicated to each house; and meals cooked in working kitchens with resident access. The NHs varied in residents per house (10 to 16), number of houses (to 22 per NH), range of other activities of the sponsor; physical plants, targeted clientele, specialized versus mainstreamed house; role definitions for professionals and front-line staff; handling of meals and food; and business models. The session describes a classification system for small-house NHs, including variation in approaches to dementia care. We studied 12 NHs that resembled small-house programs but lacked some elements of the operational definition. These comparison sites reveal the slipperiness of the boundaries for small-house NH definitions.

SMALL-HOUSE NURSING HOMES AND DEMENTIA CARE: CLIENTELE AND OUTCOMES
R.A. Kane1, L. Cutler2, T.Y. Lum, L. Peterson1, 1. Health Policy and Management, University of Minnesota School of Public Health, Minneapolis, Minnesota, 2. School of Social Work, University of Minnesota, Minneapolis, Minnesota

A 2-year longitudinal study was conducted to examine characteristics, experiences and outcomes of persons with Alzheimer’s disease and other cognitive impairment in 15 small-houses in 3 small-house communities in Ohio. Data include resident interviews and observations, staff interviews about each resident, resident MDS data, and open-ended staff interviews about dementia care issues in the setting. Residents with dementia were managed across the spectrum of their illnesses; in only 3 instances were discharges were made other settings. In the small-house setting, we observed primary relationships among residents with dementia and with other residents who had no cognitive impairments. Behavioral problems were the most difficult issue for staff, though they noted that wandering and aggressiveness were reduced in the small-scale environment compared to more traditional NHs. Most front-line staff was positive about dementia care in small-scale settings where they could intimately learn the signals of each resident and various professional staff.

SESSION 1200 (SYMPOSIUM)

THE 2010 NATIONAL SURVEY OF RESIDENTIAL CARE FACILITIES (NSRFC): A RESOURCE FOR RESEARCHERS
Chair: E. Rosenoff, Assistant Secretary for Planning and Evaluation, US Department of Health and Human Services, Washington, District of Columbia
Co-Chair: L. Harris-Kojetin, National Center for Health Statistics, Hyattsville, Maryland
Discussant: K. Polzer, National Center for Assisted Living, Washington, District of Columbia

Research in the field of residential care/assisted living has been hampered by a lack of nationally-representative data. Lack of data has been a significant limitation to understanding and improving the quality of care and outcomes for current and future generations. This symposium will preview the data sets of a first time nationally representative survey of residential care/assisted living settings and residents sponsored by the Department of Health and Human Services and the Veterans Administration. The main goals of the National Survey of Residential Care Facilities (NSRFC) were to estimate the size of the U.S. residential care industry and determine the characteristics of facilities and residents. A major goal of the government is that the NSRFC data be used widely by the research community, as NSRFC results will be of interest to policymakers, researchers, and providers. The public-use files are currently scheduled for release within months of the 2011 GSA, and so the timing of this symposium is especially opportune. In this symposium we will provide an update on the survey, give an overview of the survey content, share and discuss the data dictionaries, and field audience questions about their potential analysis topics. The symposium discussant, a senior representative from a national residential care provider association, will stimulate discussion about possible topics to examine with the NSRFC data. Individual presentations in this symposium will cover: 1. Purpose, Goals and Overview of NSRFC 2. Content and discussion of data dictionaries

PURPOSE, GOALS AND OVERVIEW OF THE NATIONAL SURVEY OF RESIDENTIAL CARE FACILITIES (NSRFC)
L. Harris-Kojetin1, E. Rosenoff2. 1. National Center for Health Statistics, Hyattsville, Maryland, 2. Assistant Secretary for Planning and Evaluation, DHHS, Washington, District of Columbia

This presentation highlights the purpose and goals of the NSRFC; provides an overview of the study definition, survey design and data collection methodology; and gives the latest update on when initial findings and products will be made publicly available. The NSRFC fills a gap in our knowledge of the U.S. long-term care system by providing nationally representative estimates of state-regulated residential care places (e.g., assisted living, board and care homes) with four or more beds and the characteristics of people living in these settings. Between April and November 2010, in-person interviews were completed with residential care directors and staff to collect information on 2,300 sampled facilities for an unweighted 79% response rate. Within participating sampled facilities, between three and six residents were randomly sampled per facility, based on facility size, resulting in data collected from staff on over 8,000 residents. No residents were interviewed.

CONTENT AND DATA DICTIONARIES OF THE 2010 NATIONAL SURVEY OF RESIDENTIAL CARE FACILITIES (NSRFC)
M. Sengupta, E. Park-Lee, CDC/NCHS, Hyattsville, Maryland

This presentation provides an in-depth look at the content collected in the NSRFC and provides examples of potential policy and practice-relevant topics that may be explored using the data. The NSRFC collected facility-level information as well as information on sampled residents. Using data from NSRFC, researchers and policymakers will be able to: describe facility characteristics, services provided, and fees
What is a natural death? How can we study this topic in the laboratory setting? To answer these questions, we also need to define how an organism ages. We use the nematode Caenorhabditis elegans (C. elegans) as our model system; a premier system for studying the aging process. We will perform a large number of assays at both the cellular and organismal levels on wild type as well as four different long-lived animals. We assay these parameters as the animals age. Therefore, we will define the biological characteristics of how an organism ages and ultimately dies. With these results, we will have a biological blueprint for defining the aging and death process in a whole organism. Ultimately, since the signaling pathways are well conserved across phylogeny, these studies will undoubtedly have implications for understanding these events in humans.

**DEATH OF AN ELDERLY PARENT: THE CHILDREN’S NARRATIVE**

H.K. Black, Behavioral Research, Arcadia University, Glenside, Pennsylvania

In this presentation, we explore the meaning of the death of elderly fathers based on adult children’s narratives about their fathers’ life and death. Their narratives show a family worldview, from which each child reveals a unique perspective of self, the deceased, other family members, and the meaning of life and death. This presentation is based on research in which 30 families (a widow and two adult children) were qualitatively interviewed six to ten months after the death of the husband and father about his dying and death. We collected in-depth data through formal ethnographic interviews and informal conversation. We offer a sampling of narrative accounts from adult children. A key finding in this presentation is that for some adult children, connectedness to the father and to the remaining family members is indicative of a particular kind of spirituality based on Buber’s “I- Thou” interaction.

**WHO GETS THE DEATH THEY WANT? PREDICTORS OF PROXY ACCURACY IN SUBSTITUTED JUDGMENT**

L. Winter, S.M. Parks, Thomas Jefferson University, Philadelphia, Pennsylvania

Central to the ideal of the good death is having one’s wishes for end-of-life care honored - the principle of patient autonomy. Yet most final treatment decisions are made by proxies, whose accuracy is known to be low. In a cross-sectional study of 202 elderly individuals and their proxies, we assessed proxy accuracy by asking elders a standard living-will question and their proxies the same question using substituted judgment. 82.7% were accurate, 17.3% inaccurate. Proxies were accurate when the elder had a living will (73.6% vs. 56.3% for inaccurate proxies), had assigned a durable power of attorney for healthcare (65.3% vs. 41.3%), had talked with a family member (88.6% vs. 53.1%), and was White (86.7% vs. 74.6%). Elders who wanted all possible care were less likely to have accurate proxies (32.1%) than elders rejecting life-prolonging care (94.6%). No differences were found for age, gender, education, or financial well-being.

**EUTHANASIA AND “NATURAL DEATH”: INTERSECTIONS OF NATURE AND CULTURE AT THE END OF DUTCH LIFE**

Euthanasia – ending the life of another person at that person’s explicit request typically for reasons of terminal illness – is a relatively new policy based on an old practice that is known to have existed in cultures around the world at least since the beginning of written records. Question is why is euthanasia, and its counterpart – assisted dying – only recently coming to the forefront of end-of-life policy debates? Using a 15-month ethnographic study of euthanasia and home death in The Netherlands, I will explore the intersections of nature and culture in the one country most often held up as the model for and against euthanasia and assisted dying policy. This paper uses ethnographic and historic studies to show how one culture negotiates the difficult boundaries of nature and culture at the end of life, suggesting that perhaps culture does have a central role to play in “natural death.”

**IS ‘NATURAL’ DEATH AN ILLUSION? THE PATH OF COMMUNICATIVE ETHICS**

H. Moody, AARP, Washington, District of Columbia

“Natural” death has had a long history in law and ethics, and appears to all who are fearful of meaninglessness of prolongation of life (e.g. Terri Schiavo) yet resist the “unnatural” path of assisted suicide. Natural death is...
part of a larger history of natural law, largely rejected by the philosophical consciousness of modernity. In bioethics, proposals for advance directives have proved problematic in practice; but, even if they succeed, the supremacy of autonomy is far from acceptance of a natural end to the course of life. Biomedical technology, which promises to extend instrumental power and choice, has in practice created new forms that constrain freedom. Here it is argued that natural death remains a regulative ideal, but an ideal that must be contextualized to individual life history and circumstance. Achieving that ideal will require social, not individual, freedom, which Jurgen Habermas has called “unconstrained communication.”

SESSION 1210 (SYMPOSIUM)

NUTRITION IN BRAIN AGING AND NEURODEGENERATIVE DISEASE

Chair: B. Shukitt-Hale, Human Nutrition Research Center on Aging at Tufts University, Boston, Massachusetts
Co-Chair: D.A. Rivas, Human Nutrition Research Center on Aging at Tufts University, Boston, Massachusetts

One just has to glance at the internet to realize that most of the supplement world is non-evidence based. There are several nutritional supplements specifically marketed to prevent, slow or reverse brain aging and neurodegenerative disease. Speakers in this session will focus on dietary interventions and the potential mechanisms that lead to changes in behavior and development and progression of brain disease in the aged.

NUTRITIONAL INTERVENTIONS IMPROVE AGE-RELATED COGNITIVE PERFORMANCE

B. Shukitt-Hale, USDA, HNRCA at Tufts Univ, Boston, Massachusetts

The onset of age-related neurodegenerative diseases such as Alzheimer’s or Parkinson’s Disease, superimposed on a declining nervous system, could exacerbate the motor and cognitive behavioral deficits that normally occur in senescence. Thus, it is extremely important to explore methods to retard or reverse age-related neuronal deficits, as well as their subsequent, behavioral manifestations, in order to increase healthy aging. In this regard, our lab has shown that consumption of fruits and vegetables high in antioxidant and anti-inflammatory activity, such as blueberries, blackberries, and strawberries, can prevent and even reverse the occurrence of the neurochemical and behavioral changes that occur in aging. Polyphenolic compounds in these foods may exert their beneficial effects either indirectly through their ability to lower oxidative stress and inflammation, or directly by altering the signaling involved in neuronal communication, calcium buffering ability, neuroprotective stress shock proteins, plasticity, and stress signaling pathways.

NEUROMUSCULAR FUNCTION AND ANABOLIC SIGNALING ARE IMPAIRED WITH AGING AND A HIGH-FAT DIET

D. Rivas, E. Morris, P. Haran, R. Fielding, Tufts University, Boston, Massachusetts

Muscle mass and strength both decline with age, but the loss of strength far surpasses what is projected based on the decline in mass. This may be explained by deterioration in muscle quality including, decreased fiber size and number, reduced contractility of fibers, motorneuron loss, and intramyocellular lipid infiltration. Interestingly, in several epidemiological studies the accumulation of fat mass has been shown to be a strong independent predictor of subsequent functional loss and disability. Therefore, we have determined in C57BL/6 mice if aging and a high-fat diet similarly impair muscular strength/function and molecular signaling associated with muscle growth pathways. Data will be presented suggesting that aging (24 months) and a high-fat diet (60% fat/kcal, 12 weeks) similarly impair neuromuscular function and growth signaling pathways in skeletal muscle after anabolic stimula-

SESSION 1215 (PAPER)

DEMENTIA: ISSUES OF DIAGNOSIS, UNDERSTANDING, AND TREATMENT

DIALOOGUES AROUND DIAGNOSTIC DISCLOSURE FOR PEOPLE WITH DEMENTIA AND CARERS

J. Manthorpe1, J. Keady2, J. Bond3, L. Robinson4, K. Sansi1, 1. Social Care Workforce Research Unit, King’s College London, London, United Kingdom, 2. University of Manchester, Manchester, United Kingdom, 3. Newcastle University, Newcastle, United Kingdom

As demand for dementia services grows, this UK-based qualitative study explored information needs of people with memory problems and carers before and after receiving a diagnosis of dementia. Face-to-face interviews were conducted with 27 people with dementia and 26 carers about their experience of the process of assessment and diagnosis disclosure. Findings highlighted that diagnosis disclosure appeared to be a poorly managed process, with limited time given to patients and carers for processing information or for asking questions. Most described
feeling unsupported at this time and none had received referral to further emotional or counselling support. Those who were discharged with a diagnosis and no further support described feeling let down by services and reported on pessimistic attitudes, and poor coping practices and resources for long-term management of the condition. Giving timely and accurate information to people referred for their memory problems should be integral to the diagnostic process. Details about how long the process takes may prepare people with memory problems and carers better and reduce anxiety and confusion. Post-diagnosis information also needs to be developed in order that newly diagnosed people and those discharged from services receive adequate support and are aware of resources which they can turn to in the future.

**LANGUAGE ANALYSIS OF WORDS FOR EARLY VS. LATE SYMPTOMS OF ALZHEIMER’S: ENGLISH, SPANISH, AND RUSSIAN**

How older adults understand and talk about Alzheimer’s disease is shaped by the language(s) that they speak. To probe similarities and differences in linguistic terms for behaviors and symptoms associated with AD, we developed natural language lists of symptoms in African American Vernacular English (African Americans), Spanish (Mexican Americans), and Russian (refugees/immigrants from the Former Soviet Union) from qualitative interviews (n=10 in each group). These translation equivalents and their linguistic contexts are compared in tabular format. To assess cross-cultural differences in the symptoms domain, we asked new samples from each ethnic group (n=10 in each group) to participate in a pile sorting exercise. Cluster analyses showed a similar structure across languages, with 5 symptom clusters: physical/medical signs, cognitive impairments (memory and thinking), self-care/self-management issues, behavioral and social implications, and mood and personality changes. To assess participants’ understanding of the progression of the disease, we recruited new samples from each group (n=36 per group) who selected the 5 symptom labels most characteristic of early AD and 5 most characteristic of late AD. Chi-square analyses showed significant differences between early vs. late symptoms for all groups (p<.001). All groups emphasized cognitive deficits as early markers (forgetting names, faces, and recent events; losing things; changes in personality) and psychological and behavioral deficits as late markers (problems with personal care; hallucinations; being in ‘one’s own world’; poor appetite; dangerous or inappropriate behavior; incontinence). The provision of services to ethnic Americans may benefit from this ‘dictionary’ of symptoms and behaviors in the three languages.

**THE CONTROVERSIAL PROMISES OF CHOLINERGIC INHIBITORS FOR DEMENTIA: A QUALITATIVE STUDY OF CAREGIVERS’ EXPERIENCES**

A. Smith, K. Kobayashi, N.L. Chappell. Sociology, University of Victoria, Victoria, British Columbia, Canada

Since their introduction, clinicians have been engaging in debates over the therapeutic benefits of cholinesterase inhibitors (ChEIs) in Alzheimer’s disease and related dementias (ADRD). Against this backdrop of controversy, caregivers’ views and experiences have been largely ignored. This has occurred despite the fact that this group may provide insights into these drugs in ways not captured by clinical research. To address this gap in knowledge, the current study examines 25 caregivers’ narratives about the treatment of relatives diagnosed with mild to moderate ADRD and treated with ChEIs. The findings reveal an appraisal of cholinergic effects whereby caregivers question the benefits of the drugs, generally not knowing whether to attribute stabilization or improvements to them or not but also fearing termination of the drug ‘just in case’ there is some benefit. Caregivers justify their belief in ChEIs’ long-term effectiveness primarily by invoking non-medicated prognostic scenarios of more rapid decline and loss of self. In addition, the study explores the meaning caregivers attribute to ChEIs effects vis-à-vis a pharmaceutical discourse which frames these drugs as a source of hope. Finally, attention is drawn to how the limited benefits associated with cholinergic drugs may due to non-pharmacological influences such as supportive caregiving practices.

**EVALUATING SERVICE NETWORKS FOR PEOPLE WITH DEMENTIA AND THEIR INFORMAL CAREGIVERS: THE “EVIDENT”-PROJECT**

M. Reichert, K. Koehler, V. Lieve, Z. Zimmer, Social Gerontology, FK 12, University TU Dortmund, Dortmund, Germany

In an ageing society efficacy of care provision and other outpatient support services for people with dementia and their informal caregivers is of particular importance. Against this background, the project “EVIDENT” (funded by the German Ministry of Health) aimed to evaluate the work of six dementia care networks in Germany. The principal purpose of these dementia care networks - which were regarded as “good practice” - was to decrease the fragmentation of community based services by linking the different parts of dementia supply (e.g., medical and nursing services, consultation, self help.) Six case studies were conducted to document structure and processes of each network and analyse facilitators for and barriers to the development and functioning of dementia networks. Data refer to the institutional and individual drivers for participating in networks, the development of networks in community care systems, the conditions necessary for success and sustainability, and the restrictions of networks referring to institutional and financial framework. Results show, for example, that dementia networks have to be adapted to the regional parameters, case management has to be developed more systematically and family doctors and other medical specialists have to be included into the networks more strongly.

**PRACTITIONER AND PATIENT ACCOUNTS OF MILD COGNITIVE IMPAIRMENT: WHAT GETS LOST IN TRANSLATION**

R.L. Beard, T.M. Neary, Department of Sociology & Anthropology, College of the Holy Cross, Worcester, Massachusetts

This paper draws on in-depth interviews (N=20) with medical practitioners, including neurologists, neuropsychiatrists, neuropsychologists, geriatricians and internal medics, to trace the nosological background of Alzheimer’s, particularly the potential precursor known as mild cognitive impairment, and professional experiences of rendering this diagnosis. Grounded theory methods were used to collect, code and analyze narrative interview data into overarching themes, which will be presented here. The interviews reveal considerable dispute and ambiguity concerning the utility and definition of this label, as well as if, when and how to disclose the diagnosis itself. Based on these findings, comparisons between the state-of-the-science and clinical practice standards and the personal accounts of MCI-diagnoses (N=18) reported elsewhere will be made. This case comparative approach demonstrates the clinical constraints of diagnosing a medically uncertain condition as well as the psychosocial significance of such ambiguity on practice and everyday life with mild cognitive impairment.

**SESSION 1220 (PAPER)**

**END OF LIFE CARE DECISIONS: INDIVIDUAL AND RELATIONAL INFLUENCES**

**ATTITUDES TOWARD DEATH AND DYING IN OLD AGE: HIGH PERCEIVED CONTROL, LOW METAPHYSICAL BELIEFS**

A.K. Leist, M. Hoffmann, University of Luxembourg, Walferdange, Luxembourg

Objectives. The awareness of the inevitability of death might constitute a major source of fear and influence behavior and psychosocial...
well-being directly or indirectly. Attitudes toward death and dying in old age were explored in the context of legal alterations in Luxembourg allowing for medically assisted suicide in case of fatal illness. Method. A sample of 62 community-dwelling individuals aged between 65 and 89 years participated in an interview exploring attitudes towards death and dying in general and the salience of this topic for their own lives in particular. Reports were analyzed using interpretative phe- nomenological analysis. Results. Three overarching themes were identified: (1) Concreteness of thoughts concerning death and dying, sug- gesting that a significant part of the respondents has already prepared for death with pragmatic organizational decisions in order to counter- act fears of a long and painful dying process. (2) The role of metaphysical and religious beliefs, demonstrating perceptions of death as a mainly corporal phenomenon that seems postponable by high-tech medicine. Few persons stated to believe in heaven, the soul, or the reunion with deceased relatives. (3) Perceived control in the dying process and death, the “right time” to die being evaluated within life review with a general tendency to regard death and dying as controllable by norms and traditions, and, now more than ever, self-determined by testament and living will. Discussion. The new law on euthanasia has apparently increased perceived autonomy and decision-making ability regarding one’s own end-of-life issues, and, simultaneously, raised normative expectations to prepare for death.

**IF MY PHYSICIAN DOESN’T BELIEVE IN GOD, WILL I GET A REFERRAL TO HOSPICE?**

R.D. Brumley1, S. Enguidanos2, A. Couloudides Kogan2, J. Kaiser 1Permanentane, Downey, California, 2. University of Southern California, Los Angeles, California

While Hospice has been identified as a program that improves quality of life at end of life among patients and caregivers, many do not receive this care prior to death or receive referrals in the last days of life. Religion has been identified as a potential barrier to hospice among some minority groups. However, most research has focused on the patient’s religion and beliefs, while only recently have studies begun to inquire about the influence of physician religion as it relates to hospice referral. The few studies that do exist were conducted outside of the U.S., thus impeding generalizability of these findings. This study reports findings from a web-based survey among a sample of health maintenance organization physicians who had a patient die of a chronic condition within six months of last seeing the patient. In 2008, 2,099 physicians were contacted via email to complete an anonymous survey on referral behaviors to EOL services, practice and personal characteristics, and personal/family experience with hospice. Among respondents (n=554), most were U.S.-born (69.1%), married (83.8%), and male (66.0%) with a mean age of 47 years (SD=8.9). About half were Caucasian (51.7%). The majority physicians (75.7%) reported having a religious affiliation, most commonly a branch of Christianity (49.5%) or Judaism (14.0%). Additionally, most physicians (84.3%) indicated some level of spirituality, with nearly one-third extremely spiritual. There was no difference in reported hospice referral by level of spirituality or religious beliefs. Further physician characteristics and their influence on hospice care will also be discussed.

**THINKING AND TALKING ABOUT THE END OF LIFE AMONG THE AGED: TWO VERY DIFFERENT THINGS**

E. Kahana1, B. Kahana2, L. Lovegren3, H. Pfaff4, J. Brown5, J. Kahana6, 1. Case Western Reserve University, Cleveland, Ohio, 2. Cleveland State University, Cleveland, Ohio, 3. University of Cologne, Cologne, Germany, 4. Mount St. Mary College, Newburgh, New York

This paper reports on findings of a study of community dwelling elders reflecting on their preferences, plans, and conversations related to end of life plans. This paper reports on findings of a study of community dwelling elders reflecting on their preferences, plans, and conversations related to end of life plans. Individual interviews were conducted with 514 urban dwelling participants in a panel study focused on the final years of life. Our findings reveal that social connections remain very salient to older adults as they contemplate the end of life. Accordingly, when thinking about the end of life, over 90% of respondents desired to have people around them, others pray for them, and to die at home if possible. In striking contrast, these elders were not talking and having conversations connecting them to significant family or health care providers regarding plans for the end of life. Only 14.7% discussed end of life issues with health care providers, and only 28.0% had conversations regarding end of life issues with family. Talking about end of life plans tended to be limited to preparation of formal advance directives. These data raise provocative questions about the absence of opportunities for meaningful end of life conversations for persons who actuarially are nearing the end of life. Clearly, elders do not wish to disengage, even at the very end, but their continuing engagement lacks facilitation.

**DISCUSSING END-OF-LIFE ISSUES IN ADVANCED DEMENTIA: WHO MAKES FAMILIES FEEL INVOLVED?**

J. Reinhardt, E. Chichin, H. Sand, Research Institute on Aging, Jewish Home Lifecare, New York, New York

Throughout the dementia disease trajectory, both the person with dementia (PWD) and the family are the focus of care. When the PWD is in the late stages of the illness, clinicians communicate exclusively with families to determine treatment preferences and goals of care. As part of a larger study, we queried families (N=99) to learn more about the end-of-life treatment discussions they had with health care professionals in a skilled nursing facility regarding their relatives with advanced dementia. Families were asked which care-providers were involved in discussions, the length of conversations, topics covered, the amount of information they wanted about the condition and particular situations, and the degree to which they were satisfied with care. Results showed that family members had conversations mostly with nurses (71%), certified nursing assistants (57%), physicians (49%), and social workers (48%). Families had an average of 27 conversations over a 3-month period with members of these four professional disciplines. Having a greater number of these conversations was significantly associated with families feeling fully involved in decision making, being more likely to discuss what is in their relative’s best interest and the amount of information they want regarding their relative’s condition. Implications for research and practice are discussed, with an emphasis on strategies to ensure that families understand risks and benefits of treatment decisions that arise in the course of advanced dementia.

**HOW DO SOCIAL RELATIONS AFFECT THE ADVANCE CARE PLANNING OF OLDER ADULTS?**

S. Bodnar Deren, Sociology, Institute for Health, Health Care Policy, and Aging Research, Rutgers University, New Brunswick, New Jersey

The aim of this study is to examine if there is a relationship between the quality of social relations and the odds that a patient engages in advance care planning (ACP). Data come from a recent survey of 305 chronically ill, non-institutionalized adults in New Jersey aged 55 years and older. Individuals who reported that they could communicate with members of their social networks were 60% more likely to have had end-of-life (EOL) discussions (p<.01). Similarly, if they were able to discuss their fears and concerns with loved ones or if they found it easy to plan activities with members of their social network they were 50% more likely to have had EOL discussions with others (p<.05). Additionally, the quality of their social relations were a significant factor in the odds that older adults had formalized their advance care plans. Those respondents who felt supported by others were 50% more likely to have named a Durable Power Attorney for Health Care (DPAHC) (p<.01). Those who felt accepted, supported in their decisions, or those who got along with family were 40% more likely to have had both discussions and to have appointed a DPAHC (p<.01). These findings broaden what
we know about ACP. By further exploring the motivations for ACP, health care providers may put into place effective strategies for facilitating end-of-life discussion and ACP with their patients.

SESSION 1225 (PAPER)

FINANCIAL SECURITY IN OLD AGE: PRESENT AND FUTURE

LONGEVITY INSURANCE: WILL IT SECURE FINANCIAL SECURITY FOR OLDER AMERICANS?
G.A. Mackenzie, Public Policy Institute, AARP, Washington, District of Columbia

Life annuities insure older people against the risk of privation and misery that an unexpectedly long life may entail. Economists have long been puzzled by the small size of the market for these instruments. Recently, insurance companies have promoted a new kind of annuity, sometimes called longevity insurance, which may escape the apparent bias against life annuities. Longevity insurance is best understood as a long deferred annuity. For example, an annuitant might pay a specific sum at age 65 that entitles him or her to receive monthly income for life starting at an advanced age like 80. The premium is not refundable if he dies before payments start. The long deferred start of payments and the possibility of premature death mean that longevity insurance is much cheaper than a conventional life annuity paying the same monthly income. Therein lies its appeal. The paper’s main aims are to assess the merits of longevity insurance and to evaluate the potential regulatory implications of a growing market for it. The paper concludes that longevity insurance is a better choice than the conventional life annuity for some potential annuitants but not others, and that annuity providers will need to ensure that their representatives are able to offer sound advice. The paper will also stress the need to ensure fiduciary safeguards are adequate to minimize the risk of self-serving advice.

THE EASTERLIN HYPOTHESIS: AN UPDATE ON THE STATUS OF THE BABY BOOMER COHORT
P. Cummins, 1. Sociology & Gerontology, Miami University, Oxford, Ohio, 2. Scripps Gerontology Center, Oxford, Ohio

The purpose of this paper is to provide data on the income status of the baby boomer cohort as compared to their parental cohort. The baby boomer cohort has been studied extensively on issues ranging from music to politics to income. In 1961, Easterlin proposed that, without substantial adjustments to their demographic decisions, the baby boomer birth cohort would not achieve the economic status of their parents. In their analysis of baby boomer economic status three decades later, Easterlin, Schaeffer, and Macunovich (1993) determined that, due to demographic decisions such as delaying parenthood and having fewer children, the baby boomer cohort had indeed achieved an economic advantage over their parents. This paper updates the work of Easterlin et al.'s (1993) analysis. Analysis of 2009 income for the baby boomer cohort indicates that younger baby boomers and those with less education are especially at risk for adverse outcomes in retirement. While the current recession is not as severe as the Great Depression, declines in retirement savings and home equity, combined with lengthy periods of unemployment, have had a serious impact on the retirement prospects of many baby boomers.

ECONOMIC WELL-BEING AMONG OLDER ADULT HOUSEHOLDS: VARIATION BY VETERAN AND DISABILITY STATUS

A growing body of gerontological research uses nationally representative data to compare later-life outcomes among veterans and non-veterans. This research has focused primarily on health outcomes and has not considered issues related to economic well-being. Recent research among the working-age population indicates veteran and disability statuses interact to influence both poverty and material hardship at the household level. This paper builds upon the extent research by using pooled data from five waves of the Survey of Income and Program Participation (SIPP) to examine the extent to which household members’ veteran and disability statuses are associated with poverty and four types of material hardship—home hardship, medical hardship, bill-paying hardship, and food insufficiency—taking into account household-level demographic characteristics. The analysis is restricted to households that contain at least one adult aged 65 years or older. Compared to households that have no veteran or person with disability, nondisabled veteran households are significantly less likely to be in poverty (OR=0.55) or experience medical hardship (OR=0.45). In contrast, disabled nonveteran households are significantly more likely to be in poverty (OR=1.53) and to experience home, medical, and bill-paying hardships (OR=2.47, 1.79, and 1.81 respectively). Disabled veteran households are not significantly different in terms of their odds of poverty, but exhibit the highest odds of home hardship (2.91), medical hardship (OR=2.56), bill-paying hardship (OR=1.98), and food insufficiency (OR=3.72). The results suggest the risk of poverty and material hardship is relatively high among disabled nonveteran and disabled veteran older adult households. The implications for policy are discussed.

ECONOMIC CRISES IMPACT EXPECTABLE LIFE COURSE TRANSITIONS: “RUSTING IN PLACE”
C. Lysack, S. Neufeld, W.D. Bartlo, M.R. Luborsky, Gerontology, Wayne State University, Detroit, Michigan

Problem: American households face historic financial erosion due to depressed housing markets and the economic meltdown. These conditions may disrupt expectable later life transitions in household composition, downsizing and relocation, retirement, and continuity of financial security. Yet, systematic data is needed, but still scant, on the extent and salience of disruptions; anecdotal evidence suggests an emerging phenomena of “rusting in place” particularly in the Midwest. Methods: Data is drawn from a 2011 population-based representative sample of Michigan adults (n=550) surveyed using computer-assisted telephone, internet, and mail methods. Measures included financial security, retirement status, household composition and changes, “under-water” mortgage to value ratios; downsizing and household relocation; and socio-demographic factors. Findings: Analyses revealed: (1) While older households (age 62+) report less financial stress, those who take in family members facing financial hardship report greater stress than younger households. (2) Older households gaining family members are significantly more likely to be lower income, be underwater on their mortgages, feel “rusting in place” and unable to move, and report more money worries and difficulty meeting needs. (3). Self-rated health and income level were not related to rusting in place. Discussion: Disrupted expectable life course transitions due to economic factors including “rusting in place” are clear, yet adaptations such as combining households selectively disadvantage older adults who, while fulfilling family care values by offering a refuge for struggling family members, also perceive a cost to older adults that requires further research. [Funding: NIH #R01AG030477; and Michigan Center for Urban Studies]
ASSOCIATION FOR THE RETIREMENT AGE DEBATE
A. Zajacova, J. Monteé, 1. University of Wyoming, Laramie, Wyoming, 2. University of Texas at Austin, Austin, Texas

The debate about raising the retirement ages of U.S. workers revolves around the longer average health expectancy of the population; consideration of socioeconomic disparities in health are absent. We analyze the socioeconomic disparities in numerous health outcomes among older adults and translate them into age-equivalents. We use the 1997-2009 National Health Interview Survey, nationally representative dataset, for information on health and functional and activity limitations of adults aged 50-80 (N=281,882). Using parametric and nonparametric regression models, we calculate predicted age-specific health levels across 5 education levels, from pre-secondary to post-baccalaureate. Early results emphasize the critical differences in health by socioeconomic status: older adults with a post-baccalaureate schooling report health levels equivalent to levels reported by high school graduates about 20 years younger. The differences hold across demographic groups and health indicators. Findings highlight the importance of considering health inequalities in the discussions about retirement age.

SESSION 1230 (PAPER)

IMPROVING THE QUALITY LIFE FOR PERSONS LIVING IN ALFS AND NURSING HOMES

CONCEPTUAL MODEL FOR EXAMINING OUTCOMES OF CULTURE CHANGE IN NURSING HOMES
C.W. Hartmann, A. Snow, R.S. Allen, P. Parmelee, J.A. Palmer, D. Berlowitz, 1. CHQOER, Bedford VA Medical Center, Bedford, Massachusetts, 2. Tuscaloosa VA Medical Center, Tuscaloosa, Alabama, 3. University of Alabama, Tuscaloosa, Alabama, 4. Boston University, Boston, Massachusetts

Nursing homes (NHs) across the country are increasingly adopting new care paradigms under a rubric generally termed “culture change.” Culture change prioritizes residents’ needs and preferences and emphasizes having facilities’ designs, routines, and care shaped by them. To understand the circumstances that best promote culture change, we developed a comprehensive model for assessing the current state of care, work, and culture of NHs. We conducted a search of the relevant literature for (a) concepts related to the various aspects of culture change and (b) instruments designed to measure these aspects. We developed a conceptual model based on our findings, using the Holistic Approach to Transformational Change (HATCH) framework. To pilot and refine the model, we conducted over 100 hours of systematic observations of residents and staff at two NHs within a large, integrated healthcare system (the Veterans Health Administration). Observations supported the existence of our 18 specific domains (e.g., Promoting Resident’s Voice; Existence and Functioning of Interdisciplinary Teams) within the three overarching HATCH categories of “care practices,” “workplace practices,” and “environment of care.” Results also suggested that assessment of resident and staff engagement with each other and in activities is important to include across all domains. The comprehensive model we developed has the potential to inform directly the care provided to residents in NHs by identifying areas in which culture change is having a positive effect. It also highlights aspects of culture change that work well from the perspective of residents and staff and those that could benefit from modification.

ASSISTED LIVING LIFESTYLE—INFORMATION FLOW TO PRIMARY PROVIDERS ON THE HEALTH OF DEMENTIA PATIENTS

Communication between assisted living (AL) staff caregivers of geriatric patients with dementia, and nurse practitioners and physicians who serve as primary care providers is critical for good decision-making. Literature that describes the communication flow between staff of AL facilities and primary care providers, however, is lacking. Using an intuitive decision making model as a framework, a study was undertaken to assess patient information flow among these providers. Qualitative and quantitative data were collected systematically from 25 participants regarding flow of patient information and the level of professional caregiver satisfaction with this information flow. Results revealed that 83% of AL staff were not often asked to provide information to primary care providers, while 100% of AL nurses were. Eighty-one percent of staff either were not satisfied or could not identify how they report information to the primary care providers for patients. Nurses were somewhat satisfied or satisfied (80%) with how they currently obtain information. A comprehensive health status reporting tool for patients in assisted living was not found in the geriatric literature, but one was identified from the field of developmental disabilities. Next steps in the study are to examine the efficacy of this tool to improve information flow to nurses and primary providers regarding the current health status of geriatric dementia patient in the assisted living settings.

INCREASING OPPORTUNITIES FOR ARTS-BASED INTERVENTION IN LONG TERM CARE
J. Eaton, University of Utah, Salt Lake City, Utah

Increased life expectancy has augmented the use of arts-based interventions to enhance quality of life through an emphasis on late life potential, yet research varies greatly in design, availability, and application. A systematic review of literature identified arts-based intervention settings as well as outcomes within long term care (LTC). Search parameters included peer-reviewed articles published between 2000 and 2010 describing interventions including dance, theatre, visual art, and music with adults 65 and older. A search of four electronic databases provided 1,536 references, 262 were relevant to preliminary criteria. Interventions were categorized within three settings: 1) community, 2) clinical (inpatient and outpatient), and 3) LTC (nursing homes, skilled nursing, and assisted living facilities). Interventions in LTC emphasized individuals with dementia compared with the overall LTC population. To better understand this difference a synthesis was conducted on ten LTC articles not targeting dementia. Results focused on quality of life, increased social interactions, and evolution of culture through leadership opportunities. Economic value was not reported and methods varied greatly. Arts-based interventions within the LTC environment heavily target individuals with dementia. This suggests that there are residents without dementia who would benefit but are not provided these opportunities. Incorporation within policy and practice will require an emphasis on economic impact and outcome based designs utilizing random selection and control groups. Interdisciplinary collaboration and the use of professional artists need to be considered for their potential to increase participation and outcomes.

URINARY INCONTINENCE (UI) IN NURSING HOMES: IMPROVING RESIDENT OUTCOMES AND STAFF USE OF EBPs
J. Specht, A. Bossen, P. Mobily, M. Stolder, K. Lane, J. Russell, D.A. Reed, 1. Nursing, University of Iowa, Iowa City, Iowa, 2. University of North Carolina, Chapel Hill, North Carolina

Urinary incontinence (UI) is a highly prevalent and costly problem in nursing homes (NH) and is often mistakenly attributed to normal
A. Walker, Sociological Studies, University of Sheffield, K., Smith, J. and Antonucci, T. (2007) ‘Social Network Types Among 2007). After attending this paper, participants will be able to appreci- improve health and increase survival rates (Fiori, Smith, and Antonucci, cific research with older people has shown that social relations can
This research explored the potential for participation in community music making to enhance older people’s social, emotional and cogni- tive well-being. The research comprised three UK case study sites, each offering a variety of musical activities. At each site a sample of people aged 50+ (total N = 398), including novices and more experienced musicians, was recruited. Participants completed quality of life measures, developed for use in research on ageing, before and after nine months of active engagement with music. A control group (N=102) completed the same measures. In- depth interviews, focus groups and observations of musical activities were carried out with a representative sample. Higher scores on the quality of life measures were found consistently amongst the music participants, in comparison with the control group. Music participants attributed significant social, emotional and health benefits to active engagement with creative music making, opportuni- ties for progression and participation in performances.

This paper presents findings from one phase of an NDA programme project exploring representations of older women. Two discrete cohorts of older women were invited to work with two purposively selected photographers charged with the brief of creating ‘alternative’ images of ageing. Whilst the photographs produced in the subsequent work- shops departed from the ‘heroes of ageing’/’bodily decline’ representa- tions dominant in popular culture (Featherstone, 1995), many of the images could nevertheless be categorised as nostalgic/melancholic or humorously carnivalesque. This indicates the difficulties of creating ‘alternative’ images of older women that are read in ways which defy established modes of categorisation. This presentation addresses the conference theme of ‘the social well being of older people’ through the analysis of a participatory initiative designed to address the Madrid International Plan of Action on Ageing objective to ‘facilitate contribu- tions of older women... to the presentation by the media of their activi- ties and concerns’ (UN, 2002).
EMOTIONAL AND PHYSICAL WELL-BEING: AN AGE-COMPARATIVE PERSPECTIVE ON STRUCTURE AND COMPLEXITY

Chair. A. Brose, Center for Lifespan Psychology, Max Planck Institute for Human Development, Berlin, Germany, Max Planck Institute for Human Cognitive and Brain Sciences, Leipzig, Germany Co-Chair: J.K. Wolff, Center for Lifespan Psychology, Max Planck Institute for Human Development, Berlin, Germany

The within-person perspective, including intraindividual variability and within-person factor structures, increasingly receives attention in psychological research. Identifications of factor structures underlying a set of variables and their complexity are mostly based on interindividual differences but rarely on intraindividual variability. Yet, research is required on both levels of analysis, because findings on, for example, relationships between different facets of affect at the interindividual level do not have to be informative on how affective states travel together across time. Age-comparative research acknowledges potential age-related changes in interindividual structures by testing invariance of constructs. This symposium suggests that (1) potential age group differences in structure and complexity also require attention at the intraindividual level and (2) more insights are needed on the degree of equivalence of inter- and intraindividual variation in order to judge the generalizability of findings across levels in different domains. We focus on age differences in structures in the domains of emotional and physical well-being. Ready investigates age differences in the congruence of multiple within-person structures of positive and negative affect with a focus on affect complexity. Ram et al. demonstrate that findings on within-person affect complexity depend on its definition and quantification and that age-related changes in context may underlie changes in complexity. Wolff et al. present different methods to compare within-and between-person structures using data on daily assessments of health complaints in two age groups. Brose et al. focus on whether the within-person structures of affect differ from the between-person structures in younger versus older adults.

INTRAINDIVIDUAL VARIABILITY IN POSITIVE AND NEGATIVE AFFECT IN YOUNGER AND OLDER ADULTS

R. Ready¹, M.I. Weinberger¹, 1. Psychology, SMAST/UMASSD, Amherst, Massachusetts, 2. Weill Cornell Medical Center, New York, New York

Intraindividual structures of positive (PA) and negative affect (NA) are similar in older and younger adults (Ready et al., in press) but it is not clear if the intraindividual structures of PA and NA are invariant across age (Mollenar, & Campbell, 2009). Intraindividual structures of PA and NA were calculated in younger (N = 16) and older adults (N = 21) and were compared to a composite affect structure. Data were from a 28-day diary study. Younger adult congruence coefficients averaged .97 for PA and 0.93 for NA, suggesting strong convergence. Older adult congruence coefficients averaged 0.94 for PA and 0.84 for NA, suggesting poor convergence for NA. These pilot data indicate greater variability in the within-person structure of affect in older relative to younger adults and are consistent with ideas of greater emotional complexity in older adults (Lawton, Kleban, & Dean, 1993; Ready, Carvalho, & Weinberger, 2008).

AGE DIFFERENCES IN AFFECT COMPLEXITY: IS IT ACTUALLY AGE-RELATED HETEROGENEITY IN CONTEXT?

N. Ram, D. Conroy, A. Pincus, A. Lorek Dattilo, A.L. Hyde, M. Roche, Pennsylvania State University, University Park, Pennsylvania

Building from theory, a number of constructs have been used to capture interindividual differences in the complexity and changing nature of affective states. Although obtained from similar types of data, emotional differentiation, heterogeneity, and poignancy are operationalized using different procedures – within-person correlations, sums or differences, and P-technique factor analysis. Using three 21-day bursts of data provided by 140 participants (aged 18-89 years) in the Penn State Intraindividual Study of Aging, Health, and Interpersonal Behavior (iSAHB) we (a) illustrate the variety of ways affective complexity can be quantified, (b) identify some of the benefits and limitations of those measures, (c) consider why age differences appear in some measures and not others, and (d) suggest that affect complexity may reflect variability in individuals’ social contexts rather than inherent individual differences. Throughout, we underscore the need for precision in the theoretical conceptions and methodological invocations of complexity-based constructs.

SYMPTOM REPORTING IN YOUNGER AND OLDER ADULTS: WITHIN-PERSON VARIABILITY AND FACTOR STRUCTURES

Intraindividual variability and within-person factor structures are widely neglected in health-related research. The current study addresses both issues from an age-comparative perspective. 101 younger (20-31 years) and 103 older adults (65-80 years) participated in 100 daily assessments of health complaints. To evaluate the within- and between-person factor structures, two approaches are used: confirmatory two-level factor analysis and P-technique factor analyses. The amount of intraindividual variability is compared between the age groups showing less fluctuation in older adults. Preliminary results show that one-factor structures of health complaints provide an acceptable fit at the between- and average-within-person levels in both age groups with age-specific loading patterns. The p-technique analyses reveal a well fitting one-factor solution for a considerable amount of individuals. However, several persons had a worse fit, indicating different individual structures. In further analyses, dynamic factor analyses will be conducted to additionally account for temporal dependencies in the data.

POSITIVE AND NEGATIVE AFFECT: FROM THE BETWEEN-PERSON STRUCTURE TO INDIVIDUALS’ DAILY EXPERIENCES

This study investigated whether the structure of affect that is based on interindividual differences is equivalent to the structures underlying variability of affective states within individuals across time. Adult age group differences were examined regarding equivalence and interindividual differences in within-person structures. For 100 daily sessions, 101 younger (20-31) and 103 older (65-80) adults rated their mood on the Positive and Negative Affect Schedule (PANAS). The structure of affect was investigated by means of confirmatory factor analyses (cross-sectional analyses, single-subject dynamic factor analysis). The results differed across subjects, but were comparable across age groups on average. The major age difference was reduced variability in older adults. According to a test of ergodicity (i.e., the equivalence across levels of analysis), younger and older individuals’ structures differed from the interindividual structure. Thus, findings on either level are not generalizable to the other. Individual differences in intraindividual structures remain to be understood.

64th Annual Scientific Meeting
SESSION 1245 (SYMPOSIUM)

IMPLEMENTING AUTONOMY IN SENIOR HOUSING: STRATEGIES AND CHALLENGES

Chair: A. Frankowski, UMBC, Baltimore, Maryland
Co-Chair: R. Rubinstein, UMBC, Baltimore, Maryland
Discussant: S. Golant, University of Florida, Gainesville, Florida

Autonomy is a core American value and a key component in the philosophy of senior housing, especially assisted living (AL). Research demonstrates that older adults' sense of autonomy - expressed as independence, choice, or control - is integral to their health and well-being. In this symposium, we explore how autonomy is defined, experienced, and negotiated by residents, their families, and staff in senior housing settings through the gaze of advocates, consumers, providers, and qualitative researchers. After a brief introduction to the theoretical construct of autonomy, two researchers present data on the experiential aspects of autonomy, as expressed specifically through alcohol use in AL and participation in communal dining in a continuing care retirement community. The third paper, framed through a provider perspective, examines the degree of autonomy afforded to AL residents with dementia, and the conflicting forces between residents, families, and providers regarding their varied preferences in the implementation of the concept. Our fourth presenter reports on a consensus project examining the needs and recommendations of the gay, lesbian, bisexual, and transgender community in long-term care (LTC) and other senior residential settings, whose goals are to promote resident autonomy, beneficence, and social justice. We conclude with an overarching look at person-centeredness in LTC, its environmental successes and barriers, operational components, and parameters for evaluation. These presentations will inform policy and practice on how implementing autonomy in everyday life results in better quality of life and care for the increasing number of adults living longer and moving into senior housing.

RESIDENT CHOICES AND CHALLENGES IN A COMMUNAL DINING ROOM

M.C. Nemec, A. Frankowski, A.D. Peeples, R. Rubinstein, Center for Aging Studies, University of Maryland, Baltimore County (UMBC), Baltimore, Maryland

Residents in assisted living, nursing homes, and some independent living apartments share meals in communal dining rooms where choices are compromised, reduced, or non-existent. They are assigned seats, offered limited food options, and adhere to the setting’s rules, resulting in their exercising minimal control. This presentation shares how the critical role of autonomy plays in the dining experience as understood by residents, staff, and management. The authors first examine 100 interviews and 150 fieldnotes from the perspective of one case study, that of a large religiously-affiliated, multi-level senior housing site located in a Mid-Atlantic state; they then compare their focal case analysis to data from ethnographic, NIA-funded studies focusing on transitions, quality, and autonomy in AL.

ONE MORE GLASS: NAVIGATING AUTONOMY AND ALCOHOL IN ASSISTED LIVING

A.D. Peeples, A. Frankowski, R. Perez, M.C. Nemec, R. Rubinstein, Center for Aging Studies, UMBC, Baltimore, Maryland

Little research has been conducted on the use of alcohol in assisted living (AL) settings. This paper explores resident autonomy as it relates to alcohol use and abuse in AL. The alcohol policies of ALs, as well as the factors that affect changes to these policies over time, are described. We examine the roles that corporate policy, the executive director, staff, families, and residents themselves play in shaping resident access to alcohol in AL. Through the use of case studies, dementia and alcoholism are each explored as complex conditions that can make autonomy and resident choice difficult to uphold when alcohol is involved. We also discuss the potential for alcohol use as an affirmation of resident autonomy in these settings. Data for this paper is drawn from four ethnographic, NIA-funded studies focusing on transitions, quality, stigma, and autonomy in AL.

AUTONOMY FOR PEOPLE WITH ADVANCED DEMENTIA IN ASSISTED LIVING: IMPLICATIONS FROM AND FOR RESEARCH

J. Hyde, R. Perez, J.P. Doyle, Gerontology Institute, University of Massachusetts, Boston, Boston, Massachusetts, University of Maryland, UMBC, Baltimore, Maryland

Assisted living (AL) is often thought of as a setting for relatively independent seniors, yet moderate to severe cognitive impairment is common among AL residents. A 2004 study (Rosenblatt et al) found that 67% of AL residents had, on full evaluation, significant cognitive impairment. Of these approximately 10% were severely impaired (MMSE<9). While the AL philosophy promotes choice and autonomy, a significant minority of residents are unable to speak more than a few words and may not recognize people who have been significant in their lives. How may these individuals participate in decisions that affect their health and quality of life, and how are AL providers successful in supporting resident autonomy? Drawing on this team’s research regarding end-of-life programs, the session will provide theoretical and practical perspectives on autonomy for the most cognitively impaired, particularly with regard to assent, informed consent and participation in research for those with advanced dementia.

ADDRESSING CONCERNS FOR LONG-TERM CARE IN THE LESBIAN AND GAY COMMUNITY

G.L. Stein, Warzweiler School of Social Work, Yeshiva University, New York, New York

Long-term care providers need to do more to address the perspectives of their LGBT residents. The authors conducted an exploratory inquiry comprised of two focus groups among gay elders receiving services at a community-based social service organization and a long-term care setting. Participants reported fear of being rejected or neglected by healthcare providers; fear of not being accepted by other residents; fear of having to go back into the closet if placed in long-term care; and a preference for gay or gay-friendly residential options. As a result of this study, the authors and a leading national provider of assisted living residences convened in 2011 elder care providers, educators, and consumers an invitational meeting to develop consensus recommendations for staff training, program development, and research. Our findings and recommendations will promote awareness of the special concerns of LGBT elders, and form the basis for further initiatives around these domains.

PERSON-CENTEREDNESS: HOW WILL PROVIDERS KNOW IF THEY ARE ACHIEVING IT AND WHAT CONSUMERS SHOULD LOOK FOR

K. Love, Pathways to Care, Falls Church, Virginia

Person-centered (PC) has its roots in Carl Rogers and Abraham Maslow’s work on humanism that values and respects the dignity of each individual and treats them as humans with unique feelings and characteristics. Loneliness, helplessness, and boredom that Bill Thomas describes many nursing home residents as suffering from are outcomes experienced in a non PC culture. Assisted living improved many environmental barriers to PC that exist in traditional nursing homes: institutional designs, nursing stations, overhead address systems, and one-size-fits-all mentality to dining and activities. Some operational components such as PC workforce practices and meaningful engagement, however, are missing. The Affordable Care Act signed into Law by quasr on 30 April 2018

The Gerontological Society of America
by President Obama has provisions for health care delivery based upon PC which encompasses aging services beyond nursing homes and assisted living to home health care and adult day care among other services. There are no national parameters of PC, so how will providers know when they are achieving it and how will consumers know what to look for? This paper will address these questions.

SESSION 1250 (SYMPOSIUM)

LIFE AFTER GRADUATE SCHOOL: NAVIGATING THE PROCESS
Chair: C.A. Mingo, Institute on Aging, University of North Carolina - Chapel Hill, Chapel Hill, North Carolina

Many emerging scholars with an interest in Gerontology experience anxiety during the transition from graduate school to their first post-graduate position. Because of the interdisciplinary nature and the wide array of Gerontology-related career opportunities (i.e., academic and non-academic), emerging scholars can benefit greatly from mentoring. Mentoring is important for individuals throughout their careers, and historically GSA has always seen it as an indispensable part of success. Discussing opportunities with a mentor can result in positive outcomes including the reduction of anxiety and the broadening of horizons of what is possible. While mentorship can come in many forms (e.g., long-term, short-term, structural, informal, formal, workshops, and conference presentations) the purpose of this symposium is to provide a forum that would advise emerging scholars on ways to approach the “what next”. The overall objectives of this symposium are to educate emerging scholars about ways to bridge the gap between student and professional life, to find the right academic position for you, to find and secure non-academic employment opportunities, and to provide information on the mentoring opportunities offered and sponsored by the GSA Task Force on Mentoring. Following the presentations, an opportunity will be provided for questions and discussion between symposium presenters and the audience. This symposium is co-sponsored by the GSA Emerging Scholars and Professional Organization, GSA Task Force on Mentoring, and the Association for Gerontology in Higher Education.

BRIDGING THE STUDENT-TO-PROFESSIONAL GAP: WHAT INSTITUTIONS CAN DO
L.K. Evans, Family & Community Health Nursing, University of Pennsylvania, PHILADELPHIA, Pennsylvania

New academics face many challenges as they begin their first positions. Learning a culture ‘from the other side,’ mastering the ‘rules for success,’ and achieving work-life balance require energy, navigational direction, and support. Universities increasingly recognize that their anxiety during the transition from graduate school to their first post-graduate position. Because of the interdisciplinary nature and the wide array of Gerontology-related career opportunities (i.e., academic and non-academic), emerging scholars can benefit greatly from mentoring. Mentoring is important for individuals throughout their careers, and historically GSA has always seen it as an indispensable part of success. Discussing opportunities with a mentor can result in positive outcomes including the reduction of anxiety and the broadening of horizons of what is possible. While mentorship can come in many forms (e.g., long-term, short-term, structural, informal, formal, workshops, and conference presentations) the purpose of this symposium is to provide a forum that would advise emerging scholars on ways to approach the “what next”. The overall objectives of this symposium are to educate emerging scholars about ways to bridge the gap between student and professional life, to find the right academic position for you, to find and secure non-academic employment opportunities, and to provide information on the mentoring opportunities offered and sponsored by the GSA Task Force on Mentoring. Following the presentations, an opportunity will be provided for questions and discussion between symposium presenters and the audience. This symposium is co-sponsored by the GSA Emerging Scholars and Professional Organization, GSA Task Force on Mentoring, and the Association for Gerontology in Higher Education.

FROM A TO Z: ACADEMIC POSITIONS ACROSS THE FULL SPECTRUM
L.G. Hodgson, Sociology, Quinnipiac University, Hamden, Connecticut

Planning for life beyond graduate school is both an opportunity and a challenge. Emerging scholars who seek academic employment face a wide array of choices, from faculty positions at community colleges to major research institutions. The mix of research, teaching, and service obligations at different types of institutions varies along a continuum but all have the potential for rewarding careers. It is critical that emerging scholars and their mentors talk openly about the full range of possibilities. On the part of the emerging scholar, that requires an honest appraisal of strengths, weaknesses, and preferences; on the part of the mentor, that requires a willingness to “hear and listen” before offering advice. Clearly the goal of both emerging scholar and mentor should always be the same—an academic career decision that offers the “best fit.”

SESSION 1255 (SYMPOSIUM)

MULTIDISCIPLINARY AND GLOBAL PERSPECTIVES ON CARE AND CAREGIVING
Chair: S.R. Williams, Anthropology, Purdue University, West Lafayette, Indiana
Co-Chair: G. Ice, Ohio University, Athens, Ohio
Discussant: M. Iris, Leonard Schanfield Research Institute, Chicago, Illinois

The impact of caregiving on well-being is a major concern within the field of gerontology. However the nature and impact of caregiving depends upon the context in which care occurs and who fulfills the role of caregiver. While research in the U.S. has increased our understanding of the connections between caregiving, health and well-being, these relationships are likely to vary across cultural contexts. The nature and circumstances of the caregiving-care recipient relationship likely differs across cultures and thus it is likely that the impact of caregiving is
THE IMPACT OF CHANGING FAMILY STRUCTURE AND CULTURAL EXPECTATIONS ON CAREGIVING IN INDIA
S.R. Williams, D.L. Howell, Anthropology, Purdue University, West Lafayette, Indiana

Context creates the need for caregiving and determines the impact that caregiving has on the caregiver. Further, cultural contexts and expectations produce different lived experiences in both aging and caregiving. In India, traditional family structure consists of multiple generations living in the same household. This pattern created stability and ensured care for older adults as they required care. In modern India, this pattern is changing as single generation households are becoming more common, especially in the rapidly growing and aging middle and upper classes. The goal of this paper is to explore the current impact of caregiving on the health of older adults in India using population level data from the World Health Organization’s Study of Global Aging and Adult Health (SAGE). Further, we attempt to draw on ethnographic data collected in Kolkata, India to explore how the shifting family structure contributes to caregiver burden and poor health outcomes.

AN UNEXPECTED DOUBLE BURDEN OF CAREGIVING: OLDER WOMEN IN AIDS-ENDEMIC SETTINGS
E.J. Schatz, Occupational Therapy/Women’s & Gender Studies, University of Missouri, Columbia, Missouri

Caregiving is gendered. In most contexts, women primarily do the physical and emotional work at home of caring for the sick, dying, and social reproduction entailed in raising children. In the global North, aging populations have led to a double burden for middle-aged women caring for children and their aging parents. In the global South, particularly places affected by AIDS, older women rather than those in middle-age often are taking on this double burden of care—for their ailing adult children and their grandchildren (fostered and orphaned). This paper examines some of the existing literature and theoretical underpinnings of the implications of carework on carers; and, it examines gendered nature and generational shifts in caregiving in AIDS-endemic settings. I focus on the impacts of caregiving for older women’s own health and wellbeing, and the intergenerational dynamics brought on by shifting roles and responsibility within older women’s households and communities.

FACTORS INFLUENCING WELL-BEING OF KENYAN CAREGIVERS
G. Ice1, A. Sadruddin1, J.V. Yogo1, E. Juma2, 1. Social Medicine, Ohio University, Athens, Ohio, 2. Kenya Medical Research Institute, Nairobi, Kenya

Numerous advocacy groups have expressed concern about African elders, who have expanded caregiving duties due to the HIV/AIDS pandemic. Recent research is on African caregivers, however, has demonstrated that caregiving in not universally detrimental yet we know little about the factors which determine the impact of caregiving. Results from Kenya have demonstrated that caregiving has a positive impact on some elders. What makes some elders vulnerable and others resilient? This presentation explores the factors which positively and negatively impact the well-being of caregivers using BMI, perceived health and mental health as outcome variables. Data were collected from 366 elders (177 caregivers). Household demographics were important predictors of outcomes, with the number of older children and women generally having a negative impact on female caregivers and the number adults having a positive impact on men. These data suggest a careful assessment of household demographics and gender be considered prior to intervention.

CAREGIVING DOSAGE EFFECTS: VARIATION IN BIOMEASURES BY CAREGIVING INTENSITY
S. Leitsch1, K.A. Morris1, S.R. Williams1, 1. NORC, Chicago, Illinois, 2. Purdue University, West Lafayette, Indiana

Physiological manifestations of emotional strain are suggested mechanisms through which caregiving affects long- and short-term health outcomes. Methodological advancements, such as blood spot collection, allow identification of biologically driven mechanisms in population-based research. Using data from the National Social Life Health and Aging Project (NSHAP), we investigate how caregiving intensity affects health and function, including blood pressure, performance-based mobility, and dried blood-spot assays of inflammation (CRP) and immune function (EBV antibody titers). In this population-based sample of older Americans (n=3,005), approximately 15% of respondents indicated caring for someone over the age of 65 who needs help with day-to-day activities because of age or disability. The intensity of the caregiving role, as defined by the number of hours per week spent caring, is significantly associated with greater impairment in activities of daily living, more impaired mobility and greater systolic blood pressure, but not inflammation or immune function.

THE LONG-RUN IMPACTS OF ADULT DEATHS ON OLDER HOUSEHOLD MEMBERS IN TANZANIA
K. Beegle1, A. Adhvaryu1, 1. World Bank, Washington, District of Columbia, 2. Yale University, New Haven, Connecticut

HIV/AIDS is drastically changing the demographic landscape in high-prevalence countries in Africa. The prime-age adult population bears the majority of the mortality burden. These “missing” prime-age adults have implications for the socioeconomic well-being of surviving family members. This paper uses a 13-year panel from Tanzania to examine the impacts of prime-age mortality on the time use and health outcomes of older adults, with a focus on long-run impacts and gender dimensions. Prime-age deaths are weakly associated with increases in working hours of older women when the deceased adult was co-resident in the household. The association is strongest when the deceased adult was living with the elderly individual at the time of death and for deaths in the distant past, suggesting that shorter-run studies may not capture the full extent of the consequences of adult mortality for survivors. Holding more assets seems to buffer older adults from having to work more after these shocks. Most health indicators are not worse for older adults when a prime-age household member died, although more distant adult deaths are associated with increased probability of acute illness for the surviving elderly. For deaths of children who were not residing with their parents at baseline, the findings show no impact on hours worked or health outcomes.
SESSION 1260 (SYMPOSIUM)

QUALITY OF CARING RELATIONSHIPS: THE ROLE OF STAFF-RESIDENT INTERACTION DURING CARE ROUTINES

Chair: A. Custers, Behavioural Science Institute, Radboud University Nijmegen, Nijmegen, Netherlands

Discussant: H. Wahl, Department of Psychological Aging Research, Heidelberg University, Heidelberg, Germany

Interpersonal relationships with staff are known to influence the experience and well-being of older people in residential long-term care. Although there is some evidence that older people describe relationships developed with staff as an important aspect of the quality of care they receive, there is limited literature that explains how positive caring relationships are developed. This symposium proposes that positive caring relationships are integral to the delivery of resident-centered care. Four papers from different countries and disciplines, using different research methods, highlight how care routines may be used to develop positive caring relationships through resident-centered interaction. The first paper describes a typology of resident-staff interaction that was developed using ethnographic data to compare two non-profit nursing homes. This is followed by a paper that examines ‘elderspeak’ used by staff in three different care settings. The fulfillment of residents’ needs of relatedness, autonomy and competence during care interactions is the focus of the third paper, which also addresses the relationship with residents’ well-being. The final paper explores how caring relationships are developed during care routines presenting an evidence-based model for supporting staff in implementing resident-centered care. The symposium will conclude with an interactive discussion that considers the characteristics of a high quality caring relationship and how this might be developed in practice.

STAFF-RESIDENT INTERACTION IN NURSING HOMES: AN ETHNOGRAPHY OF DISPARITIES AND COMMUNITY CONTEXTS

M. Ryvicker, Center for Home Care Policy and Research, Visiting Nurse Service of New York, New York, New York

Although there is growing evidence of racial/ethnic and socio-economic disparities in health outcomes of nursing home (NH) residents, less is known about disparities in the quality of staff-resident interaction. This study used ethnographic data to compare staff-resident interaction in two non-profit NHs and develop a typology of interaction. One facility served a white, middle-class community; the other served a low-income, historically underserved Black and Hispanic community. Three categories of interaction emerged - activating, relating, and attending - that were performed differently between facilities. Whereas staff in the more affluent NH interacted with residents in a dynamic fashion, adapting to residents’ responses, staff in the safety-net facility interacted with residents in a one-directional, didactic fashion. These differences reflected disparities in staff communication skills related to each NH’s relationship with its local community. This study raises further questions about how neighborhood contexts influence organizational processes that influence staff-resident interaction and resident quality of life.

RELATIONAL COMMUNICATION ACROSS LONG-TERM CARE SETTINGS: ELDERSPEAK’S IMBALANCE OF CARE, RESPECT, AND CONTROL

K.N. Williams, School of Nursing, Univ of Kansas, Kansas City, Kansas

Older adults who reside in long-term care rely on staff for interpersonal relationships that are reflected in communication. Elderspeak is a common speech style used by nursing home staff that reflects an imbalance in care, respect, and control. Naive raters listened to audio clips collected in long-term care settings and rated staff speakers on care, respect, and control dimensions of emotional tone. We examined these ratings of staff communication, comparing staff communication in traditional nursing homes, dementia care, and assisted living settings. Emotional tone of staff communication with residents varied significantly from their communication with coworkers and age peers. Staff communication was rated as less caring and more controlling in dementia care units compared to nursing homes and assisted living facilities. Respect ratings were highest in assisted living and lowest in dementia care. Implications for staff communication training to improve interpersonal relationships with residents in these settings will be discussed.

SESSION 1265 (SYMPOSIUM)

SOCIAL RELATIONSHIPS AND HEALTH OVER THE LIFE COURSE: PERSPECTIVES FROM AROUND THE WORLD

Chair: T.G. van Tilburg, VU University Amsterdam, Amsterdam, Netherlands

Co-Chair: K.J. Ajrouch, Eastern Michigan University, Ypsilanti, Michigan

In old age social relationships promote social integration, receipt of support, and aid in the prevention or delay of poor health. Having beneficial social relationships and its effects on health vary over time, place
and context. This symposium presents results from five countries to highlight this variation. Takayama & Akiyama show health outcomes of friendship and social activities for people aged 85-102 in Tokyo, Japan. Social, psychological, and behavioral factors influence longevity. Ajrouch, Antonucci & Abdulrahim examine whether network size and relationship quality varies by age in its association with health among adults in Beirut, Lebanon aged 40-96. Unexpectedly smaller networks contributed to better health outcomes among older adults. Fuller-Igle-
sias & Antonucci studied Mexican adults aged 40-95. Positive and neg-
ative social support quality mediates effect of stress on depressive symp-
toms differentially. Suane, Van Tilburg & Broese analyze networks of
Dutch older people aged 55-100. Since the 1990s networks increasingly are composed of non-kin relations, which may be due to delay of age-
related decline. Antonucci & Akiyama examine the effects of relation-
ship quality with friends as a potential buffer among those aged 70 and
above in the United States. Findings suggest that high positive and low
negative friend relationship quality attenuates the strong association
between chronic conditions and depression. Each paper contributes to
our knowledge of how social relationships operate in old age. Together
the papers add to the insight that not all relationships are beneficial,
however, specific sets of relationships in specific contexts contribute
to well-being in old age.

SOCIAL SUPPORT AS A MEDIATOR BETWEEN STRESS
AND DEPRESSIVE SYMPTOMS IN MEXICAN ADULTS
H. Fuller-Iglesias1, T. Antonucci2. 1. North Dakota State University,
Fargo, North Dakota. 2. University of Michigan, Ann Arbor,
Michigan
Recent studies have explored social support as a buffer for the effects
of stress on well-being; however, little is known about stress buffering
within Latin cultures where social support is known to be critically
important. Using data from the Survey of Social Relations and Well-
being in Mexico (Fuller-Iglesias & Antonucci, 2009), this study explores
whether positive and negative social support quality mediate the effect
of current, recent, and long-term stress on depressive symptoms in Mex-
ican adults aged 40-95 (N=680). Tests of mediation indicate that the
effects of long-term stress (i.e. education level) and current stress (i.e.
perceived stress) on depressive symptoms were mediated by negative
support quality whereas the effect of recent stress (i.e. stressful life
events) on depressive symptoms was mediated by both positive and neg-
ative support quality. Findings suggest that among Mexicans social sup-
port quality may act as a buffer for psychological well-being. Implica-
tions and future directions will be discussed.

THE BUFFERING EFFECT OF SOCIAL RELATIONS ON
THE LINK BETWEEN PHYSICAL HEALTH AND
PSYCHOLOGICAL WELL-BEING IN THE U.S
T.C. Antonucci, H. Akiyama, Institute for Social Research, University of
Michigan, Ann Arbor, Michigan
This study examines how the composition and quality of older adults’
social relations with friends and family buffers the association between
physical health and psychological well-being. Data come from the Social
Relations, Aging and Health Study, a regionally representative longi-
tudinal sample of the Detroit metropolitan area. Respondents age 70
and older at wave 1 (1992) were selected for analysis (N=285). Regres-
sion analyses reveal that respondents who reported fewer chronic con-
ditions and a greater proportion of friends in their social network were
less depressed. Among those with high positive and low negative friend
relationship quality, the strong association between chronic conditions
and depression was drastically reduced. In terms of immediate family
relationship quality, only low negative quality relationships was found
to buffer the detrimental influence of chronic conditions on mental
health. The role of social relations in buffering this relationship over
time will also be explored.

THE INFLUENCE OF THE SOCIAL, PSYCHOLOGICAL
AND BEHAVIORAL FACTORS ON LONGEVITY
M. Takayama1, H. Akiyama2,3. 1. Keio University, Yokohama,
Kanagawa, Japan. 2. University of Michigan, Ann Arbor, Michigan.
3. University of Tokyo, Tokyo, Japan
The majority of studies on longevity have focused on biological
and health-related aspects of longevity. Although biology and health
undoubtedly play an important role in determining the length of life,
there are also a number of important social, psychological, and behav-
ioral factors associated with longevity. In order to examine this
research question, we analyzed a longitudinal data among the oldest
old in Japan (Tokyo Oldest Survey on Total Health; N = 663 age 85-
102) using logistic regression analysis with controlling age and gen-
der (dependent variables: alive or dead until 2010(Wave3); inde-
pendent variables: biological, physical, cognitive, psychological and
social variables in Wave1 (2008)). The results revealed that hearing
ability (I need for someone to speak to me loudly, or need NOT), self-
efficacy, subjective well-being with calm-feeling, number of friends,
posite relations with friends, and social activities at WAVE1 (2008)
predicted life at WAVE3 (2010), while physical functional limitations
did not.

COHORT-RELATED CHANGES IN THE PROPORTION
OF NON-KIN IN OLDER ADULTS PERSONAL NETWORKS
B. Suane, T.G. van Tilburg, M. Broese Van Groenou, Sociology, VU
University Amsterdam, Amsterdam, Netherlands
Research on age-related changes in personal networks strongly sup-
ports socio-emotional selectivity theory holding that older adults expe-
rience a decline in less emotionally close relations. Various scholars
have suggested that salience of less structurally embedded relations has
increased in recent decades. We hypothesize an increase in the pro-
portion non-kin in networks across subsequent birth cohorts. Seven
observations by the Longitudinal Ageing Study Amsterdam covering a
time span of seventeen years since 1992 are analyzed, including 3516
respondents born between 1908 and 1938. Results show that younger
cohorts have a larger proportion of non-kin in networks (at age 77: 40%
versus 33% for older cohorts) and that age-related decline in non-kin
is absent for younger cohorts and large for older cohorts (12%). Find-
ings can be interpreted in several ways. First, socio-emotional selec-
tivity fits particularly with older cohorts. Second, the onset of age-
related decline is delayed. Third, societal salience of non-kin has
increased.

SOCIAL RELATIONS AND HEALTH OVER THE LIFE
COURSE: A LEBANESE PERSPECTIVE
K.J. Ajrouch1,2, T.C. Antonucci1, S. Abdulrahim1. 1. Eastern Michigan
University, Ypsilanti, Michigan. 2. University of Michigan, Ann
 Arbor, Michigan. 3. American University of Beirut, Beirut,
Lebanon
It is now widely recognized that social relations are multi-dimen-
sional, age-specific, and have effects on health outcomes. Yet, little is
known about links between social relations, age, and health in west
Asian countries. Using data recently collected from a representative
sample of adults in Beirut, Lebanon, this study examines whether net-
works size, as well as positive and negative relationship quality varies
by age in its association with health among adults aged 40-96. Hierar-
chical regression results reveal more positive and less negative relation-
ship quality with key others including spouse and child. These rela-
tionships diminished the link between age and poor health. The interac-
tion between age and network size suggests an unexpected effect
in that smaller networks compared to larger networks did better to dimin-
ish the negative influence of age on being chronically ill. Theoretical
and practical implications will be discussed.
THE BUFFERING EFFECT OF SOCIAL RELATIONS ON THE LINK BETWEEN PHYSICAL HEALTH AND PSYCHOLOGICAL WELL-BEING IN THE U.S.

K. Birditt, H. Akiyama, Institute for Social Research, University of Michigan, Ann Arbor, Michigan

This study examines how the composition and quality of older adults’ social relations with friends and family buffers the association between physical health and psychological well-being. Data come from the Social Relations, Aging and Health Study, a regionally representative longitudinal sample of the Detroit metropolitan area. Respondents age 70 and older at wave 1 (1992) were selected for analysis (N=285). Regression analyses reveal that respondents who reported fewer chronic conditions and a greater proportion of friends in their social network were less depressed. Among those with high positive and low negative friend relationship quality, the strong association between chronic conditions and depression was drastically reduced. In terms of immediate family relationship quality, only low negative quality relationships was found to buffer the detrimental influence of chronic conditions on mental health. The role of social relations in buffering this relationship over time will also be explored.

SESSION 1270 (SYMPOSIUM)

TILL DEATH DO US PART: CONTEXTS AND IMPLICATIONS OF MARRIAGE, DIVORCE, AND REMARRIAGE

Chair: K. Birditt, Institute for Social Research, University of Michigan, Ann Arbor, Michigan

Discussant: D. Carr, Rutgers University, New Brunswick, New Jersey

Marriage is often associated with better health and well-being. However, there is little research regarding the developmental course of marriage, marital dissolution, and factors predicting well-being and support. This symposium examines individuals in different marital contexts (engaged, married, divorced, and remarried) and links between aspects of those contexts (e.g., relationship quality, support) and well-being. Gilligan and colleagues examined engaged couples and their mother-in-law relationships before and after the wedding. Positive relationship quality with mother-in-laws at Time 2 varied by Time 1 positive relationship quality, frequency of contact, and familiarity with in-law preferences. Birditt and colleagues examined trajectories of marital happiness and tension over 16 years of marriage and associations with psychological and physical well-being among husbands and wives. They found distinct trajectories of happiness and tension that were associated with well-being. Brown and Birditt examined links between divorce and depressive symptoms and whether those links varied by relationship quality in the first year of marriage. Divorced men with low quality relationships reported the greatest depressive symptoms while women’s depressive symptoms were unrelated to divorce but were negatively associated with relationship quality. Sherman examined social networks among remarried wives caring for spouses with dementia. Larger negative networks and more step family disagreement were associated with lower life satisfaction, greater depression, and greater caregiver burden. Overall, these studies reveal significant variation in well-being and support within each marital context that can be attributed to variation in relationship quality, social networks, and gender among other factors.

IN-LAW RELATIONSHIPS BEFORE AND AFTER THE WEDDING: HUSBANDS, WIVES, AND THEIR MOTHERS-IN-LAW

M. Gilligan, L.E. VanderDrift, K. Fingerman, 1. Purdue University, West Lafayette, Indiana, 2. Notre Dame, Notre Dame, Indiana

In the US, married couples tend to be closer to the wife’s family of origin than to the husband’s family. To examine the formation of these patterns, sixty-five men and women engaged to be married and each of their mothers (N=260) completed interviews prior to the wedding and 6 to 8 months following the wedding. Multilevel models revealed that positive relationship quality at Time 2 was predicted by affective (positive relationship quality at Time 1), behavioral (frequency of visiting/calling in-laws) and cognitive (a quiz about the in-law’s background and preferences) aspects of the relationship at Time 1. For wives, any type of contact was associated with more positive relationship qualities after the marriage. For grooms, only contact he initiated was associated with better relationship with mother-in-laws at Time 2. Discussion focuses on gender and generational differences in the formation of in-law ties.

DEVELOPMENTAL TRAJECTORIES OF MARITAL HAPPINESS AND TENSION: IMPLICATIONS FOR WELL-BEING

This study examined trajectories of marital quality (happiness, tension) over 16 years and associations with individual well-being. Participants from the Early Years of Marriage Study (N=373 couples) completed interviews in years 1, 2, 3, 4, 7, 14, and 16 of their marriages. Group-based trajectory models (PROC TRAJ) identified trajectories of marital happiness, tension, and well-being (depressive symptoms, health) separately for husbands and wives. Analyses revealed developmental trajectories often characterized as low, moderate, and high trajectories over time. For example, wives’ marital happiness trajectories included a sharp decline, moderate decline, and consistently high and husbands’ trajectories included low, moderate decline, and consistently high. Wives’ tension trajectories included low, moderate, and high whereas husbands’ tension trajectories included low, moderate, high, and high and decline. Analyses revealed links between trajectories of marital quality and individual well-being. Findings are consistent with the enduring dynamics and emergent distress models of marital development.

MARITAL DISSOLUTION AND DEPRESSIVE SYMPTOMS: THE MODERATING ROLE OF MARITAL RELATIONSHIP QUALITY

This study examined whether the documented negative impact of divorce on depression varies depending on the quality of the marital relationship before divorce. Participants included 373 newlywed Black and White American couples who completed interviews in year 1 of their marriages and again 16 years later after 46% had divorced. Linear regressions estimated separately for men and women controlling for Year 1 depressive symptoms revealed that the effect of divorce on year 16 depressive symptoms was greater among men with low quality relationships. Divorced men reported greater depressive symptoms than married men when they had low quality relationships in the first year of marriage. Among women, first year marital quality was negatively associated with depressive symptoms regardless of marital status. Discussion is focused on the critical moderating effects of the first year marital relations on the link between divorce and depression and the context of gender.

DEMENTIA CAREGIVING IN THE CONTEXT OF REMARRIAGE: IMPLICATIONS FOR WELL-BEING

C.W. Sherman, University of Michigan, Ann Arbor, Michigan

Americans are increasingly experiencing complex marital and family histories across the life course. With rising incidence of chronic health concerns, such as dementia, it is important to examine caregiving in the context of remarriage and its effects on caregiver well-being. A new multi-method study of remarried wife caregivers (N=62) examined...
marital history, positive and negative social relationships, and wellbeing. Linear regression models revealed that caregivers with more negative relationships and greater disagreement with stepfamily reported lower life satisfaction, greater depressive symptoms and caregiver burden. Further, caregivers with lower levels of emotional support reported higher levels of depressive symptoms, whereas those with higher levels of intrusive support reported greater burden. Qualitative analyses of remarriage and stepfamily relationships were linked to reduced levels of loneliness which suggests that underpins the point prevalence rates for loneliness which are the bedrock of our knowledge about this topic. We use both quantitative and qualitative approaches to identify the trajectories into and out of loneliness in later life and identify the factors associated with these differing trajectories. We distinguish between those who never experience loneliness, those for whom loneliness in later life is an enduring experience and those for whom loneliness increases/decreases in later life. We demonstrate that it is possible to ‘recover’ from loneliness and our symposium offers several promising perspectives with regard to ameliorating loneliness which will be explored by our discussant.

A LONGITUDINAL ANALYSIS OF LONELINESS AMONGST OLDER PEOPLE IN GREAT BRITAIN
C. Victor, A. Bowling, I. Brunel University, Uxbridge, United Kingdom, 2. St Georges University of London & Kingston University, London, United Kingdom

Cross sectional surveys conducted with people aged 65+ years living in western industrial societies have consistently reported the rate of ‘severe’ loneliness at approximately 8-10% with a further 20% categorised as ‘sometimes’ lonely. There are also a range of studies indicating that loneliness is associated with a range of negative physical and mental health outcomes including mortality and with elevated health service utilisation. Researchers have also sought to examine key sociodemographic correlates of loneliness such as age, gender and ethnicity. However most of the studies concerning loneliness in later life are cross-sectional, single time point study. There are far fewer studies that have looked at loneliness within a longitudinal perspective. In this symposium we examine the dynamic nature of the experience of loneliness that underpins the point prevalence rates for loneliness which are the bedrock of our knowledge about this topic. We use both quantitative and qualitative approaches to identify the trajectories into and out of loneliness in later life and identify the factors associated with these differing trajectories. We distinguish between those who never experience loneliness, those for whom loneliness in later life is an enduring experience and those for whom loneliness increases/decreases in later life. We demonstrate that it is possible to ‘recover’ from loneliness and our symposium offers several promising perspectives with regard to ameliorating loneliness which will be explored by our discussant.

TRAJECTORIES OF LONELINESS AFTER PARTNER LOSS
M.J. Aartsen, T.G. van Tilburg, Faculty of Social Sciences, VU-University, Amsterdam, Netherlands

Sooner or later, many married older adults are confronted with the loss of the partner, which often leads to increased feelings of loneliness. However, not all become lonely after the loss of the partner. In a subgroup (N=412) of people participating in the Longitudinal Aging Study Amsterdam, who are married at baseline but lose their partner during the 16 years of follow up, 65% do not develop loneliness despite the loss of a partner; 15% are persistently lonely, and 20% become lonely. Higher levels of mastery and the absence of depressive symptoms seem to protect against emotional loneliness after the loss of the partner. Better self-perceived health and an internal locus of control seem to protect against social loneliness after the loss of the partner. Enhancing mental health, self-perceived health and mastery may help to prevent or overcome feelings of loneliness in widowed people.

“A DO YOU FEEL LONELY”?’ OLDER RESPONDENTS TALK ABOUT LONELINESS IN A SURVEY INTERVIEW
M. Jylha, School of Health Sciences, University of Tampere, Tampere, Finland

In many studies, structured personal interviews are used to collect information about loneliness in old age. The responses will be coded to give frequencies of experienced loneliness, but very little is known about the process where the responses are produced. In three rounds of Tampere Longitudinal Study on Aging (TamELSA), in 1989, 1999, and 2007, a number of the interviews (altogether 120) were tape-recorded and transcribed. This study analyzes the episodes where feelings of loneliness are discussed. The focus is on the ways the respondents answered the question, and on the reasons they spontaneously gave for their possible loneliness. Possible sensitivity of the direct loneliness question is approached by analyzing the answers in the context of other parts of the interview where social contacts and experiences of life are discussed.

EXPLORING LONELINESS TRAJECTORIES OVER THE LIFE COURSE
M. Sullivan, W. Martin, C. Victor, Brunel University, Uxbridge, Middlesex, United Kingdom

The dynamic nature of loneliness has primarily been overlooked by the numerous cross-sectional studies exploring it. Thus, less is understood about the temporal aspects of loneliness or how loneliness may change over the life course. Interviews were held with 45 older people to illuminate the meaning of loneliness in the lives of older people, and possible pathways to or from loneliness. Thematic analysis revealed a number of complex and shifting social, psychological, functional and physical features that characterize three pathway experiences or loneliness trajectories: (1) regenerative; (2) degenerative; and (3) enduring. This paper will illustrate some of the features of these trajectories and
in doing so highlight dynamic interconnections and interrelationships between our bodies, selves, identities and social worlds. The paper also draws attention to some of the particular challenges for developing intervention strategies for a diverse group of older people.

**SESSION 1280 (PAPER)**

**EXERCISE INTERVENTIONS**

**EFFECT OF RESISTANCE EXERCISE IN OLD HOSPITALIZED GERIATRIC PATIENTS**

N. Beyer1, T.S. Enevoldsen2, P.S. Magnusson3, 1. Department of Physical Therapy, Bispebjerg Hospital, Musculoskeletal Rehabilitation Research Unit, Copenhagen, Denmark, 2. Department of Physical Therapy, Bispebjerg Hospital, Copenhagen, Denmark

Background: Physical inactivity during hospitalization leads to decline in muscle function in frail older individuals. Aims of Study To determine whether resistance exercise for hospitalised geriatric patients has an effect on discharge functional status and hospital length of stay. Methods Patients aged 65 and older who were ambulatory prior to hospital admission were included in this cluster randomized cross-sectorial study. The control group (C-group, n=126) received usual care including functional training 3-5 times/week, the intervention group (I-group, n=168) was in addition offered resistance exercise 5 times/week. Assessments included self-reported patient mobility prior to hospitalization (New Mobility Score, NMS), cognitive status (MMSE), objectively measured function on admission and discharge including balance (Short Physical Performance Battery), number of chair stands in 30s and 8-foot Up&Go, and hospital length of stay (LOS). Results Results are reported as mean±SD or proportion. There were no baseline differences between the groups regarding age (I-group:86.4±6.8 yr; C-group:85.0±6.4 yr), NMS (I-group:4.4±1.6; C-group:4.8±2.5), number of diagnoses (90% had 4+ diagnoses) and MMSE (I-group:23.4±4.5; C-group:23.8±4.6), but more patients in I-group were transferred to the Geriatric Department from other hospital departments compared with patients in C-group (p<0.0001). No intervention effects were found on function and LOS. Patients in the I-group who performed resistance exercise 2+ times/week were the same age, had similar scores in MMSE, higher scores in NMS (p<0.0001), T.S. Enevoldsen1, P.S. Magnusson3, 1. American Association of Retired Persons, Washington, DC, District of Columbia, 2. Tufts University, Boston, Massachusetts, 3. Agency for Healthcare Research and Quality, Rockville, Maryland, 4. Evangelical Lutheran Good Samaritan Society, Sioux Falls, South Dakota, 5. National Institute on Aging, Bethesda, Maryland, 6. Georgetown University, Washington, District of Columbia, 7. University of Mississippi, Oxford, Mississippi

The goal of the Staying Healthy Through Education and Prevention (STEP) Study was to translate into practice an evidence-based physical activity (PA) intervention in senior housing with services (HWS) and to evaluate the impact of this program on physical functioning relative to a didactic wellness intervention. STEP was a non-randomized, cluster-allocated trial that enrolled 317 residents of 10 HWS communities. PA participants were to engage in 150 minutes of moderate exercise each week, and those in the Wellness group attended bi-monthly lectures and socials. Participants were followed for 12 months. Compliance was assessed by activity logs and bi-monthly interviews. The Short Physical Performance Battery (SPPB) was measured at baseline, 6 and 12 months. Although SPPB scores in both the PA (0.678, p<.001) and Wellness (0.643, p<.001) groups increased between baseline and 6 months, there was no overall effect of intervention on SBBP scores between baseline and 12 months. However, in both groups, greater adherence to the intervention resulted in improved SBBP scores. In the PA group, persons who adhered 100% with the protocol had SPPB scores that were 2.2 points higher than those who did not adhere at all, and a similar observation was made for the Wellness group, which was not instructed to change its PA levels. STEP suggests that both PA and didactic Wellness programs may have a favorable impact among seniors in HWS, and future research should focus on maximizing adherence.

**RESULTS OF THE STAYING HEALTHY THROUGH EDUCATION AND PREVENTION (STEP) STUDY**

The aim of the study was to evaluate the effects of a 6-month multimodal training intervention on functional fitness, body composition and quality of life (QL) in older persons and assess the long-term effects during 6- and 12-month follow-ups. At conclusion of 6-month training, statistical significant changes were found in SPPB score (0.5 95% CI; p<0.001), 8-foot up-and-go test (0.7 95% CI; p<0.001), knee extension strength (28.6 95% CI; p<.01), handgrip strength (13.0 95% CI; p<0.05), 6-minute walking (24.9 95% CI; p<0.001), physical activity...
needed.

erate levels of PA, aerobic endurance, and balance in older adults is
ness. The intervention improved some aspects of PA and fitness. Con-

studies to evaluate the use of fitness measures to increase PA and fit-

PA, aerobic endurance, and balance. Implications. This is one of the first
time (F=4.34; p<0.05) and upper body strength (F=4.03; p < 0.05). BMI
ment in lower body strength such that there was a significant interac-
tion of PA per week over time. There was also a significant improve-

for institutional care.

USING OBJECTIVE FITNESS MEASURES TO INCREASE PHYSICAL ACTIVITY AND PHYSICAL FITNESS IN OLDER ADULTS
J. Purath1, C. Keller2, B. Ainsworth2, S. McPherson1, 1. College of Nursing, Washington State University, Spokane, Washington, 2. Arizona State University, Phoenix, Arizona

Purpose. This research evaluated efficacy of a physical activity (PA) and physical fitness intervention among community dwelling older adults. Method: This was a randomized controlled trial (N = 72) with an attention control group. Self-reported PA and physical fitness (upper and lower body strength, aerobic endurance, and balance) were measured at baseline, 3- and 6-months. Intervention participants received an exercise prescription based on physical fitness tests and mutual goal setting. Repeated measures ANCOVA evaluated change in PA and fit-

session over time. Results: Most participants were: women, earned less
than $20,000 per year, underactive, and obese. ANCOVA showed sig-
nificant interactions over time between group assignment and increase
in weekly frequency of all PA (F=3.2; p<0.05 1). Income (F=8.17; p<0.05) and education (F=5.86; p<0.05) co-varied with change in fre-
quency of PA per week over time. There was also a significant improve-
ment in lower body strength such that there was a significant interac-
tion between group assignment and lower body strength change over time (F=4.34; p<0.05) and upper body strength (F=4.03; p < 0.05). BMI
was a significant covariate of lower body strength change over time (F
= 15.39, p < 0.05). There were no significant differences in moderate
PA, aerobic endurance, and balance. Implications. This is one of the first
studies to evaluate the use of fitness measures to increase PA and fit-

ness. The intervention improved some aspects of PA and fitness. Con-

stituted research to identify interventions that effectively increase moder-
eate levels of PA, aerobic endurance, and balance in older adults is

needed.

SESSION 1285 (PAPER)

NURSING HOMES

DESIGNING AND IMPLEMENTING CLUSTER RANDOMIZED TRIALS IN NURSING HOMES: INSIGHTS FROM THE PRIDE TRIAL
P.H. Van Ness, Internal Medicine/ Geriatrics, Yale University School of Medicine, New Haven, Connecticut

Nursing home residents present design and analytical challenges for researchers testing interventions intended to improve their health. Physical proximity and administrative arrangements make it difficult to deliver different interventions to persons residing in the same nursing home and so cluster randomization is often used. In this design differ-
et intervention regimens are assigned to entire nursing homes rather
than to individuals in the same and different homes. Implementing an
intervention in an entire nursing home requires integration not only into
the daily life of residents but also into the administrative procedures of
the nursing home. Thus, cluster randomized trials in nursing homes char-
acteristically have attributes of effectiveness research as well as fea-
tures designed to assess intervention efficacy. How cluster randomized
trials in nursing homes take on both aspects of efficacy and effective-
ness will be described with reference to the PRIDE (Pneumonia Reduc-
tion in Institutionalized Disabled Elders) trial in which an oral hygiene
intervention to prevent pneumonia was implemented according to a clus-
tered nursing home design. Other distinctive design and analytical issues
will be discussed. Finally, insights from the PRIDE trial will be shown
to make a valuable contribution to current discussions of comparative
effectiveness research and will provide insights for clinical researchers
planning to conduct cluster randomized trials in nursing homes.

EFFECTIVENESS OF TWO PROTOCOLS FOR TREATING NURSING HOME RESIDENTS WITH PRECEDED DEMENTIA

The Serial Trial Intervention (STI) is a decision support tool to address the problem of under assessment and treatment of pain and other unmet needs of people with dementia. Though a 5-step version of the STI was found to effectively treat discomfort and behavior change, a 9-step version was developed to improve nurses’ approach to long-term treatment of new problems. The purpose of this study was to compare the efficacy of the 5-step and 9-step versions of the STI. The design was a double-blinded two-group repeated measures experiment with randomization of matched study sites to the 5-step or 9-step STI. Participants were 125 nursing home residents with dementia. Measures were taken at baseline and 2, 4, and 6 weeks following intervention. Both the 5 and 9-step STIs significantly decreased discomfort and agitation from pre to posttest (effect sizes .45 to .90). The 9-step version was more effective for comorbid burden and cortisol slope (effect sizes .5 and .49). Process variables were all statistically significantly improved using the 9-step STI (treatment preceded by assessment, new physical problems identified and treated, scheduled dosing of effective treatments, ineffective treatments stopped, and adjunctive and preventive treatments added). Nurse time was not different between the two groups. The clinical decision support rules embedded in the STI, particularly the 9-step version, helped nurses change practice and improved resident outcomes.

INFLUENCE OF COGNITION ON TREATMENT RESULTS IN A GERIATRIC UNIT
K. Hager, A. Marahrens, M. Brecht, M. Kenklies, V. Grosse, Clinic for Medical Rehabilitation and Geriatrics, Hanover, Germany

Background: Cognitive deficits and dementia influence the results of geriatric therapy and rehabilitation. The aim of this study was to com-
pare the influence of cognitive deficits at the time of admission as mea-
ured by the Mini Mental Status Examination (MMSE) with the change of
the activities of daily living (ADL), evaluated by the Functional Inde-
pendence Measure (FIM). Patients and Methods: Data of 2527 patients
from the years 2006-2009 were analyzed. The patients were treated in
the Clinic for Medical Rehabilitation and Geriatrics in Hanover (Ger-
many), a clinic with acute and rehabilitative geriatric care. Results:
The mean age of the patients was 81.6 ± 7.7 years, the mean improve-
ment of the FIM was 14.3 ± 13.4 points. The lower the MMSE on admis-
sion, the lower was the functional state of the patients at the beginning
and at the end of their treatment. Patients with only a slight reduction
in the MMSE (20-26 points) achieved an improvement in the FIM sim-

ilar to that of the cognitively not impaired patients (15.2 ± 13.3 versus
14.9 ± 12.4 points; n.s.). In patients with a MMSE below 20 points the
improvement of the FIM was significantly lower (MMSE 10-19 points:
11.7 ± 14.9 points; MMSE 0-9 points: 7.1 ± 15.6) compared with the
cognitively intact (both p<0.01). Nevertheless 40% of the patients with
a MMSE of 10-19 points and 30% of those with a MMSE of 0-9 points
reached an improvement better than that of the average of all patients.
Conclusion: Patients with a MMSE of 20-30 points should be admitted
to geriatric rehabilitation unit without restriction concerning cognition.
Patients with 19 points or lower in the MMSE should not be generally
excluded, but individual factors should be considered, because many of
them were able to reach an improvement even better than the average
of all patients.
EDUCATIONAL NEEDS ASSESSMENT OF NURSING HOME NURSES
M.J. Dyck, M. Kim, Mennonite College of Nursing, Illinois State University, Normal, Illinois

Nursing homes continue to be cited for poor quality care. Studies during the 1990s showed that nursing home nurses have limited knowledge regarding nutritional needs of elders, pressure ulcers, pain management, end of life care, and organizational management. However, further work has not occurred since that time. The purpose of this study is to assess learning needs of nursing home nurses in central Illinois in relation to their current educational level. The sample (n = 50 nursing homes) for this study is a proportionate stratified random sample of central Illinois nursing homes based on the overall 5-star rating determined by Centers for Medicaid and Medicare Services with approximately 750 to 1000 nurses recruited from these homes. There are 152 free-standing nursing homes. Quantitative data includes nurses’ demographics and their responses to a needs assessment tool. The “Education Needs Assessment” questionnaire was used to assess the learning needs of the nurses. The questionnaire has 51 questions with one open-ended question asking nurses’ need for continuing education, each followed by a 5-point Likert-type scale (1 = Strongly Disagree; 5 = Strongly Agree). Quantitative data will be managed using SPSS 18.0. Descriptive statistics will be used to identify the continuing education needs. Multivariate analysis of variance (MANOVA) will be used to determine whether priorities for learning were affected by age, educational level, or experience. As a follow-up test to MANOVA, analysis of variance (ANOVA) will be conducted on each dependent variable (i.e., educational priorities).

SESSION 1290 (SYMPOSIUM)

BEST PRACTICES FOR USING NURSING HOMES AS CLINICAL PLACEMENT SITES FOR NURSING STUDENTS: NEW RESOURCES AND STRATEGIES
Chair: M. Mezey, College of Nursing, Hartford Institute for Geriatric Nursing New York University, New York, New York
Co-Chair: C. Mueller, University of Minnesota, School of Nursing, Minneapolis, Minnesota
Discussant: M. Gugliucci, University of New England College of Osteopathic Medicine, Biddeford, Maine

Almost all entry level nursing students have a rotation in a nursing home at sometime during their clinical years. Yet faculty and nursing home staff are concerned that students do not value nursing home rotations, and in fact come away from these rotations with negative stereotypes about care in nursing homes. There is considerable discussion in the literature as to how nursing homes are selected as placement sites, whether clinical placements should occur early or late in the student’s academic program, and how to structure rotations in nursing homes to make them responsive to learning objectives, vibrant and satisfying for students, faculty and staff. In this symposium, experts share new strategies specifically developed to help clinical faculty find themselves challenged as to how to structure rotations to maximize learning and student satisfaction. This session introduces a model designed to build capacity for LTC facilities to be excellent sites through Partnerships (ECLEPS). ECLEPS: ENRICHING CLINICAL LEARNING EXPERIENCES THROUGH PRACTICE-ACADEMIC PARTNERSHIPS IN LONG-TERM CARE: A CASE STUDY

Long term care (LTC) nursing is complex and requires excellent clinical and leadership skills. Enriching Clinical Learning Experiences through Partnerships (ECLEPS) is an academic-practice partnership model designed to build capacity for LTC facilities to be excellent sites for practice and learning. Central to ECLEPS are relationships between faculty and staff nurses. Interactive workshops address best practices in teaching and gerontologic nursing, and are designed so that faculty and staff nurses learn through and from each other. Goals for students are

RESOURCES TO HELP NURSING PROGRAMS SELECT NURSING HOMES AS CLINICAL SITES

Overview of six web-based modules prepared by the Hartford Institute for Geriatric Nursing and the American Association of Colleges of Nursing to help nursing programs select appropriate nursing homes for student placements. Two modules review demographic and regulatory structures pertaining to nursing homes, and nursing care in nursing homes. Using this information, one module then guides faculty in selecting nursing homes for student placements. Two modules specifically address culture change and resident-directed care, providing culture change concepts and strategies for building on these concepts during student rotations in nursing homes. One module advises nursing home personnel regarding how a nursing home can prepare and position itself as a clinical placement site.

NURSING HOME CLINICAL EXPERIENCES THAT ADDRESS CULTURE CHANGE AND RESIDENT DIRECTED CARE
C. Mueller, University of Minnesota, School of Nursing, Minneapolis, Minnesota

There is an increasing emphasis on transforming nursing homes to places that promote a non-institutional, resident-directed model of care. Faculty may not be as informed about this social change and the implications and opportunities for clinical teaching in nursing homes. A faculty development module about resident directed care will be described along with examples of clinical teaching strategies to assist students in learning about and providing care that promotes autonomy and control for residents residing in nursing homes and the staff that work most closely with them.

STRUCTURING THE NURSING HOME EXPERIENCE: A WEB-BASED RESOURCE FOR CLINICAL FACULTY
M. Mezey, E. Ea, College of Nursing, Hartford Institute for Geriatric Nursing New York University, New York, New York

It is often the case that faculty overseeing clinical rotations for entry level nursing students in nursing homes have limited knowledge of geriatrics and also possibly of care in nursing homes. Given the unique needs of frail nursing home residents and the nursing home environment, faculty find themselves challenged as to how to structure rotations to maximize learning and student satisfaction. This session introduces a new web-based resource specifically developed to help clinical faculty structure a nursing home experience for students. The module takes a faculty member through a “typical” clinical day, and suggests resources and experiences to enhance student learning.

64th Annual Scientific Meeting 371
that they experience learning in LTC settings as meaningful and challenging; understand the nursing roles and practice opportunities associated with working with residents, families and staff; and have positive attitudes about nursing practice in residential and long-term care settings. A case study of a successful partnership will illustrate the key components for practice-academic collaborations and the rich and varied clinical opportunities for students across multiple courses in a baccalaureate program.

SESSION 1295 (SYMPOSIUM)

CHALLENGES IN ANALYSIS OF DATA FROM LONGITUDINAL STUDIES OF AGING
Co-Chair: E.S. Strotmeyer, University of Pittsburgh, Pittsburgh, Pennsylvania
Discussant: H. Allore, Yale University, New Haven, Connecticut

Longitudinal epidemiologic studies have collected health-related variables and outcomes among cohorts of older adults over years or decades. Novel methods have been developed to analyze these data, but challenges remain around their application. Various approaches can address the same scientific questions, and no single method suffices for characterizing changes in health-related variables across time. In this symposium we will address some of the key challenges around longitudinal analyses. (1) How are death and dropout addressed, to limit survival and retention biases? (2) How do analytic approaches account for repeated measures on the same individual? Should those who survive longer have greater weight in the analyses than those who do not? (3) What approaches are used for missing data and censoring, and what techniques are used to differentiate informative from non-informative censoring? How should cases be weighted based on the likelihood of censoring? (4) How do models account for the technical and theoretical challenges of applying time-varying covariates? The speakers will discuss how these issues influence their analyses in the Cardiovascular Health Study and the Health, Aging, and Body Composition Study, two large, long-term epidemiologic studies of older adults. The discussant will synthesize the main themes and make suggestions for future research.

ASSESSING THE CARDIOVASCULAR RISK OF PERSISTENT SUBCLINICAL HYPOTHYROIDISM

Use of a single set of thyroid function tests to define subclinical hypothyroidism may lead to significant misclassification over time and could influence the findings from longitudinal studies. We sought to define the cardiovascular risks of subclinical hypothyroidism, using data from 4864 men and women enrolled in the Cardiovascular Health Study. We will compare and contrast three analytic models. In the first, subclinical hypothyroidism was defined at the first set of thyroid tests and updated over time, with up to 3 additional tests over a 7 year period (time varying exposure). In the second, the exposure was “ever” subclinical hypothyroid, also updated over time. In the third, persistent and transient subclinical hypothyroidism were defined by 2 thyroid tests performed 2 years apart, or 3 tests over 4 years, and compared to persistent euthyroidism (fixed exposure). We will conclude by discussing the merits of using repeated measures to define our exposure.

ANTIHYPERTENSIVES AND CHANGE IN KIDNEY FUNCTION IN ELDERLY: A MARGINAL STRUCTURAL MODEL ANALYSIS

The effectiveness of antihypertensive medications for slowing decline in kidney function in older adults is unknown. We examined this relationship in 1,576 hypertensive elders in the Cardiovascular Health Study, over 7 years. Kidney function was measured by estimated glomerular filtration rate (eGFR). The mean annual decline in eGFR was -2.28 ± 4.96 mL/min/1.73 m2. Antihypertensives were not associated with change in eGFR, based on traditional regression analyses. Based on a marginal structural model, participants on one and two medications had an estimated 1.43 (95% CI: 0.09, 2.77), and 1.08 (-0.28, 2.45) mL/min/1.73 m2 per year slower decline in eGFR, respectively, compared with persons on none. The estimates were larger and less precise in a model that also accounted for informative censoring. A marginal structural analysis suggests a protective effect of antihypertensives on kidney function in elders.

THE LONGITUDINAL RELATIONSHIP OF VITAMIN B12 AND INFORMATION PROCESSING SPEED
K. Leishhear1, C. Rosano1, R. Boudreau1, A.B. Newman1, S. Studenski1, L. Ferrucci1, T.B. Harris1, E.S. Strotmeyer1, 1. University of Pittsburgh, Pittsburgh, Pennsylvania, 2. National Institute of Aging, Baltimore, Maryland, 3. National Institute of Aging, Bethesda, Maryland

Vitamin B12 deficiency may cause demyelination, resulting in white matter damage and slower processing speed. We examined whether low B12 (<260pmol/L), rather than deficient, or change in B12 (2000-01 to 2007-08) were associated with decline in Digit Symbol Substitution Test [DSST] scores (2001-02 to 2007-08) in 1033 Health, Aging, and Body Composition Study participants [age:76.0±2.8; female:52.1%; black:31.4%]. Cross-sectionally low B12 (n=173;16.7%) was associated with greater annualized DSST decline, adjusting for initial DSST score, demographics, socioeconomic/lifestyle factors, CES-D, medications, and comorbidities (β=-0.267;p=.04). Improving to normal B12 (n=82) was associated with greater annualized DSST decline compared to having sustained normal B12 (n=792), after adjustment (β=-0.465;p=.01). Associations were similar for >1SD decline from mean change, and using mixed models with 4 DSST timepoints. Initial B12=260pmol/L was associated with greater DSST score declines in older adults. Maintaining adequate B12 levels is critical, because cognitive impairments associated with low B12 potentially may not be reversible.

SESSION 1300 (SYMPOSIUM)

HEALTH CARE REFORM & PRIMARY CARE MEDICAL HOME (PCMH): THE CRITICAL ROLE OF GERIATRICS EDUCATION
Chair: C.P. Brunker, Intermountain Healthcare, Salt Lake City, Utah, University of Utah Geriatrics, Salt Lake City, Utah
Co-Chair: G.A. Pepper, University of Utah Hartford Center of Geriatric Nursing Excellence, Salt Lake City, Utah
Discussant: R. Golden, Rush University Medical Center, Chicago, Illinois

Geriatrics education across various disciplines plays an important role to help span the quality chasm that the Institute of Medicine, the Commonwealth Fund and others have described in patient care. Older adults with an increased prevalence of complex illness, geriatric conditions, physiologic changes of aging, and psychosocial...
needs are at increased risk for adverse events and higher costs and thus offer an opportunity to improve quality and efficiency of health care. This symposium will provide an overview of initiatives such as the formation of Accountable Care Organizations and the High-Value Health Care Project and discuss the components, training, and evidence for Care Management Plus (CM+), as a proven, evidence-based model for Primary Care Medical Home. Advance care planning, eliciting patient goals, and respect for cultural and family perspectives are important components. Applying a patient-centered approach such as Motivational Interviewing promotes self-management and establishes relationships and trust with patients and their families and caregivers. In addition to the CM+ geriatrics training for interdisciplinary teams in practice, we will also examine curriculum developments for students and faculty to prepare for upcoming changes in health care. For example, Hartford Centers of Geriatric Nursing Excellence post-graduate course work includes evaluation of complex ethics of clinical trials and innovations in health care. And finally, the pilot of training masters' level social work interns to assess and meet the complex psychosocial needs of culturally diverse, low-income seniors crosses the breadth of research, education, and practice.

BUILDING THE MEDICAL HOME, THE TOOLS OF CARE MANAGEMENT PLUS

Care Management Plus (CM+) is a flexible, proactive model for Primary Care Medical Home (PCMH). Geriatrics-trained care managers and unique computer tools help clinic teams provide care coordination, tracking, follow up, self-management support, registries, performance reporting/monitoring – all key for PCMH. Self-management depends on health coaching for behavior change. The Motivational Interviewing (MI)-based health coaching approach differs greatly from the traditional health education model used frequently in health care settings and is a key element of the CM+ curriculum (Butterworth et al., 2007). MI is not based on the information model, does not rely on advice-giving or scare tactics, and is not confrontational, forceful, guilt-ridden, or authoritarian; rather it is shaped by an understanding of what triggers change (Miller & Rollnick, 2002). Patient-centered care includes functional assessment, advance care planning, discussion of goals and helps establish trusting relationships with patients, families, caregivers.

A TALE OF TWO DOCTORATES: PREPARING NURSE FACULTY TO EDUCATE FOR HEALTHCARE REFORM

G.A. Peppers, University of Utah College of Nursing, Salt Lake City, Utah

The critical role of nurses in healthcare reform and patient-centered geriatric care has been emphasized in two contemporary Institute of Medicine reports: “Rethinking for and Aging America” (2008) and the “Future of Nursing” (2010). Both acknowledge need for nursing faculty prepared in geriatrics to accomplish goals in elder care in the emerging healthcare environment. The central mission of the nine Hartford Centers of Geriatric Nursing Excellence is the education and retooling of nursing faculty to prepare a nursing workforce with the numbers and skills to meet the challenges of an aging population in a reformed environment. The Centers collaborate to support preparation of nursing faculty locally and nationally in PhD programs (research preparation) and Doctor of Nursing Practice (DNP—advance clinical practice), as well as master’s programs. The distinct goals of DNP and PhD programs related to healthcare reform lead to diverse, but complementary, curricula and program outcomes.

DEVELOPMENT AND ENHANCEMENT OF A MEDICAL HOME FOR LOW-INCOME SENIORS USING SOCIAL WORK STUDENTS

F. Wilby, M. Luptak, College of Social Work, University of Utah, Salt Lake City, Utah

Our intervention is an adaptation of the Care Management Plus model (CM+), piloted by Intermountain Health Care, which we implemented in a community health center for low-income chronically ill older adults. Six 2nd year MSW students completed the CM+ curriculum (8 weeks of on-line modules with discussions and assignments on topics such as pain, palliative and hospice care, advance directives, hypertension, asthma, and COPD) and served as case managers and performed the following functions: provided information on the types of Medicare available and the application process; completed the application process, including ongoing support to obtain all supporting documents; communicated directly with Medicare offices, in the role of patient advocate; assisted with medical appointment scheduling and education regarding Medical Home, once Medicare enrollment has been secured; and provided referrals to community resources.

SESSION 1305 (SYMPOSIUM)

RECRUITING, ENGAGING, AND TRAINING CLINICAL EXERCISE STAFF: THE OVERLOOKED BACKBONE OF CLINICAL TRIALS

Chair: K.K. Mangione, Arcadia University, Glenside, Pennsylvania
Discussant: R. Fielding, Tufts University, Boston, Massachusetts

Older adults after major disabling events such as stroke and hip fracture often require skilled professionals to engage in exercise programs. Similarly, frail and institutionalized older adults may require skilled professionals for the safe conduct of a study. Methods for recruiting, retaining, engaging, and training professionals, such as physical and occupational therapists, for exercise trials outside of the typical gym-based settings have not been reported in the literature. This symposium will address strategies that have been used to successfully recruit, retain, engage, and train clinicians in NIH sponsored clinical exercise trials. Examples from multicenter exercise trials that employed clinicians in both rehabilitation clinical settings and the patients’ home environment include 1) Locomotor Experience Applied Post Stroke (LEAPS) - walking recovery for patients post-stroke; 2) Extremity Constraint Induced Therapy Evaluation (EXCITE) - recovery of upper extremity function after stroke; 3) Efficacy of a Post-Rehabilitation Exercise Intervention-recovery of self-reported function and physical performance in persons after hip fracture, and 4) Community Ambulation Project (CAP) – recovery of the ability to achieve community ambulation following hip fracture. The speakers are either project managers or investigators responsible for identifying and training clinicians to be research staff for clinical trials. This symposium will highlight the important teamwork and unique collaborations between physical and occupational therapist clinicians and scientists from other disciplines in large exercise clinical trials who can work together to improve methods in this area.

RECRUITING REHABILITATION STAFF FOR EXERCISE TRIALS

N. Latham, K.K. Mangione, 1. Physical Therapy, Arcadia University, Glenside, Pennsylvania, 2. Health and Disability Research Institute in the Boston University School of Public Health, Boston, Massachusetts

Recruiting rehabilitation staff for community based studies can be challenging. Methods will be discussed to identify both per diem and dedicated intervention and assessment research staff. Recruitment models will be presented that outline clearly defined responsibilities for the therapists, the contributory role of the therapist to the larger study, identifying therapist characteristics which lead to successful recruitment and retention, and providing therapists with tangible benefits associated with

64th Annual Scientific Meeting 373
working in a clinical trial. Strategies to identify physical therapists such as conventional advertising and social networking through professional organizations, local home health care providers, universities and professional leaders will be presented. A staffing model will be discussed that involves per diem contracts to appeal to a wider pool of qualified applicants.

FOSTERING ENGAGEMENT OF REHABILITATION STAFF DURING MULTI-SITE CLINICAL TRIALS
S.R. Blanton, Emory University, Atlanta, Georgia

Once recruited, active engagement of rehabilitation staff during the course of a long clinical trial can be crucial for maintaining the quality and consistency of interventions, evaluations and overall study flow. Examples from the EXCITE (Extremity Constraint Induced Therapy Evaluation) and ICARE (Interdisciplinary Comprehensive Arm Rehabilitation Evaluation) trials will be used to demonstrate methods to foster professional growth and individual commitment of therapists during their involvement in research. The role of the site team leader in addressing site specific needs, building relationships with clinical site management and utilizing study resources to create opportunities for staff development will be explored. Finally, the concept of patient-centered care as a framework for the optimizing the interdisciplinary relationships of clinical site teams will be described.

TRAINING FOR ADHERENCE TO RESEARCH PROTOCOLS
J.K. Tilson, University of Southern California, Los Angeles, California

Optimizing consistency for the intervention and assessment procedures is an essential component of successful clinical trials. While the educational background of physical and occupational therapists makes them ideal candidates as interventionists and examiners for clinical trials, adhering to strict protocols may sometimes conflict with their clinical intuition. This session will discuss the successful strategies used during the LEAPS (Locomotor Experience Applied Post Stroke) trial to train physical therapists across two states and five sites to perform a complex assessments in a standardized fashion. Result from reliability tests will be presented. Physical therapists were also trained and monitored to conduct standardized, yet tailored ambulation programs and home exercise routines. Methods to maintain adherence and consistency of trainers in both the home and clinic environment will be reviewed.

SESSION 1310 (SYMPOSIUM)

USING DISTANCE LEARNING TECHNOLOGY TO REACH CLINICIANS WORKING WITH OLDER VETERANS IN RURAL SETTINGS
Chair: L.I. Jones, Geriatric Research Education and Clinical Center, Veterans Administration, North Hills, California
Discussant: J.L. Howe, Mount Sinai School of Medicine Dept of Geriatrics and Palliative Medicine, New York, New York

Recent developments in the use of technology for geriatric education facilitate the implementation of programs that are suited to meet the continuing education needs of clinicians. This session highlights varied technological modes which enable the implementation of education programs focused on providers working with older Veterans in rural settings. In these remote clinics, clinicians are challenged to efficiently use technology to connect to colleagues who may also be in isolated clinical settings working with patients with complex needs. In this symposium we present several effective methods to facilitate the work of these clinicians as they work both individually and collaboratively to meet their patients’ needs. Multiple technologies and their application in specific educational programs will be presented. The technologies include: 1) an online learning community; 2) webinar series; 3) video; and 4) educational resources in mobile formats. The symposium will also highlight the way each of these technologies can be modified to fit the needs to the distinct groups of learners. Program evaluation of the learners’ use of these technologies will also be discussed.

CREATING A LEARNING COMMUNITY AND WEBINAR SERIES FOR CLINICIANS WORKING WITH OLDER VETERANS IN RURAL SETTINGS

In this paper, the experience of creating an Intranet learning community as well as a webinar series for clinicians working with older Veterans in rural settings will be discussed. Learning community content is developed through needs assessments of the target audience, participants in the Geriatric Scholars Program. The Geriatric Scholars Program, a collaboration of eight VA Geriatric Research Education and Clinical Centers, provides focused geriatric education to practitioners in rural VA Community Based Outpatient Clinics (CBOCs). Usage of and experiences with the learning community by these adult learners are assessed three and six months after they enter the program. In addition, a webinar series was created in response to the participants’ professional development needs. Past topics in this 2-year-old series have included peer-to-peer education, adult learning, health literacy, keys to effective leadership, and management of team dynamics. These webinars complement the asynchronous learning that occurs on the learning community site.

MAKING TRAINING VIDEOS FOR USE IN GERIATRIC EDUCATION
M. Johnson, Geriatric Research, Education and Clinical Center, University of Texas Health Science Ctr in San Antonio & VHA-South Texas Veterans Hlth Care System, San Antonio, Texas

If you cannot have a live professor in your classroom, why not have a recorded one on your desktop or in the palm of your hand? This talk will focus on how to find content and, if necessary, convert it and repurpose it to fit the format that works best for you in your unique geriatric education settings. Students today have grown up with laptops, iPods and YouTube—consequently, it’s best to work with them using the modern methods they’re accustomed with—and that means Video.

GERIATRIC EDUCATION IN A MOBILE FORMAT: POSSIBILITIES FOR RURAL PRACTITIONERS
S.T. McKee, 1. GRECC, CAVHS, Little Rock, Arkansas, 2. Univ of Ark for Med Sciences, Little Rock, Arkansas

Providing educational resources in a mobile format has been found to be a successful tool towards the goal of meeting the needs of clinicians working with older Veterans in rural settings. A January 2011 survey of participants in the Geriatric Scholars Program, a geriatric education program for practitioners working in rural VA Community Based Outpatient Clinics (CBOCs), found that nearly 60% of current participants would access program resources if they became available in a mobile format. Thus it is important to explore the challenges and possibilities of integrating educational resources in mobile formats into the program, a collaboration of eight VA Geriatric Research Education and Clinical Centers. Successful utilization of geriatric education in mobile formats in other programs will be explored. As well, strategies to use mobile formats meet the specific needs identified by the participants in the Geriatric Scholars Program will be examined.

The Gerontological Society of America
THE ROLE OF EVALUATION RESEARCH IN SOCIAL GERONTOLOGY: A TEN-YEAR TREND
M. Rivera-Hernandez, S.R. Kunkel, Gerontology, Miami University, Oxford, Ohio

For many disciplines, including gerontology, there is a long-standing (though increasingly blurry and problematic) distinction between basic and applied research. Evaluation research (ER) is one obvious forum where the integration of theory, basic, and applied research can and should occur. Even though ER contributes in many areas in the social sciences and is crucial to the improvement of programs and services for older adults, its place in mainstream scientific literature in gerontology is not clear. The purpose of this paper was to evaluate the ten-year (2000 to 2010) trend in visibility of ER in peer-reviewed journals in gerontology. Two journals were analyzed: The Gerontologist and Journal of Applied Gerontology, based on the assumption that these are among the well-respected journals in the field most likely to publish evaluation research. Overall the number of ER articles published from 2000 to 2010 appears to be rising. The highest proportion of studies that incorporated some form of program evaluation occurred in 2009 (16.5%), and only 4% of the articles in 2003 were ER-based. Program effectiveness, needs assessment and process evaluation were the most frequent categories of evaluation published in both journals (43.5%, 24%, and 23.5%, respectively). ER appears to be more visible in peer-review journals than before. This may reflect that programs and services for older adults are expanding, and the field of gerontology is more committed to an evidence-based approach. ER has important roles in translating basic research in community programs for older adults including long-term care, and evidence-based programs.

GERONTOLOGY IN THE PRIMARY GRADES: COMMUNICATING THEORY THOUGH PICTURE BOOKS
E.F. Ansello, Virginia Center on Aging, Virginia Commonwealth University, Richmond, Virginia

There has long been awareness that children’s first literature can serve as an indirect socialization to aging and older adults (Ansello, 1977, 1978; Homer, 1982; Vasil & Wass, 1993). Similar findings pertain regarding media socialization to race, gender, disabilities, and more (e.g., Henneberg, 2010). In the primary grades with regard to the subject matter of aging, the focus by many well-intentioned gerontologists has been to provide reading lists of books with positive portrayals of older characters, e.g., Cohen (2004) enlisted help from the Association for Library Service to Children to produce a list of 91 books called “Books with Positive Portrayals of Aging and Older Characters” for grades PreK to 6. Such lists tend not to offer a rationale for the books selected nor reference to gerontological principles; rather they may simply substitute positive stereotypes for negative stereotypes. The author has field-tested a unit with six 20-30 minute modules for grades K-2 reflecting basic gerontological theories, including: life course developmental tasks, generativity, cycle of life, and most importantly, heterogeneity. Each book in a regularly updated bibliography of 120 or more titles is coded for use in these modules; older characters reflect a full range of characteristics, not only positive, regarding behaviors, health, personalities, etc. All titles are in active circulation in neighborhood libraries, rather than being compilations of what book sellers have just published. The current annotated bibliography is newly updated; the modules are presented and explicated, with use of representative titles.

YES, WE NOW HAVE GERONTOLOGY COMPETENCIES: BUT HOW DO WE TEACH THEM?

The Council on Social Work Education (CSWE) Gero-Ed Center, funded by the John A. Hartford Foundation, prepares faculty and students to meet the geriatric workforce needs of our aging society through a competency-based approach to gerontological social work content infusion. The competency-based education approach of the CSWE 2008 Educational Policy and Accreditation Standards (EPS) focuses on student outcomes that are based in practice behaviors; that is, what a student must learn and be able to do. It stipulates 10 competencies common to all social work practice. Programs may build on and apply these 10 competencies in an area of advanced practice, such as aging, which derives from their mission, goals, and context. The question is: how do faculty at social work programs teach these competencies to ensure that their students attain them? What teaching resources can measure competency attainment? This presentation will suggest strategies to answer these important questions. First, the Gero-Ed Center co-Principal Investigator will provide an overview of the work the Center has undertaken to develop gero-specific competencies and support faculty in designing and infusing their own gero competencies throughout their curriculum. Next, a Lead Faculty member in the Center’s Specialized Gerontology Program, which provides faculty with the resources to design, implement, and institutionalize gero competencies at generalist and advanced levels of practice, will describe the challenges and achievement of her part process to integrate and teach the competencies in her social work program. Ample time for questions and comments will be provided to engage the audience.

THE NEW WORKFORCE PARADIGM? TRAINING IN AGING AND DISABILITIES FOR WORKERS IN PENNSYLVANIA
S.M. Geron, B. Keefe, Boston University Institute for Geriatric Social Work, Boston, Massachusetts

Recognition of the growing intersection of the aging and disability workforce is increasingly recognized in policy, but there are relatively few states that have actively developed workforce solutions to address this issue. This presentation describes a partnership between the Institute for Geriatric Social Work (IGSW) and the Pennsylvania Association of Area Agencies on Aging (P4A’s) Office of Long Term Living to create interactive, skill-based, multi-media online training courses for practitioners providing long-term services to older adults and persons with disabilities in Pennsylvania. A central feature of the project was the involvement of key stakeholders, including consumers, in the aging and disability communities in Pennsylvania in all phases of the project, beginning with developing the topics to include in the courses. Two online training courses for were developed: Core Training, a course intended for new workers in Pennsylvania’s Long-term Care Living programs, and Assessment Training, a specialized course designed for workers who will conduct assessments. IGSW brings over five years of experience and a national reputation in developing skill-based, online educational programs for practitioners, with a proven track record of helping states and agencies incorporate online learning programs to find creative workforce solutions. The presentation will describe the innovative collaboration and technology used in the project, provide a demonstration of the online courses, and present findings from the field test of the online courses with samples of practitioners from different agencies. These findings were very extremely positive, and showed that participants improved in key competencies areas.
SESSION 1320 (SYMPOSIUM)

ADVANCES IN RESEARCH, PRACTICE AND POLICY ON PHYSICAL ENVIRONMENTS SUPPORTIVE OF AGING-IN-PLACE

Chair: H. Chaudhury, Gerontology, Simon Fraser University, Vancouver, British Columbia, Canada
Discussant: M. Calkins, IDEAS Consulting Inc., Kirtland, Ohio

The physical environment of the home and community has a crucial role in fostering, supporting and maintaining lifestyle behaviors in older adults to age-in-place. This session will include four presentations that examined recent issues and challenges in the physical environmental features in the home and community environments related to “aging-in-place.”

H. Chaudhury, Gerontology, Simon Fraser University, Vancouver, British Columbia, Canada, 1.

1. How do the physical environment and social context of neighborhoods affect the physical activity of older adults? Eight neighborhoods are selected across eight neighborhoods in Vancouver, British Columbia and Portland, Oregon. Finally, Parker’s presentation will focus on accessibility guidelines and utilization of the Virginia Livable Home Tax Credit Program that provides a state tax credit to owners of homes, who make specified accessibility improvements and to buyers of new houses that meet these same requirements. After attending this activity, participants will be able to discuss current research issues and challenges in environmental design related to the potential of aging-in-place. The session will also provide a forum for discussion on appropriate public policy and programs that have an important role in creation of physical environment supportive of aging-in-place.

NEIGHBORHOOD INFLUENCES ON ACTIVE AGING: PRELIMINARY FINDINGS BASED ON SURVEY IN TWO METROPOLITAN AREAS

A. Mahmood1, H. Chaudhury1, Y.L. Michael2, M. Campo1, I. Gerontology, Simon Fraser University, Vancouver, British Columbia, Canada, 2, Drexel University, Philadelphia, Pennsylvania

The neighborhood environment becomes increasingly salient to older adults faced with multiple physical, cognitive and social changes. Previous studies have shown that the physical environment impact physical activity levels by providing safe and accessible venues and creating opportunities for social interaction that in turn promotes physical activity in older adults. The overarching research question of this study is “How do the physical environment and social context of neighborhoods affect the physical activity of older adults?” Eight neighborhoods are selected across Vancouver, British Columbia and Portland, Oregon. Samples of 60 to 65 older adults (60+ years) are surveyed from each of the study neighborhoods. Data are collected on demographics, health status, physical activity type, frequency and location, neighborhood and housing characteristics, perception of neighborhood, relationship between physical activity and physical- and social environment. This presentation covers preliminary findings from this survey highlighting similarities and differences across the two study regions.

HAZARDS IN THE BUILT ENVIRONMENT AND LONG TERM TRAJECTORIES OF DISABILITY FOR OLDER ADULTS AGING IN PLACE

P. Clarke, University of Michigan, Ann Arbor, Michigan

Hazards in the built environment can create barriers to independence among older adults aging in place. We investigated the relationship between urban built environment characteristics and trajectories of mobility disability in a sample of 2269 older adults (mean age=77.5±8.7 years) living in Detroit, a city that has undergone rapid economic and structural decline. Built environments were assessed using the “Street View“ feature of Google Earth where a trained rater did a “virtual” audit of each residential block. Growth mixture models were used to examine the effect of built environment characteristics on different trajectories of outdoor mobility disability over a 15 month period. Controlling for sociodemographic and health risk factors, individuals with steadily increasing trajectories were more likely to live in areas with poor quality streets and sidewalks (p<.01) and were more likely to be admitted to a nursing home over time (p<.05). This research aims to understand how hazards in the built environment prevent adults from aging in place.

SESSION 1325 (SYMPOSIUM)

ADVANCING UNIVERSAL MULTIDISCIPLINARY COMPETENCIES IN THE CARE OF OLDER ADULTS

In June of 2008, over 20 organizations representing healthcare providers who care for older adults met to review the Institute of Medicine (IOM) report, Retooling for An Aging America: Building the Healthcare Workforce. These organizations discussed ways they could work together to advance the IOM report recommendations and to improve the capacity of America’s healthcare workforce to provide quality geriatric care. Now called the Partnership for Health in Aging, this coalition, representing over 30 organizations, identified as its first and highest priority action step the development of a set of universal competencies that all healthcare professionals should have at the completion of their entry-level health professional degree to ensure quality care for older adults. This symposium presents the PHA multidisciplinary competencies and the process by which they were developed, discusses how the multidisciplinary competencies relate to existing discipline-specific geriatrics competencies, addresses how the competencies may apply differently to different health professions, and discusses strategies for the competencies’ implementation. This will be an interactive symposium during which the audience will be encouraged to share ideas on how the competencies can be used most effectively to enhance the training and certification of all health professionals to ensure that they have sufficient knowledge and skills in the care of older adults as they enter the healthcare workforce.
THE RATIONALE AND DEVELOPMENT PROCESS FOR THE PHA MULTIDISCIPLINARY COMPETENCIES

While several healthcare disciplines have existing geriatrics competencies for the entry-level of training, other disciplines involved in the care of older adults have not yet identified entry-level competencies specific to the care of older adults. Therefore, the Partnership for Health in Aging identified the need for a set of universal geriatrics/gerontology competencies that could direct the training and evaluation of all entry-level healthcare professionals. A workgroup representing ten healthcare disciplines reviewed a comprehensive matrix of competencies across these disciplines, recognizing that many were at different stages in geriatrics competency development. Through an iterative process, the workgroup identified common themes and overlapping areas, and developed draft competencies that were circulated to over 250 organizations for comment. The final competencies were endorsed by 30 organizations. The competency development process will be discussed, including challenges inherent in developing competencies applicable to multiple professions at differing stages of competency development and with varying terminologies.

WHAT’S NEXT WITH GERIATRICS COMPETENCIES? PUTTING THEM INTO ACTION!

The 2010 PHA Multidisciplinary Competencies provide an encompassing foundation for geriatrics training within and across professions. PHA has addressed the IOM Retooling for an Aging America assertion that healthcare professionals require geriatrics skills. These entry-level competencies join the ranks of discipline-specific competencies and address the need for cross-discipline work. These competencies must be integrated into geriatrics training and professional education. Now is the time to move geriatrics competencies forward. A framework for use of competencies must address a number of issues, including: level of education and skill; disciplinary, multidisciplinary or interdisciplinary focus; domains of learning such as content and practice context; the process of educational delivery and evaluation. Models of how these issues are being addressed by the Geriatric Education Centers will be described. Additionally all panelists and the audience will be called upon to provide examples for next steps in applying competencies to geriatrics workforce development.

MULTIDISCIPLINARY EDUCATIONAL STANDARDS FOR THE CARE OF OLDER ADULTS: DOMAINS AND COMPETENCIES

The Partnership for Health and Aging multidisciplinary competencies address six domains: Health Promotion and Safety; Evaluation and Assessment; Care Planning and Coordination Across the Care Spectrum (including End-of-Life Care); Interdisciplinary and Team Care; and Caregiver Support. The competencies are intentionally broad, in order to provide a baseline for geriatrics and gerontology training in multiple disciplines. It is expected that there will be variations in the way these competencies apply to each discipline, including variations in the depth of knowledge or level of involvement in the competency. This presentation will discuss the competencies and provide several examples of how these competencies are being addressed differently in individual disciplines.

SESSION 1330 (SYMPOSIUM)

DEVELOPING A MULTIFACTORIAL FALL PREVENTION PROGRAM: INCREASING STABILITY THROUGH EVALUATION AND PRACTICE (INSTEP)

Chair: J. Pynoos, Leonard Davis School and Andrus Gerontology Center, University of Southern California, Los Angeles, California Discussant: M. Kullman, Archstone Foundation, Long Beach, California

This symposium will describe the Fall Prevention Center of Excellence’s (FPCE) multifactorial program aimed at reducing seniors’ fall risk. Increasing Stability through Evaluation and Practice (InSTEP). The InSTEP program, targeted to older persons at moderate to high risk of falls, are part of FPCE’s mission to build a fall prevention infrastructure in California and develop evidence-based models, provide technical assistance, and information. FPCE staff analyzed the relative effectiveness of three basic InSTEP models, which differ by intensity of professional involvement (high, medium and low). Validated instruments were used to measure fall risk behaviors, concerns about falling, fall history, and current physical activities. Multiple physical performance tests were also conducted pre- and post-intervention. The first presentation evaluates the InSTEP models’ impact on reducing fall risks and identifies characteristics of participants who benefited from the programs. The second presentation will share results of the home modification component of the programs. The third presentation will present findings of the moderate intensity InSTEP model conducted with English and non-English speaking older adult groups. Lastly, future directions for InSTEP will be discussed, including sustainability strategies and development of a toolkit for dissemination. FPCE is a consortium of the University of Southern California’s Andrus Gerontology Center; the Center for Successful Aging at California State University, Fullerton; the VA Greater Los Angeles Healthcare System Geriatric Research, Education and Clinical Center and David Geffen School of Medicine at UCLA; and the California Department of Public Health, State and Local Injury Control Section.

INSTEP: MAJOR RESEARCH QUESTIONS

J. Kramer1, J.O. Harker2, M. Mitchell1, L. Rubenstein1, 1. VA Greater Los Angeles Healthcare System, Geriatric Research Education Clinical Center (GRECC), David Geffen School of Medicine at UCLA, Sepulveda, California, 2. VA Greater Los Angeles Healthcare System, Geriatric Research Education Clinical Center (GRECC), Sepulveda, California, 3. Department of Veterans Affairs, Center for the Study of Healthcare Provider Behavior, Sepulveda, California, 4. University of Oklahoma, Reynolds Department of Geriatric Medicine, Oklahoma City, Oklahoma

The three InSTEP intensity models were evaluated in longitudinal design using a logistic regression and multi-level modeling to determine: 1) Which model(s) reduce fall risk factors, 2) Characteristics of participants who benefit from these FP models, 3) Do the models have similar impacts on falls and 4) Which of the risk factors that were modified by InSTEP participation have an impact on falls. Risk assessment and participant characteristics were evaluated at baseline, immediately post intervention, and then at 3 and 6 month intervals up to 12 months;
OUTCOME ANALYSIS OF THE INSTEP HOME MODIFICATION COMPONENT

B. Steinman¹, A. Quyen Do Nguyen², ¹, Center for Gerontology and Health Care Research, Brown University, Providence, Rhode Island, ², Leonard Davis School and Andrus Gerontology Center, University of Southern California, Los Angeles, California

This discussion will focus on implementation of an environmental risk assessment tool called the Falls Home Assessment (FHA) which is being developed by the FPCE. The FHA assesses nine areas of concern in homes of InstEP participants, evaluates whether common hazards are present, and provides potential solutions to address hazards. On average, occupational therapists administering the FHA identified 12.4 (SD = 7.2) hazards in homes of high-intensity participants at baseline; by contrast, social workers identified 9.9 (SD = 4.5) in homes of medium intensity participants. These findings suggest that FHA may function differently depending on assessor type. A home modification intervention was available to fix up to five home hazards. On average, participants agreed to fix 2.7 (SD = 1.8) hazards in their homes; as a result of participation in the program, participants identified an average of 1.8 (SD = 1.6). A conclusion will discuss potential barriers to making home modifications.

INSTEP: TESTING PROGRAM EFFICACY IN MONOLINGUAL KOREAN- AND SPANISH-SPEAKING OLDER ADULTS

D. Rose, Center for Successful Aging, California State University, Fullerton, Fullerton, California

Following its successful implementation with English-speaking older adults, the efficacy of the moderate intensity InstEP model was tested with monolingual Korean- (N = 37) and Spanish- (N = 29) speaking older adults. Outcome and process evaluations were conducted after the three program rotations for each ethnic group. The combined results of the Medical Risk Assessment (MRA) and baseline balance testing indicated that 21 of the 66 participants (32%) were at high risk for falls with significant differences across ethnic groups. At follow-up, most participants screened (93.3%) had discussed their MRA assessment results with their doctor as directed. The Home Assessment and Modification component was less successful with only 38 of 66 participants (58%) consenting to a home assessment and 29 (44%) recommended modifications. After 12 weeks in the group exercise program, significant improvements in balance, lower body strength, and functional mobility were observed for the total sample.

FUTURE DIRECTIONS: LESSONS LEARNED AND NEXT STEPS

J. Pynoos, Leonard Davis School and Andrus Gerontology Center, University of Southern California, Los Angeles, California

Based on evaluation findings and lessons learned regarding sustainability and feasibility, future directions for InstEP focus on refining the model, additional testing, and the development of a toolkit to guide implementation. Issues to consider include auspices of the program; appropriate target groups; recruitment of participants; necessary resources; validation of instruments; coordination of the medical, exercise, and home modification components; cost of the program; and the development of toolkit.

SESSION 1335 (SYMPOSIUM)

FAMILY CARE, LIVING ARRANGEMENTS AND HEALTH OF OLDER PEOPLE IN CHINA

Chair: T.Y. Lum, University of Minnesota, St. Paul, Minnesota

This symposium examines family caregiving and health of older adults in China. The first paper examines how culture influenced family caregiver's perception of dementia and caregiving. Using qualitative data collected in two urban Chinese cities, the authors found that traditional Chinese culture might protect family caregivers against caregiving stress. The second paper examines the structure of intergenerational relationships in rural China. Using survey data from the Anhui province, the authors found that typologies of intergenerational relations reflected adaptations of family relations to contemporary socioeconomic and cultural conditions in China. The third paper examines generational differences in filial piety and living arrangements for elders in Hong Kong. Using survey data from 1,004 adults, the authors found a U-shape relationship between age and filial piety and willingness to living with aging parents. The fourth paper examines trajectories of social engagement and depressive symptoms among nursing home residents in Hong Kong. Using 5 years nursing home assessment data, the authors found that the two trajectories were negatively related. The last paper examines rural-urban health disparities among adults in China. Using data from the Chinese Health and Retirement Longitudinal Study, the authors found that that people living in rich, urban areas in China were increasingly experiencing "compression of functional limitations", whereas decreased physical functioning associated with age was accelerated in poor province and rural areas.

TRAJECTORIES OF SOCIAL ENGAGEMENT AND DEPRESSIVE SYMPTOMS IN OLDER ADULTS IN RESIDENTIAL CARE IN HONG KONG

V. Lou¹, C. Kwan², I. Chi³, A.Y. Leung³, ¹, Social Work & Social Administration, The University of Hong Kong, Hong Kong, Hong Kong, ², Department of Statistics & Actuarial Science, The University of Hong Kong, Hong Kong, Hong Kong, ³, School of Social Work, University of Southern California, Los Angeles, California, 4, School of Nursing, Sau Po Centre on Aging, The University of Hong Kong, Hong Kong, Hong Kong

Objective: This study examines the relationship between changes in social engagement and depressive symptoms among Chinese older adults who have lived in residential facilities for over 6 years. Method: A latent growth model was used to analyze six waves of data from the Resident Assessment Instrument (RAI) used in the Longitudinal Residential Home Study Hong Kong Sheng Kung Hui Welfare Council (HKS KW) from 2005 to 2010. Results: While controlling for baseline measures, trajectories for social engagement are strongly related to trajectories for depressive symptoms. Those participants who recorded positive growth in social engagement report negative growth in depressive symptoms. Conclusion: Depressive symptoms are among the most commonly observed mental health problems for older adults in residential care. The findings of our study extend previous research by showing that the dynamic relationship changes across time.

AREA DISPARITIES IN HEALTHY AGING IN CHINA

L. Li, J. Zhang, School of Social Work, University of Michigan, Ann Arbor, Michigan

This study examines area disparities in health and in the way health varies by age among adults in China. The analysis was based on the Chinese Health and Retirement Longitudinal Study which collected data from a probability sample of adults (age 34-93, N=2,685) in a rich coastal province (Zhejiang) and a poor inland province (Gansu) of China in 2008. We found that older age and rural residence (vs. urban) lower physical functioning, and their effects are greater for those living in Gansu than in Zhejiang. Nonetheless, rural and Ganzu residence pro-
THE STRUCTURE OF INTERGENERATIONAL RELATIONS IN RURAL CHINA: A LATENT CLASS ANALYSIS

M. Guo, I. Chi, M. Silverstein, J. USC School of Social Work, Los Angeles, California, 2. Davis School of Gerontology, Andrus Gerontology Center, University of Southern California, Los Angeles, California

Most existing typology studies of intergenerational relations have used samples in North America and Europe. The present study expands on the previous research by determining whether similar family relation typologies could be found by using a sample of Chinese elderly. The data was derived from a survey of 1,224 older adults in rural Anhui province, China in 2009. The results of Latent Class Analysis showed five types of intergenerational relations among Chinese rural elderly: tight-knit, nearby but discordant, distant and discordant, distant reciprocal, and distant ascending. Among them, “distant reciprocal” is a unique pattern different from those of western studies and it reflected collaborative and mutual beneficial parent-child relations in the context of large out-migration of adult children in rural China. We conclude that the typologies of intergenerational relations found in our study reflected adaptations of family relations to contemporary socio-economic and cultural conditions in rural China.

FAMILY CAREGIVER’S PERCEPTION OF DEMENTIA AND CAREGIVING IN CHINESE CULTURE

Objective: This study examined views of perception of dementia and caregiving among family caregivers of individuals with mild cognitive impairment (MCI) and dementia in China. Methods: Semi-structured interviews were conducted in 2009 in Wuhan and Beijing, China. Participants included 38 spouses, seven adult children and one sibling, aged between 41 and 85. Results: One common theme is that family caregivers thought the Chinese terminology of dementia brings discrimination to individuals with cognitive impairment. Caregivers who were children were less traditional and more pragmatic in their practice of filial piety than those who were spouses or siblings. Conclusions: A culturally appropriate terminology of AD/dementia would help in decreasing the stigma of dementia. Though divergences emerged, a mainstream culture of filial piety persisted. This study suggests that traditional culture provides positive influence on caring for elders with cognitive impairment and AD/dementia, and reduces the stress of caregiving.

GENERATIONAL DIFFERENCE IN ATTITUDE TOWARD FILIAL PIETY AND ELDER CARE IN HONG KONG

T.Y. Lum, E. Yan, A. Ng, G. Leung, D. Lam, M. Chow, 1. University of Minnesota, St. Paul, Minnesota, 2. The University of Hong Kong, Hong Kong, Hong Kong

Objective: The objective of this study was to understand intergenerational difference in support of filial piety and its implication for family care frail elderly among Chinese people. Methods: We conducted a telephone survey with 1,014 adults and focus groups with 32 people in Hong Kong. A grounded theory approach was used to analyze the focus group data while multivariate regression analysis was used to analyze the survey data. Findings: Support for filial piety was stronger among the elderly and younger adult populations, but lowest among middle age people. Older people were very willing to live with their adults children. However, most non-elderly adults were reluctant to live with their aging parents. Among non-elderly adults, the willingness to live with aging parents was highest among younger adults than middle age adults. Implications of these findings to the future of family care in Chinese society will be discussed.

SESSION 1340 (SYMPOSIUM)

HEALTHY AGING IN MASSACHUSETTS: COMMUNITIES FOR LIFELONG WELLNESS

Chair: W. Leutz, Heller School, Brandeis University, Waltham, Massachusetts
Discussant: N. Whitelaw, National Council on Aging, Washington, DC, District of Columbia

After a 2.5-year planning and development effort supported by the Tufts Health Plan Foundation, Massachusetts is launching a statewide healthy aging (HA) initiative in late 2011. The initiative’s HA model seeks to integrate a statewide network of evidence-based programs into new community-level initiatives that build on existing health and supportive services, existing healthy community efforts, social networks, and other local institutions. These efforts will be supported by a coordinated public awareness campaign, as well as a Healthy Aging Academy to train and inspire leadership. All initiatives will include older adult engagement, involvement of community leaders, systems linkages, and evaluation. This symposium describes the development of the MA initiative and details the HA model to be used. It includes reports on the foundation’s journey into healthy aging as a funding priority, the use of the Massachusetts Health Policy Forum to build a representative state-wide planning effort, the models for HA that guided the planners, and the plan that will be launched in late 2011.

DEVELOPMENT OF A STATEWIDE HEALTHY AGING INITIATIVE

D. Abelman, 1. Tufts Health Plan Foundation, Watertown, Massachusetts, 2. Tufts Health Plan, Watertown, Massachusetts

In 2009, the Tufts Health Plan Foundation launched an initiative focused on healthy aging for older adults 60+. Leveraging that grant making initiative, the foundation began a partnership with the Massachusetts Health Policy Forum (MHPP) at Brandies University to develop policy and public education approaches aimed at building a Healthy Aging (HA) movement in Massachusetts. The Foundation partnered with MHPP to create a series of three Issue Briefs and two statewide conferences in 2009 and 2010 that first reviewed models of HA and HA efforts in the state, second supported a steering committee to prioritize components of the initiative, and third created subcommittees to develop detailed and integrated plans to foster HA. This presentation will detail the process, including involvement of outside experts and a broad constituency in the background research, forums, and committees; leveraging resources from the Foundation and other sources; and plans for sustainability and expansion over time.

THE MASSACHUSETTS MODEL FOR HEALTHY AGING

W. Leutz, Heller School, Brandeis University, Waltham, Massachusetts

The model for healthy aging (HA) that is being implemented in Massachusetts is the result of a two-year research and development effort backed by the Tufts Health Plan Foundation and the Massachusetts Health Policy Forum. The project is guided by a vision of HA that was derived from a synthesis of the policy and research literature on HA, interviews with 28 experts inside and outside the state, and site visits to a variety of HA programs. This presentation summarizes the findings
of the investigation, including concepts and ingredients of HA, a systems model of HA, programming for HA, and approaches for promoting HA in communities.

THE MASSACHUSETTS PLAN FOR HEALTHY AGING
C. Jakubiak, D.P. Stevens, 1. MA Association of Older Americans, Boston, Massachusetts, 2. Massachusetts Councils on Aging, Easthampton, Massachusetts

The details and coordination of the Massachusetts plan for healthy aging (HA) have been worked out by a steering committee, which formed three subcommittees to: (1) solidify evidence-based HA programming, (2) foster HA communities, and (3) support the first two subcommittees with public awareness activities. This presentation details the formation and operations of these committees, as well as the plans to be implemented. For HA programming, this includes solidifying the statewide infrastructure of trainers, recruitment, and classes as well as political and financial support. For healthy communities, this involves developing cross-program, intergenerational partnerships in cities and towns, plus support from a state-level healthy aging “academy.” Public awareness activities will be developed to support the HA programming and communities efforts.

STATE AGENCY VIEWS OF THE MASSACHUSETTS PLAN FOR HEALTHY AGING
R. Palombo, A. Albright, 1. MA Executive Office of Elder Affairs, Boston, Massachusetts, 2. MA Department of Public Health, Boston, Massachusetts

Over the last several years, the Massachusetts Executive Office of Elder Affairs (EOEA) and Department of Public Health (DPH) have collaborated closely to implement both evidence-based healthy aging (HA) programs and broader healthy communities initiatives. The initiatives are supported by a variety of federal, state, and local funds. Since 2009 EOEA and DPH have also collaborated with the statewide HA planning and development effort supported by the Tufts Health Plan Foundation through the Massachusetts Health Policy Forum. In this presentation, a state agency staff member discusses the challenges and opportunities related to coordinating their ongoing programming and commitments with an independent HA initiative outside of state government.

SESSION 1345 (SYMPOSIUM)

REFINEMENTS AND NEW MEASURES IN THE NATIONAL BALANCING INDICATORS
Chair: S. Ruiz, IMPAQ International, Washington, District of Columbia
Co-Chair: O. Urdapilleta, IMPAQ International, Washington, District of Columbia

This symposium will present findings from Year 1 of the National Balancing Indicator Project (NBIP). Approximately 42% of elders and 19% of adults currently report having functional limitations due to physical or intellectual disabilities, and/or mental illnesses. These individuals require a range of long-term support and services (LTSS) to live independently in the community. Despite substantial research efforts studying rebalancing, there remains a gap in the availability of common indicators to measure rebalancing efforts and measures of choice, control and access of the full array of quality services that assure independence, optimal health and quality of life across all States. To address this gap, the NBIP is assisting the Centers for Medicare & Medicaid Services (CMS) and States in the refinement of the indicators that measure States’ progress in offering a rebalanced system of LTSS. The presentations will focus on three areas: 1) the refinement and improvement of balancing indicators; 2) additions and expansions of the indicators; and 3) the development and collection of the developmental indicator cultural competence. Federal mandates and initiatives (e.g., Americans with Disabilities Act, Olmstead Decision) provide an impetus for State agencies to pursue community integration for all individuals. As States continue to reform their LTSS systems, there is a growing interest in determining their successes in attaining and maintaining person-centered care, and achieving a more equitable balance between the provision of Medicaid institutional care and community-based services and related expenditures. These rebalancing issues continue to be critical components of long-term support system discussions at the Federal and State levels.

REFINEMENTS OF THE NATIONAL BALANCING INDICATORS

One core component of the NBIP project is refining and improving balancing indicators developed in the first phase. This presentation will describe the ways in which the indicators are being improved through feedback from state grantees and federal partners. Individual States provided a range of feedback from preferences in wording to philosophical changes in how the indicators were calculated. Some States also felt that several of the indicators should be consolidated or shifted to another principle. It was argued that some indicators should be consolidated because of overlap in those two indicators. States also suggested that some indicators be shifted. Several States wanted to update indicators based on changes within the state or new legislation. States sometimes gave critiques about how the indicator was calculated and suggested alternative calculation strategies. An example of such a critique would be a unified mission/vision statement. It was argued that there is debate about whether such a statement is important for the operation of the agency. A description and analysis of State suggestions for refinement of the indicators will be included in the presentation.

ADDITIONS AND EXPANSION OF INDICATORS IN THE NATIONAL BALANCING INDICATOR PROJECT

This session will present findings from the development of new balancing indicators, with a focus on indicator development for Direct Service Workforce (DSW). After a summary of the NBIP’s work with State Grantees and federal partners to expand balancing indicators, the presentation will focus on the creation of indicators to measure states efforts in DSW. The National Direct Service Workforce (“DSW”) Resource Center released a set of recommendations for state agencies about which workforce data to collect and which indicators to track to help them measure the impact of their workforce initiatives over time. The set of six core data elements identified in the article were identified through a collaborative effort of the DSW Resource Center technical assistance team, representatives from 13 states, CMS, and several Federal partner agencies. As part of the Prime Contract, IMPAQ will work with the DSW Resource Center team to assist CMS State Profiling Tool (SPT) grantees to collect the recommended core data elements and build the infrastructure needed to track these workforce indicators over time. In addition the new measures, the presentation will consider the applicability and implementation of these measures in context to the availability of existing data sources and future data collection and reporting efforts mandated by the Affordable Care Act (ACA) and other initiatives within CMS and across the Federal government designed to reform and improve the LTSS system.

THE DEVELOPMENT OF INDICATORS TO CAPTURE CULTURAL COMPETENCE
S. Ruiz, J. Howard, IMPAQ International, Washington, District of Columbia

This presentation will summarize the ongoing efforts among the ten SPT Grantees to implement a culturally competent long-term supports and services (LTSS) system as well as previous efforts by the NBC...
in the development of the Cultural Competency principle and indicators. Due to the fact that States have unique terminology to represent a culturally competent LTSS system, the general definition used is a system that provides accessible information and services that take into account people’s cultural and linguistic needs. Specifically, a culturally competent LTSS system includes the following key components: 1) Service offerings to a diverse population, supported by staff that reflect that diversity; 2) State and local communities provide ongoing education, training and awareness activities in cultural competence for providers and others; 3) Prevention of prejudice and discrimination related to disability or accommodation in the workplace; 4) Successful communication with people of all ages with disabilities and/or chronic conditions.

SESSION 1350 (PAPER)

ENVIRONMENTAL CHANGES THAT IMPROVE THE QUALITY OF LONG TERM CARE

THE EFFECT OF BRIGHT LIGHT ON PERSONS WITH DEMENTIA: A REVIEW OF THE CURRENT RESEARCH ON THE ABILITY OF BRIGHT LIGHT IN RESIDENTIAL SETTINGS TO REDUCE AGITATION AND IMPROVE SLEEP IN PERSONS WITH DEMENTIA

With the development of the special care unit as a residence for those with dementia, the relationship between the environment and health outcomes gains increased importance. As the model continues to grow, designers and health care providers need to be able quantify the effect of specific environmental interventions on improved health. This paper presents the findings of an in depth literature review on the effects of exposure to bright light on persons with dementia. Specifically this review includes only those studies that measured either reduction in agitation or sleep improvements. Dementia was defined to include those with Alzheimer’s Disease and other dementias. The review includes research studies that use both artificial bright light and daylight interventions. Studies reviewed were primarily conducted in special care dementia units, skilled nursing facilities, or supportive living environments and included only adults aged 65 and over with a diagnosis of dementia. The research confirmed that exposure to bright light does have a positive affect on reducing agitation and improving sleep patterns in persons with dementia. However, the research shows conflicting findings on the appropriate dosage of light or method of administration. This suggests that further research is needed in order to better understand the biologic response to bright light. Two areas identified as being of primary importance are dosage of light required and type of light that is most effective.

THE PRESENCE OF FAMILY DURING MEALTIME: IMPACT ON FEEDING ASSISTANCE CARE QUALITY

D.W. Durkin, S.F. Simmons, Center for Quality Aging, Vanderbilt University School of Medicine, Nashville, Tennessee

Inadequate staffing is a common problem in long-term care (LTC) facilities that often results in inadequate mealtime assistance. New federal regulations allow non-nursing staff to provide feeding assistance. The use of family/volunteers could be an effective way to augment LTC staff to improve mealtime assistance. However, we have limited knowledge about how often family members visit during mealtime and what types of assistance they provide, when present. The purpose of this study was to examine data from a larger study. Trained research staff conducted observations (n=1,443) during meals for a sample of 44 LTC residents. Specifically, we examined the prevalence and quality of family/volunteers assistance and the relationship between the presence of family/volunteers and mealtime care quality. Results showed that assistance from family/volunteers was infrequent, occurring only 6% of the time; however, when assistance was provided residents benefited. Residents with family/volunteer assistance ate significantly more of their meal, were provided assistance for significantly longer periods of time and were significantly more likely to receive physical guidance/encouragement to promote mealtime consumption. Regression analyses determined that residents who were older, female, and non-white were more likely to receive family assistance. LTC facilities that encourage family involvement in mealtime assistance would free up time and staff to help assist other residents and may improve the intake of residents who get assistance from families. In addition, it would give the families something to do when they visit their loved one. This may be particularly beneficial to family members of residents with dementia.

PERSON-CENTERED CARE IN THE FACE OF ‘AGGRESSIVE’ BEHAVIORS OF PEOPLE WITH DEMENTIA LIVING IN A LONG-TERM CARE SETTING

P.J. Doyle, Center for Aging Studies, Erickson School, University of Maryland Baltimore County, Baltimore, MD

Person-centered care is considered to be among the best practices in providing formal dementia care. However, there are limitations in the application of person-centered care and information regarding the limitations is lacking in the literature. The ethnographic research project, in which this paper draws from, sought to examine the complexities of this approach to care in one focal dementia care setting that had an explicit organizational commitment to a person-centered model of care. The ethnographic interviews and participant observations of both staff members and residents will be used to discuss some of the challenges faced when applying person-centered care principles. Specifically, this paper will focus on how documented aggressive behaviors of residents influenced the provision of person-centered care. To look at this relationship between aggressiveness and person-centered care, this paper will focus on three residents who exhibited aggressive behaviors. In these situations, there was often a delicate balance between what is best for the ‘aggressive’ resident and the well-being of others living/working in the environment. This study found that aggressive behavior, perceived to be problematic, triggered acute attention to the resident to minimize the undesirable behavior. However, the solutions to reduce the behavior did not always match the principles which underlay person-centered care. Discussion will focus on how and why the approach to aggressive residents at times conflicted with the overall model of care in this setting and if this deviation is problematic.

THE DINING ENVIRONMENT IN SPECIAL CARE UNITS: OPPORTUNITIES FOR SOCIAL CONNECTION FOR RESIDENTS LIVING WITH DEMENTIA

E. Roberts, Human Environmental Sciences, University of Missouri-Columbia, Columbia, Missouri

Lee, Draper & Lee (2001) define social connection as the subjective awareness of being in a close relationship with the social world, suggesting that social connection includes a sense of closeness to others that is critical to one’s sense of belonging. Incorporating the framework of a social ecology perspective, this multi-method case study addressed social connection for the residents of a 70-bed special care unit (SCU) for cognitively impaired individuals with dementia. While past studies have shown that the organizational and physical structure of SCUs can have an impact on resident social interaction, the purpose of the study was to gain a better understanding of the role that the physical environment plays in supporting important social interactions in dining room settings. The SCU in the study had two dining options for residents, one a large institutional dining room, and the other a residentially scaled dining room with a dining table where 8-10 residents are served meals directly from a residentially scaled kitchen. Through observations and staff and family interviews, it was determined that despite the different settings, social bonds created during mealtimes are complex relational
ties formulating a cohesive social community, and offer potential for improved quality of life and a sense of social connection for residents living in SCUs.

PROMOTING CHOICE IN NURSING HOME DAILY CARE: A STANDARDIZED OBSERVATIONAL PROTOCOL OF STAFF BEHAVIOR

J. Palmer1,2, V. Parker2, D. Berlowitz1,2, J. Burgess2, C.W. Hartmann1,2, I. CHQOER, Bedford VA Medical Center, Bedford, Massachusetts, 2. Boston University, Boston, Massachusetts

The burgeoning "culture change" movement in nursing homes champions resident choice as key to resident-centered care. Staff plays a pivotal role in soliciting and honoring resident choice; thus the question arises: how well do nursing home staff do at achieving such a goal? Little has been done to measure this phenomenon. We have developed a preliminary standardized observational protocol to address this gap. In the first phase of tool development, we relied on the use of qualitative methodology within a large, integrated healthcare system (the Veterans Health Administration). This consisted of 22 hours of ethnographic observations and over 30 interviews of residents and staff in two nursing homes. We refined the tool further using a comprehensive literature review on the topics of resident choice and observational instruments in nursing homes. Finally, we established face validity of the tool by consulting a five-member expert panel of nursing home workers and research experts in the field using a modified Delphi approach. The final tool includes the following coded dimensions for each observed instance of staff-initiated choice opportunity: choice domain (e.g., meals), choice type (e.g., when), staff language use (e.g., open-ended question), staff behavior when choice is solicited (e.g., asks in an anticipatory fashion), staff behavior when choice is not solicited (e.g., suggests what is to be done), and potential conflicts to offering resident choice (e.g., treatment recommendations). This tool holds significant promise for informing operationalization of resident choice, advancement of its research, and internal and external quality measurement in nursing homes nationwide.

SESSION 1355 (PAPER)

GLOBAL PERSPECTIVES ON INTERGENERATIONAL SUPPORT

BONDING WITH ONE CHILD: CONSEQUENCES ON DEPRESSION AND DISABILITY OF ELDERS IN RURAL CHINA

Z. Cong1, M. Silverstein2, 1. Human Development and Family Studies, Texas Tech Univ, Lubbock, Texas, 2. University of Southern California, Los Angeles, California

This paper examined how relationships with children influenced the trajectory of depression and disability of elders in rural China. Our working sample included 1640 elders from a four-wave longitudinal study in Anhui Province, China, interviewed in 2001, 2003, 2006, and 2009. In rural China, on average elders have 4 children, with whom elders experience various interactions. We categorized elders’ relationships with children into three groups: one dominant, shared support, and all distant. We further used growth curve analysis to examine the effects of these types of relationships on the trajectories of depression and disability respectively, as well as the buffering effects of relationship types on the reciprocal relationships between depression and disability. Results showed that having one dominant relationship reduced the development of depression and disability, and deterred the reinforcing effects between depression and disability. This investigation brings forth the importance of having at least one supporting child in elders’ well-being. When children play a very important role in elders’ support network in rural China, the best strategy for elders to improve their well-being is to be closely bonded with one child.

WHAT EXCHANGES MEAN TO JAPANESE OLDER PARENTS AND THEIR “ON-CALL” FAMILIES

S. Lum, Waseda University, Tokyo, Japan

Many quantitative research and surveys have found exchanges within Japanese families to be at a low level. Although situated in Asia, Japanese family structures have undergone significant changes over the past century. Compared to families in other Asian societies, Japanese family relationships can be said to be distant and recent phenomena lamenting the “collapse” of family have created an even bleaker picture. The purpose of this research was to explore in depth the intra-family relationships of middle-class, healthy older adults living in the Greater Tokyo area. A total of 35 older adults (age ranged from 60 to 85 years) and 10 adult children (age ranged from 30 to 59 years) were interviewed to understand the living arrangements, contacts and exchanges and relationships between parent(s) and child(ren). Interview data were analyzed for family structure, contacts and exchanges and generational relationships. Results found that parents fiercely guarded their independence as well as that of their children. The infrequent contacts and exchanges became important times and events for both generations. The adult children, generally living apart from parents, were deeply committed to see to the needs of their parents, when and if such a need arose. Needs became the overriding criteria for action, resulting in what could be described as “on-call” families.

HOUSEHOLD CONTEXT AND HEALTH OF THE ELDERLY IN INDIA

T. Samanta, Sociology, University of Maryland, College Park, Maryland

Support for the elderly in developing countries is becoming an increasingly important issue in the face of accelerated population aging. This population aging is occurring at a time when developing countries are also experiencing rapid socioeconomic changes including globalization, urbanization, occupational mobility and outmigration of young people. Notably, family still remains the central source of support for the elderly as institutional systems of care (e.g., elderly homes, geriatric clinics etc) are largely inadequate in most developing countries. Given this resilience to norms of filial piety, governments and policy makers in some developing countries (including India) have enacted filial responsibility laws mandating familial support, rather than introducing government funded institutional programs such as social security pensions and public medical systems. Academic research, however, has been largely inadequate to assess the multifaceted implications of such family-care policy. This paper draws on the nationally representative, multi-topic dataset-India Human Development Survey (2004-05) and attempts to fill this gap by examining the association between household context (especially co-residence with adult children) and elderly health (short term morbidity) in the Indian context. In addition, the study also aims to focus on the association between elderly health and differences in health expenditures by family types (living alone, with adult children or with other family members) in situations where there is no universal social security or national health care scheme to protect the elderly. Statistical analyses such as logistic regression and propensity score matching are used to investigate the hypothesized associations.

REFLECTIONS ON A STUDY OF THE UK'S FIRST PURPOSE-BUILT INTERGENERATIONAL CENTRE

J. Melville, Centre for Social Gerontology, Keele University, Stoke on Trent, United Kingdom

Many changes in society, such as increased geographic mobility and improved technological advances, have led to generations frequently becoming segregated from one another. One response to these social and economic changes has been to develop intergenerational shared sites (IGSS). IGSS are unique as they present the opportunity for frequent structured and informal activities with the potential to establish age-integrated communities that meet the diverse needs of their members.
Whilst IGSS are well established across the US, very few centres with a specific ‘intergenerational focus’ operate in the UK. In 2008, the London Borough of Merton, England, received capital funding to establish the country’s first purpose-built intergenerational centre. Since then, the Acacia Intergenerational Centre has been developed as a one-stop resource of shared services and facilities for older people, children and younger people, and families. This paper presents preliminary findings from in-depth qualitative interviews conducted with stakeholders responsible for the design and development of the Centre, documentary analysis highlighting the processes and decision-making behind its establishment, and non-participant observation of how the Centre’s social and built environments promote interaction between participants. In particular, the study explores stakeholders’ expectations and their proposed strategies for how the Centre will foster intergenerational interaction. Findings highlight the interplay between the objectives set for the centre, and the extent to which the environment has met the needs of participants and fostered intergenerational interaction.

**EFFECTS OF GRANDPARENT CAREGIVING: EVIDENCE OF HEALTH IMPROVEMENTS FOR GRANDPARENTS IN TAIWAN**

Background: Grandparents in Taiwan often volunteer to help care for grandchildren due to traditional family values. However, little is known about the health impact of caregiving on these grandparents. Although research in the U.S. has found negative health effects on grandparent caregivers, the results are likely to differ in Taiwan considering cultural differences. The objective of this study is to determine whether caring for grandchildren has a positive impact on the health and health services use of grandparents in Taiwan. Methods: Data came from 5,245 grandparent respondents in four waves of the Survey of Health and Living Status of the Elderly in Taiwan (1993-2003), a nationally representative survey of Taiwanese elderly. Grandparent caregiver was a binary indicator of whether the respondent has ever helped care for his or her grandchildren. Panel data analyses were used to estimate health impact of caregiving while controlling for selection into caregiving by healthier grandparents using both fixed effects and instrumental variables. Results: Caring for grandchildren was associated with improvements in caregivers’ physical and mental health measured by self-rated health, life satisfaction, mobility limitations, and depression. Caregivers were also less likely to report having unmet health need, although no significant effect was found in their outpatient care utilization. Instrumental variables analysis showed that after controlling for endogeneity, the protective effects of caregiving was even larger on mobility limitations and depression. Conclusions: Evidence from grandparents in Taiwan supports our hypothesis that that caring for grandchildren can be beneficial for grandparents’ health within a culture that emphasizes intergenerational reciprocity.

**SESSION 1360 (PAPER)**

**RISKS FOR FUNCTIONAL LIMITATIONS**

**IMPACT OF COGNITIVE AND MANUAL DUAL-TASKS ON GAIT OF OLDER ADULTS AT HIGH AND LOW FALL RISK**

C. Hall1,2, M. Hackney1,2, 1. Rehab R & D Center of Excellence, Atlanta VAMC, Decatur, Georgia, 2. Emory University, Atlanta, Georgia

Background: Impaired ability to walk under dual-task conditions contributes to falls. Results of previous studies vary depending on the dual-task used, making it difficult to apply findings. One purpose of this study was to determine the impact of different secondary tasks on gait. A second purpose was to determine the impact of dual-tasks on gait of participants at high versus low fall risk. Methods: Sixty-two healthy, community-dwelling older adults (range: 65-86 years) without cognitive impairments participated. Gait, with and without dual-tasks (verbal, math, or manual), was measured using an electronic walkway. A 3x2x2 (cognitive task by manual task by fall risk group) RM MANOVA was performed. Results: There were significant (p<0.001) main effects of task (cognitive and manual) and group. While performing either cognitive task, participants walked slower; had shorter stride length, longer stance time, and increased swing time variability. While performing the manual task, participants walked slower and had shorter stride length. With or without dual-tasks, participants at high risk for falls walked slower, had shorter stride length, longer stance time, wider steps, and more variable swing time, than those at low fall risk. Dual-task conditions did not differentially affect participants at high fall risk. Conclusion: A verbal task had the greatest effect on gait and so may be appropriate for identifying fall risk in older adults. Gait performance decrements (i.e., dual-task costs) were similar for individuals at high and low fall risk; therefore, an actual time cutoff to determine fall risk with dual-task paradigms may be most appropriate.

**AN EXAMINATION OF RURAL VS. URBAN FALLS USING GIS**

D.J. Van Dussen1, B.M. Hileman2, B.A. Shellito3, B.A. Craig2, K. Covinsky4, 1. Sociology, Anthropology, and Gerontology, Youngstown State University, Youngstown, Ohio, 2. St. Elizabeth Health Center, Youngstown, Ohio

The current research examines the associations between the number and severity of falls and the distance from a hospital as well as the urban and rural development of the location in the Youngstown/Warren regional area in Ohio. This study uses GIS to show the distribution of falls and the distance from the three hospitals that deal with trauma in the area. Our sample consists of 1600 individual fall locations representing traumas resulting in hospitalization. Performing calculations on these locations with ArcGIS, the fall locations were linked to their closest trauma facility. GIS distance calculations were then used to determine the distances traveled to reach the facility. Entering ISS trauma data provided by the trauma facilities into ArcGIS, there is an obvious trend towards increased ISS levels as distance increases. This information can be used to improve care that is provided by these trauma facilities, enabling them to provide better service to an expanded service area.

**INSUFFICIENT PERSONAL ASSISTANCE FOR ADL DISABILITY AND RISK FOR DEATH AMONG COMMUNITY-LIVING OLDER ADULTS**

S. He1, H. Xu2, L.P. Sands3, P. Stallard2, B.A. Craig1, J. Thomas1, K. Covinsky4, 1. Purdue University, West Lafayette, Indiana, 2. Indiana University School of Medicine, Indianapolis, Indiana, 3. Nursing, Purdue University, West Lafayette, Indiana, 4. Duke University, Durham, North Carolina, 5. University of California San Francisco, San Francisco, California

BACKGROUND. To assess whether self-reports of insufficient help for ADL disabilities reflect vulnerability that cannot be captured by traditional indicators of disability and disease status, we determined whether they were associated with time to death after controlling for demographics, functioning, and illness status. METHODS. Community respondents to the 1994, 1999, and 2004 National Long-term Care Survey (NLTCS) reported demographics, co-morbidities, ADL disability and whether they needed more help for their ADL disabilities. Hospitalizations and date of death were determined from linked Medicare and vital statistics data. RESULTS. During the interview, 6688 respondents reported at least one ADL disability; 80% were aged 75 or older; 72% were female, 87% were white, 31% were hospitalized within 12 months of the interview, and 21% reported lack of sufficient ADL help. Results of a Cox proportional hazards model that adjusted for demographics...
and illness status revealed the reports of insufficient ADL help were associated with an increased risk for death among respondents with 1 to 3 ADL disabilities (HR = 1.35, 95% CI: 1.05-1.74), but not among respondents with 4 to 5 ADL disabilities (HR = 0.92, 95% CI: 0.72-1.19). CONCLUSION. For older adults with 1-3 ADL disabilities, self-reports of insufficient help appear to reflect vulnerability that is not captured by ADL and disease status.

INSUFFICIENT ADL HELP AND HOSPITAL READMISSION

G. DePalma¹, H. Xu², K. Covinsky³, B.A. Craig¹, P. Stallard³, J. Thomas³, L.P. Sands¹, 1. Purdue University, West Lafayette, Indiana, 2. Indiana University School of Medicine, Indianapolis, Indiana, 3. University of California, San Francisco, San Francisco, California, 4. Duke University, Durham, North Carolina, 5. Nursing, Purdue University, West Lafayette, Indiana

BACKGROUND. ADL disability increases risk for hospital readmission among older adults. We hypothesized that insufficient human help for activities of daily living (ADL) disabilities is a stronger predictor of re-hospitalization than level of ADL disability. METHODS. Self-reported data about presence of ADL disability, insufficient help for ADL disability, demographic and health characteristics were available from the 1994, 1999 and 2004 community interviews of the National Long Term Care Survey (NLTCS). Hospital data were obtained from linked Medicare claims records. Respondents lived in the community and had a hospital discharge within 90 days prior to the NLTCS interview. A Cox proportional hazards model was computed to determine the association between insufficient ADL assistance and hospital readmission between 90 days and one year after the prior hospital discharge after adjustment for demographics, ADL level, and co-morbidities. RESULTS. All subjects had at least one ADL disability; 28% were less than 75 years old, 68% were female, 87% were white, 39% were living alone, and 24% of subjects reported insufficient help for one or more ADL disabilities. ADL status was not associated with time to readmission, but insufficient ADL help was. Rates of readmission were 51% and 36%, respectively, for those who did and did not report insufficient ADL help (HR= 1.95, 95% CI =1.26-3.00). CONCLUSION. Results indicate that insufficient ADL help better identifies older adults at risk for hospital readmission than level of ADL disability. The potential for insufficient ADL help at home should be considered in hospital discharge planning.

WAYFINDING EFFICACY IS ASSOCIATED WITH BALANCE IN OLDER ADULTS: RESULTS FROM THE HEALTHY AGING RESEARCH NETWORK

Balance facilitates a healthy lifestyle in ways such as walking for exercise, preventing falls, and maintaining mobility. Cognitive processing plays an important role in balance. Numerous studies have linked balance to cognition demonstrating that balance degrades as cognitive processes are taxed under dual-task conditions; however this association has not been demonstrated in a large community-based cohort. As supported by the Multiple Component Model of Working Memory, it is possible that visuospatial capacity plays a role in motor movements. This study investigates whether wayfinding efficacy – a proxy for visuospatial skills – is associated with balance or falls in older adults. Method: The Healthy Aging Research Network administered a survey on walking and environmental characteristics to older adults across the US. One-way ANOVAs were used to explore the association between wayfinding efficacy and two outcomes: balance and history of falls. Results: The 884 participants were males (23%) and females (77%) age 65 and older. Participants who were not confident in their ability to navigate through a familiar environment when faced with an obstacle were significantly more likely to have poor balance (F(1,870)=16.47, p<0.001). However, low wayfinding efficacy was not significantly associated with a self-reported fall within the last 6 months (p=0.231). Discussion: This study provides support for the association between balance and visuospatial efficacy. Degradation in wayfinding efficacy may be indicative of decreased postural stability since it is likely that balance taps into the same cognitive process (visuospatial skills) as wayfinding. Lifestyle choices that promote cognitive health may also enhance physical health through better balance.

SESSION 1365 (SYMPOSIUM)

AFRICAN AMERICAN MEN’S HEALTH: THE ROLE OF PSYCHOSOCIAL AND LIFESTYLE FACTORS

Chair: R. Thorpe, Hopkins Center for Health Disparities Solutions, Baltimore, Maryland, Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland

Discussant: J. Jackson, University of Michigan, Ann Arbor, Michigan

A key objective of the public health agenda is to reduce, if not eliminate, health disparities. However over the past three decades modest progress has been achieved with regard to race and sex inequalities. At the intersection of race and sex are African American men who have the worst health profile of all American subgroups as they experience greater morbidity, premature mortality, earlier onset of disease, and present with disease at later stages. Little is known about factors that are related to this important, yet understudied population. While there are research documenting group differences between African American and white men, it is important to identify and understand factors that will enhance the lives of African American men. This symposium highlights research that focuses on how lifestyle and psychosocial factors affect African American men’s health. Thorpe and colleagues examine associations between lifestyle factors and longevity. Whitfield and colleagues examine how health impacts cognitive functioning. Clay and colleagues determine the impact of physical, psychosocial and lifestyle measures on physical functioning. Bruce and colleagues present results from a study examining the relationship between perceived discrimination and blood pressure. These studies provide information that will bolster our knowledge of how lifestyle and psychosocial factors can improve the lives of African American men, lead to reductions in health disparities and improve overall population health.

HEALTH AND COGNITIVE AGING IN AFRICAN AMERICAN MEN

K.E. Whitfield, A. Aiken Morgan, J.C. Allaire, Psychology and Neuroscience, Duke University, Durham, North Carolina

Recently scholars have argued that understanding minority aging needs within group analyses to advance. The same could be argued for gender among these groups. African American men experience greater morbidity, premature mortality, earlier onset of disease, and present with disease at later stages than other men or women of other minority groups. This investigation examined the impact of health status and demographic factors on cognitive functioning of African American men. Data include 243 men from the Baltimore Study of Black Aging and individuals from the Carolina African American Twin Study of Aging. Using linear regression, peak expiratory flow and demographic factors (age, education, and marital status) were found to be significant predictors of cognitive functioning. The results indicate that health factors identified as leading indicators of disparities are important sources of variability in cognitive functioning.
PERCEIVED DISCRIMINATION AND BLOOD PRESSURE AMONG MEN IN THE JACKSON HEART STUDY

M.A. Bruce, M. Sims, R. Thorpe, D.A. Hickson, B.M. Beech, K.E. Whitfield, 1. Internal Medicine, University of Mississippi Medical Center, Jackson, Mississippi, 2. Jackson State University, Jackson, Mississippi, 3. John Hopkins University, Baltimore, Maryland, 4. Wake Forest University, Winston Salem, North Carolina, 5. Duke University, Durham, North Carolina

Hypertension is a major contributor to the compromised health status among African-American men. An emerging segment of the scientific community has begun to acknowledge that hypertension is a complex condition developing from complex interactions of biological (i.e., obesity) and non-biological influences such as discrimination. The purpose of this paper was to use baseline data from the Jackson Heart Study to examine the relationship between perceived discrimination and blood pressure among African-American men. The results from descriptive analysis indicate that nearly 20% of the men in the study noted that lifetime discrimination made their lives very stressful and findings from logistic regression analyses indicated that moderate to high levels of stress derived with lifetime discrimination were associated with hypertension prevalence (OR: 1.92 CI 1.15, 3.22). These findings suggest that the health implications of discrimination for African American men may be linked to the accumulation of toxic discriminatory experiences.

CORRELATES OF LOWER EXTREMITY FUNCTION IN OLDER AFRICAN AMERICAN AND CAUCASIAN MALE MEDICARE BENEFICIARIES

Maintaining functional status and reducing/eliminating health disparities in late life are key priorities. Although race differences in lower extremity functioning have been observed, little is known about the correlates between African American and Caucasian men. The goal of this investigation was to identify race-specific correlates of lower extremity function in a sample of 501 community-dwelling African American and Caucasian male Medicare beneficiaries. The mean age of the participants was 74.9 years (SD=6.5), and the sample was 50% African American, and 55% rural. A linear regression model revealed that African American males had scores on the Short Physical Performance Battery (SPPB) that were significantly lower (p<0.01) than their Caucasian counterparts. Additional multivariable models stratified by race revealed a pattern of similar correlates of the SPPB including medical conditions, psychosocial factors and lifestyle measures, but differences did emerge. The results of this investigation can be helpful for researchers planning targeted interventions.

LIFESTYLE FACTORS AND LONGEVITY IN AFRICAN AMERICAN MEN

R. Thorpe, S. Wilson-Frederick, J.V. Bowie, T. LaVeist, 1. Hopkins Center for Health Disparities Solutions, Baltimore, Maryland, 2. Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland

Despite the well-documented findings of premature death among African Americans, few studies have examined whether lifestyle determinants affect longevity among African American men. Linking the Third National Health and Nutrition Examination Survey (1988-1994) to the 2007 National Death Index, we examined the relationship between lifestyle factors and all-cause mortality in 2503 African American men using Cox regression models. Lifestyle measures included smoking, drinking, physical inactivity, and obesity. After adjusting for age, education, poverty, insurance status, and number of health conditions, current drinking (OR= 0.55, 95% CI 0.32-0.94), smoking (OR= 1.93, 95% CI 1.25-2.99), and physical inactivity (OR= 1.56, 95% CI 1.05-2.33) were associated with all-cause mortality. Obesity was unrelated to all-cause mortality. Efforts to improve longevity among African American men should focus on health promoting strategies aimed at increasing physical activity and smoking cessation in African American men.
the optimal construction of temporal sequences may depend on the age and time horizons of the target population.

AGE DIFFERENCES IN TEMPORAL DISCOUNTING OF EMOTIONAL EXPERIENCES
C.E. Loockenhoff, E. O’Donoghue, D. Dunning, Cornell University, Ithaca, New York

We examined age differences in temporal discounting, the tendency to devalue delayed outcomes relative to immediate ones. Hypothetical choices involved trade-offs between immediate and delayed exposure to aversive photos. Participants (N = 85, aged 20-88, M = 50, SD = 20, 60% female) were asked to imagine that they would view sets of aversive photos immediately and 1, 14, and 90 days in the future. Choices involved adding or removing negative photos at different time points. Compared to younger adults, middle-aged and older adults were more likely to postpone exposure to aversive photos, F(2, 84) = 4.6, p < .01. Age effects were not explained by cognitive functioning, personality traits, affective responses to the photos, or willingness to pay to avoid aversive photos. Results suggest that age groups differ in their preferences for the distribution of emotional events over time.

AGE, CONFIDENCE, LOSS AVERSION, AND DECISIONS ABOUT INVESTING MONEY
L. Schlosnagle, J. Strough, West Virginia University, Morgantown, West Virginia

Younger (N=50, M age=20.49 yrs; 66% women) and older adults (N=50, M age=69.74; 56% women) indicated confidence in their knowledge of food calories and were given a monetary budget with the option to purchase advice that could be used to earn more money on a calorie estimation task. After controlling for income, compared to younger adults, older adults were more confident of their knowledge prior to purchasing advice; F(1, 95) = 14.62, p < .001, η2p = .13, invested more money to purchase advice; F(1, 95) = 32.75, p < .001, η2p = .26 and tolerated larger monetary losses on a hypothetical trade-off task; F(1, 95) = 21.53, p < .001, η2p = .19. Implications of these findings for understanding age differences in monetary investments will be discussed, and attendees will learn about age differences in monetary loss aversion, investor knowledge, and how these factors relate to each other.

WARNING OLDER ADULTS AGAINST CONSUMER FRAUD: THE ROLE OF INFORMATION VERSUS EMOTION FOCUS
N. Notthoff1, S. Scheibe2, M.J. Decy1, L. Carstensen1, 1. Department of Psychology, Stanford, Stanford, California, 2. University of Groningen, Groningen, Netherlands

The Federal Trade Commission estimates that people lose approximately $3 billion per year to consumer fraud. We evaluated the effectiveness of an AARP fraud prevention program (n1=1155), and tested whether the effectiveness of warnings could be increased by instructing older adults who generally focus on their emotional reactions to devalue delayed outcomes relative to immediate ones. Hypothetical choices involved trade-offs between immediate and delayed exposure to aversive photos. Participants (N = 85, aged 20-88, M = 50, SD = 20, 60% female) were asked to imagine that they would view sets of aversive photos immediately and 1, 14, and 90 days in the future. Choices involved adding or removing negative photos at different time points. Compared to younger adults, middle-aged and older adults were more likely to postpone exposure to aversive photos, F(2, 84) = 4.6, p < .01. Age effects were not explained by cognitive functioning, personality traits, affective responses to the photos, or willingness to pay to avoid aversive photos. Results suggest that age groups differ in their preferences for the distribution of emotional events over time.

SESSION 1375 (SYMPOSIUM)
AGING AND THE LIFESPAN: ‘NEXT GENERATION’ INTENSIVE LONGITUDINAL EXAMINATIONS OF EMOTIONAL AND PHYSICAL HEALTH
Chair: N. Ram, Pennsylvania State University, University Park, Pennsylvania
Co-Chair: D. Gerstorf, Pennsylvania State University, University Park, Pennsylvania
Discussant: M. Sliwinski, Pennsylvania State University, University Park, Pennsylvania

Health and well-being figure prominently as antecedents, mediators, moderators, and consequents of human functioning and development - day-to-day and decade-to-decade. In this symposium, we highlight ongoing work that targets health at multiple time scales and in multiple contexts. Explicitly considering the interplay between theory and methods, we take a critical look at burst designs, mobile technologies, and the benefits and costs associated with their use. C. Bergeman and colleagues illustrate the use of burst designs and analysis of intraindividual covariation in examining the interplay of social relationships, stress, and well-being across adulthood. M. Riediger and colleagues illustrate the use of mobile-phone technologies and a burst design to examine age differences in affect-regulation orientations, short-term affect-regulation effectiveness, and longer-term emotional adjustment. N. Ram and colleagues illustrate the utility of real-time data transfer and analysis within the burst design framework to examine changes in interpersonal, affective, and stress-related processes across a total of four time scales. M. Sliwinski frames the discussions of study design and empirical findings with theoretical models of affect, stress, and health and provides an outlook as to how innovations in data collection methods and study designs are poised to speed up the research process and our ability to guide individuals’ daily lives towards more healthy development and aging.

EFFECTS OF DAILY STRESS ON NEGATIVE AFFECT IN THE NOTRE DAME STUDY OF HEALTH AND WELL-BEING: DO SOCIAL INTERACTIONS HELP OR HINDER?
C.S. Bergeman, L. Pitzer, A. Russell, Univ Notre Dame, Notre Dame, Indiana

The Notre Dame Study of Health and Well-being (NDHWB) is a 5-year longitudinal study of mid- and later life that includes five waves of yearly data and three 56-day daily diary bursts (Years 1, 3, and 5; N=750). Using multilevel modeling, the NDHWB data was used to identify 1) the extent to which positive and negative daily social interactions, and the perceived intrusiveness of those exchanges, influence the effects of stress on well-being, 2) the extent to which global perceptions of these relationships moderate the Level 1 effects; and 3) the stability of these effects across multiple data bursts. Results indicated that on stressful days, negative exchanges with family or friends exacerbated negative affect more than positive ones buffered it. Global perceptions of these relationships, however, differentially moderated the effects of these exchanges, suggesting differing expectations of support from family and friends. Differences were noted by age and across burst.

PRO- AND CONTRA-HEDONIC ORIENTATION FROM YOUTH TO OLD AGE: A LONGITUDINAL EXPERIENCE SAMPLING STUDY
M. Riediger1, C. Wrzus1, U. Lindenberger1, G.G. Wagner1,2, 1. Max Planck Institute for Human Development, Berlin, Germany, 2. German Socio-Economic Panel Study, Berlin, Germany

We report a longitudinal experience-sampling study on age differences in, and functions of, pro- and contra-hedonic orientations in everyday life. Prohedonic orientation, or wanting to feel good, is central to human motivation. Occasionally, however, people also seek to maintain or enhance negative, or to dampen positive affect. Four hundred participants aged 12 to 85+ years carried mobile phones with them for
three weeks. The phones prompted participants 54 times to report, among other things, their momentary affect and affect-regulation orientations. The procedure was repeated after three years. Here, participants additionally completed Implicit Association Tests measuring the implicit valence of various emotions. Results indicate age differences in explicit and implicit measures of pro- and contra-hedonic orientations, as well as associations with short-term affect-regulation effectiveness and longer-term emotional adjustment. We discuss theoretical implications regarding the lifespan development of affect regulation, and address the feasibility of mobile-phone based experience sampling in age-heterogeneous samples.

MOVING TOWARDS REAL-TIME ASSESSMENT AND INTERVENTION: DYNAMICS OF AGE, HEALTH, AND WELL-BEING

Lifespan development is characterized by the complex interplay of processes that manifest at different levels of analysis and time-scales. Extensive study designs like the Penn State Intraindividual Study of Aging, Health, and Interpersonal Behavior (iSAHIB), an investigation of 140 adults aged 18-89 years wherein data are collected at four time scales using mobile and web technologies, may allow for more direct tests of developmental theory. Three 21-day bursts of interpersonal, affect, and stress data are used to demonstrate how (a) quantifications of hour-to-hour variability in social context, (b) models of day-to-day stress processes (c) trajectories of month-to-month change in health, and (d) age-heterogeneous samples that span all of adulthood can be used to (1) articulate hypotheses of age-related change in the interplay of affect regulation and reactivity with physical and mental health, and (2) develop and deliver recommendations for individualized, context- and time-sensitive interventions at population-level scale.

MEASUREMENT BURST DESIGNS: NEW DIRECTIONS AND CHALLENGES
M. Sliwinski, HDFS, Pennsylvania State University, University Park, Pennsylvania

The measurement-burst design is an approach to study intraindividual processes that transpire over very different temporal intervals. Consisting of repeated bursts of intensive (i.e., daily or momentary) assessments, the burst design can augment the type of information obtained from conventional daily diary and prospective longitudinal designs. The use of new technologies and tools hold promise for improving cost-effective implementation of intensive data collection design. Examples that include automated systems for providing real-time feedback to participants to improve compliance, and eventually, to implement interventions will be discussed an demonstrated.

SESSION 1380 (SYMPOSIUM)

ASPECTS OF GENERATIVITY IN LATER LIFE
Chair: R. Rubinstein, University of Maryland, Baltimore County, Baltimore, Maryland

This symposium reports on various aspects of generativity among older women. Five papers present materials gathered in an on-going NIA-funded study, Lifestyles and Generativity of Childless Older Women (GLOW), in which we have interviewed approximately 100 women, who have no children, in different age groups and marital statuses, as well as some women with children for comparison purposes. Each woman was interviewed in three open-ended interviews that collect a life story and detailed information about health, social relations, and self-conceptions. Besides gathering information on these topics, a focus of the study is the notion of generativity, defined generally as caring about future generations or caring for the self through generative outlets over time. Theoretically, we rely on the work of Erikson, Kotre and McAdams as well as work in cultural anthropology and narrative for guidance. However, the data gathered makes an independent contribution to theory about generativity over the life course. These insights are developed in the papers we will present. The papers concern the following issues: adoption and other forms of non-biological parenthood as forms of generativity; the relationship of generativity and personal biographic themes; women’s careers in the 20th century when options for women’s careers were limited or socially circumscribed; generativity as a form of personal triumph in the face of poverty; and questions of the efficacy of the notion of generativity for understanding elders’ views of the future and future generations.

WORKING TOWARDS GENERATIVITY: WOMEN’S CAREERS AS AN EXPRESSION OF GENERATIVITY
A. Mosby, University of Maryland, Baltimore County, Baltimore, Maryland

Women joined the work force in growing numbers during the latter half of the 20th century. Furthermore, they entered historically male professions and held positions of increasingly high status, often being forced to choose between having a career or raising a family. This paper presents findings from a subsample of two women who participated in a larger qualitative study on childless older women. Interviews addressed questions on life history, career development, generativity, and meaning of family and childlessness. Themes that arose from the data include: 1) professional careers as generative tasks, 2) a strong commitment to work is associated with happiness and satisfaction, 3) colleagues as significant mentors, and 4) serving as a mentor for others’ development is an important achievement in one’s own development. Future implications include programs that encourage mentorship in the workplace and encore careers.

GENERATIVITY AND PERSONAL BIOGRAPHIC THEMES IN LATER LIFE
R. Rubenstein, University of Maryland, Baltimore County, Baltimore, Maryland

Generativity has been viewed as a psychological construct with life developmental features. While generativity can be viewed as a direct manifestation of personality, it can also be viewed as an element of the culturally constructed self. In this paper, we present the case of an 87-year-old women who, by many objective measures, would not be considered especially generative. Her primary relations are with nieces and nephews, who live in another part of the country, and with co-residents of her retirement community. A primary aspect of her identity is her continuing affiliation with a branch of the military, with whom she served only two or three years when she was quite young. Critical in her account was her development of key thematic markers of identity. The paper discusses the relationship of these markers of personal identity to important forms of late life generativity.

GENERATIVITY IN LATER LIFE AMONG WOMEN WITH ADOPTIVE CHILDREN
S.M. Hannum, R. Rubinstein, Sociology and Anthropology, University of Maryland, Baltimore County, Baltimore, Maryland

For many, reproduction and parenting can be viewed as highly generative experiences. Whether through miscarriage, infertility, or other reasons, however, some women are not able to achieve biological reproduction and may therefore choose to adopt a child. Little is known about the impact of the role of an adoptive parent/child relationship on feelings of generativity and self-concept among women as they age. This paper therefore seeks to describe this phenomenon, using interview data from a subsample of four women, ages 65+. Transcripts were analyzed for larger order themes, indicating two prominent areas of focus: 1) women find meaning in experiences of pregnancy and childbirth, which does not appear to affect feelings of generativity, and 2) definitions of
parenthood are not affected by the specificity of the parent/child relationship. This paper illuminates the role of adoptive versus biological relationships in notions of generativity, descriptions of parenthood, and later life needs.

REDEMPTION AND GENERATIVITY IN LATER LIFE
L. Keining, University of Maryland, Baltimore, Maryland

Although she did not bear children of her own, Norma, a 65-year-old African American woman, describes herself as the matriarch of her extended family. The financial independence she has achieved in her career enables Norma to provide for various family members and friends, on her own terms. This paper examines how Norma practices generativity in later life, in the context of her personal history and self-redemption. Norma overcomes abuse and adversity in her early years, pursues education, gains financial security through hard work and thrift, renews contact with her family, and ultimately cultivates a sense of optimism in life. The dimensions of generativity raised in this case study include the meaning of kinship, the role of religious beliefs in fostering concerns beyond the self, and the power of redemption. Implications relate to a broader understanding of the construct of generativity in later life.

“DO FUTURE GENERATIONS NEED ANYTHING FROM ME?”: PERCEIVED RELEVANCE IN “GENERATIVITY”
K. de Medeiros, Miami University, Oxford, Ohio

“Generativity” is a concept originally associated with middle age, a time a person is presumably able to act on generative tendencies (e.g., having children) or work on creating some ending legacy. Recently, generativity has been considered within the realm of old age. One important question worth exploring is: does perceived relevancy play a role in how generativity is understood and undertaken. Specifically, as people age, there is a time when their connection with future generations seems too disconnected to matter, that their actions are no longer relevant to future generations. This theoretical paper draws from a large qualitative study on generativity in childless older women. Specifically, I argue that generative acts (e.g., nurturing, volunteering, perpetuating an historical tradition or community) cease to be important once the person feels disconnected from the younger generation. The importance in recognizing this shortfall in the concept of generativity is aimed at pushing gerontological theory away from a glamorized notion of old age from the perspective of the middle age, to one that recognizes and respects insights from those who are old.

SESSION 1385 (SYMPOSIUM)

END-OF-LIFE ISSUES IN UNDERSTUDIED SUBGROUPS OF THE U.S. POPULATION
Chair: S.M. Moorman, Sociology, Boston College, Chestnut Hill, Massachusetts
Discussant: B. Hayslip, University of North Texas, Denton, Texas

Much of what is known about Americans’ advance care planning and end-of-life medical care preferences is based on studies of dying older adults grouped by illness category, for example, advanced cancer patients or persons with dementia. Persons with the same illness can be assumed to have similar symptoms and to face similar decisions about treatment. In this symposium, we explore other shared group experiences that may influence end-of-life planning and preferences: incarceration, military service, race/ethnicity, and birth cohort. Allen and colleagues interviewed male prison inmates about their care preferences, and find that factors including expectation of future parole and level of trust in the prison health care system are related to level of desire for life-prolonging treatment. Garrido and Penrod note that anxiety and depression are especially common among veterans, and use chart review data to analyze how veterans’ psychological distress is assessed and treated in palliative care. Carr tests whether previously-documented racial and ethnic differences in rates and contents of terminally-ill adults’ advance care planning persist among healthy adults. She finds racial and ethnic differences not only in rates of planning, but also in the reasons why persons choose to plan or not plan. Moorman and Inoue study young and middle-aged adults’ plans and preferences, and find that younger cohorts may be more disposed to think about and prepare for end-of-life than their older counterparts. Hayslip will summarize these studies and suggest implications for policy and practice.

AGING PRISONERS’ TREATMENT SELECTION

With the rapid growth in the older inmate population and the economic impact of end-of-life treatments within the cash-strapped prison system, consideration should be given to inmate treatment preferences. We examined end-of-life treatment preferences and days of desired life for several health scenarios among male inmates incarcerated primarily for murder. Inmates over the age of 45 who passed a cognitive screening completed face-to-face interviews (N = 94; mean age = 57.7; SD = 10.68). End-of-life care for the burgeoning inmate population is costly and active life-sustaining treatments may not be desired under certain conditions. Specifically, expectation of parole but not current functional ability interacts with future illness condition in explaining inmates’ desire for active treatment or days of desired life in the future. Moreover, inmates desired more days of life when they had less negative affect, a greater fear of dying, and less trust in the prison healthcare system.

DEPRESSION AND ANXIETY ASSESSMENT AND TREATMENT IN VETERANS RECEIVING PALLIATIVE CARE
M.M. Garrido1,2, J.D. Penrod1, 1. James J Peters VA Medical Center, Bronx, New York, 2. Mount Sinai School of Medicine, New York, New York

Depression and anxiety co-occur with advanced illnesses such as metastatic cancer and influence quality of life and end-of-life care preferences. Depression/anxiety screening and treatment rates for veterans receiving palliative care (PC) for life-limiting illnesses are unknown. We reviewed medical records of 20 hospitalized veterans with and 21 without depression and/or anxiety who were over 50 years old and received PC consultations. Assessments of depression/anxiety symptoms were recorded for 30% of those with and 57% of those without depression/anxiety diagnoses. Reasons for missing assessments included cognitive impairment and intubation. Less than half who reported depression/anxiety symptoms received psychotropics or psychotherapy. Anti-depressants and anxiolytics were documented for 55% of those with depression/anxiety diagnoses. Others were taking psychotropics at admission, but contraindications precluded further use. Psychologists or psychiatrists visited one-third of patients for evaluation, medication management, psychotherapy, or counseling. These preliminary data suggest the need to improve depression/anxiety treatment rates for PC patients.

RACIAL AND ETHNIC DIFFERENCES IN ADVANCE CARE PLANNING (ACP): IDENTIFYING SUBGROUP PATTERNS AND OBSTACLES
D. Carr, Institute for Health, Health Care Policy, and Aging Research, Rutgers University, New Brunswick, New Jersey

Research demonstrates that blacks and Latinos are less likely than whites to engage in ACP, yet these studies typically focus on terminally ill populations. I use data from a national sample of married and cohabiting adults ages 18-64 who participated in the Knowledge Networks study (N=2111). Logistic regression analyses reveal that Latinos are less likely than whites to have a living will, durable power of attorney for health care (DPAHC), and to discuss treatment preferences.
Asians are less likely than whites to have had discussions. Blacks and whites do not differ significantly. I find pronounced differences in obstacles to ACP; Asians are most likely to say they do not want to burden others, their preferences are known by family, and they don’t want to think about death. Hispanics say they don’t know about ACP instruments and these instruments would not affect treatment. Implications for culturally sensitive interventions are discussed.

AGE, SELF-REPORTED HEALTH, AND END-OF-LIFE PLANNING AMONG YOUNG AND MIDDLE-AGED AMERICANS
S.M. Moorman, M. Inoue, Sociology, Boston College, Chestnut Hill, Massachusetts

Because most deaths in the United States today occur to older adults, little is known about the end-of-life medical plans and health care preferences of young and middle-aged adults. Some professionals, expressing concern about potential unpreparedness, urge that it is never too early to create an advance care plan and begin discussing end-of-life. We examine data from a national internet survey of 2,150 American adults aged 18-64. Thirty percent report having a living will, a durable power of attorney for health care, or both. Over half (57%) report having discussed end-of-life with a family member, friend, or professional. Net of self-reported health and other demographic variables, each additional year of age increases the odds of having a living will or durable power of attorney for health care by 5 to 6%, and increases the odds of a conversation by 3%. We discuss implications for health care providers.

SESSION 1390 (SYMPOSIUM)
INFLUENCES ON RELIGION AND SPIRITUALITY ACROSS THE COURSE OF LIFE
Chair: V.L. Bengtson, Davis School of Gerontology, University of Southern California, Los Angeles, California

This symposium brings together recent research and theorizing concerning influences on spirituality and religion across the course of life. One set of influences are cohort and historical effects, creating trends of change and innovation over time; a countervailing force involves family influences and intergenerational transmission, reinforcing religious continuity over time. Parental religious socialization practices produce non-religious outcomes as well, as seen in the link between parental religious encouragement to depressive symptoms in later life as well as a sense of connection to others and a willingness to forgive. Another important influence is access to and utilization of clergy who represent an important resource for both spirituality and social support, particularly for older adults from minority communities and those with mood or anxiety disorders. Research on religion across the life course has escalated in both volume and quality over the past 30 years, but an alarming trend has been a growing focus on smaller and increasingly focused dimensions of religiosity—endangering perspective of the holistic and powerful phenomenon of religious and spiritual experience. But there are new research directions in which religion and spirituality are being conceptualized as unique social institutions, a worldview in which the whole is greater than the sum of its parts.

RELIGIOUS CONTINUITY AND CHANGE ACROSS GENERATIONS AND OVER TIME
V.L. Bengtson, N. Putney, S. Harris, M. Silverstein, M. Silverstein, Davis School of Gerontology, University of Southern California, Los Angeles, California

This study examines religious transmission over generations and how this has changed over recent decades. We assess 35 years of survey data from the Longitudinal Study of Generations and in-depth interviews on subjective meanings of religion and spirituality from 25 multi-generational families selected from this longitudinal panel. Results indicate (1) there is an unexpectedly high degree of cross-generational religious continuity; (2) the degree of parent-youth transmission has not decreased since 1970; (3) grandparents—sometimes great-grandparents—represent significant influences on religious outcomes of young adults; (4) we find transmission effects among the religious “nones”—parents providing non-religious moral socialization; (5) there are cohort (or “generational”) contrasts in religious expression as well as long-term trends over time, such as the increasing separation of “spirituality” from “religion” with successive cohorts. Findings pose challenges for theorizing—for example how to explain family religious transmission in the context of inter-cohort religious contrasts.

PARENTAL RELIGIOUS SOCIALIZATION PRACTICES AND DEPRESSIVE SYMPTOMS IN LATER LIFE
N. Krause, University of Michigan, Ann Arbor, Michigan

This study has two aims: (1) to examine whether parental religious socialization practices influence religious beliefs and behaviors of older adults; (2) to assess whether these socialization practices and the religiousness they promote are associated with depressive symptoms in late life. Data come from an ongoing nationwide survey of older people. Findings from a latent variable model provide support for the following relationships: (1) older people whose parents encouraged them to become more involved in religion are more likely to attend worship services in late life; (2) older people whose parents promoted religious involvement and individuals who attend church more often are more likely to report that they see a fundamental connection among all human beings; (3) older individuals who feel more closely connected to others will be more likely to forgive people for the things they have done; and (4) older people who are more forgiving are likely to experience fewer symptoms of depression over time.

INFLUENCES OF CLERGY AMONG AFRICAN AMERICANS, BLACK CARIBBEANS AND NON-HISPANIC WHITES
L. Chatters, R. Taylor, University of Michigan, Ann Arbor, Michigan

Research on help-seeking demonstrates that people turn to clergy to address serious life problems, mental health disorders, and substance misuse. Although clergy operate outside of the formal mental health care system, their contributions as ‘natural helpers’ in providing informal mental health care are substantial. Clergy are more likely than psychiatrists to provide counseling for psychiatric disorders such as mood disorders and anxiety disorders. However, unlike other mental health professionals, clergy typically have little or no formal training in mental health screening and counseling. This study investigates the use of clergy among African Americans, Black Caribbeans and Non-Hispanic whites, using data from the National Survey of American Life. It examines the religious, demographic and psychiatric disorder (mood, anxiety, substance disorders) correlates of the use of clergy. Study findings indicate that younger adults are less likely to utilize clergy than older adults. Frequent church attendees, Pentecostals, women and those coping with the death of a loved one had higher rates of clergy use. Respondents with substance use disorders were less likely to seek assistance from clergy than those with mood or anxiety disorders. Discussion of these findings highlights ways that (1) social status factors are selectively associated with different forms of religious participation and access to social resources within churches; (2) problem type characteristics are important in help-seeking and accessing clergy for assistance.

RELIGION/SPIRITUALITY AND HEALTH ACROSS THE LIFE COURSE AND GENERATIONS: MOVING AWAY FROM REDUCTIONIST INQUIRY
L. George, Duke University, Durham, North Carolina

The volume and quality of research on religion across the life course and across generations has grown in both volume and quality over the
past quarter century. The major trend in this research has been to examine smaller and highly specific dimensions of religious experience, outcomes, and possible mechanisms. Although this approach has been useful, when it is the only level of analysis, there is great danger of reductionism – of losing sight of the overall phenomenon of religious/spiritual experience. In this presentation, I first document the clear trend toward reductionist inquiry in the field and then describe several promising research directions in which religion/spirituality is conceptualized as a unique social institution, a worldview, and a “package” in which the whole is greater than the sum of its parts.

SESSION 1395 (SYMPOSIUM)

INTERGENERATIONAL RELATIONSHIPS IN LATER LIFE: CHANGING NORMS AND CHANGING CONTEXTS
Chair: J.R. Smith, Social Service, Fordham University, New York, New York
Discussant: R. Blieszner, Virginia Polytechnic Institute, Blacksburg, Virginia

This symposium brings together four qualitative researchers, each of whom has investigated the intergenerational relationship from the standpoint of the older adult. Despite the significant change in life expectancy and the growth in the aging population, very little research has focused on what older adults experience, and hope for, in their relationships with their adult children and grandchildren. The majority of studies in family gerontology have focused on the effect of caregiving on the adult child when a parent becomes frail and in need of care (Pillemer, 1991). In this symposium, the papers use qualitative methods to examine parenting in later life, focusing on the older person’s coping strategies as parent/grandparent. In addition, the papers highlight the context of culture or place on the parenting in later life. The methods of analyses include ethnography, phenomenology, grounded theory and content analysis. The papers include: 1) Analysis of videotaped visits among family members and their relatives in nursing homes; 2) Parents’ perceptions of their current relationships with their adult children, comparing South Indian, African-American and Jewish older adults; 3) Vietnamese grandparents’ experience as they grieve for their adult children’s death from AIDS, while parenting their orphaned grandchildren; and 4) the influence of filial responsibility on the decision-making of Chinese elders regarding entering nursing homes. The symposium contributes to needed knowledge on how intergenerational relationships impact well-being among older people who are parents.

DECIDING TO ENTER NURSING HOMES: INTERGENERATIONAL COMMUNICATION AMONG ELDERLY CHINESE IMMIGRANTS AND THEIR CHILD CAREGIVERS
L. Chen, Social Welfare, University of California, Los Angeles, Los Angeles, California

The purpose of this study is to understand the nature of deciding to enter a nursing home among Chinese elders and their child caregivers in Los Angeles, CA. The reconstructed decision-making process explores how filial responsibility influenced their choice of institutionalization over other available health care services. This study is conceptualized through a theoretical framework, which systematically combines crisis theory, uncertainty management theory, and the Andersen Behavioral Model. This study used a phenomenological approach. The first phase of data collection consisted of 8 semi-structured interviews with elderly Chinese residents and one focus group with their child caregivers. Results found that both generations assessed, appraised and reappraised caregiving alternatives to reach the final decision to enter nursing homes. Location, service quality, and cultural competency were the major concerns. Both generations reported experiencing intergenerational conflicts in the decision-making process, with elderly residents expressing their understanding of the transforming filial obligations.

CHARACTERIZING ELDERSPEAK DURING MEALTIMES IN NURSING HOMES AMONG RELATED INDIVIDUALS: IMPLICATIONS FOR IMPROVING THE QUALITY OF FAMILY VISITS
L. Levy-Storms, B. Barba, UCLA, Los Angeles, California

“Elderspeak” represents specific types of verbal and vocal, non-verbal communication that may be negatively perceived by older adults. The purpose of this study was to explore “elderspeak” during mealtimes among visiting family members and their relatives in nursing homes. Four videos of family members who visited their relatives in a nursing home during mealtimes were analyzed qualitatively in order to investigate naturally-occurring interactions. Three themes capture the variation from these systematic comparisons and represent the most compelling illustrations of “elderspeak” during mealtimes using subtle and non-verbal communication behaviors: 1) disguised elderspeak, (e.g. ask a question but mean as a command); 2) unnecessary effort for the not hearing impaired (e.g., using unnecessary gestures); and 3) doing the opposite of the obvious (e.g., being physically present but mentally absent). These less tangible characterizations of “elderspeak” may be incorporated into future training curricula for improving family members’ communication.

GRANDPARENTS RAISING GRANDCHILDREN AFFECTED BY HIV/AIDS IN VIETNAM: HOW MEANING AND CONTEXT AFFECT COPING AMONG SKIPPED GENERATION CAREGIVERS
L.B. Marakil Harris, B. Kim, Social Welfare, UCLA, Los Angeles, California

This ethnographic study of skipped generation caregivers in Vietnam examines how caregivers make sense of their role, and identifies how these meanings inform their coping strategies. In-depth qualitative interviews and participant observations were conducted with 15 older caregivers. Caregivers experience coping through three different dimensions: coping with the past, present and future. These coping dimensions occur because participants experience a cross-generational role that involves an alternating flow of caregiving. For skipped generation caregivers, this role begins by caregiving for an adult child living with HIV/AIDS, and then moves to simultaneously caregiving for an adult child dying of AIDS and grandchildren, to finally becoming the sole caregiver of orphaned grandchildren after the death of the adult child. Participants’ understandings of coping with the present involve problem-focused coping, for example a set of caregiving actions around the completion of a daily routine, childcare, making money, borrowing money, cooking and daily chores.

OLDER ADULTS’ VIEWS OF THE PARENTING RELATIONSHIP: HOW MUCH TO SAY OR DO FOR ONE’S ADULT CHILDREN
J.R. Smith, M. Pardasani, Social Service, Fordham University, New York, New York

This study examines older adults’ beliefs regarding the parenting role with adult children, among South Indian, African-American and Jewish parents over age 65. Our work builds on the research of those who have investigated the older adult’s view of the parenting relationship in later life (Bleizner & Mancini, 1987; Levitki, 2009). We conducted four focus groups in senior centers. Subjects responded to vignettes of family conflict. Content analysis was used to analyze the responses. Participants also filled out survey instruments addressing attitudes about filial responsibility (Lee, et al., 1994) and the perceived expectations of a parent and current parenting role (Vassallo, Smart & Price-Robertson, 2009). Ethnic differences were found, with first generation, immigrant parents (mainly South Asian) more likely to experience conflict about parenting roles and responsibilities. The analyses reveal that the utility of the theoretical perspective of ambivalence (Pille-
SESSION 1400 (SYMPOSIUM)

LIFESTYLE PREDICTORS OF HEALTH & DISEASE IN AGING LATINOS
Chair: A. Watts, Lifespan Institute, University of Kansas, Lawrence, Kansas
Co-Chair: D.K. Johnson, Lifespan Institute, University of Kansas, Lawrence, Kansas
Discussant: K. Markides, University of Texas Medical Branch, Galveston, Texas

This symposium addresses the meeting’s theme, Lifestyle -> Lifespan, focusing on Latino older adults. Presenters discuss lifestyle factors in industrialized and developing nations reflecting several distinct Latino populations. The Tsimane in Bolivia are a geographically isolated group who live a very active traditional lifestyle, yet have very short life expectancy (Vasunilashorn et al). By contrast, rural Costa Ricans may have protective lifestyle factors which may explain their relative longevity compared to urban Costa Ricans (Brenes-Camacho et al). Michaels-Obregon et al. present longitudinal, cross-national comparisons of Mexico and the United States that consider the effect of obesity on ADL disability and possible paths of disability in developing Latin America countries given lifestyle transitions. Beltran-Sanchez et al. will discuss 8-year changes in smoking behaviors in the Mexican Family Life Survey, a nationally representative sample. Finally, Johnson et al present on The Pura Vida project, a developing cross-national endeavor that aims to extend the clinical research infrastructure of an established U.S. research center to the Costa Rican healthcare system to build clinical research expertise for aging-related diseases. These five studies of Latinos provide a unique demonstration of the relevance of lifestyle factors to healthy aging and longevity. This symposium offers several unique qualities. It is centered on the meeting theme, focused on understudied populations, and represents many scholars at universities in the U.S., Central America, and South America. Dr. Markides, the PI of the Hispanic EPESE study, will provide an integrative discussion linking the talks together in a broader framework.

AGING WITH A TRADITIONAL LIFESTYLE: THE TSIMANE OF BOLIVIA
S. Vasunilashorn1, C. Finch2, J. Kim2, J. Winking3, M. Gurven4, H. Kaplan4, E. Crimmins2, 1. Population Studies, Princeton University, Princeton, New Jersey, 2. University of Southern California, Los Angeles, California, 3. Texas A&M University, College Station, Texas, 4. University of California, Santa Barbara, Santa Barbara, California, 5. University of New Mexico, Albuquerque, New Mexico

The aging process is variable as it is determined by the interaction of internal and external factors experienced by an individual living in a specific context. In countries with high life expectancy like the U.S., a number of markers of biological risk for health outcomes related to aging have been associated with poorer cognitive and physical functioning, more heart disease, and higher mortality. Few studies, however, have examined how these biomarkers vary with age in populations living in very different circumstances. This paper compares age differences in biomarkers related to aging in two populations with very different health conditions: the Tsimane, an indigenous forager-farmer population in lowland Bolivia with current mortality rates similar to historical populations 150 years prior, and the U.S. (NHANES 1999-2004). Discernible differences in age patterns were found in a majority of the biomarkers.

RURAL/URBAN LIFESTYLES DIFFERENCES AMONG MIDDLE-AGED COSTA RICANS: FINDINGS FROM TWO AGING STUDIES
G. Brenes-Camacho, F. Coto-Yglesias, L. Rosero-Bixby, P. Jimenez-Fontana, Centro Centroamericano de Poblacion, Universidad de Costa Rica, San Jose, Costa Rica

Previous research has found that, among Costa Rican elderly, there are no urban/rural differences or small rural advantages in mortality and in several lifestyles that are considered as risk factors of cardiovascular mortality. These characteristics might be changing if rural residents progressively adopt urban lifestyles, according to the Nutritional Transition perspective. The present article analyzes urban/rural differences among Costa Ricans aged 55 to 65 in order to explore whether rural advantages remain at younger cohorts of people who will become elderly in the following years, using the CRELES and the CRELES-HRS datasets. We find that rural residents are on average leaner (lower BMI and smaller waist circumference) than urban Costa Ricans. Rural males, but not women, are on average more physically active than their urban counterparts. However, better glycated hemoglobin (HbA1C) level is the only rural/urban advantage in cardiovascular health biomarkers that is partially accounted for lifestyle differentials.

SMOKING ONSET AND CESSION IN MEXICO
H. Beltran-Sanchez2, D. Thomas2, F. Wheaton1, E. Crimmins2, 1. University of Southern California, Los Angeles, California, 2. Duke University, Durham, North Carolina

Smoking is a major health issue in Mexico and recently public health programs in Mexico have focused on eliminating smoking. We investigate both the initiation and cessation of smoking in Mexican adults aged 20 and older using the Mexican Family Life Survey (MXFLS). The MXFLS is a longitudinal nationally representative survey with 3 waves of data. Data from Wave 1 in 2002 and Wave 3 in 2010 are used to examine change in smoking behavior. People in rural areas are more persistent in their behavior; they are both less likely to start smoking and less likely to quit. Better educated women are more likely to start smoking; on the other hand, higher education is linked to less smoking onset for men. Education is not linked to quitting behavior. Young age is strongly linked to initiating smoking and older age is linked to a lower likelihood of cessation.

THE EFFECT OF OBESITY ON ADL DISABILITY ONSET AMONG OLDER ADULTS IN MEXICO AND THE UNITED STATES
K. Gerst1, A. Michaels-Obregon2, R. Wong1, 1. Institute of Gerontology, University of Georgia, Athens, Georgia, 2. University of Texas Medical Branch, Galveston, Texas

Purpose: Explore the impact of obesity on the onset of disability in two countries at different stages of the epidemiologic transition, US and Mexico. Data: Longitudinal data from two waves of the Mexican Health and Aging Study (2001 and 2003) and the Health and Retirement Study (2000 and 2002) with persons over age 50. Multinomial models examine the effect of being overweight, normal weight, overweight or obese at baseline on reporting ADL limitations at follow-up. Results: Obesity prevalence is higher in the US compared to Mexico. Models show obesity as a significant risk factor for developing one ADL limitation at follow-up but also for developing two or more limitations in the US. In contrast, the Mexico models show obesity as significant predictor only for developing one ADL limitation at follow-up. Conclusion: Obesity may affect physical disability progression differently according to the stage of the epidemiological transition that societies are undergoing.
THE PURA VIDA STUDY
D.K. Johnson1, M. Salazar2, F. Coto3, J.M. Burns3, A. Watts1, 1. Lifespan Institute, University of Kansas, Lawrence, Kansas, 2. University of Costa Rica, San Jose, Costa Rica, 3. University of Kansas Medical Center, Kansas City, Kansas

Developing nations like Costa Rica must plan to address the needs of an aging population. Low and middle income nations will experience unprecedented growth of the elderly population and subsequent increases in age-related disorders that requires effective strategies for promoting healthy aging. The Pura Vida project, a developing cross-national endeavor, aims to extend the clinical research infrastructure of an established U.S. research center to the Costa Rican healthcare system to build clinical research expertise for aging-related diseases. We will accomplish these goals by 1) extending preexisting information technologies to underdeveloped Costa Rican clinical research centers, 2) training existing faculty at University of Costa Rica for clinical assessment and research methods in the assessment and treatment of neurological diseases in the developing world to support future clinical research in Costa Rica and across Central America, and 3) creating a baseline for a sustainable longitudinal study of Latin American aging and neurological diseases modeled on the KU Alzheimer and Memory Program.

SESSION 1405 (SYMPOSIUM)

MAKING PARTICIPATORY ARTS PROGRAMS FOR OLDER ADULTS A LIFESTYLE BEHAVIOR FOR IMPROVED HEALTH
Chair: L.S. Noelker, Katz Policy Institute, Benjamin Rose Institute on Aging, Cleveland, Ohio
Discussant: G. Hanna, National Center for Creative Aging, Washington, DC, District of Columbia

Less than one-third of community-dwelling older adults regularly participate in physical activity. Yet, it is the primary lifestyle behavior that favorably affects a broad range of physiological systems. Because exercise programs have low adherence rates, calls have been issued for evidence of the health benefits of novel types of activity programs for older adults such as dance and movement programs, however, existing research on their health benefits is limited. With better designed and theoretically driven research documenting their health benefits and the mechanisms by which benefits are achieved, they can be a valuable addition to the evidence-based toolkit of health promotion programs. This symposium aims to increase interest in theoretically-guided and more rigorously designed research on the health benefits of performing arts programs. The presenters will focus on: 1) the theoretical underpinnings of the health benefits of participatory performing arts programs for older adults, drawing upon an expanded social cognitive model to identify mechanisms by which these programs are associated with specific health outcomes; 2) approaches to the translation and dissemination of arts programs to diverse older populations and linkages between the research and arts communities to extend the reach of these programs for their public health benefits; and 3) the effects of a pilot dance program on the physical and cognitive health of older Latino adults. The discussant will explicate the role of the National Center for Creative Aging as a resource linking health science researchers and professional artists to expand the evidence base for arts programs.

THEORETICAL APPROACHES TO UNDERSTANDING THE HEALTH BENEFITS OF PERFORMING ARTS FOR OLDER ADULTS
L.S. Noelker1, M. Castora-Binkley2, M. Rose1, 1. Katz Policy Institute, Benjamin Rose Institute on Aging, Cleveland, Ohio, 2. University of South Florida, Tampa, Florida

The relatively sparse research literature on the health benefits of participatory performing arts programs for community-dwelling older adults is typically not well-grounded in theoretical models. Existing models are rudimentary and when tested, usually yield substantial amounts of unexplained variance. This presentation draws upon social cognitive theory, which has been applied to research on health-related behaviors to investigate factors related to the adoption of behavior change. The social cognitive model is expanded here to explore mechanisms by which performing arts interventions (e.g., dance and movement programs) may be associated with health outcomes specific to the intervention, namely gait, balance, cognition, and mood. In the past, it has been argued that model variables are mediated by intention and perception of the behavior change. This expanded model suggests that behavior change is mediated by mechanisms, including mastery and self-efficacy, that are important to understand for mapping causal pathways and for hypotheses generation.

TRANSLATING DANCE INTO AN EVIDENCE BASED HEALTH PROMOTION PROGRAM
T. Prohaska, University of Illinois Chicago, Chicago, Illinois

Not all successful interventions in promoting health of older adults are translated into evidence-based programs that are widely disseminated in community settings. This presentation will discuss the multiple phases for integrating findings from dance interventions for older adults into organizations and community settings to maximize the public health impact. Using elements from the RE-AIM framework (Reach, Effectiveness, Adoption, Implementation and Maintenance) strategies are provided for successful adoption while assuring treatment fidelity. Methods are provided for satisfying criteria for a performing arts dance program to become evidence-based such as identifying program essential elements and standardized program implementation. Finally, strategies for successful recruitment and retention of diverse older participants into dance programs are suggested based on lesions learned from successful dissemination of existing evidence based programs in health promotion and chronic disease management.

DEVELOPMENT AND PILOT TESTING OF THE BAILAMOS© DANCE PROGRAM AND ITS IMPACT ON PHYSICAL AND COGNITIVE FUNCTION IN OLDER LATINOS
D.X. Marquez, E.E. Bustamante, S. Aguiñaga, Kinesiology and Nutrition, University of Illinois at Chicago, Chicago, Illinois

Physical activity (PA) can influence declines in physical and cognitive function. Unfortunately, Latinos aged 65-74 are 46% less likely to engage in leisure time PA than older non-Latino whites. Walking and dancing are the most commonly reported forms of PA among older Latinos. However, urban older Latinos cite unsafe neighborhoods and extreme weather conditions as significant barriers to walking. Dance holds promise as a culturally appropriate form of PA that challenges individuals physically and cognitively. BAILAMOS© is an innovative dance program developed in collaboration with an accomplished Latin dance instructor. A total of 12 previously sedentary Latinos began the 3-month pilot of BAILAMOS© and 9 (M age = 65.2) completed the 24-session program. Effect sizes (Cohen’s d) indicated improvements in physical function (mobility, d=−.56; usual gait speed, d=−.10) and cognitive function (d=−.11−.12). Evidence suggests that Latin dance is a feasible way of impacting upon the physical and cognitive function of older Latinos.

SESSION 1410 (SYMPOSIUM)

THE USE OF VISUAL METHODS IN AGING RESEARCH
Chair: W. Martin, School Of Health Sciences and Social Care, Brunel University, Uxbridge, United Kingdom
Co-Chair: J. Twigg, University of Kent, Canterbury, United Kingdom
Discussant: T. Calasanti, Virginia Tech, Blacksburg, West Virginia

Visual Methods are increasingly being used within ageing research. Exploring the visual is seen as a means to uncover significant insights
into how micro processes of daily life are linked to wider socio-cultural discourses; to make visible the taken-for-granted; and reveal meanings and understandings in context. Whilst the use of visual methods can be experienced as empowering and participatory by older people; the development of visual research has also presented researchers with new complexities and challenges in relation to ethical, theoretical, analytical and methodological issues. The aim of this symposium is to bring together researchers who are using a wide variety of different visual methods to study social aspects of ageing. In particular, we will draw on data from four research projects to explore the opportunities, challenges and experiences of using visual methods. Twigg provides insights into gender, fashion, ageing and the body through the analysis of four UK magazines. Dickinson questions the use of photography and possible moral implications when researching certain topics, such as, diet and food choices. Martin and Williams explore the use of photographs as a form of “visual diary” to make visible the ordinary and everyday as a means to explore perceptions, narratives and meanings about daily lives. Victor et al. show how significant insights can be revealed into familial and social relationships when participants are asked to draw maps of their social networks. This symposium will conclude by debating the possibilities and difficulties when developing visual methodologies.

GENDER, MAGAZINES AND FASHION IN THE CONSTITUTION OF AGED BODIES
J. Twigg, Sociology and Social Policy, University of Kent, Canterbury, United Kingdom

We are accustomed, from a wealth of work on young women, to see magazines as significant in the constitution of gendered and classed identities. There has been little work, however, taking these perceptions forward in relation to aged ones. This paper explores the role of women’s magazines in shaping the ways in which ageing is experienced, understood and imagined in modern culture, focussing on the subject of clothing and dress. Magazines are inherently visual phenomena. In order to understand how they work, we need to be able to explore how they operate at the level of images. The study thus presents an example of the growing interest in visual methods in gerontology. It is based on an analysis of four UK magazines: Vogue, Woman & Home, SAGA, and Yours.

I WOULD BE EMBARRASSED FOR YOU TO SEE WHAT I EAT. OLDER PEOPLE REJECTING THE VISUAL?
A. Dickinson, J. McClinchy, Centre for Research in Primary and Community Care, University of Hertfordshire, Hatfield, Hertfordshire, United Kingdom

This paper will present data from a pilot study carried out in a faith-based community-meal setting. Data was collected using a number of qualitative methods including researcher and participant generated visual images. Using cameras to capture the social context of eating and food eaten, was limited due to poor uptake. Uptake appears not to be influenced by technical phobias but by the subject matter. Food and its consumption is surrounded by strong moral discourses and older people living alone were embarrassed to expose their eating behaviour to visual scrutiny. Using visual devices to explore eating behaviour in older people, particularly those who live alone, should be used cautiously and with sensitivity. Images when collected have the potential to add context to the data provided in food diaries and interviews, however, it appears that alternative methods of data collection alongside visual images are needed.

PHOTOGRAPHING EVERYDAY LIFE: AGEING, BODIES, TIME AND SPACE
W. Martin, V. Williams, School Of Health Sciences and Social Care, Brunel University, Uxbridge, United Kingdom

As people grow older, daily practices can become increasingly problematic as everyday routines become more frequently disrupted. People in mid to later life may increasingly be required to make sense of these biographical and bodily changes. The aim of this paper is to highlight the significance of the ordinary and day-to-day by focusing on everyday meanings, lived experiences and spatio-temporal contexts. We will draw on data from the pilot phase of an empirical study funded by the ESRC. The pilot study included 10 participants (age range 50-70 years) with different daily routines. Data collection methods included self-directed photography and in-depth interviews. The photographs allow us to explore narratives and meanings of everyday life, and make visible the rhythms and patterns that underlie our habitual and routinised everyday worlds. We will discuss themes underpinning these issues including gender; space and time; identities; mess and dirt; social networks; and ageing bodies.

VISUALISING THE SOCIAL NETWORKS OF OLDER PEOPLE FROM BANGLADESHI AND PAKISTANI COMMUNITIES LIVING IN THE UK
C. Victor, W. Martin, M. Zubair, Brunel University, Uxbridge, United Kingdom

Introduction: Within the next 20 years the proportion of older people living in minority black and ethnic communities within the UK will significantly increase. We have limited evidence documenting the family and social networks of these groups. Methods: We draw on data from our ESRC New Dynamics of Ageing project: Families and Caring in South Asian Communities to explore how our 110 participants’, a diverse group of Bangladeshi and Pakistani men and women aged 50+ years, visualize their social networks and family relationships and link to the data generated from in-depth interviews. Findings and Conclusions: The range of styles of the 109 network maps created by participants ranged from ‘traditional’ networks diagrams to ‘lists’ of network members. We highlight the role of the network maps in revealing relationships which provide meaning and context for our participants social relationships, such as religion, which do not always emerge in the interviews.

SESSION 1415 (SYMPOSIUM)

UPDATE ON NIMH PROGRAMS AND PRIORITIES IN GERIATRIC MENTAL HEALTH RESEARCH
Chair: G. Niederehe, Geriatrics Research Branch, NIMH, Bethesda, Maryland
Co-Chair: J. Evans, Geriatrics Research Branch, NIMH, Bethesda, Maryland

In this session, National Institute of Mental Health (NIMH) staff members will describe current priorities for the Institute, inform the audience of NIMH programs that support research efforts on aging and mental health, and outline particular areas of opportunity for new studies. The initial two presentations will discuss the current funding context at the National Institutes of Health and NIMH, including trends, recent developments, and changes in the business practices affecting the review and award process for grant applications, and provide an overview of how funding programs at NIMH are organized. Particular emphasis will be placed on the NIMH Strategic Plan as a key articulation of current priorities, and on the report of an NIMH Advisory Council working group on new directions in intervention research. The subsequent two presentations will describe the various areas in which the NIMH Geriatrics Research Branch supports studies of mental health and aging, highlighting particular interests and priorities relating to its programs on Translational Behavioral Science, Translational Neuroscience, Pharmacologic Intervention Research, Psychosocial Intervention Research, and Multi-Modality Intervention Research. The final portion of the session will be a question and answer period during which audience members will be encouraged to pose questions to the presenters about whichever aspects of seeking NIMH support may be of interest.
THE NIH RESEARCH CONTEXT: RECENT DEVELOPMENTS PERTINENT TO GERIATRIC MENTAL HEALTH RESEARCH
G. Niederehe, Geriatrics Research Branch, NIMH, Bethesda, Maryland

This presentation will describe the current research funding context at NIH and NIMH for proposing projects on mental health and aging, both in terms of long-term trends and recent events. This will include the status of the Congressional appropriations process for the coming year, and other special initiatives or situational elements that may bear upon aging-related research (such as recent NIH Funding Opportunity Announcements, noteworthy recent scientific advances, organizational changes, or the like). Particular emphasis will be placed on the centrality of the NIMH Strategic Plan in prompting current Institute priorities.

NIMH FUNDING PROGRAMS AND APPLICATION PROCESSES: AN OVERVIEW
J. Evans, Geriatrics Research Branch, NIMH, Bethesda, Maryland

This presentation will cover how funding programs are organized at NIMH, typical funding mechanisms, forms of support available for aspiring investigators in early stages of a research career, and the basic steps in applying for an NIH grant. Included will be information on requirements regarding the length, format, and timing of applications, and on the steps in the grants review and funding process. The presenter will also identify resources that can be useful to investigators interested in applying for funding support.

TRANSLATIONAL BEHAVIORAL SCIENCE AND PSYCHOSOCIAL INTERVENTION OPPORTUNITIES IN GERIATRIC MENTAL HEALTH RESEARCH
G. Niederehe, Geriatrics Research Branch, NIMH, Bethesda, Maryland

This presentation will review the priorities for and types of research supported by the Translational Behavioral Science and Psychosocial Intervention research programs within the NIMH Geriatrics Research Branch. Areas to be discussed will include the recommendations of an NIMH Advisory Council work group on new directions in intervention research, and the increasing priority placed on intervention studies that examine various avenues to personalizing care for older adults with mental disorders. The latter may include studies of modularized interventions and stepped care approaches, as well as studies of potential predictors of the individual’s response to varied treatment options. The presenter will discuss NIMH viewpoints on and priority given to the development of innovative new treatments, and also to research that instead proposes to modify or adapt existing treatment approaches (e.g., to increase their cultural sensitivity, their applicability in typical care settings, and/or their uptake and use by typical providers).

GERIATRIC TRANSLATIONAL NEUROSCIENCE AND PSYCHOPHARMACOLOGIC INTERVENTION RESEARCH: PRIORITIES AND SCIENTIFIC OPPORTUNITIES
J. Evans, Geriatrics Research Branch, NIMH, Bethesda, Maryland

This presentation will discuss NIMH efforts to expand its geriatric translational neuroscience research program and highlight areas of particular opportunity for advancing neuroscientific and psychopharmacological research on late-life mental disorders. Themes to be emphasized will include: studies directed at clarifying the neural circuits and biological processes associated with mental disorders in later life; the desirability of integrating genetic, brain imaging, and other technologies (e.g., cognitive and affective neuroscience) to advance a mechanistic understanding of disorder pathophysiology; new approaches to assessing symptomatic or functional domains that cut across traditional diagnoses; the importance of studying how specific aspects of the biological aging process interact with the trajectories of neurobiological changes seen in chronic mental disorders as affected individuals age; and studies aimed at identifying biomarkers indicative of vulnerability to developing mental disorder in late life, useful in tracking the progression of underlying disease processes over time, or informative about older adults’ likely response to particular treatments.

SESSION 1420 (SYMPOSIUM)

WHAT DOES THE FUTURE HOLD FOR ME? VIEWS ON DEMENTIA IN ADULTHOOD
Chair: B. Hayslip, Psychology, University of North Texas, Denton, Texas
Co-Chair: K.S. Page, Psychology, University of North Texas, Denton, Texas
Discussant: D. Wadsworth, Preston Hollow Presbyterian Church, Dallas, Texas

Given the incidence of Alzheimer’s disease and other forms of dementia in the United States, diagnosis and treatment have become public health issues. Indeed, it is critical for middle aged and older persons to seek information about dementia, driven by the possibility that they themselves or a family member might be victims of this disease. This symposium addresses such behaviors and related concerns in view of the fact that either a lack of information or misinformation about dementia undermines proactive efforts to seek a timely diagnosis, engage in efforts to stave off dementia all together, or minimize the cognitive decline associated with Alzheimer’s disease or other forms of dementia. Hodgson and Cutler discuss findings from their ongoing panel study of adult children with and without a family history of dementia, concentrating upon explicating relationships between memory functioning and worry within the framework of what is termed anticipatory dementia, significant in that awareness of and knowledge are key in seeking help for dementia’s cognitive manifestations. Hayslip, Page, and Wadsworth present several papers based upon a substantial data set of middle age and older adults exploring the dispositional antecedents of fear of dementia, differential concerns held by middle aged versus older adults regarding the disease, and views about end-of-life choices in light of the possible diagnosis of dementia. Wadsworth summarizes these studies’ findings, concentrating on their value for middle aged and older adults as well as for practitioners.

SUICIDE AND THE POTENTIAL DEMENTIA DIAGNOSIS
K.S. Page, B. Hayslip, D. Wadsworth, Department of Psychology, University of North Texas, Denton, Texas

Millions of Americans seriously consider suicide each year. Knowing that physical health and illness are risk factors, we examined the extent to which middle aged and older adults (N = 719) would consider ending their life, if they were to receive a diagnosis of Alzheimer’s disease. Thirty percent of the sample indicated some level of ambivalence or consideration for ending their life in the face of a diagnosis, while the remaining percentage reported they definitely would not consider suicide. Respondents’ reasoning ranged from not wanting to be a burden to religious prohibition. Furthermore, significant correlations were found between level of consideration, knowledge of Alzheimer’s, and fear of dementia.

CONTEMPLATING ALZHEIMER’S: THE PHENOMENON OF ANTICIPATORY DEMENTIA
L.G. Hodgson1, S. Cutler2. 1. Sociology, Quinnipiac University, Hamden, Connecticut. 2. University of Vermont, Burlington, Vermont

Millions of older adults have Alzheimer’s disease (AD); many more fear it. Anticipatory dementia describes concerns among middle-aged (and older) persons that everyday memory lapses are the first signs of AD. For 15 years, we have been studying these concerns as well as the consequences that result. Findings from our ongoing panel study offer insights into the processes that link memory functioning at mid-life to worries about future cognitive impairment. For example, adult children of persons with AD, not surprisingly, exhibit high rates of antici-
MIDDLE AGED AND OLDER PERSONS’ CONCERNS ABOUT DEMENTIA: THE IMPACT OF DEMENTIA CAREGIVING EXPERIENCE

B. Hayslip,1 K.S. Page,2 D. Wadsworth,1 1. Psychology, University of North Texas, Denton, Texas, 2. Preston Hollow Presbyterian Church, Dallas, Texas

Many middle aged adults seek information about dementia, driven by concerns about the disease. Fears about dementia were investigated among 383 middle aged and 220 older adults, 512 of whom did not have dementia caregiving experience, while 91 did so. A 2 (age group) X 2 (caregiving experience) ANOVA of Fear of Dementia factor scores suggested main effects for age and the interaction of age and caregiving involvement (p < .05), wherein middle age persons with dementia caregiving experience scored higher relative to those middle aged persons without such experience, while the opposite was true for older adults. Middle aged persons also reported more concerns about dementia. These findings suggest that middle aged persons’ concerns about dementia are more prevalent and that such concerns are especially salient for adult children who caring for an older family member with dementia, highlighting the need for information about diagnosis and treatment among such persons.

PERSONALITY TRAITS, AGING, AND FEAR OF DEMENTIA

K.S. Page, B. Hayslip, D. Wadsworth, Department of Psychology, University of North Texas, Denton, Texas

The concern for developing dementia is an unspoken concern for many. Understanding what factors may contribute to reported fear of dementia could allow us to better understand the individual’s view and experience. In a sample of middle-aged and older adults (N = 730), participants were asked about personality traits, knowledge of both Alzheimer’s disease and aging, fear of aging, and fear of dementia (FOD). Results yielded a positive correlation between FOD and Neuroticism for both age groups, but only a positive correlation between FOD and Agreeableness among the middle-aged participants. Furthermore, a positive correlation was found for both age groups between fear of aging and Neuroticism, while a negative correlation was found between fear of aging and Extraversion, Openness, Agreeableness, and Conscientiousness. Several significant correlations were also found between the personality domains and the other related measures. Implications for future research will be discussed.

SESSION 1425 (PAPER)

BLADDER HEALTH AND INCONTINENCE

AGING AND MATURATION PRODUCE DIFFERENT EFFECTS ON BLADDER FUNCTION IN A MOUSE CYSTOMETRY MODEL

P. Smith, A. DeAngelis, L. DeAngelis, G.A. Kuchel, Center on Aging, University of Connecticut Health Center, Farmington, Connecticut

BACKGROUND: Degradation of lower urinary tract function and control is thought to contribute to disorders of urine storage and voiding in the elderly. Effects attributable to aging are difficult to separate from associated morbidities. We utilized a mouse cystometric model to evaluate the impact of aging on micturition cycle. METHODS: Groups of ten Young (2 mo), Mature (10 mo), Aged (22 mo), and Elderly (26 mo) female B6 mice underwent multichannel pressure/flow cystomet-ric study under urethane anesthesia. Comparisons of storage and voiding parameters between groups used ANOVA with Bonferroni test. RESULTS: Young, Mature and Aged mice reliably generated typical cyclic contractile voiding. Half of Elderly mice failed to demonstrate cyclic contractile voiding. Baseline bladder pressure and voiding pressure thresholds were greater in Young compared to older groups, however maximum bladder pressures during voiding were not statistically different between groups. Young mice demonstrated poorer compliance than the older groups. Voiding flow rates, volumes and intervals increased with aging. Estimators of contractility were less in Young compared to older groups, however older groups did not differ. Estimators of urethral resistance did not differ between groups. CONCLUSIONS: Contrary to expectation, if cyclic contractile voiding is established, old mice did not demonstrate impaired storage and voiding when compared to young and mature mice. However, maturational differences exist. Unlike younger mice, Elderly mice do not reliably demonstrate typical contractile voiding. The impact of aging may be related to system responsiveness rather than alterations of specific functions. Supported by NIA AG028657 and the Jahnigen Scholars Program

IN-HOSPITAL USE OF CONTINENCE AIDS AND NEW-ONSET URINARY INCONTINENCE IN ADULTS AGED 70 AND OLDER

A. Zisberg1, G. Sinoff2, N. Gur-Yaish1, H. Admi1, E. Shadmi1, 1. Haifa University, Haifa, Israel, 2. Carmel Medical Center, Haifa, Israel, 3. Rambam Health Care Campus, Haifa, Israel

Objectives: To describe the types of continence aids of older adults hospitalized in acute medical units and to test the association between new use of continence aids and development of new urinary incontinence (UI) at discharge. Methods: Three hundred twenty two older (age 70 or older) acute medical patients hospitalized for a non-disabling diagnosis in a large tertiary medical center in Israel were followed prospectively from admission to discharge. Only participants who were continent prior to admission were included in presented study. The development of new UI was defined as patients’ report of inability to control voiding at discharge. Results: Of the 352 patients continent at admission, 58 (16.5%) used adult-diapers and 27 (7.7%) had a urinary catheter (UC) during most of the hospital stay. Sixty (17.1%) patients developed new UI at discharge. The odds of developing new UI were 4.26 (95% confidence intervals – CI: 1.53-11.83) and 2.62 (CI: 1.17-5.87) higher for UC or adult-diaper users, respectively, than for the self-toileting group, controlling for baseline functional and cognitive status, disease severity, age, and length of stay. Conclusion: The use of adult-diapers and UC during acute hospitalization is associated with the development of new UI at discharge. The management of continence among hospitalized older adults requires more diligence, and further investigation is needed to devise continence promotion methods in hospital settings.

URINARY CONTINENCE INTERVENTIONS: ASSESSING OUTCOMES MEASUREMENT

K. Southall1, J.W. Jutai1,3, E. van den Heuvel1, 1. Élisabeth-Bruyère Research Institute, Ottawa, Ontario, Canada, 2. Brael University, London, United Kingdom, 3. Interdisciplinary School of Health Sciences, University of Ottawa, Ottawa, Ontario, Canada

Urinary incontinence (UI) is a condition frequently experienced by older adults. Individuals with UI are commonly stereotyped as frail and incompetent, which can sometimes lead to humiliation, embarrassment and social isolation. There are numerous effects of UI on psychological and social well-being that make it a challenge to measure the relative success of a particular treatment. A systematic review examined the psychometric and administrative properties of commonly used subjective measures for urinary incontinence. Each measure was examined for content that addresses social- and self-stigma. In this presentation, we will provide a brief overview of the tools identified to assess
the outcomes of UI intervention, and discuss the extent to which the various tools assess stigma. Recommendations are provided on how measures might be improved, giving particular attention to challenges encountered by older adults.

MEASURING THE OUTCOMES FOR CONTINENCE MANAGEMENT TECHNOLOGIES
J.W. Jutai, K. Southall, E. van den Heuvel, N. Cotterill, A. Long, 1. Interdisciplinary School of Health Sciences, University of Ottawa, Ottawa, Ontario, Canada, 2. Elisabeth Bruyere Research Institute, Ottawa, Ontario, Canada, 3. Brunei University, London, United Kingdom, 4. Bristol Urological Institute, Bristol, United Kingdom

Current technologies and interventions to help manage incontinence are not completely effective and accepted by persons with continence problems. One acknowledged weakness in the field of continence management technologies is the lack of controlled outcomes studies. To measure the psychosocial impact of assistive technology in a standardized, objective and measurable fashion requires specifically designed tools. One such tool is the Psychosocial Impact of Assistive Devices Scale (PIADS). The purpose of this research was to produce a modified version of the PIADS, for continence aids, that is understandable and acceptable to this population, and to investigate its reliability and validity. In the current study, we conducted interviews with older persons who have continence difficulties to help determine how well the PIADS seems to capture important areas for impact of continence technologies and identify modifications and enhancements that might be needed. In this presentation we will present themes generated from interview analyses, and overview proposed modifications.

A QUALITATIVE INQUIRY OF PATIENT-REPORTED OUTCOMES: THE CASE OF LOWER URINARY TRACT SYMPTOMS

Patient-reported outcomes provide a particularly important source of evidence for assessing healthcare for symptom-based conditions that lack definitive physiological measures of treatment efficacy, such as lower urinary tract symptoms (LUTS). Although LUTS increase in prevalence and severity over the life course and can significantly reduce quality of life, research shows a lack of concordance between provider and patient assessments. Semi-structured interviews were conducted with a stratified subsample of a larger representative community survey. The qualitative sample included 90 men and women from three race/ethnic groups (black, Hispanic, and white) who had spoken with a provider about LUTS. Respondents were asked to describe symptom relief after seeking medical care for LUTS, adherence to providers’ recommendations, and satisfaction with care. Interviews were transcribed, coded, and analyzed for themes. Most patients experienced either no symptom relief or partial relief, reported that they adhered to provider recommendations, yet also stated that they were satisfied with the care received. The primary reason for no symptom relief was not receiving a treatment recommendation from a provider. For patients, even partial relief made symptoms more manageable both physically and emotionally. Satisfaction with care was mediated by the patient/provider relationship and a patient’s expectations other than symptom relief. Patients’ assessments of the outcomes of seeking care for this symptom-based condition broadened the criteria for quality of care beyond providing a cure. For providers and researchers, the context acquired through a qualitative approach can enhance understanding of patients’ perspectives and the ability to construct meaningful quantitative measures.

SESSION 1430 (PAPER)
QUALITY OF LIFE AND WELL-BEING

DOES PEG FEEDING TUBES IMPROVED SURVIVAL IN ADVANCE DEMENTIA?

BACKGROUND: Earlier work suggests that feeding tubes are not associated with improved survival. However, these prior studies are limited in that they did not distinguish between nasogastric tubes and percutaneous endoscopic gastrostomy (PEG) tubes, examined samples from single institutions or states, and did not use state-the-art methods to control for selection bias. The objective this study was to examine survival with and without a feeding tube using rigorous method to account for selection bias. A second objective was to examine whether the timing of feeding tube impacted on survival. METHOD: Retrospective cohort study using data from the Minimum Data Set and Medicare Claims from 1999-2007 to examine survival for advanced dementia NH residents with and without a feeding tube insertion using multivariate survival model with a propensity score. RESULTS: Of the 36244 NH residents (88% white, mean age, 84.9, 88% with one feeding tube risk factor), 1943 (5.3%) had feeding tube inserted. After multivariate analysis that included the propensity score, no difference was found between the survival of the 2 groups (AHR 1.03 95% CI. 94 to 1.13). Among residents who were tube-fed, the timing of PEG tube insertion relative to the onset of feeding problems was not associated with survival (AHR, 0.89 95% CI 0.72 to 1.11). CONCLUSION: This national study confirms that neither feeding tubes nor the timing of the insertion of a PEG feeding tube improved survival.

RISK FACTORS FOR NEGLECT IN ASSISTED LIVING
C.E. Ziminski1, L.R. Phillips1, G. Guo2, 1. Nursing, University of California, Los Angeles, Los Angeles, California, 2. Peking University School of Nursing, Beijing, China

It is estimated nearly 1 million elders live in an assisted living facility (ALF). While research has shown elder mistreatment to be a prevalent threat in ALFs, little is known specifically about neglect. ALFs were designed to be an alternative to skilled nursing facilities, though they are serving an increasingly larger population of sicker and more dependent elders with complex healthcare needs. As this population grows so does the opportunity for neglect. Research suggests risk factors such as use of unlicensed assisted personnel, lack of education requirements for staff, level of services provided, and for-profit motive of ALFs attribute to the occurrence of elder mistreatment. This study used archived public data from Arizona to examine the prevalence and types of neglect (environmental, medical, personal). Analysis explored relationships of institutional and staff risk factors and resident outcomes. Staff risk factors included citations pertaining to education requirements, qualifications, and attitudes. Institutional risk factors included citations pertaining to staffing, hiring practices, care practices and business practices. Results have implications for policy and interventions.

FACTORS INFLUENCING QUALITY OF LIFE IN OLDER ADULTS WITH OSTEOARTHRITIS
J.B. Jenkins, P.B. Crane, The University of North Carolina at Greensboro, Greensboro, North Carolina

Background: Over one-third of older adults have osteoarthritis (OA). OA of the knee is the most significant source of pain and physical disability in older adults and one of the five leading causes of disability. The consequences of OA may be detrimental to the older adult resulting in a decreased quality of life (QOL). Purpose: The purpose of this
study was to examine factors that influence the older adult’s QOL prior to total knee replacement (TKR) surgery. Methods: A cross-sectional, correlational study design of a convenience sample of adults ages 50 and older was used. Data were collected using established instruments and standardized anthropometric measures. Results: The sample (N=75) was mostly married (73%), White (67%), females (76%) with a mean age of 69 years (SD = 8.179) who were planning first time TKR. Age, race, sex, expectations, social support, BMI, pain, fatigue, depression, functional status, and general health perception (GHP) explained 62% of the variability in overall QOL (p<0.001). Social support (β = 0.399, p<0.001), depression (β = 0.313, p = 0.002), functional status (β = 0.263, p = 0.023), and GHP (β = 0.236, p = 0.007) significantly contributed to QOL. Implications: Findings from this study add important knowledge of older adults with chronic disease and provide the foundation for future studies to further examine factors that influence an older adult’s assessment of QOL. Intervention studies are needed to assist older adults to effectively responding to the challenges of physical, psychological, and social aspects of life impacted by OA.

OLDER WORKERS WITH CARDIOVASCULAR DISEASE: THE RELATIONSHIP OF JOB CHARACTERISTICS, SELF-CARE AND QUALITY OF LIFE

V. Vaughan Dickson, A. Howe, J. Deal, M.M. McCarthy, College of Nursing, New York University, New York, New York

Older workers with cardiovascular disease (CVD) must meet the challenges of today’s work processes including increased stress and intense production demands while managing the complexities of CVD. Adherence to self-care practices (medication, diet, exercise and symptom monitoring) is essential to maintaining physiological stability of CVD. This study explored the relationship of job characteristics (job stress and workplace support), self-care and health-related quality of life (HRQL) among older workers with CVD. Methods: In this cross-sectional study 88 older workers (>age 55) with CVD (mean age 63.3 years SD 7.1) were recruited from clinical and community settings and completed standardized instruments about job characteristics, self-care, physical functioning and HRQL. Correlational and regression analyses examined relationships between variables. Results: The sample was 56.8% female, 34.4% African American, 79.6% were employed (59% full or part time; 20% self-employed). Hypertension was common (36%); 33.6% had coronary heart disease. Self-care behaviors varied. Although most reported medication adherence (70.5%), few adhered to diet (25%), exercise (19.3%) or symptom monitoring (30.7%). Increased job demands were negatively correlated to self-care (r=-0.302, p<.007). Better self-care was reported by those with workplace support (r=.331, p=.004) Overall, job characteristics explained 22% of self-care variance. Self-care and physical functioning were significant determinants of HRQL (p<.001). Conclusions: Since job characteristics may influence self-care, clinicians should assess job demands and resources as part of self-care education for older workers with CVD. As the workforce ages, worksite programs that facilitate self-care are needed and may help maintain physical functioning and HRQL among the growing aging workforce.

GRANDMOTHERS RAISING GRANDCHILDREN: RESULTS OF AN INTERVENTION TO IMPROVE PSYCHOLOGICAL WELL-BEING

S.J. Kelley, D.M. Whitley, P.E. Campos, School of Nursing, Georgia State Univ, Atlanta, Georgia

A substantial body of research indicates that grandmothers raising grandchildren are at increased risk for depression, as well as other forms of psychological distress. To date, the majority of research is limited by use of unidimensional symptom scales, such as those that measure only depression. The current study expands on knowledge of the psychological status of custodial grandmothers by use of the Brief Symptom Inventory, a multidimensional measure that examines psychological symptoms across nine primary symptom dimensions. The goal of the current study was determine if an interdisciplinary intervention can be effective in decreasing psychological distress in grandmothers raising grandchildren. The sample comprised 449 predominantly low income, African American grandmothers raising one or more grandchildren. Their mean age was 57 years, with a range of 38 to 82. Participants were enrolled in an interdisciplinary, community-based program with the goal of improving the well-being of family members. Support services included home-based visitation by social workers and registered nurses, access to support groups and parenting classes, early intervention services for young children, and referrals for legal services. Participants are enrolled in the program for one year. Data are obtained at pre and post intervention. Results indicate that overall psychological distress decreased significantly from pre to post test (p < .000). Of the nine primary symptom dimensions, there were statistically significant (p < .005) decreases in scores on the following: Obsessive Compulsive, Interpersonal Sensitivity, Depression, Anxiety, Hostility, Phobic Anxiety, and Paranoid Ideation. Implications for practice, policy, and future research will be discussed.

SESSION 1435 (SYMPOSIUM)

POSITIVE AGING: FROM THEORY TO PHENOTYPE

Chair: B.B. Cochrane, School of Nursing, University of Washington, Seattle, Washington, Fred Hutchinson Cancer Research Center; Seattle, Washington
Co-Chair: N.F. Woods, School of Nursing, University of Washington, Seattle, Washington

This symposium aims to ignite dialogue about positive aging and the assessment of one or more phenotypes from which to understand positive aging determinants and health outcomes and to posit hypotheses regarding new biomarkers. In the first paper we address theoretical and methodological foundations for studying positive aging, focusing on models posited from biobehavioral perspectives. In the second paper we address the question: what is the structure of positive aging? We will summarize results of principal components analyses completed with data from the Women’s Health Initiative, a large longitudinal study of postmenopausal women’s health, and examine the utility of functional and self-report measures as indicators of positive aging. In the third paper we examine the relationships between positive aging phenotypes and health outcomes, including: mortality, hospitalizations, years of independent living, and years of healthy living. In the fourth paper we present results from trajectory analyses of positive aging indicators and thereby address the sensitivity of individual items assessing functional capacity in comparison with other indicators of positive aging. Together, the authors of these papers will identify the theoretical foundations of positive aging, posit phenotypes useful for advancing the science of positive aging, and analyze the contributions of a variety of indicators to this effort. Discussion of the utility of relevant measures in both clinical and research initiatives will complete the symposium.

POSITIVE AGING: THEORETICAL AND METHODOLOGICAL FOUNDATIONS

The aims of this paper are to review the theoretical foundations of positive aging and to link these historical views explicitly to methodological foundations for studying positive aging. Literature on positive aging was reviewed to identify conceptual and theoretical foundations that have motivated the development of research on positive aspects of aging, as well as such constructs as successful aging and healthy aging. Models of positive aging, including those developed from theoretical domains within the social and biomedical sciences will be compared and contrasted with those grounded in data provided by older adults.
The linkages among theory, models, and methodological approaches to the study of positive aging will be explicated.

TRAJECORIES OF POSITIVE AGING: COMPARISON OF INDICATORS
O. Zaslavsky1, J. Liu2, J.R. Herting3, N.F. Woods4, B.B. Cochrane1,2, J. Liu1, A.Z. LaCroix2, O. Zaslavsky1, J. Herting3, N.F. Woods4, B.B. Cochrane1,2, J. Liu1, A.Z. LaCroix2, O. Zaslavsky1, J. Liu1, A.Z. LaCroix2, O. Zaslavsky1, J. Herting3, N.F. Woods4, B.B. Cochrane1,2, J. Liu1

The purposes of this paper are to characterize the trajectories of multiple indicators of positive aging using longitudinal data obtained from the Women’s Health Initiative participants 65 years and older at baseline and followed over an average of 7-8 years. Previous longitudinal studies revealed that multiple indicators of physical and emotional functioning have been strongly associated with positive aging. However, there is a scarcity of studies addressing the longitudinal trajectory of change in these indicators. We applied an innovative statistical approach, namely Latent Class Growth Modeling (LCGM) to this dataset, which allowed us to describe different trajectories of both subjective and objective positive aging indicators over time (e.g., constant over time, rapidly declining) and to differentiate those baseline characteristics that predict trajectory group membership. We will discuss the utility of these approaches in both clinical and research contexts.

POSITIVE AGING PHENOTYPES: PRINCIPAL COMPONENTS ANALYSIS
N.F. Woods1, J. Liu2, B.B. Cochrane1,2, A.Z. LaCroix2, O. Zaslavsky1, J. Herting3, N.F. Woods4, B.B. Cochrane1,2, J. Liu1, A.Z. LaCroix2, O. Zaslavsky1, J. Herting3, N.F. Woods4, B.B. Cochrane1,2, J. Liu1, A.Z. LaCroix2, O. Zaslavsky1, J. Herting3, N.F. Woods4, B.B. Cochrane1,2, J. Liu1, A.Z. LaCroix2, O. Zaslavsky1, J. Herting3, N.F. Woods4, B.B. Cochrane1,2, J. Liu1, A.Z. LaCroix2, O. Zaslavsky1, J. Herting3, N.F. Woods4, B.B. Cochrane1,2, J. Liu1, A.Z. LaCroix2, O. Zaslavsky1, J. Herting3, N.F. Woods4, B.B. Cochrane1,2, J. Liu1, A.Z. LaCroix2, O. Zaslavsky1

The purpose of this paper is to examine the dimensions of positive aging using data from the Women’s Health Initiative, a large longitudinal study of postmenopausal women’s health that began in 1993 at 40 clinical centers across the United States and continues in long-term follow-up through 2015. Over 70,000 women were 65 years and older at baseline measurement and included in these analyses. Data collected at baseline, year 3, and at closeout from Clinical Trial participants and at baseline and year 3 from Observational Study participants were analyzed using principal components analysis to identify dimensions of positive aging. Results revealed two important dimensions: physical functioning and emotional functioning. These dimensions are examined for their utility in future research in contrast with the use of individual items.

OUTCOMES OF POSITIVE AGING: MORTALITY, YEARS OF HEALTHY LIVING, YEARS OF INDEPENDENT LIVING
A.Z. LaCroix1, N.F. Woods2, B.B. Cochrane1,2, J. Liu1, O. Zaslavsky1, J. Herting3, N.F. Woods4, B.B. Cochrane1,2, J. Liu1, O. Zaslavsky1, J. Herting3, N.F. Woods4, B.B. Cochrane1,2, J. Liu1, O. Zaslavsky1, J. Herting3, N.F. Woods4, B.B. Cochrane1,2, J. Liu1, O. Zaslavsky1

The multidimensional phenotype of positive aging using a two-factor solution, as well as individual indicator scores, were examined for their ability to predict health outcomes among participants in the Women’s Health Initiative who were aged 65 and older at baseline. Outcomes examined included time-to-death, years of independent living (e.g., first report of nursing home admission) and years of healthy living (e.g., no hospitalizations or major health conditions). Adverse outcomes were estimated based on the years prior to death. All models were adjusted for age, race/ethnicity, education, and WHI component enrollment. Cox proportional hazard modeling revealed that both factors and the independent indicators informing the factors were significantly associated with each of the estimated outcomes. The differential relation-nes of the two-factor positive aging phenotype versus individual indicators will be discussed.

SESSION 1440 (SYMPOSIUM)

SLEEP DISTURBANCE AND ADVERSE HEALTH OUTCOMES IN OLDER ADULTS
Chair: A.P. Spira, Department of Mental Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland
Co-Chair: K.L. Stone, California Pacific Medical Center Research Institute, San Francisco, Maryland
Discussant: S. Ancoli-Israel, University of California, San Diego, La Jolla, California

Sleep disturbances, including poor sleep quality and sleep-disordered breathing, are common among older adults, and a growing body of research suggests that they are associated with—and perhaps cause—a range of adverse health outcomes. Given the prevalence of sleep disturbances in this population, and the fact that they often can be treated, evidence for an association with poor health outcomes could have substantial implications for the prevention of morbidity and maintenance of independence in older adults, or for prognosis, with respect to these outcomes. In this symposium, we will present research regarding the association between sleep disturbances—assessed using several methodologies (i.e., actigraphy, polysomnography, self-report)—and a range of adverse outcomes. Specifically, the session will include studies of: the association between actigraphically measured sleep duration and fragmentation in older women and subsequent placement in nursing homes or personal care homes (e.g., assisted living); the interaction of actigraphic and self-report measures of sleep disruption and the risk of falls in older women; the link between sleep disturbance and pain in older adults; and the extent to which obstructive and central sleep apnea predict incident heart failure in older men. We will discuss the implications of results for the health of the large and growing population of older adults, including opportunities for prevention of disease and maintenance of quality of life.

OBJECTIVELY MEASURED SLEEP FRAGMENTATION AND NURSING HOME PLACEMENT IN OLDER WOMEN
A.P. Spira1, K. Covinsky2, G. Rebok1, K.L. Stone2, S. Redline2, N. Punjabi1, K. Yaffe1, J. Liu1, A.P. Spira1, K. Covinsky2, G. Rebok1, K.L. Stone2, S. Redline2, N. Punjabi1, K. Yaffe1, J. Liu1, A.P. Spira1, K. Covinsky2, G. Rebok1, K.L. Stone2, S. Redline2, N. Punjabi1, K. Yaffe1, J. Liu1

Although sleep complaints are common among older adults, little is known about the association between objectively measured sleep and placement in long-term care (LTC). We studied 1,664 women (mean age = 83) with data indicating residence in a “private home or apartment” or “retirement home or senior complex” at baseline, who completed wrist actigraphy for quantification of sleep/wake. Residence data were collected five years later. Sleep fragmentation was measured as WASO (wake after sleep onset duration), expressed as quartiles. Women in the fourth compared to the first quartile for WASO were almost three times more likely to reside in a nursing home (adjusted odds ratio (AOR) = 2.78, 95% CI 1.30, 5.95) or a personal care home (AOR = 2.40, 95% CI 1.31, 4.42) five years later. There was no association between sleep duration and LTC residence. Objectively measured sleep fragmentation, but not duration, predicts LTC placement in older women.
OBJECTIVE AND SUBJECTIVE SLEEP MEASURES AND RISK OF FALLS IN OLDER WOMEN AND MEN
K.L. Stone1, T. Blackwell2, P. Varosy1, K. Ensrud1, A.P. Spira4, S. Redline1, 1. Research Institute, California Pacific Medical Center, San Francisco, California, 2. University of California, San Diego, San Diego, California, 3. University of Minnesota, Minneapolis, Minnesota, 4. Johns Hopkins University, Baltimore, Maryland, 5. Brigham and Women’s Hospital, Boston, Massachusetts

Sleep disruption is associated with increased risk of falls, yet most studies have relied on subjective sleep assessment. Many individuals with subjective sleep complaints do not have objective evidence of poor sleep. We used data from the SOF (n=2974 women, mean age 83.5) and MrOS (n=3023 men, mean age 76.4) Sleep Studies to explore the associations of subjective and objective (based on wrist actigraphy) sleep and risk of 2+ falls during the subsequent year. In multivariate models, objective sleep was associated with increased fall risk in both women and men. For example, relative to those who slept 7-8 hours per night, short sleep duration (<= 5 hours) was associated with a 1.60-fold (95% CI 1.08 - 2.38) and 1.75-fold (1.20 - 2.54) increased fall risk in women and men, respectively. Subjective sleep significantly predicted fall risk in women but not men. The interaction of subjective and objective sleep measures were also explored.

INTERACTIONS OF SLEEP DISTURBANCE AND PAIN IN OLDER ADULTS: IMPLICATIONS FOR EFFECTIVE TREATMENT
M.V. Vitiello, Psychiatry, University of Washington, Seattle, Washington

Pain due to osteoarthritis (OA) affects over half of all older adults, with the majority of these individuals experiencing significant co-morbid sleep disturbance. Sleep disturbances have typically been assumed to be secondary to pain syndromes. However, emerging evidence demonstrates that while pain may initiate and exacerbate sleep disturbance, disturbed sleep in turn maintains and exacerbates chronic pain and related dysfunction. This interaction suggests that optimal OA interventions should target not only perceived pain and related dysfunction but co-morbid sleep disturbance as well. Evidence demonstrating sleep/pain interactions will be reviewed and synthesized and the implications for enhancing the treatment of co-morbid pain and disturbed sleep in older adults by treating both conditions simultaneously will be discussed.

OBSTRUCTIVE AND CENTRAL SLEEP APNEA: ASSOCIATIONS WITH INCIDENT HEART FAILURE IN OLDER MEN

It is unclear whether sleep disordered breathing (SDB) increases risk of heart failure (HF) in elderly individuals, whether associations are bi-directional, and if HF risk is associated with central or obstructive apneas. The association between SDB and incident HF over 5 years was evaluated in 2878 men (mean age 76±5.5 years) in the MrOS Sleep Study who underwent baseline polysomnography. After adjusting for age, race and clinic, incident HF was associated with an Apnea Hypopnea Index >15 (OR: 1.58; 1.22, 2.27, 95% CI); % sleep time at oxygen saturation levels <90% (1.18; 1.05, 1.33), increased wake (>1.5 hrs) after sleep onset (1.76; 1.25, 2.49); and Cheyne-Stokes Breathing (CSB) (3.00; 1.91, 4.70). After excluding men with prevalent HF, associations weakened, but remained significant for CSB, increased wake time and sleep hypoxemia. CSB, a breathing pattern associated with central apnea, is a marker for HF incidence, even in men without HF at baseline.

SESSION 1445 (SYMPOSIUM)

TAILS OF CARE: RESEARCH AND PRACTICE IN ANIMAL ASSISTED INTERVENTIONS (AAI) AND OLDER ADULTS
Chair: R.J. Karasik, Gerontology, St. Cloud State University, St. Cloud, Minnesota
Co-Chair: J. Berry, Dementia Care Foundation, Darwin, Minnesota

While the use of Animal Assisted Interventions (AAI) in health care is not new (Johnson et al., 2002; Odendaal, 2000), its place in the care of older persons, including persons with dementia is now coming to the forefront (Sellers, 2006; Williams & Jenkins, 2008). Despite a growing body of literature, limited information is found on the practical applications and challenges associated with implementing AAI with older adults. This symposium examines the integration of AAI into a continuum of settings (from home and community to specialized and institutional care) and with populations varying significantly in their care needs. Particular emphasis is placed on the practice of AAI as a cost effective, non-chemical healthcare intervention. The first paper examines the effectiveness of dog walking as a physical activity, factors that facilitate and prevent dog walking in older adults, and the methodological challenges of assessing such AAI. The second paper explores the impact of dog walking on the endurance and mobility of older persons in institutions. The third paper presents findings from a 3 phased study examining the impact of an aquarium on the food intake of persons with severe dementia in an institutional setting. The fourth paper describes a 10 year case study where AAI with a variety of domestic and exotic animals has been incorporated into a new care approach for persons needing specialized dementia care. The final paper addresses the overall theme of putting AAI into practice and explores available resources to assist with implementing AAI across the care continuum.

BACK AT THE RANCH: PRACTICAL APPLICATIONS OF ANIMAL ASSISTED INTERVENTIONS (AAI) IN DEMENTIA CARE
R.J. Karasik1, J. Berry2, 1. Gerontology, St. Cloud State University, St. Cloud, Minnesota, 2. Dementia Care Foundation, Darwin, Minnesota

This case study reflects 10 years of Animal Assisted Intervention (AAI) practice (1999-2010) with residents of the Lakeview Ranch Model of Specialized Dementia Care (N=145). Animal Assisted intervention is a key component of the model, along with a high staff: resident ratio, interdisciplinary teamwork, medication reviews, attention to residents’ emotional needs, and specialized staff training. The model re-allocates funding toward “up front” care programs (e.g., AAI) geared to prevent challenging dementia-related behaviors, rather than toward more expensive and often less desirable “after the fact” interventions (e.g., medication, hospitalization). Since its inception, LR has been home to a variety of domestic, farm, and exotic animals. Current findings document numerous AAI benefits including: increased emotional connections, sensory stimulation, physical activity/exercise, and socialization, along with decreased challenging behaviors. Type of animal/intervention was found as an intervening variable. Logistical concerns identified include: state regulations/health issues, program cost, therapist availability, staff buy-in, and animal care.

THEORETICAL AND PRACTICAL FACTORS ASSOCIATED WITH DOG WALKING FOR OLDER ADULTS
R. Johnson, Sinclair School of Nursing, University of Missouri, Columbia, Missouri

Premise & Process: Globally there is growing research investigating dog walking to enable people to meet PA recommendations. Epidemiological evidence suggests people who walk dogs are more likely to meet recommendations. This paper explores factors facilitating and preventing dog walking among older adults. It will draw upon data from the rapidly expanding global evidence base on dog walking, and refer
to findings from 3 of the author’s studies. Methodological issues of designing and implementing dog walking studies with older adults will be presented. Practical issues of older adults’ dog walking will be discussed (including safety, walking speed, balance, and PA). Conclusions: Dog walking may be beneficial to improve or maintain PA in older adults given attention to safety issues particular to this population. Objectives: 1. Describe factors facilitating and preventing dog walking among older adults. 2. Analyze issues associated with implementing dog walking research and programs with older adults.

HOW TO PRACTICALLY APPLY ANIMAL ASSISTED INTERVENTIONS (AAI) IN ANY SENIOR SETTING

K.S. McGilton, Research, Toronto Rehabilitation Institute, Toronto, Ontario, Canada, Faculty of Nursing, Toronto, Ontario, Canada

Objective: To determine if walking a dog would result in an increase in walking endurance and mobility among institutionalized elderly. Design: Experimental pre and post test two group randomly assigned design. Setting: Three long-term care facilities Participants: Thirty subjects, male and female (mean age, 72) Intervention: A 6-week walking program where the experimental group walked with a dog and handler and the control group with only a handler Measures: Outcomes Expectations for Exercise Scale (OES), 2-minute walk test and 30 second chair stand test Results: All of the participants showed an increase (7 minutes) in walking time during the 6-week period (p=0.048, mean 15.08, SD 7.6). The OES scores did not significantly predict adherence to the program. The pre- post-chair stand and the 2-minute walk test did not show statistical significant differences. Conclusions: Walking three times a week for 6 weeks has the potential to increase walking endurance.

THE INFLUENCE AQUARIUMS ON FOOD INTAKE IN INDIVIDUALS WITH DEMENTIA

N.E. Edwards, A.M. Beck, Purdue University, West Lafayette, Indiana

The project examined the effects of introducing an aquarium in the dining areas of specialized dementia units in long term care facilities. The sample consisted of 71 residents with severe dementia. The 10 week study consisted of 3 phases: Week 1-2 baseline food intake; week 3-4 food intake with aquarium in dining area; and week 5-10 follow-up phase. Food intake was measured by weighing the food prior to and after each meal. Resident body weight was assessed at the beginning of each phase. Using a repeated measure ANOVA, a significant increase in food intake was noted between the baseline and treatment phase. When assessed by facilities, all three facilities had significantly higher intake in Phase II compared to Phase I and the effect was maintained through Phase III. A significant increase was noted in resident weight

SESSION 1450 (SYMPOSIUM)

VALUING THE ROLE AND CONTRIBUTIONS THE REGISTERED NURSE BRINGS TO LTC: PROCEEDINGS FROM AN INTERNATIONAL MEETING

Chair: K.S. McGilton, Research, Toronto Rehabilitation Institute, Toronto, Ontario, Canada, Faculty of Nursing, Toronto, Ontario, Canada

Discussant: B. Bowers, University of Wisconsin-Madison, Madison, Wisconsin

An invitational two day meeting was held to focus on valuing the contributions an RN brings to LTC. The symposium brought together international, national and local stakeholders to highlight the value of registered nurses in long-term care and to develop strategies to develop sustainable roles in LTC nursing homes. Despite coming from 6 different countries several similar key concerns were identified and these were summarized into three themes: (1) Role Clarification and Delineation, which focuses on issues of how the RN role is defined in different organizations, scope of role, expanse of authority and professional role extension; (2) Gerontological Nursing Expertise, which focuses on the nature and focus of education programs for practice in LTC, and (3) Models of Care, which focuses on the way in which LTC models are changing and the implications of these changes on the RN role in LTC. The symposium will focus on describing recommendations made by this international alliance. The first paper describes the persons we care for in LTC and possible RN sensitive outcomes based on their needs. The second paper examines the RN role and RN role performance within a systems-focused context. The third paper examines competencies for RNs that practice in nursing homes and components of nurse practice acts that are considered within the RN’s scope of practice. The final paper is focused on moving the agenda forward. Recommendations made by the international alliance on future research and policy will be discussed.

A PROFOUND UNDERSTANDING OF THE PERSON LIVING IN LTC AND OUTCOMES ASSOCIATED WITH RN SENSITIVE CARE

B. Mc Cormack, T.J. Roberts, J. Meyer, D.G. Morgan, nursing, university of ulster, Newtownabbey, United Kingdom

Long-term care for older people is undergoing significant change internationally. This change reflects a shift in philosophy from an institutional model of care to one that seeks to recognize and celebrate the continuing place of the older person in community, ensuring the ‘person’ is at the heart of decision-making about models of care delivery. Changes require reconsideration of the role of the registered nurse (RN) in facilitating relationships that enhance the personhood of the older person and others significant to them. This paper will explore the meaning of “person” in the context of long term care for older people. It will suggest approaches to care delivery that can enhance both quality of life for service users and staff well-being. It will be argued that cultures of care need to embrace the personhood of residents, relatives and staff and that RN outcomes need to be sensitive to these cultures of care.
A SYSTEMS-FOCUSED CONTEXT FOR UNDERSTANDING THE RN ROLE AND PERFORMANCE

A myriad of sociocultural, political, organizational, and micro unit-level systems comprise contexts in which the registered nurse (RN) role is defined, operationalized, and evaluated. This paper offers several systems-focused perspectives for understanding the RN role and performance within and across systems of care. An organization-level systems approach highlights the interaction effect of the organizational design factors that link organizational structure to RN work. Another approach addresses one specific aspect of the RN role – delegation of nursing services – highlighting the regulatory and functional mechanisms that influence ways the RN role is operationalized. A micro-systems approach addresses specific RN practices associated with prevention of pressure ulcers, and the unit-level interactions that facilitate and/or limit RN knowledge, beliefs, and values associated with best practices. The knowledge gained from applying systems-focused perspectives to understanding the RN role provides critical insights and directions for interventions aimed to maximize RN role effectiveness in long term care.

REGISTERED NURSE COMPETENCIES AND SCOPE OF PRACTICE: IMPLICATIONS FOR QUALITY OF CARE IN NURSING HOMES

Reviews of international literature highlight that nursing practice in a nursing home is perceived as routine care delivered to people with non-complex needs and that nurses require less expertise to practice in those environments. This misconception has led to substituting licensed practical nurses (LPNs) for registered nurses (RNs) in many nursing homes. We analyzed all the U.S. state nurse practice acts (NPAs) regarding RN and LPN scopes of practice for nursing assessment, care planning and evaluating, delegating and supervising. Twenty-four states (47%) permit LPNs to delegate and supervise, but care quality was better in states that were more restrictive about LPN delegation and supervision. These NPA dimensions were mapped to endorsed RN geriatric nursing competencies (e.g., AACN 2010; NLN 2010). By relating scope of practice to RN competencies, findings illustrate the adverse care outcomes associated with limited RN scope of practice to RN competencies, findings illustrate the adverse care outcomes of RN nursing interventions aimed to maximize RN role effectiveness in long term care.

MOVING THE AGENDA FORWARD: RECOMMENDATIONS MADE BY THE INTERNATIONAL ALLIANCE ON FUTURE RESEARCH AND POLICY

The main recommendation from the international alliance is that the role and scope of the RN role requires a redesign. The role of the RN has evolved to meet the demands of the system with limited regard to what matters most to the resident (i.e. well-being), or the competencies required of the RN to lead the team to these outcomes. To refocus what the role of the RN should be, outcomes have been identified based on residents’ needs that we believe are sensitive to RN care. Next steps include the development of evaluation criteria for these outcomes and an international research project to test the framework. In addition, recommendations will determine the infrastructure support and best care delivery models that are required in order to enable realization of the full scope of the role so that RNS can ensure residents enjoy and engage in life despite their complex health conditions.

SESSION 1455 (PAPER)

ISSUES IN CHRONIC CARE — SERVICE DELIVERY

PROMOTING CONSIDERATION OF THE SOCIAL DIMENSION IN EFFECTIVE DELIVERY OF COMPREHENSIVE CARE COORDINATION

In the United States, nearly half the population suffers from at least one chronic condition and the prevalence of multiple chronic conditions is increasing. The National Coalition on Care Coordination (N3C) comprised of leading health and aging professionals representing 40+ social, family caregiver, and professional organizations, formed in 2008 to advocate for better coordinated health and social services for older adults with chronic conditions. By its very nature, chronic disease requires ongoing attention and management of medical, psychological, economic, and social factors. N3C contributed to assuring that the Patient Protection and Affordability Care Act (ACA) includes access to care coordination as a key strategy for improving the quality and cost effectiveness of health care. As ACA moves into implementation, it is critical that consideration of innovative models hold as much regard for the behavioral/social support dimension as what is typically afforded the medical realm. N3C efforts to build and disseminate evidence for the effectiveness of care coordination delivered by an interdisciplinary team process links medical care with community and long-term care. The continuing focus on medical care alone is not enough to also address the behavioral and social support needs of these individuals. Evidence on the importance of this behavioral/social support dimension and on models of care that incorporate it is increasingly becoming available and deserves broader dissemination. This presentation will focus on N3C efforts to produce the evidence and disseminate this more comprehensive approach to care coordination that will benefit older adults with chronic conditions.

POTENTIALLY AVOIDABLE HOSPITALIZATIONS AMONG DUAL ELIGIBLES: DEFINITIONS, RATES AND COSTS

E. Walsh1, J.G. Ouslander2, S. Haber1, A.W. Bragg2, J. Wiener1, 1. RTI, Waltham, Massachusetts, 2. Florida Atlantic University, Boca Raton, Florida

Reducing the incidence of potentially avoidable hospitalizations (PAHs)—either by preventing conditions warranting hospitalization or by managing conditions at home or in nursing facilities—has the potential to substantially reduce Medicare costs, as well as improve health outcomes and beneficiaries’ quality of life. To analyze PAH rates and costs we developed a comprehensive list of conditions associated with potentially avoidable hospitalizations (and their associated ICD-9 codes) for nursing facility residents, based on input from experts in geriatrics, ambulatory care sensitive conditions, and other quality measures. We identified a subset of this list as most appropriate for HCBS waiver enrollees and other community-residing beneficiaries, to reflect the.
lower levels of support available to them compared to those in nursing facilities. We created and analyzed a linked data set incorporating 2005 Medicare and Medicaid claims, eligibility data regarding dual eligibility, and other data sources. We incorporated state Medicaid policy characteristics, facility characteristics, and measures of area supply and demand for health care services from other data sources including the Online Survey and Certification Reporting System, and the Area Resource File. Among the 5.6 million dual eligibles, we found 700,000 PAHs costing $5.6 billion: 338 per 1000 person years among those Medicaid-covered nursing facility stays, 942 among those with in skilled nursing facility stays, and using the reduced PAH list, 250 and 88 among those in HCBS waivers and all other community-residing dual eligibles. We present results by state, condition, and demographic characteristics as well as multivariate analyses.

THE ROLE OF CONSUMER ADVOCACY IN MEDICAID NURSING HOME REIMBURSEMENT: LESSONS FROM NEW YORK AND MINNESOTA

E.A. Miller, C. Rudder, J. Gerontology, Univ. of Massachusetts Boston, Boston, Massachusetts, 2. Long Term Care Community Coalition, New York, New York

Medicaid is the major purchaser of nursing home care in the United States. Lack of consumer advocacy involvement in Medicaid payment policy has resulted in reimbursement systems that favor industry and government interests at the expense of issues important to residents and their families. The purpose of this study is to draw on qualitative case studies of New York and Minnesota to identify factors promoting positive consumer participation in Medicaid nursing home reimbursement. In-depth interviews were conducted with 22 individuals with known or demonstrable experience in this area. Pertinent documents were also reviewed. Consumer advocates in both states played a critical role in the adoption of case-mix reimbursement. Whereas advocates in New York convinced policymakers to consider a number of rate setting components intended to improve access, quality and efficiency, those in Minnesota successfully supported such reimbursement system attributes as rate equalization and add-ons targeted to direct care staff. Findings suggest the importance of developing, demonstrating, and volunteering expertise in nursing home reimbursement as a means of gaining legitimacy, which, once earned, will lead to an ongoing role in state reimbursement policy discussions. Findings also suggest supplementing higher-level participation in stakeholder meetings and taskforce memberships with grass roots activities—e.g., press release, Op-Ed pieces, action alerts—that draw more widespread attention to an issue. Here, a division of labor may be useful with those advocates becoming expert in reimbursement partnering with other organizations capable of marshalling the resources necessary to conduct mass rallies, letter writing, email, and other broad-based campaigns.

IMPACT OF TRANSITION TO PART D FOR DULLY ELIGIBLE AGED MEDICARE BENEFICIARIES

As Medicare Part D was implemented (2006), there was concern that shifting from 51 state Medicare drug programs to random enrollment in 600+ private Low Income Subsidy plans might harm dually eligible Aged Medicare beneficiaries. To investigate this, we used claims and enrollment status for a 5% sample of full Medicare-eligible fee-for-service Medicare beneficiaries for two analyses. First, monthly population means for three outcomes (inpatient hospitalizations, acute days and emergency department visits) for 2001-2007 were analyzed using interrupted time series methods accounting for trends and seasonality. Second, multivariate panel analysis of beneficiary-level data estimated the effect of Part D on outcomes adjusting for beneficiary characteristics and trend; outcomes considered included hospital admissions, hospital days, emergency department utilization, physician encounters, nursing home entry and ambulatory-care-sensitive hospitalizations. The interrupted time series and the bulk of the multivariate analyses showed no negative effects for Part D. Multivariate full and subgroup analyses revealed small but statistically significant negative outcomes in only three instances: hospital admission rates for urinary tract infection; for beneficiaries diagnosed with chronic heart failure; and for nursing home residents. Several analyses showed improvement in outcomes. Conclusions: Although some dually eligible Aged Medicare beneficiaries may have had better access to prescription drugs under Medicaid prior to the implementation of Part D, this study adds to growing evidence that Part D “did no harm” for these beneficiaries. Beyond this null finding, the analyses demonstrate improved health care outcomes for some high risk subpopulations in the first year of the Part D program.

SESSION 1460 (SYMPOSIUM)

AGING AND ADVANCE CARE PLANNING

Chair: J. Harrison, Center for Gerontology & Health Care Research, Brown University, Providence, Rhode Island

Rates of advance care planning (ACP) in the general population are unknown, however, estimates are as high as 30% among older age community dwelling and insured Americans. Interventions to increase advance care planning have limited success. Recent attempts to incorporate voluntary ACP as a service offered during annual wellness visits for Medicare beneficiaries was met with rigorous debate and eventually removed. In general, the medical community, including hospice providers, supported the Medicare regulation for ACP, citing lower psychosocial distress on patients and their families and better quality of death. Self-reported barriers to ACP among patients include: confusion over the meaning of advance directives, anxiety about death, avoidance, procrastination, denial and lack of information. The purpose of this symposium is to assemble an expert panel to address issues in aging and advance care planning from the perspective of gerontological nursing, gerontological social work, emergency medicine, health services, and public policy. Each presenter will discuss issues related to aging and advance care planning in their area of expertise. The symposium will conclude with the distinguished discussant providing a general summary of the presentations and offering some final suggestions for making policy recommendations informed by data regarding advance care planning in old age.

PROMOTING ADVANCE CARE PLANNING THROUGH NATIONAL INITIATIVE

K. Black, College of Arts and Sciences, University of South Florida Sarasota - Manatee, Sarasota, Florida

National Healthcare Decisions Day is a nationwide campaign aimed at increasing advance care planning among adults throughout the country. This broad-scale initiative simultaneously seeks to encourage Americans to express their wishes regarding future healthcare decision making, rally a national media campaign to promote the importance of planning in advance for care, and mobilize national, state, and community organizations to develop a wide range of educational activities. The movement culminates in an annual day of multiple events throughout the country designed to inundate the public about advance care planning. The national event originated from the successful statewide Virginia Advance Directives Day’s inaugural event, conducted on April 18, 2006. Healthcare professionals are encouraged to participate in this growing initiative through a variety of activities and roles. A descrip-
BEYOND ADVANCE DIRECTIVES: PHYSICIAN ORDERS FOR LIFE-SUSTAINING TREATMENT (POLST)
M. Kapp, Center for Innovative Collaboration in Medicine & Law, Florida State University, Tallahassee, Florida
A tremendous amount of time and energy have been devoted over the past thirty-five years to lobbying state legislatures, educating physicians, and cajoling actual or potential patients regarding the creation and documentation of advance medical directives (both instruction directives and proxy directives). Sometimes, these efforts have resulted in better quality of medical care for particular individuals near the end of their lives. Often, however, advance directives prove to be unhelpful for a variety of reasons. It is time to move beyond traditional patient-authored advance directives to a more sophisticated approach to assuring that the patient’s personal values and preferences are honored: namely, POLST (Physician Orders for Life-Sustaining Treatment). This presentation will describe the practical, legal, and ethical foundations of the POLST Paradigm, its developmental status, and an example of the current efforts of professionals in one state (Florida) to implement the POLST Paradigm within that jurisdiction.

PLANNING FOR CARE AT THE END OF LIFE: A FAMILY PERSPECTIVE
M. Luptak, University of Utah College Social Work, Salt Lake City, Utah
Planning for care at the end of life is a dynamic multifaceted issue that affects the entire family constellation. Families often lack accurate and/or adequate information regarding end-of-life care planning: 1) as they begin care planning, 2) when someone is actively dying, and 3) during the bereavement process. Families also adopt widely varied approaches to end-of-life care planning such as avoidance of discussions, shared decision-making, and expression of desires to hasten death. This presentation will address end-of-life decision making as a social process between older adults and their family members. It will deepen understanding of the experiences of families as they plan for, make decisions about, and organize around end-of-life care; the needs that surface and the coping strategies employed to meet those needs; and how family members view professionals, services and systems involved in providing care.

TRUST, CARING, ADVICE, AND CONTACT: RELATIONAL ATTRIBUTES OF PERSONS NAMED TO ADVANCE CARE PLANNING ROLES AMONG WOMEN WITH RECURRENT CANCER
J. Harrison¹, M. Clark², J. Center for Gerontology & Health Care Research, Brown University, Providence, Rhode Island, 2. Brown University, Providence, Rhode Island
This presentation will focus on exploring the relationship between persons named to advance care planning roles (i.e., emergency contact, health care proxy, and primary support) and relational attributes in the social networks of women with recurrent cancer. We used an ego-centric network approach, to collect data from an ego respondent (women with cancer) about persons (alters) with whom they have relationships and direct contact. Five single-name-generating items were used to collect names and relationships of up to ten persons: Please name those who you (1) care about the most, (2) care the most about you, (3) trust the most, (4) are in most contact with either by phone, mail, or in person, and (5) would most likely go to for advice. We developed models to help explain how the different relational attributes were associated with the odds of an alter being selected to each advance care planning role.

SESSION 1465 (SYMPOSIUM)
COST-EFFECTIVE COMMUNITY LIVING FOR LOW-INCOME OLDER ADULTS: COORDINATING AFFORDABLE SENIOR HOUSING WITH HEALTH AND LONG-TERM SERVICES AND SUPPORTS
Chair: L. Alecxih, The Lewin Group, Falls Church, Virginia
Co-Chair: R. Stone, LeadingAge Center for Applied Research, Washington, District of Columbia
This symposium presents preliminary findings of an effort funded by HHS and HUD to develop options for the design of a demonstration of (targeted) coordinated housing, health, and long-term services and supports for older residents of subsidized housing and their surrounding communities. First, the session reviews the effort’s public policy rationale, including a strong interest in the development of innovative service delivery models that allow older adults to remain in their communities while also achieving program efficiency (savings) and positive outcomes (health and well-being). There is a specific interest in the role of subsidized housing as the platform for achieving these effects. Each of these policy interests warrants a stronger evidence base that a demonstration would provide. Next, this session describes the effort’s guiding conceptual framework as well as a summary of findings from six places that hold promise as models of coordinated housing, health, and/or long-term supports that could inform the larger demonstration’s design. Finally, the session describes the feasibility and utility of matching HUD and HHS administrative data to inform this effort (specifically) and to serve as a basis for using matched data to better describe and plan for the needs of aging residents in HUD subsidized housing.

POLICY RATIONALE FOR HOUSING WITH SERVICES TO ENHANCE AGING IN PLACE FOR OLDER ADULTS
R. Stone, LeadingAge Center for Applied Research, Washington, District of Columbia
This presentation summarizes the major policy issues driving this study. The first is an overarching policy interest in helping older adults—particularly those with limited financial resources—to successfully age in their communities. This concern is manifested in such policy efforts as the Obama administration’s “Community Living” initiative and the shift from institutional to home and community-based services supported by health care reform and ongoing state Medicaid reforms. A second driver is the commitment to higher quality at lower costs through improved care coordination and integration for chronically ill and disabled individuals, especially Medicare/Medicaid enrollees. The observed lack of affordable housing linked to services as a barrier to the success of the Money Follows the Person program illustrates the importance of this study’s focus. HUD’s growing recognition of the aging of its subsidized housing residents and recent efforts to reform its congregate housing programs is another key motivator.

A CONCEPTUAL FRAMEWORK FOR COORDINATED HOUSING, HEALTH CARE, AND LONG-TERM SERVICES AND SUPPORTS FOR LOW-INCOME OLDER ADULTS
R. Stone, M.F. Harahan, LeadingAge Center for Applied Research, Washington, District of Columbia
This presentation describes the conceptual framework developed by the research team to examine the role that affordable housing for lower-income older adults linked with health and long-term services and supports can play in facilitating successful, cost-effective “aging in community.” It combines various aspects of person-centered care and chronic care models but recognizes the unique contribution that congregate housing (where large numbers of older adults reside) can play in providing an efficient platform for delivering preventive services and health education, encouraging self-care management and achieving better service coordination and integration. This framework uses a population-based approach which attempts to address the needs and preferences of
all elderly residents in the property and surrounding community from the healthiest to those with chronic care and end of life concerns. It has guided the ASPE/HUD-funded project in its exploration of questions related to policy and practice challenges, targeting resources, and designing demonstration options.

AFFORDABLE SENIOR HOUSING WITH SERVICES MODELS & STRATEGIES
A. Sanders1, J. Carson2, 1. Leading Age Center for Applied Research, Washington, District of Columbia, 2. Peter Sanborn Place and Sanborn Homecare, Reading, Massachusetts

This presentation provides findings from six case studies of affordable housing with services models representing different auspices and strategies for helping low-income seniors to age safely in place. One of the six models is described in detail to illustrate how such a program is implemented within current policy and resource constraints. The team observed a wide range of programs from those offering a comprehensive set of wellness activities, primary health, personal care, and chronic care management to those that target services to individuals needing primarily long-term care services and supports. Operational challenges include assessing resident needs and targeting interventions effectively, establishing formal housing/community service provider partnerships, and identifying sustained funding for services. The potential for these models to produce Medicare and Medicaid savings as well as improve quality of care/life outcomes are discussed. Challenges to large scale replicability are also highlighted.

FEASIBILITY OF LINKING HUD AND HHS DATA TO STUDY OLDER ADULTS IN LOW-INCOME HOUSING
L. Alecxih1, G.J. Watson2, J. The Lewin Group, Falls Church, Virginia, 2. The Moran Company, Arlington, Virginia

To explore the potential benefits of linking low-income housing with services, it is essential to understand the health/functional status and service utilization of elderly residents in these settings. This study represents the first attempt to link HUD and HHS administrative data to describe this population. Data from HUD administrative files and the CMS Chronic Condition Warehouse (Medicare/Medicaid enrollment and claims, MDS and OASIS health and functional assessment data) were matched for elderly low-income housing residents in five cities with a large number of senior housing properties. Presenters describe the analytical and operational challenges associated with the data matching process and present preliminary findings including hospital, ED, physician, nursing home and home health use over the calendar year, use and spending for individuals with 12 months enrollment; and use and spending per member per month.

SESSION 1470 (SYMPOSIUM)

LESSONS FOR CLASS – WHAT EXISTING PUBLIC PROGRAMS CAN TEACH US
Chair: P. Nadash, Gerontology, University of Massachusetts, Boston, Massachusetts
Co-Chair: P. Doty, Department of Health and Human Services, Washington, District of Columbia
Discussant: S. Crisp, Boston College, Chestnut Hill, Massachusetts

Nations across the world have increasingly incorporated into social safety nets the need for long-term supports and services (LTSS) – personal assistance services and supports for frail elderly and younger persons with functional disabilities. In the US, however, public support for LTSS is limited to the poor and highly disabled. To address this gap, the Patient Protection and Affordable Care Act (PPACA) establishes a new, federally administered, voluntary public insurance program: Community Living Assistance Services and Supports (CLASS). However, written into the legislation were mandated design features that pose substantial challenges to its success: the program’s voluntary nature; its self-financing mandate; its $50 pd average benefit; its 3% cap on administrative costs; and its requirement to pay benefits in cash. This symposium brings together research on the lessons that existing public programs that pay cash to people who need LTSS have for CLASS. Pamela Nadash will present data from Austria, England, France, Germany, and the Netherlands on some key issues presented by CLASS, focusing on mechanisms to ensure that benefits are used appropriately—particularly, that workers are hired legally—while allowing beneficiaries the broadest discretion in using their cash benefit. In two further presentations, Mollie Murphy will present data from US programs regarding mechanisms for maximizing the purchasing power of consumers, and Lori Simon-Rusinowitz will present data on how consumers use this flexibility in ways that result in improved outcomes. Discussants Pamela Doty and Suzanne Crisp will offer federal and state policymaker perspectives.

CASH BENEFITS FOR LTSS IN EUROPE — ISSUES AND OPTIONS
P. Nadash1, P. Doty2, K.J. Mahoney3, 1. Gerontology, University of Massachusetts, Boston, Boston, Massachusetts, 2. ASPE/DHHS, Washington, District of Columbia, 3. Boston College, Chestnut Hill, Massachusetts

This paper presents data from Austria, England, France, Germany, and the Netherlands that address a key issue presented by CLASS: the level of accountability beneficiaries should be held to in how their cash benefit is used. What, if any, limits should be imposed? How might limits be operationalized in a cost-effective way, given the restriction on administrative costs imposed by the legislation and the goal of maximizing participant control? Among countries that allow unfettered use of cash, the use of illegal workers has become an issue; there are also fears of political backlash associated with the perceived misuse of funds and cost overruns. Conversely, other countries have imposed controls over the use of benefits via mechanisms such service plans and expenditure audits, or, as in France, via a payment mechanism that authorizes reimbursement of approved expenditures only. This paper discusses the issues associated with these policy choices.

HOW DID CASH AND COUNSELING PARTICIPANTS SPEND THEIR BUDGETS, AND WHY DOES THAT MATTER FOR THE CLASS ACT?
L. Simon-Rusinowitz4, D.M. Loughlin1, K.J. Mahoney2, 1. School of Public Health, University of Maryland, College Park, Maryland, 2. Boston College, Chestnut Hill, Massachusetts

The Community Living Assistance Services and Supports (CLASS) Act—a groundbreaking component of the Affordable Care Act—creates a publicly administered voluntary insurance program for long-term services. The CLASS program offers a cash (or cash equivalent) budget benefit that is designed to assist people with disabilities remain independent. Parallels between Cash and Counseling (C&C) and the CLASS Act include participant control over the budget, the ability to develop an individualized spending plan that includes assistive equipment, the ability to hire family members as workers, and the availability of a range of supports to help participants manage their responsibilities. This presentation will describe how participants used their cash allowance under the C&C option, and suggest how these findings can inform the development of the CLASS program.

GETTING PURCHASING POWER INTO THE HANDS OF PARTICIPANTS: LESSONS FROM PARTICIPANT DIRECTION PROGRAMS
K.J. Mahoney1, M.G. Murphy4, L. Simon-Rusinowitz1,2, D.M. Loughlin2, C.C. Parker1, J. Selkov1, 1. National Resource Center for Participant-Directed Services, Boston College, Chestnut Hill, Massachusetts, 2. University of Maryland, College Park, Maryland

Parallels exist between the CLASS Act and participant-directed home and community-based services offered to public program beneficiaries.
under the Cash and Counseling budget authority system and other participant direction programs. Implementation of the CLASS Act can be informed by decades of experience in these programs. Drawing on data and lessons learned from Cash and Counseling and other participant direction programs, researchers will discuss the challenges and benefits of different approaches for participants to access program benefit funds. Methods for getting purchasing power into the hands of participants must balance flexibility, choice and control, with fiscal accountability and tax compliance. We will review approaches including: a cash benefit, a debit card infrastructure customized to the program, and a professional Financial Management Service to manage funds and make payments. Researchers will outline appropriate approaches under various circumstances, ultimately recommending a model that includes aspects of each.

SESSION 1475 (SYMPOSIUM)

TO LIVE AND LET DIE: INSIGHTS INTO ENHANCING THE CARE OF OLDER PRISON INMATES
Chair, A. Bishop, Human Development and Family Science, Oklahoma State University, Stillwater, Oklahoma
Discussant: S.A. Eisenhandler, University of Connecticut-Waterbury, Waterbury, Connecticut

Offenders age 50 years and older represent one of the fastest growing age demographics across state prisons. This pattern is projected to persist throughout the coming decades. Continued growth in the number of persons who will grow old and die in prison represents an emergent challenge relative to how correctional institutions address the complex physical and mental healthcare needs of older inmates. Older prison inmates are primary consumers of mental and physical health services during imprisonment. A key policy concern is how to provide quality-of-care in a way that will sustain inmate health and well-being but not substantially increase cost to the public. Yet, many older inmates typically suffer from multiple chronic and life-threatening conditions which demand continued extensive long-term or end-of-life care. Most prisoners maintain a high degree of distrust toward correctional medical staff. As a result, their perception of support, meaning, and well-being continues to erode through the end-of-life. Gerontological investigation into the physical and mental well-being issues and end-of-life challenges faced by older prison inmates has remained limited. The purpose of this symposium is address key influences in the physical and mental health functioning of older prison inmates, as well as to address perceptions and strategies for insuring end-of-life care within the context of correctional institutions. Empirical results will be discussed relative to implications for addressing the physical and mental well-being of older prison inmates, as well as providing recommendations for improving research, policy, and end-of-life care practices within the correctional context.

DIRECT AND INDIRECT EFFECTS OF RELIGIOUS PRACTICES ON VALUATION OF LIFE THROUGH FORGIVENESS AND SOCIAL PROVISIONS AMONG OLDER INCARCERATED MALES
G. Randall1, A. Bishop2, 1. Family & Consumer Sciences, Bradley University, Peoria, Illinois, 2. Oklahoma State University, Stillwater, Oklahoma

To date, few studies have investigated the influence of religious practices, forgiveness, and social resources on incarcerated individuals’ attachment to their lives, or valuation of life (Lawton, et al., 2001). Based upon the literature, we hypothesized a mediational model linking religious practice (RP) to valuation of life (VOL) through the three subscales of the Heartland Forgiveness Scale (Self, Others, and Situations) and social provisions (SP). Data was collected from 261 prison male inmates, aged 45 to 82. The final model fit the data well: Satorra-Bentler χ2 (N=261; df=3) = 7.40; p = .06; CFI=.99; RMSEA=.08; SRMR=.02 (using FIML). Significant indirect effects of RP on VOL through Forgiveness of Others and Social Provisions, and of RP on SP through Forgiveness of Others, were found. Analyses controlled for age, race, sex, education, physical health, and mental health. Implications of the findings for those involved with prisoner care are discussed.

THE POWER OF FORGIVENESS: IMPACT OF SPIRITUAL, SOCIAL, AND EMOTIONAL VULNERABILITY ON THE PERCEIVED HEALTH OF OLDER PRISON INMATES
A. Bishop1, M.J. Merten1, G. Randall2. 1. Human Development and Family Science, Oklahoma State University, Stillwater, Oklahoma, 2. Bradley University, Peoria, Illinois

This study involved a pilot examination of N = 261 male inmates (M = 57.59 years, SD = 8.41) incarcerated in Oklahoma. Path analysis was used to explore an integrated model. Controlling for age, race, education, and type of crime, spiritual ambivalence (β = -.28, p < .01), loneliness (β = -.25, p < .01), and depressive affect (β = -.35, p < .01) were negatively associated with forgiveness. However, forgiveness was positively associated with perceived health (β = .29, p < .01). Forty percent of the variance in forgiveness was explained by spiritual ambivalence, loneliness, and depressive affect. Only 11% of the variance in perceived health was attributed to forgiveness. Spiritual ambivalence, loneliness, and depression diminish forgiveness, yet greater forgiveness improves health perceptions. This appears most salient in the association between depressive affect and perceived health. Results have implications relative to pastoral care services for older prison inmates.

DYING BEHIND BARS: DETERMINING THE CURRENT STATUS OF END-OF-LIFE CARE IN CONTEXTUALLY DIVERSE PRISONS
S.J. Loeb, J. Penrod, Penn State University, University Park, Pennsylvania

Managing the care, custody, and control of offenders who are aging and dying within prison walls is a source of growing concern for corrections officials. Dying in prison among inmates’ greatest fears. The purpose of this study is to describe the values, beliefs, and perceptions of end-of-life care held by stakeholders who care for or are administratively responsible for dying inmates. Descriptive qualitative findings from semi-structured interviews conducted with 188 Department of Corrections workers are presented. Data were analyzed using content and thematic analysis. Major themes that emerged were: Prison as Home; Special Dispensation; Facilitators and Barriers to End-of-Life Care; Images of Dying in Prison; Impact of Death on Others; Needed Improvements; and Comparisons with the Free World. These insiders’ perspectives provided baseline information that contributed to the development of an intervention toolkit of generalist strategies for end-of-life care in prisons.

SHAPING CHANGE: ENHANCING EOL CARE USING PARTICIPATORY ACTION RESEARCH METHODS
J. Penrod, S.J. Loeb, Penn State University, University Park, Pennsylvania

The complexity of providing healthcare to offenders is profound, as the mission of providing care is balanced with securing custody and maintaining control. Effective integration of enhanced end-of-life care in corrections requires that strategies be tailored to fit the context of dying in prison by addressing unique contextual barriers and the scope of influence exerted by non-clinicians. The purpose of this paper is to describe the application of Participatory Action Research (PAR) methods in order to shift complex organizational systems of six distinct state corrections institutions toward enhanced end-of-life care. Three cardinal principles of PAR are illustrated using a large federally-funded study as an operational exemplar: Developing a Collaborative Network; Promoting Co-Ownership; and Translation of Contextual Reality into System Change. Stimulating sustainable change in prison health care

64th Annual Scientific Meeting

by guest on 30 April 2018
FINDING A CAREER IN GERONTOLOGY THAT MATCHES YOUR PERSONALITY
S. Ruiz, IMPAQ International, Washington, District of Columbia
Finding a good career match is often a matter of finding a position that matches your personality and interests. After applying to dozens of ill-fitted assistant professor positions at the end of her doctoral program, Dr. Ruiz entered into a post-doctoral program in an attempt to expand her knowledge and skill base. At the end of that pursuit, she considered again careers in academia, government, and the private sector. This session will discuss the process of finding a career that fits into your overall goals and interests outside of academia. Currently, Dr. Ruiz works as a research associate in Long Term Care, managing national program evaluation projects and using her gerontology education in an applied setting. This symposium will also discuss the process and costs and benefits of a career in the private sector, as well as the value of staying linked to the academic community.

LIFE HAPPENS - THE IMPORTANCE OF BEING CREATIVE
K.B. Dassel, Arizona State University, Glendale, Arizona
Doctoral gerontology programs are designed to provide students with a specific skill set that prepares them for research careers, typically within an academic setting. Unfortunately, it is not common for programs to equip students with the skills that are needed to navigate the unexpected life events that impact one’s family and early career path. Such unanticipated events include a poor job market, personal or family health issues, relocation, pregnancy, or the decision to pursue a non-research career in gerontology. The purpose of this presentation is to discuss methods of creatively maneuvering unexpected life circumstances that can have a significant impact doctoral students and graduates career and family trajectories. In addition, non-traditional careers within the senior living industry, non-profit sector, and adjunct faculty roles will be explored.

EXPANDING YOUR OPTIONS

SESSIon 1480 (SYMPOSIUM)

WHAT CAN I DO WITH A GERONTOLOGY DEGREE?
Chair: C. Leach, National Cancer Institute, Bethesda, Maryland

An endless number of career trajectories are possible for gerontologists. With an aging population, our skills and areas of expertise are of high value to numerous industries. However, when in graduate school, we commonly are only exposed to tenure-track positions at doctoral level institutions. This type of position is an excellent fit for many trainees, but not always the best fit for everyone. This symposium will highlight many different potential career paths in the field of aging. We will also address ways to make yourself as marketable as possible for the career path you feel will suit you best. First, Dr. Ewen will talk about different types of careers in academia. She will emphasize the importance of position “fit” for faculty candidates, departments, and universities. Next, Dr. Leach will discuss alternative post-doctoral programs in the federal government, potential careers in the federal government, and career potential in the non-profit world. Dr. Ruiz will discuss moving from the academic track and a post-doctoral position to working for a health policy research firm. Finally, Dr. Dassel will address other non-traditional careers in aging and ways of being creative in your career path when unexpected life events change your original plans.

CAREER UTOPIA IS THE IVORY TOWER?
H. Ewen, Miami University, Oxford, Ohio

Current and prospective doctoral students are largely familiar with the academic career path due to their own educational experiences and the mentoring of faculty throughout their academic journeys. Students who are considering an academic career may follow several paths to get to their destination of “tenured professor”. Academic careers are competitive and may be aided through post-doctoral fellowships. However, there is not a one-size fits-all tenured position at the end of the tunnel. Each position is created for a purpose within a department and a university with specific goals and aspirations. Faculty jobs can be considered research-intensive, teaching-intensive, or balanced. This presentation will discuss the various academic tracks and the ways that gerontology and other interdisciplinary scholars are experiencing and changing the experience of academe.

EXPANDING NEW CAREER POSSIBILITIES IN GOVERNMENT AND THE NON-PROFIT WORLD
C. Leach, National Cancer Institute, Bethesda, Maryland

Throughout graduate school, Dr. Leach wasn’t 100% positive a tenure track academic position was the right fit. With little exposure available to alternative types of careers in aging, it was difficult to know what careers were even possible that would value the skills developed in a Gerontology PhD program. By selecting a post-doctoral program in the federal government, Dr. Leach was able to acquire additional training, skills, and networking opportunities that a typical academic post-doctoral program typically would not have allowed. This choice proved to be the ideal stepping stone to a position at a large non-profit organization with a nice balance between research and applied public health. This presentation will explore jobs in the federal government and non-profit world as well as ways of building a skill-set more applicable to careers outside academia.

ANTIOXIDANTS AND OTHER SUPPLEMENTS FOR THE ELDERLY: WHAT IS THE RIGHT RX?
Chair: S.N. Meydani, USDA Human Nutrition Research Center at Tufts University, Boston, Massachusetts
Co-Chair: L. Ceglia, USDA Human Nutrition Research Center at Tufts University, Boston, Massachusetts

I want to age gracefully! Help, what can I take!! There are hundreds of dietary supplements marketed to prevent the cellular damage that appears to accumulate and result in aging. This accumulated damage may prevent normal cellular function and thus result in declines in physiological function. We will hear from the experts in the oxidative stress field and from individuals working at the USDA/Tufts Human Nutrition Research Center in Boston. Find out which supplements may be helpful as we reach the golden years.

ANTIOXIDANTS AND THE ELDERLY – WHO NEEDS DIETARY SUPPLEMENTS?
K.J. Davies, Bio-Gerontology, University of Southern California, Los Angeles, California

The Oxygen Paradox is that oxygen is simultaneously essential for human life and yet toxic to our DNA, proteins, and lipids. We cope with this ‘oxidative stress’ by using antioxidant enzymes to minimize oxidative damage to our cells and tissues, and removing or repairing those cellular constituents that still do get damaged. We also consume dietary antioxidants that are major constituents of fruits and vegetables. Many of these ‘antioxidants’ actually work by regulating the expression of key genes, and not by directly preventing oxidation. Mounting evidence suggests that the effectiveness and, especially, the adaptability of damage...

agreement # 58-1950-7-707, NIA 1R01-AG 13975, and NIA 2R01 supplementation on immune response of elderly such as genetic back-
eases. Furthermore, factors that influence the efficacy of antioxidant 
ential antioxidant food components on reducing the decline of the 
complications, including death. Contributing to the increased incidence 
of infection with age is the well-documented age-associated dysregu-
ation of immune function. Adequate levels of antioxidants nutrients are 
necessary for maintaining the optimal function of the immune and 
flammatory responses; however, not all antioxidants behave the same 
way. This presentation will focus on the efficacy of essential and non-
ential antioxidant food components on reducing the decline of the 
immune response in the elderly and their susceptibility to infectious dis-
eses. Furthermore, factors that influence the efficacy of antioxidant 
supplementation on immune response of elderly such as genetic back-
ground and appropriate dose will be discussed. Supported by: USDA 
ment # 58-1950-7-707, NIA 1R01-AG 13975, and NIA 2R01 AG009140-10A1.

ROLE OF VITAMIN D IN SKELETAL MUSCLE

L. Ceglia, Tufts Medical Center, Tufts University, Boston, Massachusetts

Profound vitamin D deficiency can cause a proximal muscle weak-
ness of variable severity. Several randomized placebo-controlled clin-
cal trials indicate that vitamin D supplementation improves tests of 
muscle performance, reduces falls, and may impact on muscle fiber 
composition and morphology in vitamin D-deficient older adults. This 
session will review the genomic and nongenomic effects of vitamin D 
with respect to skeletal muscle development, proliferation and preser-
vation. The role of 1,25-dihydroxyvitamin D in signal transduction and 
calcium uptake and data on the vitamin D receptor gene knockout mouse 
will be reviewed.

THE ROLE OF NUTRITION SUPPLEMENTS IN AGE-
RELATED EYE DISEASE PREVENTION

E.J. Johnson, Jean Mayer USDA Human Nutrition Research Center on 
Aging at Tufts University, Boston, Massachusetts

Age-related macular degeneration and cataracts are major causes of 
visual impairment and blindness in the aging population. Attention has 
focused on efforts to stop the progression or to prevent the damage lead-
ing to these conditions. Modifiable risk factors include dietary compo-
nents. The nutrients that may be important are vitamins C and E, B vita-
mins, the carotenoids, lutein and zeaxanthin, zinc and omega-3 long 
chain polyunsaturated fatty acids. Given that the retina and lens suffer 
oxidative damage, the antioxidant nutrients are thought to be protective 
through their role as antioxidants. The B vitamins may lower homo-
cysteine levels and improve function of blood vessels in the eye. Addi-
tionally, lutein and zeaxanthin may provide protection as filters against 
light damage. Omega-3 fatty acids may affect membrane composition 
of the retina. This presentation will evaluate recent evidence for a role 
for dietary and supplemental intake of these nutrients in age-related eye 
disease prevention.
Within Couple Analysis of Physical Health and Psychological Distress

M. Thomeer, University of Texas at Austin, Austin, Texas

This study integrates theory on life course, mental and physical health, gender, and marriage to examine what degree an individual's psychological distress is influenced by his or her spouse's physical health. An important concept in the life course perspective is linked lives, the idea that individuals are interdependent and reciprocally connected on multiple levels. Previous research indicates that the concept of linked lives is particularly key in understanding the mental and physical health of married adults, as the health of one spouse is highly influential on the health of the other, and thus individual's health can be better understood by studying it in the context of the spouse's health. Past research identifies that psychological distress and physical health are closely correlated within individuals. This present study examines how influential these factors are across spouses, specifically the degree to which one spouse's physical health influences the other spouse's level of psychological distress, and tests three pathways which might explain this correlation. The pathways tested to explain how the respondent's physical health impacts the spouse's psychological distress are the amount of money spent on the respondent's healthcare, the physical health of the spouse, and the psychological distress of the respondent. Additionally, I pay particular attention to the degree to which these pathways vary according to gender, testing whether husbands or wives are more influential over their spouse's health. I use structural equation modeling to analyze couples from multiple waves of the Health and Retirement Survey (HRS).

The Relationship Between Marital Happiness and Physical Health: A Latent Growth Model Approach

L.A. Snyder, C.M. Proulx, Human Development and Family Studies, University of Missouri, Columbia, Missouri

Although research has explored the connection between marital quality and physical health in marriage, the existing cross-sectional research on this topic fails to consider the evolution of marital relationships as people age. To address this gap in the literature, this study investigated how adults' marital happiness in mid- to late life changed over a 12-year period and how those changes related to their current physical health. The study's sample included 708 married adults who participated in the last four waves (collected in 1988, 1992, 1997, and 2000) of the Marital Instability Over the Life Course panel study. Participants ranged in age from 38 to 76 at the last wave (M = 56 years) and were continuously married to the same spouse over the four waves used. The eleven marital happiness indicators included happiness with the spouse's understanding and love, as well as a comparison to other marriages. Physical health was a latent construct that included indicators of self-rated health, physical symptoms of illness, and mobility. Latent growth modeling in AMOS 18 assessed how changes in marital happiness are linked to current physical health. Our findings demonstrate that marital happiness significantly increased over the four waves as indicated by a positive slope value. This increase was positively related to health outcomes at the last wave of data collection. These results support the notion that long-term marriages can continue improving and offer insight into how evolving interpersonal relationships are related to health status in marriages in mid- to late life.

Session 1495 (Paper)

Mental Health in Later Life: Impacts of Gender, Race, and Age

More of Life's Pleasures with Age, But Less Benefit?

T. Gruenewald, Medicine/Geriatrics, University of California, Los Angeles, Los Angeles, California

A number of theoretical perspectives and empirical investigations converge to suggest that the seeking of positive life experiences and the associated experience of positive affect increases with advancing age. The goals of the current investigation were to examine age variations in the frequency and associated pleasure/reward of positive life experiences, as well as potential age differences in psychological and physiological well-being correlates of such experiences. Analyses utilized data from the Biomarker Substudy (n = 1,255; age 35 to 86; 55% female) of the Study of Midlife in the U.S., including data on the frequency of occurrence, and associated enjoyment/reward/pleasure, of 49 positive experiences in the last month in various life domains (social, leisure, productivity, relationship, relaxation), and depressed mood and levels of allostatic load (a multi-system index of physiological dysregulation), as indicators of mental and physical well-being. There were no significant age variations in the reported frequency of positive life experiences in the past month. However, greater age was associated with slightly greater pleasure/reward experience (older vs. younger B = .12, p < .01) conjunction with positive experiences. Greater frequency of positive experiences and associated pleasure/reward predicted lower levels of depressed mood regardless of age, however, an age variation emerged for physiological well-being, such that greater frequency of positive life experiences only predicted lower levels of allostatic load (B=−.70, p < .01) in young adults (age 35 to 49). Findings suggest that older adults may derive more pleasure, but younger adults may derive more physiological benefits, from positive life experiences.

Understanding Gender Differences in the Perception of Depression and Its Impact on Health and Well-Being: A Qualitative Study of U.S. Chinese Older Adults

E. Chang1, M.A. Simon1, E. Wong1, B. Wong1, X. Dong1, I. Rush1 University Medical Center; Chicago, Illinois, 2. Northwestern University Medical Center; Chicago, Illinois, 3. Chinese American Service League, Chicago, Illinois

Background: There exist vast knowledge gaps in assessing the psychological needs of U.S. Chinese older adults who reportedly have one of the highest suicide rates than any other racial groups nationwide. Specifically, suicide rate among older Chinese women is a higher leading cause of death compared with the general population. Investigating gender differences in how Chinese older men and women understand and perceive depression is a critical step in promoting the health of this rapidly growing population. Methods: A community-based participatory research approach was utilized to partner with Chicago Chinese community. Data were collected from semi-structured interviews with 41 men and 37 women over the age of 60. Results: Results show existing gender variations in the perception, perceived determinants, and perceived health outcomes associated with depression. For both genders, depression was most frequently identified through the feelings of helplessness. Feelings of getting bored, feelings of dissatisfaction with life, loss of interests in activities and suicidal ideation were also common descriptions of depression for both men and women. However, men were most likely to perceive social conflicts as contributing factors to depression, whereas women were most likely to report family conflicts. In addition, men most often associated worsening of health outcomes with the impact of depression, whereas women perceived worsening social isolation in association...
with depression. Conclusion: This study has implications for health-care professionals, social services agencies and policy makers. Understanding gender-related differences will contribute to better optimizing the prevention and intervention of depression among U.S. Chinese older adults.

SOCIAl TIES, AGE EFFECTS, AND SELF-IDENTIFICATION OF MENTAL HEALTH SERVICES NEEDS AMONG LATINO OLDER ADULTS

This study examined age differences in social ties with family or friends on perceptions about having a mental health condition and needing mental health services among Latino older adults. The Latino population aged 65 years and older will increase 224 percent by 2030. Yet, there is a large unmet need for mental health services within the Latino older adult population living in the United States. Previous research has explored the importance and benefits of social ties on health. However, few have examined it comparing older groups with younger counterparts and different types of social ties in relation to mental health in Latinos. We used logistic regression to examine relationships between social ties and identifying a problem as well as perceived need for formal mental health services among a national sample of community-dwelling individuals data from the National Latino and Asian American Survey (N=16,772,343). We compared Latinos 30-54 years of age with those 55 or older. The younger Latinos were twice as likely to identify having a problem and more likely to perceive a need for formal care (p<.05). Both young and old who frequently contact and tell family about problems were less likely to identify having a problem or perceive a need for formal mental health services (p<.05). In sum, this study highlights the significance of layered social connections and age on perceptions of mental health care among Latinos. Future studies of perceived need should account for intra-group differences and community interventions that incorporate social networks among older Latinos.

WHY DO OLDER AFRICAN-AMERICANS REMINISCE? AN EXAMINATION OF REMINISCENCE FUNCTIONS

J. Shellman, M.C. Brown, Nursing, University of Massachusetts Lowell, Lowell, Massachusetts

Reminiscence functions have been shown to be associated with positive mental health and well-being in certain older adult populations. However, there is little known regarding the functions of reminiscence and associations with mental health in older African-Americans. This paper will present the results of a descriptive survey study that examined the reminiscence functions in sample of 184 community-dwelling older African-Americans. Data were collected using the Modified Reminiscence Functions Scale (MRFS) (Washington, 2009) in two urban areas in the northeast. The 43 item Likert type scale was found to be culturally acceptable and understandable to this population. The sample was mostly female with an average age of 70.3. Sixty percent of the sample reported they had completed high school. Results show that these participants reminisce very often for the purposes to teach/inform, for conversation, and self-regard. On the other hand, respondents reported they rarely reminisced for the functions of death preparation, intimacy maintenance or bitterness revival. These findings support contextual data previously obtained through focus groups and key informant interviews (Shellman 2011). Furthermore, the results have implications for how reminiscence is facilitated with older African-American adults to improve their mental health and well-being. Recommendations for future reminiscence research with older African-Americans will be discussed.

RACIAL DIFFERENCES ON DEPRESSION MEASURES FOR OLDER WOMEN WITH CHRONIC ILLNESS

K.B. Adams, C.B. Warner, A.R. Roberts, J. Lee, M. Paek. Case Western Reserve University, Cleveland, Ohio

Measurement invariance between racial groups is a desired psychometric feature for depression screening scales. This study compared scores and individual responses of 138 African American and white older women with chronic illnesses on the 20-item CES-D and the 30-item Geriatric Depression Scale (GDS) to identify differences between the two racial groups on these two well-known depression screening measures. The sample included 44 black and 94 white women, ages 65 to 88, average age 72.7 years, who reported an average of 3.9 chronic illnesses. Using cut-offs of 11 points or higher (GDS) and 17 points or higher (CES-D) to indicate depression, these measures agreed on categorization for 86.8% of the sample. There was no significant difference between the racial groups on proportion categorized as depressed with the GDS, but black women were significantly more likely than white women to fall in the depressed category on the CES-D (p = .041). Of the black women, 50% were depressed by CES-D, in contrast to 35% by GDS, and in contrast to 32% of whites by either measure. Income adequacy, a dichotomous variable, was not differentially associated with depression on either measure; rather, women with inadequate income were more likely to be in the depressed category on both CES-D and GDS. Black women had significantly higher scores than whites on eight individual CES-D items, including the four positively-worded items. Differences between these two depression measures and the cultural significance of specific CES-D items will be highlighted in discussion.

SESSION 1500 (SYMPOSIUM)

DYADIC INTERRELATIONS IN COGNITIVE AND EMOTIONAL DEVELOPMENT ACROSS ADULTHOOD AND OLD AGE: EVIDENCE FROM EXPERIMENTAL, DAILY LIFE, AND LONGITUDINAL INQUIRY

Chair: C.A. Hoppmann, University of British Columbia, Vancouver, British Columbia, Canada
Co-Chair: D. Gerstorf, Department of Human Development and Family Studies, Pennsylvania State University, University Park, Pennsylvania
Discussant: K.S. Rook, University of California, Irvine, California

Development occurs in the context of close relationships such as marriage. This is particularly true in old age when networks decrease and spouses share long histories. This symposium brings together couple research in two domains of functioning that are key for successful aging: Cognitive and emotional functioning. Gerstorf and colleagues use longitudinal data from couples dealing with a debilitating disease that often challenges the emotional experiences of both partners. They demonstrate that daily-life emotional transmission between spouses accumulates over time and is also found in perceived stress and negative social interactions. Margrett and colleagues use cross-sectional data from Hispanic couples in the EPESE study to examine spousal successfull aging profiles. They demonstrate that very few Hispanic couples in the US were aging successfully, with both partners being free of impairments in physical, mental, and cognitive health. Rauers and colleagues combined an experiment with experience-sampling data to investigate two different facets of emotion-recognition abilities in younger and older couples. Differential age effects using these two empirical paradigms suggest that older adults’ emotion-recognition abilities rely more on knowledge-based, and less on sensory information. Hoppmann and colleagues examine associations between spousal goals and everyday problem solving using time-sampling data. They show that joint goals are positively associated with collaborative problem solving. Collaborative problem solving, although rated as very effective, is not always appreciated. The discussion by Karen Rook focuses on the potentials.
of examining socially interrelated aging trajectories using couple data and addresses the challenges that this line of research has to confront.

**SPOUSAL INTERRELATIONS IN EMOTIONS, PERCEIVED STRESS, AND NEGATIVE SOCIAL INTERACTIONS OVER ONE-MONTH AND SIX-MONTH PERIODS**

Aging researchers have become aware that chronic strains often trigger daily emotional transmissions between spouses. Less is known, however, about whether daily-life effects accumulate over time and generalize to perceived stress and negative social interactions. We applied change score models to three waves of data one month and six months apart from 228 couples (aged 47 to 92 years) where one spouse has osteoarthritis – an often debilitating disease that can challenge the emotional experiences of both spouses. Transmission of negative emotions of husbands to wives was found consistently, whereas the opposite predictive effects of wives for husbands were only observed over the six-month period. For perceived stress and negative social interactions, reciprocal lead-lag interrelations between spouses were found over the one-month period. Over the six-month period, however, it was only husbands’ perceived stress that was associated with increases in wives’ perceived stress. Our findings provide impetus for studying the role of perceived stress and negative social interactions as possible underlying mechanisms.

**SUCCESSFUL AGING PROFILES: CONGRUENCE AMONG OLDER MARRIED HISPANIC SPOUSES**

J. Margrett1, K. Daugherty1, G.I. Caskie2, D. Russell1, 1. Dept. of Human Development and Family Studies, Iowa State Univ, Ames, Iowa, 2. Lehigh University, Bethlehem, Pennsylvania

Successful aging is viewed as a multidimensional construct comprised of physical, mental, and cognitive health components. Research suggests that spouses influence one another’s functioning across these domains. Data from 553 married couples who participated in the Hispanic Established Populations for Epidemiologic Studies of the Elderly (EPESE) were examined. Individuals were categorized as successful agers based on four criteria: few depressive symptoms, social support availability, no impairment in instrumental activities of daily living, and unimpaired mental status. Considerable variation existed within the sample; thirty percent of males and 26% of females in the sample achieved this distinction at baseline. From a dyadic standpoint, spousal scores were significantly related (ICC = .30), but only 13% of couples achieved successful aging status for both spouses. These couples reported higher household income, but did not differ in marital length or contact with children. Discussion focuses on the longitudinal implications of spouses’ successful aging profiles.

**EMPATHIC ACCURACY IN YOUNGER AND OLDER COUPLES – RECONSIDERING AGE DIFFERENCES**

A. Rauers, E. Blanke, M. Riediger, Max Planck Institute for Human Development, Berlin, Germany

Evidence suggests that emotion-recognition abilities decline across adulthood. These findings typically stem from studies that investigated how accurately people interpret decontextualized emotional expressions. Such approaches thus specifically focus on people’s ability to interpret sensory cues. However, empathic accuracy in daily life may also rely on additional competencies (e.g., using contextual and knowledge-based information), which are disregarded by traditional paradigms. We propose that this may lead to an underestimation of emotion-recognition abilities, particularly in older adults. Fifty younger (20–30 years of age), and 50 older (70–80 years) couples completed a traditional emotion-recognition task and participated in experience sampling with mobile phones. Six times daily for 15 days, both partners simultaneously rated their own, and their partners’ current emotional states. Our results confirm that traditional paradigms selectively emphasize facets of emotion-recognition abilities that decline with aging, while disregarding other important facets that are more stable across adulthood.

**GOALS AND EVERYDAY PROBLEM-SOLVING IN OLDER COUPLES: EVIDENCE FROM DAILY TIME-SAMPLES**

C.A. Hoppmann, F. Blanchard-Fields, Psychology, University of British Columbia, Vancouver, British Columbia, Canada

Personal goals reflect changing themes of life and are meaningfully associated with everyday problem-solving and emotion regulation. Goals are rarely pursued in isolation and require the coordination of efforts within partnerships. The present study uses 10-day time-sampling information from 49 couples aged 60 to 85 to investigate how spousal goals relate to individual and collaborative everyday problem solving both within and between spouses. Findings show that spousal progress on self-focused goals is associated with elevated concurrent positive affect whereas progress on joint goals is related to decreased negative affect. Spouses with joint goals further reported high more collaborative problem solving than spouses with self-focused goals. Interestingly, collaborative problem solving was not always appreciated even though it is generally rated as very effective. These findings are in line with an interactive minds perspective which proposes that everyday problem solving requires both individual agency and interpersonal cooperation.

**SESSION 1505 (SYMPOSIUM)**

**EARLY AND MIDLIFE PREDICTORS OF COGNITION, DEPRESSION, HEALTH BEHAVIORS, AND MORTALITY IN LATE LIFE**

Chair: P. Herd, University of Wisconsin-Madison, Madison, Wisconsin

This set of papers will focus on life course predictors of cognitive functioning, depression, health behaviors, and mortality in late life. One set of papers will explore the links between life course measures of employment and job characteristics and cognitive functioning, health behaviors, and mortality at older ages. The second set of papers focuses on the links between attractiveness, gender, marriage and alcohol use and depression in late life. All papers utilize the Wisconsin Longitudinal Study, which is a 1 in 3 sample of Wisconsin high school graduates (and a selected sibling) from the class of 1957. This set of papers emphasizes the critical role of early and mid life factors, ranging from attractiveness and marital status to employment, and late life well-being, health, and mortality.

**MARITAL STATUS, GENDER, AND ALCOHOL USE IN LATE MIDLIFE**

T. Padovska, J. Melvin, University of Texas-Austin, Austin, Texas

We explore how marital status affects alcohol use in late midlife among men and women. Our findings reveal that although married women drink more frequently than unmarried women, both married and unmarried women consume roughly the same number of drinks on occasions when they drink. In contrast, married men drink as often as unmarried men, yet married men consume less alcohol than their unmarried counterparts on the days they drink. This study suggests that marriage may protect men from unhealthy levels of alcohol use, perhaps, because wives function as gatekeepers for their spouse’s alcohol consumption. Moreover, women experience stronger social constraints attached to alcohol use and may be more likely to drink with their husbands than by themselves. This study will improve participants understanding of how marital transitions in later life may affect gendered patterns of alcohol use and help identify marital status groups at risk for unhealthy drinking patterns.
ENVIRONMENTAL MASTERY AS A MEDIATOR BETWEEN MID-LIFE JOB CHARACTERISTICS AND LATER-LIFE HEALTH BEHAVIORS
A. Karraker, Sociology, University of Wisconsin-Madison, Madison, Wisconsin

Occupational status may impact health not only via economic resources such as income but also via psychosocial resources such as environmental mastery. Marmot (2004) and others have hypothesized that an individual’s position in hierarchies, including those related to employment, impact one’s sense of control over one’s life (i.e., environmental mastery). Not being able to control one’s environment in one area of life such as one’s work may lead an individual to feel a loss of control over other areas of life, such as one’s health. Health behaviors (e.g., obesity, smoking, alcohol use) may be particularly sensitive to an individual’s sense of environmental mastery because they are largely under the individual’s control. I examine first whether mid-life occupational status characteristics (e.g., frequent supervision by a superior) are related to environmental mastery. Second, I investigate the extent to which environmental mastery explains the relationship between mid-life job characteristics and later-life health behaviors.

EMPLOYMENT HISTORIES AND COGNITION IN LATE MID-LIFE

We examine the association between work histories and cognitive ability in late midlife (age 53-54). We construct latent trajectories of employment status and the number of different employers across midlife using life history data for the large cohort of men and women in the Wisconsin Longitudinal Study. Preliminary results indicate that those who were continuously employed between 36 and 53 but had more employment spells had higher cognitive ability than those who were continuously employed with a single employer. We observe this difference for both men and women and find that it primarily reflects differences in early-life cognitive ability – those with higher cognitive ability in adolescence were more likely to both change employers and have higher cognitive ability at midlife. Participants attending this session will have a descriptive understanding of relationships between employment trajectories and cognitive ability in late midlife and will be able to discuss mechanisms underlying these relationships.

PRETTY IN HIGH SCHOOL AND HAPPY IN OLD AGE: LINKS BETWEEN ATTRACTIVENESS AND EMOTIONAL WELL-BEING ACROSS THE LIFE COURSE
P. Herd1, K. Sliwinski1, D. Cant2, 1. University of Wisconsin-Madison, Madison, Wisconsin, 2. Rutgers University, New Brunswick, New Jersey

While there is evidence demonstrating links between attractiveness and financial well-being and marital prospects, especially for women, there is little evidence demonstrating whether attractiveness influences emotional well-being. Does attractiveness garner higher levels of emotional well-being? And if so, are there greater effects for women given evidence that women’s physical appearance influences how they are perceived and treated? We utilize the Wisconsin Longitudinal Study, a sample of 1 in 3 Wisconsin high school graduates from the class of 1957, to answer this question. The WLS includes attractiveness scores for participants, measured based upon yearbook photos from 1957. We find a strong association between attractiveness in high school and emotional well-being outcomes in late life (CESD, Self Acceptance, and Sense of Purpose in Life measured in 1992 and 2004), controlling for a host of potentially confounding variables. Further, we find that this association only holds only for women.

SESSION 1510 (SYMPOSIUM)

FAMILIES AND THE END OF LIFE
Chair: L. Winter, Thomas Jefferson University, Philadelphia, Pennsylvania

Family members of patients approaching the end of life assume a complex and central role, both exerting influence on the process and absorbing the impact of the patient’s experience. Because most patients are decisionally incapacitated at the end of their lives, family members usually make final treatment decisions. Their perceptions, fears, hopes, values, and attitudes toward the relative’s healthcare influence the goals of care, specific treatments, and the patient’s general experience of the end of life. In turn the patient’s end-of-life experience has a signal impact on the family’s well-being. Family experiences are therefore considered important indices of the quality of dying. Our symposium explores several aspects of families’ perceptions, preferences, and experiences surrounding a relative’s end of life, presenting a multidisciplinary perspective provided from psychology, sociology, social work, family medicine, and religious studies, using both qualitative and quantitative methodologies. Symposium presentations will examine sociodemographic predictors of accuracy in families’ substituted judgment, proxy decision making in relation to the elder’s current health, concerns of cancer patients’ families regarding settings of care, and explorations of the meaning that adult child construct surrounding a parent’s death and dying.

ELDERS’ AND PROXIES’ ACCEPTANCE OF LIFE-PROLONGING TREATMENTS IN FUTURE HEALTH SCENARIOS: EFFECTS OF THE ELDER’S CURRENT HEALTH
L. Winter, S.M. Parks, Thomas Jefferson University, Philadelphia, Pennsylvania

People in poor health tend to view life-prolonging treatments (e.g., tube feeding) as more acceptable than do healthier people, as a substantial body of research attests. Do proxies’ substituted judgments about their relatives’ treatment preferences show a similar tendency to vary with the elder’s health status? In a cross-sectional study of 202 elderly individuals and their proxies, preferences for 4 life-prolonging treatments in 7 health prospects were examined in relation to the elder’s current health status, operationalized as number of deficits in activities of daily living. Stronger preferences for life-prolonging treatments in worse-health prospects were expressed by both elders and proxies when the elders’ currently health was relatively poor. The interaction effect was stronger for proxies’ substituted judgment than for elders’ own preferences. We discuss implications for proxy decision making, especially on behalf of patients with long-term decisional incapacity.

FATHER’S END OF LIFE: TWO SISTERS’ PERSPECTIVES
S. Moss, M.S. Moss, Arcadia University, Glenside, Pennsylvania

End-of-life of an elderly person often has different meanings for adult children. Using qualitative ethnographic interviews with each of two bereaved adult daughters, we focus on an extreme example. The two sisters describe similar medical conditions of the father, but their perspectives on his end-of-life – as rooted in their past views of father and family — are strikingly different. For Jane, who had been the father’s primary caregiver, her father was her “hero and mentor”, and for Grace he was an “abusive alcoholic”. For Jane, at the end of his life, he “was still Dad”, and for Grace he was “an incontinent broke down man”. Both daughters agreed to remove father’s life supports, but with different rationales. The narrative of neither of these daughters represents the family experience as a whole. Discussion examines implications for providing terminal care and understanding family bereavement. (NIH 1R01AG031806)
MEANING AT THE END OF LIFE: A FAMILY AFFAIR
H.K. Black, Behavioral Research, Arcadia University, Glenside, Pennsylvania

Adult children find meaning in their elderly father’s end of life based upon the messages they received from parents about life and relationships, from childhood until the present. This presentation is based on research in which 30 families (a widow and two adult children) were qualitatively interviewed six to ten months after the death of the husband and father about his end of life. We collected in-depth data through formal ethnographic interviews and informal conversation. We offer a sampling of narrative accounts from the adult children about their fathers’ end of life. Accounts reveal how the perceived “we” of each family bears on children’s perceptions of the father’s end of life. Our findings show that the significance of what adult children learned from the father about love and the nature of family early in life, shapes their experience about his end of life.

FAMILY PERSPECTIVES OF PSYCHOSOCIAL CHALLENGES RELATED TO SETTING OF CARE AT THE END-OF-LIFE
M. Bern-Klug, University of Iowa, Iowa City, Iowa

The National Consensus Project includes psychological and social aspects of care as key domains for quality palliative care. Findings from qualitative interviews with 24 family members (mostly spouses and adult children) of nursing home residents with cancer document that psychological and social (psychosocial) issues related to the setting in which care was received proved to be common and often complex. Multiple transitions between and within settings (NH to hospital; hospital to hospice; NH to NH; home to NH) were disclosed by family members who were surprised by the transitions and often confused and disappointed, and also sometimes relieved. Common concerns include: social isolation of the older adult and (the relief when the resident’s social connections improved in the nursing home) and the capacity of the staff to meet needs. Anticipating, assessing, and addressing psychosocial issues is an important part of providing excellent palliative end-of-life care.

ACCURACY OF PROXIES’ SUBSTITUTED JUDGMENT: EFFECT OF THE ELDER’S GENDER
S.M. Parks, L. Winter, Thomas Jefferson University, Philadelphia, Pennsylvania

The present study of elders and their proxies explored sociodemographic predictors of accuracy in proxies’ substituted judgment, defined as the difference between elders’ preferences for life-prolonging treatments (e.g., CPR, tube feeding) and their proxies’ substituted judgment. In a survey of 202 community-dwelling elder-proxy dyads, elders expressed their preferences for 4 life-prolonging treatments in each of 7 scenarios, and proxies’ substituted judgment was elicited for each treatment and scenario. Elders’ gender emerged as the sole sociodemographic characteristic associated with accuracy of substituted judgment. When the elder was female, inaccurate substituted judgment (i.e., elder-proxy discordance) was more than four times larger than when the elder was male. Thus, proxies of female elders are much more likely to be inaccurate than are men’s proxies. Possible reasons for this dramatic difference are discussed.

SESSION 1515 (SYMPOSIUM)

GENDER & AGING: AGEISM, HEALTH, AND CAREWORK
Chair: M. Loe, soan dept, colgate university, Hamilton, New York
Co-Chair: A. Brooks, Boston College, Boston, Massachusetts
Discussant: A. Brooks, Boston College, Boston, Massachusetts

This symposium focuses on the gendered realities of aging and the life course, with particular focus on ageism, health, and care-work. Coming from a feminist gerontology tradition, this symposium centers research on the gendered structural realities related to age, aging, and ageism, as well as elder agency in the context of health, healing, and grandparenting. Margaret Morganroth Gullette and Margaret Cruikshank will review feminist gerontology past and present, and discuss new and old iterations of ageism as it intersects with gender. Kelly Joyce and Crystal Moore will share their research on gendered patterns of illness and self-care, with a focus on autoimmune disease and alcohol-use, respectively. And Madonna Harrington-Meyer will discuss her research on work/family balance among grandmothers. This session aims to promote and achieve constructive dialogue and cross-fertilization among diverse perspectives, scholarship, and empirical research on the topic of gender and aging.

GRANDMOTHERS AT WORK: JUGGLING WORK AND GRANDCHILDREN ACROSS THE LIFECOURSE
M. Harrington Meyer, Syracuse University, Syracuse, New York

We tend to think of balancing work and family as something only relatively young families contend with, yet many middle-aged grandmothers are employed and proving routine childcare for their grandchildren. This paper uses a life course perspective to explore the strategies of, and impacts on, US grandmothers who are juggling work and grandchildren. I draw on data from my Grandmas at Work Study, a convenience sample of 40 in-depth interviews with US grandmothers who juggle working and minding their grandchildren. I find that while nearly all grandmothers are pleased to mind the grandchildren, many are re-adjusting work schedules, using vacation and sick leave time, gutting retirement accounts, postponing retirement, and caring for their frail older parents. The grandmothering is intense in part because many grandmothers reported having more security and flexibility on the job than their daughters.

OVERCOMING THE TERROR OF FORGETFULNESS: EXPECTATIONS AND CARE-GIVING AND THEIR CULTURAL CONTEXTS
M.M. Gullette, WSRC, Brandeis, Women’s Studies Research Center, Brandeis, Newton, Massachusetts

What historical and gendered factors make memory loss worse? We are constantly told that women live longer than men: women will thus be more subject to Alzheimer’s and cognitive losses; and women will be the “expensive” ones in the ongoing and virulent national debate over end-of-life care. What role do expectations play in the national Terror of Forgetfulness? Does sexist ageism worsen actual cognitive losses when they begin to appear, and if so, how? How might these cultural and personal factors affect filial care-givers, and how can we overcome them? Based on care-giving for her own mother in her nineties, and research on the latest theories of personhood in later life, Margaret Morganroth Gullette, noted age critic and author most recently of Agewise: Fighting the New Ageism in America, will describe the interaction between the personal and the contextual in these various scenarios.

RE-EXAMINING 1980S FEMINIST WORK ON AGING: MACDONALD, RICH, AND COPPER
M.L. Cruikshank, center on aging, university of maine, Corea, Maine

Early feminist challenges to ageism in the 1980s assumed that ageism was the central issue for old women and assumed further that “old” was a core identity. Work by feminist gerontologists in the past decade, apparently moving beyond ageism, has tended to see “old” as a fluid, changing, and indeterminate identity. A re-examination of books by Barbara Macdonald, Cynthia Rich, and Baba Copper illustrates the relevance of their work. Current on women’s aging considers such topics as women’s feelings about their bodies, the massive overdramming of old women, the problems with mainstream gerontology’s embrace of “successful aging” and narrative gerontology all hark back to ageism. The radical critiques of Macdonald, Rich, and Copper may find a more receptive audience today than in the 1980s. Participants in this session
will be able to contrast early feminist work on women’s aging with more recent work.

ALCOHOL USE AND QUALITY OF LIFE INDICATORS AMONG SWEDISH AND AMERICAN ELDERS

L. Pitzer, 1 A. Jakobsson, 2 K. Wilkinson, 1 Skidmore College, Saratoga Springs, New York. 2 University of Gothenburg, Gothenburg, Sweden

Recent research reveals that alcohol misuse is among elders in the United States and Sweden is a public health concern (Blazer & Wu, 2009; Hallgren et al., 2009). Alcohol misuse is related to physical and psychological co-morbidities that can shorten quantity and decrease quality of life (Lin et al., 2010). This research examines the relationships among alcohol use and misuse and quality of life variables (depression, life satisfaction, self-described health status) among a sample of American (n=285) and Swedish (n=620) elders age 65 and older. Data were collected via mail survey (American) and face-to-face interviews (Swedish). Findings are discussed vis-à-vis culture and gender to develop a better understanding of late-life drinking patterns and correlates. Implications for public health are presented.

GENDER, AGING, AND AUTOIMMUNE ILLNESSES

K. Joyce, Sociology, College of William and Mary, Williamsburg, Virginia

The National Institutes of Health estimates that autoimmune illnesses affect approximately 5 to 8% of the U.S. population. Autoimmune-related illnesses (for example, Multiple Sclerosis, Lupus, Sjogren’s Syndrome) are chronic illnesses where one’s immune system is triggered against the cells of one’s own body (instead of disease). Drawing on in-depth interviews with forty participants and fieldwork, this paper examines how people’s sense of aging changes (or does not change) when living with autoimmune illness. How aging is a gendered process will also be discussed. Men and women encounter different societal expectations about gender and aging; how people negotiate these in relation to chronic illness will be explored in this talk. Social scientific research on autoimmune illnesses has focused on diagnostic pathways; in-depth analysis of aging with autoimmune illnesses has not been the focus of scientific inquiry.

SESSION 1520 (SYMPOSIUM)

HIGHLIGHTING STRESS AND RESILIENCE WITH BURST DATA: THE NOTRE DAME STUDY OF HEALTH AND WELLBEING

Chair: L. Pitzer, Univ Notre Dame, Notre Dame, Indiana
Co-Chair: S. Scott, Georgia Tech, Atlanta, Georgia
Discussant: A.D. Ong, Cornell University, Ithaca, New York

Innovative methods to understand individual differences in stress and resilience processes include the use of daily diary data. The major objective is to highlight the Notre Dame Study of Health and Well Being (NDHXB), a five-wave longitudinal study of mid- and later-life that includes three separate 56-day daily bursts. Four papers explicate successful methods used to examine daily burst data, specifically pertaining to stress and resilience processes as they relate to well being, stress-management, and affective synchrony. B. R. Jackson and C. S. Bergeman examine daily variability in stress appraisal and how it impacts longitudinal perceived stress and health and well being. L. Pitzer, C. S. Bergeman, and S. B. Scott explore how positive emotions help loosen the hold that negative affect gains during times of stress through examination of different levels synchrony between daily positive and negative affect. M. A. Montpetit, C. S. Bergeman, and K. H. Banks use dynamical systems analysis to understand resilience and individual differences in stress management as related to race and discrimination, and C. S. Bergeman, P. R. Deboeck, and L. Pitzer present the Reservoir Model, a useful perspective to explaining the accumulation of stress over time, how people simultaneously take steps to decrease the effects of stress, and how this may be used to predict well being. Anthony Ong (discussant) will integrate and emphasize the different methods to assess daily diary data and how each brings a unique (not better) perspective to the concepts of stress and resiliency.

RESILIENCE IN MID- AND LATER LIFE: THE ROLE OF AFFECTIVE SYNCHRONY

L. Pitzer, 1 C.S. Bergeman, 2 S. Scott, 1 Univ Notre Dame, Notre Dame, Indiana, 2 Georgia Tech, Atlanta, Georgia

Resilient individuals optimize positive emotions to loosen the hold of negative affect during stress. Using the NDHXB 56-day burst assessments from distinct samples of midlife (N = 326) and later life (N = 305) adults, analyses replicate and extend the model of Affective Synchrony. Assessment of individual differences in covariation of affect in adulthood (represented by patterns of a-synchrony, synchrony or desynchrony), and how different contextual (stress) and individual (ego resilience) factors account for individual differences was explored through multilevel modeling. Results indicate that the nomothetic average of the synchrony scores indicates a negative (de-synchronous) relationship between positive and negative affect; however, significant individual differences in synchrony suggest synchronous, a-synchronous, as well as de-synchronous patterns among associations between positive and negative affect for individuals. Trauma, perceived stress, ego resilience, and emotion regulation explain variability in synchrony scores. Implications of this study on resilience and recovery in adulthood will be discussed.

THE UPS AND DOWNS OF DAILY STRESS: HOW VARIABILITY IN STRESS APPRAISAL PREDICTS GLOBAL WELL-BEING

B. Jackson, C.S. Bergeman, Psychology, University of Notre Dame, South Bend, Indiana

Day-to-day variability in stress appraisal has emerged as an important index of overall well-being, and is a potential predictor of well-being trajectories over time. The Year 1 daily burst of the NDHXB (N=696; aged 31-91 years) was used to investigate the impact of day-to-day variability in appraisals of positive and negative life events on 1) global perceived stress, somatic health, and psychological health at Year 1, and 2) trajectories of these global variables across the 4 yearly assessments. Age was included as a moderator of all effects. Results: variability in both positive and negative appraisals is predictive of all well-being outcomes in the same year; variability in the appraisal of daily negative events significantly predicted the trajectory of somatic health, moderated by age. Findings highlight the importance of examining daily stress variability—in addition to mean levels—in understanding the impact of daily stress on health and well-being over time.

RACIAL IDENTIFICATION, DISCRIMINATION, AND STRESS-RECOVERY: A DYNAMICAL SYSTEMS APPROACH

M. Montpetit, 1 C.S. Bergeman, 2 K. Hudson Banks, 1 Illinois Wesleyan University, Bloomington, Illinois, 2 University of Notre Dame, Notre Dame, Indiana

Dynamical systems approaches allow researchers to capture the process of resilience, defined in terms of stress-resistance and stress-recovery, in real time. Using data collected from 176 older adults (Mage=68.5 years, SDage=5 years) in the NDHXB, the current study investigates individual differences in stress-management as they relate to individuals’ identification with their endorsed racial group, the experience of discrimination, and the interaction of the two. Results indicated that there is a significant interaction between identification with one’s racial group and discrimination on stress-management, with greater identification and more reported discrimination relating to increased stress-recovery over 56-days. Although seemingly counter-intuitive, the
results corroborate extant literature: people for whom race is more central also report more experiences of discrimination; those individuals, however, tend to be at lower risk for negative mental health outcomes in the face of discrimination. Implications for both developmental and clinical science will be discussed.

THE EFFECTS OF STRESS REACTIVITY AND STRESS RECOVERY ON LONGITUDINAL WELL-BEING OUTCOMES: THE RESERVOIR MODEL OF PSYCHOLOGICAL CAPACITY

C.S. Bergeman1, P.R. Deboeck2, L. Pitzer3, 1. Univ Notre Dame, Notre Dame, Indiana, 2. University of Kansas, Lawrence, Kansas

We describe the Reservoir Model, which assess both the current state of a system and the way in which the system is changing. If we consider stress, the contents of the reservoir depend on the number and magnitude of incoming events as well as their dissipation. That is, stressors can “add up” over time, but it is also possible to take steps to “blow off steam,” resulting in varying “levels” in the reservoir. This model provides two parameters: one that describes the average magnitude (or level) of the perceived events (e.g., stress reactivity) and the person’s ability to dissipate negative events (e.g., stress recovery). The model is applied to the daily reports from the NDHWB. Parameter estimates representing stress reactivity and stress recovery are then used to predict psychological and subjective well-being, not only at the same point in time, but 2, 3, and 4 years later.

SESSION 1525 (SYMPOSIUM)

MORE THAN CAREGIVING STRESS: LESSONS FROM THE DESIGN, MEASURES, AND RESULTS OF CAREGIVER-SOF STUDY

Chair: L. Fredman, Epidemiology Department, Boston University School of Public Health, Boston, Massachusetts
Co-Chair: A. Hemmesch, Epidemiology Department, Boston University School of Public Health, Boston, Massachusetts
Discussant: J.E. Gaugler, University of Minnesota, Minneapolis, Minnesota

Studies of the health effects of caregiving have evolved from describing caregivers’ psychological well-being, to investigating biomarkers and physical health outcomes, and to identify factors that modify health consequences of chronic stress. These studies provide information not only about caregiving outcomes, but about factors that influence the quality of life in older adults. For caregiving studies to yield these broad results, researchers must consider sampling frames, study designs and measures. In this symposium, we will use the Caregiver-Study of Osteoporotic Fractures (Caregiver-SOF) as an example of a study that branched from caregiving into other areas. Caregiver-SOF is a prospective cohort study of 1069 older women participants from the SOF study (375 caregivers and 694 non-caregivers at baseline). Participants had 5 interviews between 1999-2009, generally spaced at 12- and 18-month intervals. Study design features included establishing a classic cohort sample of caregivers and non-caregivers; utilizing a longitudinal design in which caregiver status was re-assessed for all participants at each follow-up interview; documenting changes in caregiving and other time-varying variables; and including epidemiologic measures of physical, cognitive, and self-reported health status that were applicable to non-caregivers as well as caregivers. Presentations provide examples of how Caregiver-SOF bridges several areas of gerontology: cognitive functioning in continuous caregivers compared to former caregivers and non-caregivers; prospective associations between performance-based functioning and incident ADL/IADL limitations, mortality, and other health outcomes; and the short-term effects of caregiving transitions on perceived stress. Discussion will address the methods and contributions of studies on health effects of caregiving.

BETTER COGNITIVE FUNCTIONING IN CONTINUING CAREGIVERS: SUPPORT FOR THE HEALTHY CAREGIVER HYPOTHESIS

R.M. Bertrand1, J. Saczynski2, C. Mezzacappa3, K. Ensrud4, L. Fredman1, 1. Health Policy, Abt Associates Inc, Cambridge, Massachusetts, 2. University of Massachusetts Medical School, Worcester, Massachusetts, 3. Boston University, School of Public Health, Boston, Massachusetts, 4. University of Minnesota School of Medicine, Minneapolis, Minnesota

Most studies of caregiving outcomes focus on physical health rather than cognitive functioning. Our previous research found that older caregivers had better baseline health than non-caregivers, and those who continue caregiving had better functional health than other respondents, supporting the ‘Healthy Caregiver Hypothesis’. We tested this hypothesis in cognitive function using measures of memory (Hopkins Verbal Learning Test) and processing speed (Digit Symbol Substitution Test) at the third Caregiver-SOF interview. Participants were classified as continuous caregivers (n=194), former caregivers (n=148) or continuous non-caregivers (n=574). In adjusted analyses, continuous caregivers had significantly better memory than former caregivers and continuous non-caregivers (mean = 18.4, 16.6, and 15.8, p<0.001) and faster processing speed (mean = 35.9, 35.6, and 34.4, p=0.09). These results utilized caregiver status from multiple interviews, extended findings from physical health outcomes, and suggest that older women who continue caregiving may be cognitively, as well as physically healthier than their peers.

CHANGE IN PERCEIVED STRESS IN THE YEAR FOLLOWING CAREGIVING TRANSITIONS, A MIXED-MODEL APPROACH

C. Mezzacappa1, T. Heeren1, K. Ensrud2, L. Fredman1, 1. Epidemiology, Boston University School of Public Health, Boston, Massachusetts, 2. University of Minnesota, Minneapolis, Minnesota

Most studies of caregiving transitions focus solely on the cessation of caregiving and suffer from low statistical power. In Caregiver-SOF, transitions into and out of caregiving were documented for all participants over 4 follow-up intervals, allowing analyses of multiple transitions and comparisons to participants who continued caregiving or non-caregiving. We observed 426 transitions among the 1042 Caregiver-SOF participants with > 1 follow-up interviews: 178 care recipient deaths (42%), 44 nursing home placements (10%), 128 cessations for other reasons (30%), and 76 caregiving initiations (18%). Multiple regression analyses found Perceived Stress Scale (PSS) scores decreased in caregivers whose care recipient died (adjusted mean PSS change = -3.32, p<0.001) or was placed in a nursing home, while it remained stable in those who continued caregiving and increased in non-caregivers who became caregivers. Stratified analyses revealed significant differences by caring for a spouse versus a non-spouse, and by caregiver age.

PHYSICAL PERFORMANCE ASSOCIATIONS WITH INCIDENT ADL/IADL LIMITATIONS AND MORTALITY AMONG OLDER WOMEN

J. Lyons1, J. Keysor1, T. Heeren1, J.A. Cauley1, M. Hochberg3, L. Fredman1, 1. Boston University, Boston, Massachusetts, 2. University of Pittsburgh, Pittsburgh, Pennsylvania, 3. University of Maryland, Baltimore, Maryland

Prospective cohort studies on health outcomes increasingly include standardized performance-based assessments of physical function that are easily replicable and comparable across different populations, whereas studies of caregiving rely more on self-reported measures, such as basic and instrumental Activities of Daily Living (ADLs/IADLs). Caregiver-SOF included both self-report and performance-based measures at each interview. We analyzed associations between functional performance and health outcomes over 7 years in 491 Caregiver-SOF participants without ADL/IADL limitations at baseline. In Cox Pro-
portional Hazards analyses, participants with lower summary performance scores (i.e., poorer functioning) had increased risk of incident limitations (adjusted Hazards Ratio, HR: 1.25, 95% Confidence Interval, CI: 1.09-1.45) as well as mortality (HR: 1.20, CI: 0.92-1.59). These analyses explored epidemiologic questions about physical functioning in Caregiver-SOF, and considered caregiving as a covariable. The results suggest that the relationship between functional performance and health outcomes that has been observed in younger populations applies to older populations.

**SESSION 1530 (SYMPOSIUM)**

**ONE SIZE DOES NOT FIT ALL: DIFFERENTIAL TRAJECTORIES OF LATE-LIFE CHANGE**

Chair: J. Morack, Pennsylvania State University, State College, Pennsylvania
Co-Chair: D. Gerstorf, Pennsylvania State University, State College, Pennsylvania
Discussant: D. Dannefer, Case Western Reserve University, Cleveland, Ohio

Lifespan researchers have long been interested in the diversity of developmental pathways throughout adulthood and old age across domains, time, and persons. The major objective of this symposium is to bring together a collection of papers showcasing contemporary approaches of inquiry into differential development and its antecedents, correlates, and consequences. Using pooled data from four Swedish longitudinal studies of aging, Morack and Gerstorf apply latent profile analysis to identify groups of old and very old adults who experience different trajectories of late-life changes in the domains of social integration, well-being, and cognition. Ryan and Smith utilize group-based trajectory modeling of longitudinal data obtained in the Health and Retirement Study to identify subgroups of individuals with differential trajectories of positive and negative well-being over a period of 10 years. Berg and Johansson apply multi-level modeling to six-year longitudinal data to examine health predictors of differential patterns of late-life change for the personality facets of extraversion and neuroticism. Aldwin and colleagues employ latent class growth analysis to data collected from men in the Normative Aging Study. They identify several distinct patterns of stressful life event trajectories over 17 years and link those to differential mortality hazards. Dannefer will integrate the four papers to recognize within the life-span developmental model.

**DISTINCT TRAJECTORIES OF SUBJECTIVE WELL-BEING DURING OLD AGE: STABILITY, LABILITY AND CHANGE**

L.H. Ryan, J. Smith, Institute for Social Research, University of Michigan, Ann Arbor, Michigan

The maintenance of subjective well-being contributes to healthy longevity. However, less is known about whether sub-groups of individuals share similar trajectories of well-being in late life. We examined this question using 10-year longitudinal data from the AHEAD cohort between 1998 and 2008 (N = 1375; age 75 – 97 in 1998; 65% women). Participants were interviewed at 2-year intervals (potentially six occasions). We applied longitudinal group-based trajectory modeling to identify differential trajectories in self-reported depressive (psychosomatic) symptoms and in positive well-being. In addition, we examined demographic and psychosocial covariates (age, education, gender, health, personality, loneliness, life satisfaction, marital status) to differentiate trajectory group type. Initial analyses reveal multiple distinct trajectory groups in terms of level and pattern variability over time. Covariates also significantly differentiated trajectory group membership. Implications for theories of differential aging and health are discussed.

**STRESS TRAJECTORIES AND MORTALITY AMONG OLDER MEN: FINDINGS FROM THE VA NORMATIVE AGING STUDY**

We examined long-term patterns of stressful life events (SLE) and their impact on mortality contrasting two theoretical models: allostatic load (linear relationship) and hormesis (inverted U) in 1443 NAS men (45 – 88 in 1985) with at least two reports of SLEs over 17 years (total observations = 7,634). Using a zero-inflated Poisson modification of a proportional Hazards analyses, participants with lower summary performance scores (i.e., poorer functioning) had increased risk of incident limitations (adjusted Hazards Ratio, HR: 1.25, 95% Confidence Interval, CI: 1.09-1.45) as well as mortality (HR: 1.20, CI: 0.92-1.59). These analyses explored epidemiologic questions about physical functioning in Caregiver-SOF, and considered caregiving as a covariable. The results suggest that the relationship between functional performance and health outcomes that has been observed in younger populations applies to older populations.

**DISTINCT PROFILES OF DIFFERENTIAL LATE-LIFE TRAJECTORIES ACROSS MARKERS OF COGNITIVE, SOCIAL, AND WELL-BEING FUNCTIONS**

J. Morack, D. Gerstorf, Pennsylvania State University, State College, Pennsylvania

Lifespan research has long been interested in intra-individual changes within and structural relations between domains of functioning. Using a more variable-oriented approach, research in this area has revealed seminal insights into the intricacies of human development. In our study, we opted for a more subgroup-oriented approach using multiple-indicator information at the person level. To do so, we applied latent profile analysis to eight-year longitudinal data pooled across four Swedish studies (N = 1,008; 70-95 year olds; 61% women). Results revealed four psychological profiles with distinct psychological trajectories across indicators of cognitive, social, and well-being functions. These groups were also differentiated by cross-disciplinary characteristics that may have served as antecedents, correlates, or consequences of the profile trajectories (e.g., sociodemographics, functional limitations, mortality). We discuss the promises and challenges of a systemic-wholistic perspective for studying differential aging.
SESSION 1535 (SYMPOSIUM)

RECRUITING AND RETAINING MINORITY OLDER ADULTS FOR A LIFESTYLE HEALTH PROMOTION TRIAL: LESSONS LEARNED
Chair: E. Tanner, School of Nursing and Center on Aging and Health, Johns Hopkins University, Baltimore, Maryland
Co-Chair: J.M. Parisi, School of Nursing and Center on Aging and Health, Johns Hopkins University, Baltimore, Maryland
Discussant: K.E. Whitfield, Duke University, Durham, North Carolina

Recruiting and retaining minority older adults in health promotion intervention research is essential for identifying interventions which will reduce population health disparities. Unfortunately, most health promotion research has been conducted with middle-aged, non-minority populations, limiting knowledge about factors impacting recruitment and retention of minority older adults, especially in lifestyle health promotion intervention studies. We will review lessons learned from the Baltimore Experience Corps® Trial (BECT), an experimental evaluation of Fried’s social model of health promotion, which tests the health and well-being effects of high-intensity volunteering. The session will begin with a discussion of the effectiveness of evidence-based strategies for recruiting, enrolling and retaining of 702 minority older adults (91% African American, 85% women) in the trial. The second presentation will highlight findings from a trial sub-study which examined volunteer-associated benefits and burdens impacting retention at key stages across the first year of volunteer service, illuminating both the challenges and rewards of high-intensity volunteering and links with psychological and physiological well-being in older adults. The final presentation will provide an overview of individual and environmental factors which affect the volunteer role experience and retention in the intervention, gleaned from focus groups with BECT volunteers.

VOLUNTEER BENEFIT AND BURDEN EXPERIENCES: LINKS TO PSYCHOLOGICAL AND PHYSIOLOGICAL WELL-BEING
T. Gruenewald, Medicine/Geriatrics, University of California, Los Angeles, Los Angeles, California

The Experience Corps (EC) volunteer role is designed to provide older adults with social, cognitive, and physical activity thought to promote psychological and physical well-being, as well as the opportunity to engage in a meaningful social role, fulfilling generative desires. Despite the enormous potential benefits of EC volunteering, engagement in such a high-intensity volunteer role might also present considerable challenges for older adults. The BECT Volunteer Experiences Substudy was conducted to provide an in-depth examination of both the rewards and challenges of EC volunteering during the first volunteer year. This presentation highlights volunteer-associated daily burden and benefit experiences during key stages from the beginning to the end of the school year and associations between such experiences and affective and physiological well-being. Analyses help to elucidate characteristics of volunteer activity which help promote, or in some cases hinder, health and well-being benefits, and impact volunteer retention in the intervention.

RECRUITING, ENROLLING AND RETAINING PARTICIPANTS IN THE BALTIMORE EXPERIENCE CORPS TRIAL
E. Tanner1, M. Carlson4, G. Rebok4, T. Seeman4, K.D. Frick4, J.M. Parisi4, L.P. Fried3, 1. School of Nursing and Medicine, Center on Aging and Health, Johns Hopkins University, Baltimore, Maryland, 2. University of California, Los Angeles, Los Angeles, California, 3. Mailman School of Public Health of Columbia University, New York, New York, 4. Department of Mental Health, School of Public Health, Johns Hopkins University, Baltimore, Maryland

Volunteering among minority older adults is reported as less than the general population; in fact, formal volunteering through certain organizations excludes some groups from participation in civic engagement. We will describe strategies used to recruit and enroll 702 older adults for the Baltimore Experience Corps Trial (BECT), including gospel radio ads, print media, mass mailings, word of mouth, and community outreach. Enrollment motives related to retention in the BECT will also be discussed. Strategies used to retain predominately African American female participants in this study throughout the process of recruitment and randomization will be discussed. We will report retention outcomes across the 2-year enrollment period in both the control arm and intervention arm in which participants volunteered in EC elementary schools (K-3) 15 hours per week. Techniques for overcoming cultural barriers to volunteering among AA older adults will be described, along with important lessons learned for health promotion research.

VOLUNTEER STRESS IN EXPERIENCE CORPS BALTIMORE
V.R. Varma, J.M. Parisi, M. Carlson, Center on Aging and Health, Johns Hopkins University, Baltimore, Maryland

Volunteering is beneficial to adults as they age; however, volunteers engaged in high stress environments can experience burnout from stressors associated with volunteering and lack of adequate support structures. Although most studies of volunteering have been conducted with white, female, middle to upper income populations, we explored the adverse effects associated with volunteering in a predominately low-income, urban, Black, female population of EC volunteers, through a series of focus groups. Our results suggest that lack of clarity surrounding volunteer roles, as well as cultural and generational gaps, when working with children and teachers, often drive many of the challenging experiences of volunteers in the schools. Coping resources include spirituality and drawing on motivations to help the younger generation in persisting in the volunteer role. Findings illuminate both the negative perceptions of volunteering and potential coping and support structures which may affect retention of minority older adults in intergenerational volunteer interventions.

SESSION 1540 (SYMPOSIUM)

RESEARCH ON THE OLDER PERSON AND THE ENVIRONMENT: THE LEGACY OF M. POWELL LAWTON
Chair: C. Hoffman, Planning, Philadelphia Corporation for Aging, Philadelphia, Pennsylvania
Co-Chair: A. Glicksman, Planning, Philadelphia Corporation for Aging, Philadelphia, Pennsylvania
Discussant: H. Wahl, university of heidelberg, heidelberg, Germany

This year marks ten years since the death of Dr. M. Powell Lawton, who pioneered the field of environmental gerontology. The four presentations on this panel each describe the impact of Lawton’s work on research conducted post 2001, demonstrating the continued influence his work represents in the field of aging. Sharlach’s paper looks at the relation of Lawton’s coined phrase “person-environment fit” for the popular aging-in-place paradigm called “The Village Model.” Chaudhury examines Lawton’s work on environmental quality of life issues for patients in dementia care settings. Pruchno looks at neighborhood...
characteristics, such as crime reports and their impact on older adults. Glicksman et. al consider Lawton’s work in the context of developing a research-based model involves a variety of professions working collaborative to create an age-friendly community. Walth’s response will consider these papers within the larger context of Lawton’s work. The discussion among panelists and audience will be guided by Hoffman who worked with Lawton for many years. At the end of the session participants will be able to: 1) identify at least two significant contributions Lawton made to the field of environmental gerontology2) describe how Lawton’s work has influenced studies that relate to the environment of both neighborhoods and institutions 3) name at least two community-based initiatives aiming to improve the quality of life for older adults that were directly influenced by Lawton’s work.

LAWTON’S LEGACY: DEFINING OBJECTIVE ENVIRONMENTS
R.A. Pruchno, UMNDJ - School of Osteopathic Medicine, Stratford, New Jersey

In his 1983 Kleemeier lecture Lawton identified the ‘objective environment’ as one of four components of the ‘good life’. This objective environment “lies outside the individual and is capable of being counted or rated consensually by observers.” Lawton lamented that standardized measures for many aspects of the environment were underdeveloped and pushed for the advancement of environmental taxonomies. Answering Lawton’s call for scientists to better define and recognize the salient role played by the environment efforts are underway to identify the neighborhood characteristics most salient to the health of older people. Using data readily available from secondary sources (Census, crime reports, Departments of Agriculture and Law & Public Safety, HRSA) I will present a multidimensional model of neighborhood characteristics and demonstrate its psychometric properties. Plans for the next phase of my research including examination of how neighborhoods influence the mental and physical health of community-dwelling older people will be discussed.

ENVIRONMENTAL ASSESSMENT OF DEMENTIA CARE SETTINGS: A TOOL LINKING ENVIRONMENT AND BEHAVIOR
H. Chaudhury, Simon Fraser University, Vancouver, British Columbia, Canada

M. Powell Lawton’s contribution on the topic of dementia care includes, among other issues, an articulation of quality of life in people with dementia and development of an effective language to capture the built environmental properties as relevant for enhancing quality in dementia care settings. In this recent project, I have linked Lawton’s conceptualization of QOL in dementia to the larger discourse of personhood in dementia and developed an environmental assessment tool (Dementia Care Mapping - Environment or DCM-ENV) that works along with the existing well-known care practice assessment tool “Dementia Care Mapping (DCM)”. This environmental coding scheme is influenced by Lawton’s idea of developing a more systematic lexicon of the built environment for dementia care. The newly developed tool (DCM-ENV) is based on 23 Environmental Category Codes (ECC) that allow a trained mapper to systematically capture real time affect of the built environmental aspects and properties with observed behaviours. In that respect the tool and method generate evidence-based data on how the physical environment influences behaviors in people with dementia. This contrasts with the other environmental assessment tools that are based on perceived role of the environment on behavior as identified in the previous literature.

LIFESPAN DEVELOPMENT AND P-E FIT: IMPLICATIONS FOR AGING-FRIENDLY COMMUNITIES
A.E. Scharlach, University of California at Berkeley, Berkeley, California

Powell Lawton made seminal contributions in the areas of person-environment (P-E) fit, individual functioning, environmental salience in later life, and competence as a function of PxE interaction. This presentation begins by examining the question of “competence for what?”, drawing upon lifespan developmental psychology for a conceptually- and empirically-derived framework of five late life psychosocial “challenges.” “Aging-friendly” communities can then be understood as those in which P-E transactions foster developmentally-salient functioning in these five areas. To the extent that well-being in later life involves the active engagement of older persons, it becomes important to consider the ways in which elders themselves are involved in helping community environments to become more “aging-friendly.” Findings from current research on the Village model will be presented, in order to examine possibilities for engaging older persons in community development activities designed to enhance P-E fit in response to the physical and psychosocial challenges of later life.

M. POWELL LAWTON AND AGE-FRIENDLY PHILADELPHIA
A. Glicksman1, M.H. Kleban2, K.O. Clark1, C. Hoffman1, L. Ring1, 1. Planning, Philadelphia Corporation for Aging, Philadelphia, Pennsylvania, 2. Polisher Research Institute, Horsham, Pennsylvania

M. Powell Lawton’s impact on the development of Philadelphia Corporation for Aging’s Age-friendly Philadelphia (AfP) agenda is multifaceted. Since 2008 PCA has pursued an AfP policy agenda designed to inspire changes in the physical and social environment with the aim of enhancing the health and quality of life of the city’s older adults. Two aspects of Lawton’s work have played especially important roles in the development of this effort. First, his concept of “environmental press” continues to influence our understanding of the impact of the environment on the older adult population and shape the research agenda supporting our AfP effort. Second, the personal example Lawton set of building collaborative efforts with practitioners in various fields (three of the five authors worked directly for him) to translate research directly into practice have shaped the role research has played in the AfP work.

SESSION 1545 (SYMPOSIUM)

THE DIGITAL FRONTIER OF AGING RESEARCH: EMERGING METHODS IN MICROLONGITUDINAL STUDIES
Chair: S. Mejia, Human Development and Family Sciences, Oregon State University, Corvallis, Oregon Discussant: K. Hooker; Human Development and Family Sciences, Oregon State University; Corvallis, Oregon

The daily processes underlying developmental mechanisms of stability and change have traditionally been difficult to study due, in part, to the limits of traditional data collection methods. Innovative applications of current technologies, coupled with older adults’ increased internet use, provide opportunities to capture these processes, opening new windows into older adults’ daily lives. Papers in this symposium uncover the nuts and bolts of designing, implementing, and evaluating microlongitudinal research using these technologies. Sliwinski, Wilmoth, and Mogle examine whether the impact of physical health and cognitive functioning on engagement in self-care can be adequately assessed over 7 days using a web-based measure. Using experience sampling methods from two studies, Chui, Rebuscal, Lumley, Labouvie-Vief, and Diehl examine different temporal sampling designs to determine whether parameters describing adults’ emotional processes will differ significantly by study design. To examine self-regulatory processes Mejia, Pham, Choun, Motoyer, and Hooker designed a custom web-based application for a 100-day idiographic study, where initial survey responses uniquely populated daily surveys and provided participants with visual feedback. Smith, Ofstedal, Ryan, and Stawski speak to the future of
large longitudinal studies, and the potential of including microlongitu-
dinal components to reveal snapshots of daily lifestyle processes. Pre-
sentations will highlight the emerging opportunities to deepen our under-
standing of the daily processes behind established constructs known to
support wellbeing in adulthood. The discussant, Karen Hooker, has expe-
rience in both traditional and web-based microlongitudinal methods and
will provide her perspective on how advances in methods are bringing
new theoretical insights into studies of adult development.

ASSESSING DAILY ACTIVITIES IN OLDER ADULTS:
DESIGNING A BRIEF WEB-BASED SURVEY TO EXAMINE
THE IMPACT OF PHYSICAL HEALTH AND COGNITIVE
FUNCTIONING ON SELF-CARE AND SOCIAL
ENGAGEMENT
M. Sliwinski1, J. Wilmot2, J. Mogle3, J. Cohen-Mansfield, Herczeg Institute on Aging, Tel Aviv
L. Poon, Institute of Gerontology, University of Georgia, Athens, Georgia

Age-related declines in physical health and cognitive functioning
may have profound effects on the daily lives of older adults. For exam-
ple, these declines may hinder the ability to perform self-care tasks and
engage in social activities, thus impairing quality of life. Little is known
about this relationship, however, due to the lack of appropriate meas-
dures for the daily assessment of activities in this population. The cur-
rent study piloted a web-based measure designed to capture the fre-
cuency of a range of daily activities in older adults as well as the
relationship between the frequency of activities and daily physical symp-
toms. One hundred older adults (ages 60-80) completed a brief (~15
minutes) activities assessment once each day for 7 consecutive days. At
each assessment, participants indicated the number of activities and
physical symptoms over the past 24 hours. Results suggest the pilot
measure adequately assessed the impact of physical health and cogni-
tive functioning on engagement in self-care and social activities in this
age group.

EMOTION REGULATION IN ADULTHOOD: HOW
DIFFERENCES IN STUDY DESIGN AFFECT FINDINGS

Momentary ecological assessment methods are increasingly used
to study emotion regulation in adults and late life. Although these meth-
ods have been praised as the new “gold standard” for studying tran-
sient aspects of human behavior, such as emotion regulation, little is
known about how a specific study design affects the resulting findings.
Using Boker’s damped and coupled oscillator models and data from two
experience sampling studies, this paper examines how the study design
affects the findings that may be observed with regard to adults’ emo-
tion regulation processes. Specifically, we will analyze data from 239
adults who participated in a 30-day diary study with one assessment per
day. Findings will be compared against the data from 114 adults who
participated in a 7-day experience sampling study with up to 5 assess-
ments per day. We expect that the key parameters that describe adults’
emotion regulation processes will differ significantly by study design.

CAPTURING 100 DAYS OF SELF REGULATION
PROCESSES VIA THE WEB: DESIGN, IMPLEMENTATION,
AND EVALUATION
S. Mejia1, T. Pham2, S. Choun1, R. Metoyer3, K. Hooker1, J. Oregon State University - Department of Human Development and Family Sciences, Corvallis, Oregon, 2. Oregon State University - School of Electrical Engineering and Computer Science, Corvallis, Oregon

Studying daily processes of self-regulation requires a simple, flex-
ible, customizable, and accessible approach to data collection. This paper
describes the design, implementation, and evaluation of the Personal
Understanding of Life and Social Experiences (PULSE) project, an inter-
et-based 100-day study of Oregon residents over the age of 50 (n = 105), which examined intraindividual variation in progress towards
health and social goals. We designed a web-based application that
allowed participants to log their daily health and social goal progress,
provided access to visual representations of their data, and served as a
data management tool for the researchers. We will discuss design ele-
ments of our system, recruitment and orientation methods, and partic-
ipant feedback on their experience with the study, including the unique
opportunities and challenges that emerged. Social and computer scienti-
stists collaborated in the design and implementation of this study, which
was funded by the Oregon State University Center for Healthy Aging Research.

WEB-BASED DIARIES AND NATIONAL LONGITUDINAL
SURVEYS OF AGING: CURRENT STATUS AND FUTURE
SCENARIOS
J. Smith, M. Olstedal, L. Ryan, R.S. Stawski, Institute for Social
Research, University of Michigan, Ann Arbor, Michigan

Most longitudinal representative studies of older adults, such as the
Health and Retirement Study (HRS), use computer-assisted telephone
or in-person interviews. The internet is undeniably a cost-effective alter-
native that offers new opportunities to monitor data quality and enhance
survey design. Despite concerns about the digital divide, there is evi-
dence of increased computer and internet usage in cohorts born after
1940. Indeed, HRS conducts a longitudinal biennial web survey with
participants who have internet access. In 2009, a subsample of 4433
HRS participants aged 50 to 96 (M age = 66) completed a study on the
impact of the economic crunch. This was repeated in 2011. We present
our findings regarding period effects on global and experienced well-
being in older workers and retirees and outline future scenarios for web-
based modules in large national surveys. In particular, we discuss the
feasibility of adding intermittent internet diaries (measurement bursts)
to large national surveys.

THE U.S.-ISRAEL BI-NATIONAL SCIENCE FOUNDATION
SYMPOSIUM ON WELL-BEING AMONG THE OLDEST OLD
Chair: L. Poon, Institute of Gerontology, University of Georgia, Athens, Georgia
Discussant: J. Cohen-Mansfield, Herzeg Institute on Aging, Tel Aviv University, Tel Aviv, Israel

Although the concepts of well-being, life satisfaction, and success-
ful aging have attracted unprecedented research attention in the last 30
years, we know very little about these concepts among the oldest old.
A reality among the oldest old is the increasing variability in both sub-
jective and psychological well-being found within an individual owing
to variations in cumulative experiences and differences in strategies
to survive into very old age. In conjunction with the U.S.-Israel Bi-National
Science Foundation, the institutes of gerontology at the University of
Georgia and Tel Aviv University convened a think-tank conference/workshop in Israel to describe and advance our state-of-the-
art on well-being among the oldest old. The workshop addressed (a)
the conceptions of well-being among the oldest old, (b) the accumula-
tion of trauma throughout the life span and how it affects the perception of
well-being, (c) the influence of moderating, mediating and proximal
processes on well-being, and (d) issues relating to the measurement of

SESSION 1550 (SYMPOSIUM)
well-being. This symposium will highlight key issues that may impact new research directions among older adults and the oldest old.

UNDERSTANDING WELL-BEING AMONG THE OLDEST OLD
L. Poon, J. Cohen-Mansfield, 1. Institute of Gerontology, University of Georgia, Athens, Georgia, 2. Herzeg Institute on Aging, Tel Aviv University, Tel Aviv, Israel

The life course is marked by individuality and diversity. An individual’s life is a process that, if scrutinized at a singular instance, would yield incorrect assumptions about its trajectory. Instead, the gradual accumulation of events in a person’s life provides perspective into how that person arrived at his or her present state of well-being. This paper will briefly introduce our approaches in conceptualizing well-being among individuals who are older than 75 years of age. This cohort deserves its own conception of well-being because of its distinctiveness in comparison with younger generations. For example, individuals in the fourth age are referred to with ethereal adjectives, such as gerotranscendence, empowerment, maturation, and resilience. Nonetheless, there are minimal data and discourse available on the oldest old; the lack of exploration can be attributed to the large amount of individual variability within the cohort, which makes it difficult to reach generalizations for the group.

MEASURING MAGIC: PSYCHOLOGICAL AND CULTURAL APPROACHES TO THE CODIFICATION OF WELL-BEING
A. Bishop, C. Fry, 1. Human Development and Family Science, Oklahoma State University, Stillwater, Oklahoma, 2. Loyola University of Chicago, Chicago, Illinois

The purpose of this symposium presentation is to address measurement and operational definitions used to empirically investigate well-being in old-old age. Three key issues will be addressed. First, historical implications of qualitatively and quantitatively assessing the welfare of older persons will be addressed. Second, advancement of psycho-metric and ethnographic approaches used to strategically evaluate well-being of the oldest old will be identified. Third, empirical problems arising from the theoretical and operational definitions used to capture the well-being construct will be critiqued. Of particular interest is how well-being has come to represent a complex phenomenon rooted in human physiology and conditioned by familiar psychological, social, and cultural inputs. Further consideration of how language and cultural meanings are linguistically coded to transform the complexities of well-being into a more simplified and measureable variable within gerontological research will be noted.

SOCIAL NETWORK AND WELL-BEING AMONG OLD-OLD EUROPEANS: IS IT THE SAME ASSOCIATION?
H. Litwin, K.J. Stoeckel, Hebrew University, Jerusalem, Israel

Aim: To investigate the associations between social network and well-being among Europeans aged 80 and older. Method: The study addressed respondents aged 60 and over from the second wave of the Survey of Health, Ageing and Retirement in Europe (N=13,946). Three well-being outcomes—depressive symptoms, the CASP scale and life satisfaction—were regressed on three domains of social network: structural interaction, exchange and engagement. The analysis controlled for background, health and region, and included interaction terms for oldest-old age (80+) by each of the network variables. Results: Differences were observed in the nature of the associations between the network variables and the well-being outcomes among the oldest-old. Discussion: The findings show that the association between social network and well-being in late-life is age-dependent, and that the oldest old have unique associations. The social networks of older people should be seen differentially in relation to age, especially when designing social interventions.

THE LINGERING IMPACT OF PAST TRAUMA IN LATE LIFE: CONCEPTUAL AND CLINICAL PERSPECTIVES
D. Shmotkin, L. Hyer, 1. Tel Aviv University, Department of Psychology and Herzeg Institute on Aging, Tel Aviv, Israel, 2. Mercer University School of Medicine, Macon, Georgia, 3. Georgia Neurosurgical Institute, Macon, Georgia

The aftereffects of major traumas experienced along life never really end. We address their significance in three modes of survival into old-old age. In robust survival, individuals maintain well-being in face of age-related challenges, and control the trauma’s remnants through a balance between general resilience and specific vulnerabilities. In embattled survival, predominated by frailty and losses, past trauma may continue in a chronic formation, such as posttraumatic stress disorder, or undergo a reactivation by the recent adversity. In dementia-molded survival, it is largely obscure whether cognitive impairment sensitizes or blunts traumatic memories. To further understand how earlier trauma is regulated in late life, we present findings illustrating mechanisms (e.g., meaning generation, time perspective, autobiographical memory) that sustain well-being in the face of hostile-world scenarios. Turning to psychotherapeutic implications, we finally examine whether treatment of posttraumatic reactions among the old-old can reflect variability of restorative strengths or rather a common decline.

OLDER ADULTS’ WILL TO LIVE: CHARACTERISTICS AND APPLICATION TO PROFESSIONAL PRACTICE
S. Carmel, J. Damron-Rodriguez, 1. Ben-Gurion University of The Negev, Department of Sociology of Health and Gerontology, Beer-Sheva, Israel, 2. University of California Los Angeles, School of Public Health, Department of Social Work, Los Angeles, California

Based on systematically repeated results of 6 large scale studies, the will to live (WTL) was found to be an important indicator of general well-being, encompassing psychological and physical dimensions, and predicting survival over 7.3 years. Conceptually, the WTL is defined as the psychological expression of a natural instinct of human beings - the striving for life, which is comprised of rational and irrational components, and can be self-assessed. The WTL is unique, since it not only expresses a state of general well-being, but also one’s commitment to life and desire to continue living. The WTL is assessed by a 5-item scale with scores ranging from 0 to 5, is easy to use, and well accepted by older adults. Its internal reliability (Cronbach’s alpha) ranges from .82 to .89. All of these characteristics, especially the WTL’s significant diagnostic and prognostic value, led us to adopt this simple evaluative tool to daily practice by integrating it into geriatric competency-based educational programs for professional caregivers. Training focuses on using this tool for assessing well-being of older adults, evaluating changes over time, and applying individual-based interventions for improving the personal determinants of the WTL, which can be improved. Moving from the description of WTL as a concept, its value and correlates, we will explore how WTL relates to the geriatric competencies for health professions developed by the American Geriatric Society, Professional Health Alliance (2010). Teaching and training program applications will be presented from the perspective of faculty experts in the U.S.A. and Israel.

MODELS IN UNDERSTANDING WELL-BEING
P. Martin, J. Cohen-Mansfield, 1. Iowa State Univ, Ames, Iowa, 2. Tel Aviv University, Tel Aviv, Israel

Much research concerning the well-being of old and very old adults is conducted without reference to explicit conceptual frameworks or theories. This presentation will provide a brief overview of current well-being models and highlights two specific theoretical approaches that help to understand the relatedness of proximal and distal influences on well-being in late life: the first approach, the developmental adaptation model, highlights the importance of distal and proximal resources for understanding well-being. This symposium will highlight key issues that may impact new research directions among older adults and the oldest old.
optimal well-being in late life. The second approach, the shifting baseline theory, explains the relatively high levels of well-being among the old-old. Similarities and differences of these conceptualizations will be discussed. Together, these theoretical frameworks demonstrate the variability in the understanding of the importance of past experiences, resources, and experiences of daily living as determinants of well-being.

SESSION 1555 (PAPER)

CANCER

TRENDS IN COLONRECTAL CANCER INCIDENCE AND MORTALITY BY SUB-SITE, SEX AND AGE: UNITED STATES AND EUROPE

K. García, E. Crimmins, USC, Los Angeles, California

Colonrectal cancer is the third most common cancer and the fourth most common cause of cancer deaths worldwide. Cross-country variations in colonrectal cancer incidence and mortality trends have been documented. However, no study has examined colonrectal cancer trends by sub-site, sex and age group for the U.S. and Europe. We use population-based cancer registry data from Cancer Incidence in Five Continents Plus (CISPlus) and the WHO Mortality Database to examine temporal changes in age-standardized colonrectal cancer incidence trends from 1990-2002 and mortality trends from 1990-2005 for the U.S. and nine European countries. Data were extracted by national or regional cancer registries, anatomical site, year of diagnosis, sex and 10-year age group. Joinpoint regression is used to identify significant changes in trends and to estimate average annual percent change (AAPC). Incidence and mortality trends vary widely between the U.S. and Europe, and across Europe as well. From 1990-2002, incidence rates for cancers of the colon, rectum and anus increased or remained stable in most European countries examined, however significant declines were observed in the U.S. across most age groups for both males and females. From 1990-2005, most countries experienced significant mortality declines in cancers of the colon, rectum and anus. The AAPC in colon cancer deaths for males and females are greatest in the U.S. (2.1-2.9%; 2.3-2.9%), Austria (0.8-3.5%; 1.2-3.5%), and England (1.6-3.3%; 2.3-4.5%), while greatest in Austria (2.2-3.3%; 2.3-3.9%) and Denmark (1.1-3.3%; 1.2-2.8%) for rectal and anal cancer. Variations in risk factors, screening and treatment practices are discussed.

THE IMPORTANCE OF PHYSICIAN ENCOURAGEMENT OF COLONRECTAL CANCER SCREENING AMONG LATINO PATIENTS

A.M. Nakopels¹, J. Santoyo-Ólsson¹, E.J. Perez-Stable¹, A. Stewart¹, 1. Medicine, University of California San Francisco, San Francisco, California, 2. Institute for Health & Aging, University of California San Francisco, San Francisco, California

Background: Latinos are less likely to obtain colorectal cancer (CRC) screening and experience poorer 5-year CRC survival than Whites. Objective: Assess associations between patient-reported CRC-specific communication and CRC screening. Participants: Latino primary care patients aged > 50 with > 1 visit during the preceding year (N=1,314) were sampled from four clinics. Design: Cross-sectional telephone survey assessing whether (yes or no) physicians: provided explanations; elicited barriers; and the amount of physician encouragement of CRC screening (on a 5-point scale from 0 to 5); and the amount of physician encouragement of CRC screening (on a 5-point scale from 0 to 5). Results: Of 504 patients completing the survey; mean age was 61 years (SD 8.4), 69% were women, and 53% had < high school education. 46% reported obtaining endoscopy (+/- FOBT), 13% FOBT only, and 41% no screening. In bivariate analyses, physician explanations, responsiveness to concerns, and greater encouragement for screening were associated with receipt of FOBT and endoscopy. Adjusting for sociodemographic factors, patients reporting quite a bit/a lot of physician encouragement were more than 6 times as likely to receive FOBT as those reporting none/a little encouragement (OR=6.54; 95% CI 2.76, 15.48). Adjusting for sociodemographic factors, physician explanations (OR=1.27; 95% CI 1.03, 1.58) and greater physician encouragement (OR=6.4; 95% CI 3.57, 12.72) were associated with endoscopy. Conclusions: The degree to which Latino patients perceived that physicians encouraged CRC screening was more strongly associated with screening than providing information, eliciting barriers, and responding to their concerns about screening.

THE RELATIONSHIP BETWEEN REPORTED CANCER PAIN AND PERSONALITY IN OLDER ADULTS RECEIVING OUTPATIENT CANCER CARE

J. Krok, T. Baker, University of South Florida, School of Aging Studies, Tampa, Florida

It is well-established that personality has a significant impact not only on physical health and longevity, but mental health and coping mechanisms as well. Despite what is known regarding the significance of personality and well-being, there is a dearth of empirical data defining the relationship between cancer pain and personality, particularly among older adults. The objective of this investigation was to examine how an individual’s personality traits influence the experience of cancer pain. The sample consisted of older patients (x = 66.7 years of age, SD= 7.60; 80% White) receiving outpatient treatment at a comprehensive cancer center. Pain severity (Brief Pain Inventory, Patient Pain Questionnaire), pain frequency, psychological symptoms, and personality (Ten Item Personality Inventory (TIPI) and the Positive and Negative Affect Scale (PANAS) were assessed. Preliminary data showed the average pain score of 4.28 (SD = 1.93, scale = 0-10). Negative affect was found to be associated with higher distress associated with pain (F2, 27 = 3.26, p<.05). Having high neuroticism (b=1.27, p=.05), low agreeableness (b=1.98, p=.05), and low openness to experience (b=1.04, p=.05) were similarly found to be related with worse expectations of pain in the future (F10,16 = 2.65, p<.05). These findings indicate that different personality types may influence the perceptions and experience of cancer related pain. More empirical research is needed to understand the impact of pain and its relationship with personality in more diverse and marginalized cancer populations across the age continuum.

TYPE AND PREVALENCE OF SYMPTOMS EXPERIENCED BY OLDER ADULTS OVER TIME AFTER CANCER SURGERY

J.H. Van Cleave¹, E. Ercolano², B.L. Egleston², R. McCorkle², 1. College of Nursing, New York University; New York, New York, 2. Yale School of Nursing, New Haven, Connecticut, 3. Fox Chase Cancer Center, Philadelphia, Pennsylvania

OBJECTIVES: Older adults undergoing cancer surgery often experience symptoms, leading to adverse outcomes. Identifying and understanding the pattern of symptoms over time may lead to early interventions, thus improving older adults’ outcomes. The purpose of this study was to describe type and prevalence of symptoms over time reported by older adults undergoing surgery for thoracic, digestive, gynecologic, and genitourinary cancers. METHOD: Secondary analysis using combined subsets of data of 326 adults ages 65 or older from five clinical trials of nurse-directed interventions targeting patients post-surgery. Patients were interviewed at baseline (post-surgery period), and 3 and 6 months. Presence or absence of symptom was assessed using the Symptom Distress Scale and summed for total number of symptoms. Descriptive statistics and Poisson regressions by Generalized Estimating Equations (GEE) were used. RESULTS: While controlling for type of cancer, results from the GEE analysis demonstrated the total number of symptoms reported by patients significantly decreased over time (p<0.001). Type and prevalence of symptoms reported by patients also changed over time. At baseline interview during the post-surgical period,
40% or more of study patients reported typical surgical symptoms of fatigue, appetite, insomnia, pain, or bowel symptoms. At 6 months, 25% or more of study patients reported fatigue or pain symptoms. CONCLUSION: The results suggest that older adults undergoing thoracic, digestive, gynecologic, and genitourinary cancer surgery may follow a typical post-operative course of decreased symptoms over time. Some older adults, however, may experience pain and fatigue up to 6 months post-surgery.

MEDICAL CONDITIONS BEFORE AND AFTER CANCER AMONG LONG-TERM CANCER SURVIVORS

C. Leach1, N. Aziz2, C.M. Alfano1, J. Rowland1, K. Weaver1, L. Fosythe1, J. National Cancer Institute, Bethesda, Maryland, 2. National Institute of Nursing Research, Bethesda, Maryland, 3. Wake Forest University School of Medicine, Winston-Salem, North Carolina

Multiple medical co-morbidities are common at the time of cancer diagnosis and additional health conditions may develop after cancer. Studies examining medical conditions post-dating the cancer diagnosis remain sparse, especially with respect to the effect of age at and time since diagnosis. Data from the population-based Follow-Up Use among Survivors (FOCUS) study were used to examine medical conditions (ever developed; developed after cancer) among 1582 long-term breast, prostate, colorectal, and gynecological cancer survivors by age at diagnosis (<65, 65+) and time since diagnosis (4-9 years, 10+ years). In general, long-term survivors suffered from a large number of co-morbidities. The top 5 most prevalent conditions include (ever; new-onset post-diagnosis): hypertension (53.8%; 17.6%), arthritis (45.8%; 16.5%), other heart-related conditions (35.0%; 17.4%), cataracts (39.4%; 25.1%), and diabetes (21.3%; 10.2%). Older age at diagnosis was associated with higher numbers of medical conditions (65+: 5.9; <65: 4.4). However, time since diagnosis was not associated with the total number of medical conditions. Heart-related conditions and cataracts post-cancer diagnosis were more common among patients diagnosed with cancer at a later age (respectively, 65+: 20.5%, 34.0%; <65: 11.1%, 6.7%) whereas hypertension, arthritis, and diabetes saw no difference by age at diagnosis. Co-morbidities acquired after cancer varied by age at diagnosis. Findings suggest that health professionals may need to consider patient age when managing the post-treatment care of survivors. Future research should examine why older age at diagnosis increases risk for heart-related conditions and cataracts after cancer, but not other conditions.

SESSION 1560 (PAPER)

COGNITIVE IMPAIRMENT

DELAY OF GRATIFICATION IN OLD AGE: COMPARISON OF INDIVIDUALS WITH AND WITHOUT COGNITIVE IMPAIRMENT

R. Drobetz, A. Maercker, S. Forstmeier, Psychology, Psychopathology and Clinical Intervention, University of Zuerich, Zuerich, Switzerland

Delay of gratification (DoG) is the postponement of immediate smaller for the sake of later larger rewards. DoG predicts cognitive, motivational, social and health variables; however DoG has not sufficiently been explored in the elderly up to now. Findings in the DoG-related construct of executive functions suggest a decline with increasing age and cognitive impairment. We primarily focused on differences in DoG-behavior between individuals with and without cognitive impairment as well as on influencing variables. Study participants were 60 individuals with Mild Cognitive Impairment (MCI) and mild Alzheimer’s dementia and 120 cognitively unimpaired controls (all participants were aged 60 and older). We experimentally measured DoG with the Delay of Gratification Test for Adults (Forstmeier, Drobetz & Maercker, 2011) using primary (food) and secondary (money) reinforcers. While cognitively unimpaired individuals had higher DoG when snacks were rewards, they showed lower DoG when money was used. Additionally, cognitively unimpaired participants preferred significantly more often immediate money with increasing age. The lower individuals’ DoG in snacks the higher their self-reported impulsiveness. Further, DoG correlated significantly negatively with apathy, a common syndrome in MCI and Alzheimer’s dementia. Besides, patients’ DoG predicted mental, but not physical health of their caregivers. In conclusion, DoG linked with impulsiveness seems to decrease in primary reinforcers (food) with cognitive impairment. In contrast, money as an abstract secondary incentive seems to lose its relevance for cognitively impaired individuals. Both positive effects of high self-control on relationships and fewer stressing symptoms might explain the link between patients’ DoG and caregivers’ wellbeing.

DOES THE NDB MODEL EXPLAIN WANDERING?

D. Algase1,2, C. Antonakos2, E.R. Beattie1, C. Beel-Bates1, L. Yao1, J. Song1, G.S. Hong2, J. University of Toledo, Toledo, Ohio, 2. School of Nursing, University of Michigan, Ann Arbor, Michigan, 3. Queensland University of Technology, Brisbane, Queensland, Australia, 4. Grand Valley State University, Grand Rapids, Michigan, 5. Michigan State University, Lansing, Michigan, 6. Hanyang University, Seoul, Republic of Korea, 7. Korea University, Seoul, Republic of Korea

Wandering is a potentially hazardous behavior affecting approximately 60% of people with dementia (PWD). The basis of wandering is poorly understood and, thus, interventions for it are more palliative than therapeutic. We evaluated the need-driven dementia-compromised behavior (NDB) model for its explanatory power for wandering among PWD in long-term care settings. Using a convenience sample from 23 settings, we analyzed data from 143 wanderers who were: 1) assessed on NDB background factors (cognitive impairment, health status, mobility status, circadian rhythm, personality, behavioral response to stress) and 2) observed up to 12 times for NDB proximal factors (emotion, social interaction, hunger, thirst, pain, wandering rate and duration. Proximal environmental characteristics (sound and light levels, crowding, ambiance, caregiver familiarity with resident) also were assessed at each observation. Based on preliminary analyses, variables significant at p<.15 were retained for evaluation of the overall model. Using SAS (PROC GENMOD), the data were shown to be a good fit to the model (scaled deviance/df=97 full model log likelihood=−1658.79, null model log likelihood=−1673.45; Chi-square=29.31, df=10, p<.001). At p<.10, higher MMSE scores, keeping busy under stress, negative facial expression, and a soothing environment were significantly associated with lower wandering rates; anxious behavior under stress, positive emotion, and upper GI problems were significantly associated with higher wandering rates. In a similar analysis using wandering duration as the dependent variable, results were similar. In sum, a trimmed NDB model was supported as a basis for designing wandering interventions. Refined measures may expand the number of original concepts supported.

STRATEGIES IDENTIFIED DURING WAYFINDING IN A VIRTUAL REALITY ENVIRONMENT IN MIDDLE AGED AND OLDER ADULTS

R. Davis, Kirkhof College of Nursing, Grand Valley State University, Grand Rapids, Michigan

Place learning, the ability to learn and remember environments is a critical cognitive function for wayfinding in new or changed environments that becomes impaired in many people with age. Older adults are often slower, less accurate, and more likely to get lost than younger adults. Little is known about the types of strategies that older adults use in wayfinding, or how these strategies relate to wayfinding performance. In this study, 3 groups of older adults (aged 55-64, 65-74, and >75) were asked to find their way in 4 computerized virtual reality environments for 3 consecutive days. At the end of the experiment on days 1 and 3 subjects were asked several qualitative questions related
to wayfinding strategies. Qualitative analysis revealed eight separate strategies, including: 1) Lining self up with cues/pictures/corners; 2) Psycho-motor patterns 3) Random movement 4) Using distance/depth 5) Using memory 6) Moving towards one specific cue 7) Searching a specific quadrant and 8) Triangulating between more than 2 environmental features/cues. Individuals reported using more than one strategy, ranging from 0 – 5 strategies (mean 2.08 strategies on day 1, and 2.03 strategies used on day 3). There were no significant differences between age groups except for two strategies. The oldest age group (age >75) was significantly less likely to report using a distance strategy (day 1, F(2)=17.147 (p<.0001) and triangulation on day 3 (F (2)=14.292, p=.001) when compared to the youngest age group. Less use of these allocentric strategies may explain some of the difference seen in place learning in older adults.

EFFECTIVENESS OF A NUTRICEUTICAL FORMULATION ON COGNITIVE PERFORMANCE IN MCI AND AD

A nutriceutical formulation (NF); vitamins E, B12, folic acid, S-adenosylmethionine, N-acetylcysteine, acetyl-L-carnitine) has been demonstrated in prior studies to maintain or improve cognitive performance and mood in persons with Alzheimer’s disease (AD) and boost cognitive performance in adults with no known or suspected dementia. Herein, we report initial results from an ongoing multi-site, placebo-controlled study of NF for AD and mild cognitive impairment (MCI). Individuals with AD (age 82.4±9 years, education 12±3 years, MMSE 22±6) or MCI (age 62±2 years, education 15±2 years), randomly assigned to receive either NF or placebo, completed cognitive tests at baseline, 3 and 6 months. Family or staff caregivers completed mood/behavior (NPI) and activities of daily living (ADCS-ADL) inventories. AD participants receiving NF but not placebo improved in Clox1 within 3 months (p<0.01) and maintained improvement at 6 months. NF participants improved versus placebo in AEMSS of the Dementia Rating Scale at 6 months (effect size 0.9). Placebo participants declined 30% in ADL at 6 months (p<0.09); NF participants declined only 12%. MCI participants receiving placebo but not NF declined (p<0.05) in the WAIS Digit Span by 6 months. Placebo but not NF participants declined in Clox1 over 6 months (effect size 0.86). NF participants displayed a moderate effect size (0.4) versus placebo in AEMSS at 3 and 6 months. These findings indicate that NF can maintain or improve cognitive performance and function prior to and during MCI and AD. Multi-site studies are ongoing and additional sites are recruiting; forthcoming data will also be presented.

TESTING THE MOUTH INTERVENTION TO PROVIDE ORAL HYGIENE TO PERSONS WITH DEMENTIA WHO RESIST CARE

R. Jablonski1, B. Therrien2, A.M. Kolanowski3, E. Mahoney1, E. Gabello1, C. Kassab1, 1. School of Nursing, Penn State, University Park, Pennsylvania, 2. University of Michigan, Ann Arbor, Michigan, 3. Boston College, Chestnut Hill, Massachusetts, 4. By The Numbers, West Decatur, Pennsylvania

The primary purpose of this pilot study was to test the feasibility of an intervention designed to reduce care-resistant behaviors (CRBs) in persons with moderate to severe dementia during oral hygiene activities. The intervention, Managing Oral Hygiene Using Threat Reduction (MOUTH), combined best oral hygiene practices with CRB reduction techniques. The MOUTH intervention is based the on neurobiological principles of threat perception and fear response governed by the amygdala. As perception and reasoning become distorted, persons with dementia attribute high threat to low or non-threatening situations. Eight NH residents with dementia received twice daily mouth care for 14 days; 7 completed the study. Oral health was operationalized as the total score obtained from the Oral Health Assessment Tool [OHAT]. CRB was measured using a refinement of the Resistiveness to Care (RTC) Scale. The baseline OHAT mean score of 7.29 (SD=1.25) improved to 1.00 (SD= 1.26) (p<.001); CRB improved from 2.43 CRBs/minute (SD=4.26) to 1.09 CRBs/minute (SD= 1.56)(t = 1.97,df 41, p=0.06). The threat reduction strategies most often employed were priming, gestures/pantomime, and chaining. Time of day the resident received oral hygiene (morning versus evening) was not related to CRBs (p=.039); however, the day of care had a significant negative relationship to CRB (p=0.030). This latter finding suggests that as the NH resident was consistently exposed to the MOUTH intervention over time, CRB rates dwindled.

SESSION 1565 (PAPER)

FRAILTY

DOES FRAILTY EXPLAIN “AGE-RELATED” DECLINES IN WELLBEING IN LATER LIFE?

I. Lang1,2,3, R. Hubbard4, V. Goodwin1, D.J. Llewellyn1, I. Peninsula College of Medicine and Dentistry, Exeter, United Kingdom, 2. NHS Devon, Exeter, United Kingdom, 3. Peninsula Collaboration for Leadership in Applied Health Research and Care, Exeter, United Kingdom, 4. Cardiff University School of Medicine, Cardiff, United Kingdom

Background. In a number of countries there have been moves to make wellbeing a central outcome of policy. Previous studies have identified an age-related decline in wellbeing after age 65 of unknown cause. In this study we assessed the relationship between subjective wellbeing and frailty cross-sectionally and longitudinally in a population-based sample of older people. Our aim was to assess the extent to which age-related change in wellbeing is explained by frailty. Method Longitudinal analysis of data on 1495 individuals aged 65 to 80 participating in the English Longitudinal Study of Ageing (ELSA) in 2002 and 2008. We used adjusted linear regression analyses to assess the relationship between frailty (measured using a Frailty Index) and wellbeing (measured using the CASP-19 instrument) at baseline and longitudinally. Results At baseline there was a strong correlation between wellbeing and frailty (r=-0.53, p<.001). In cross-sectional analyses, apparently age-related decline in wellbeing was mostly explained by frailty. In models controlled for age, socioeconomic status, and baseline frailty, change in wellbeing was a modest predictor of change in frailty (p<.001, independent contribution to r2=.12). Similarly, in models controlled for age, sex, socioeconomic status, and baseline wellbeing, change in frailty was a modest predictor of change wellbeing at follow-up (p<.001, independent contribution to r2=.11). Conclusions Frailty and wellbeing are linked and may decline together. Apparently age-related declines in wellbeing may be driven largely by frailty and need not be regarded as inevitable. Efforts to prevent and reduce frailty are likely to benefit wellbeing.

FRAILTY AND OBESITY IN LATER LIFE

I. Lang1,2,3, R. Hubbard4, V. Goodwin1, D.J. Llewellyn1, I. Peninsula College of Medicine and Dentistry, Exeter, United Kingdom, 2. NHS Devon, Exeter, United Kingdom, 3. Peninsula Collaboration for Leadership in Applied Health Research and Care, Exeter, United Kingdom, 4. Cardiff University School of Medicine, Cardiff, United Kingdom

Background. Frailty is sometimes conceptualized as a wasting disorder involving weight loss but there is some evidence obesity in later life is associated with higher levels of disability. In this study we explored...
the longitudinal relationship between frailty and obesity in a cohort of older people. Methods. Data were from 5,602 community-dwelling adults aged 50+ who participated in the English Longitudinal Study of Ageing in 2004 and 2008. Frailty was assessed using an index of accumulated deficits (Frailty Index). BMI was divided into five categories (below 20, 20-25, 25-30, 30-35, 35 plus) and waist circumference 88 cm or more (in women) and 102 cm or more (in men) was defined as high. Analyses were adjusted for sex, age, wealth, education, and smoking. Results. The BMI-frailty association was U-shaped at baseline. Over four years, those in the highest BMI category were significantly more likely to experience a further increase in frailty compared to those of recommended weight. This effect was more pronounced in younger age groups: for example, comparing recommended weight to the highest weight category the adjusted odds ratio for experiencing a frailty decline of ten points or more (out of 100) was 3.32 (95% CI 1.71 to 6.43) in those aged 50 to 64 at baseline, 1.82 (95% CI 1.02 to 3.24) in those aged 65 to 79, and not significantly different in those aged 80+. Conclusions. Obese older adults experience higher levels of frailty than those of recommended weight and are at elevated risk of further decline.

### EFFECTS OF PREVENTIVE HOME VISIT PROGRAM ON QOL AND CARE COSTS IN AMBULATORY FRAIL ELDERS

A. Kono, Y. Kanaya, T. Fujita, C. Tsunura, T. Kondo, K. Kushiyama, L. Rubenstein, 1. School of Nursing, Osaka City University, Osaka, Japan, 2. School of Nursing and Rehabilitation, Konan Women’s University, Kobe, Japan, 3. Municipal Community-based Comprehensive Care Center, Izumiotsu, Izumiotsu, Japan, 4. Department of Health and Welfare, Misisaki Local Government Office, Misaki, Japan, 5. Department of Geriatric Medicine, the University of Oklahoma, Oklahoma, Oklahoma

The aim of the present analysis from a randomized controlled trial was to examine effects of a preventive home visit program for ambulatory frail elders living in three Japanese communities on QoL parameters, health and long-term care costs. Eligible and willing subjects (n=323) were randomly assigned to intervention (n=161) or control group (n=162). Community health nurses and care managers provided structured preventive home visits to intervention group subjects every six months over two years. QoL measures (including ADLs, IADLs, depression, and social support) were collected via mail questionnaire at baseline and at the 12- and 24-month follow-up points. Costs of public health and long-term care insurance were documented. At 24-month follow-up, 6.8% of intervention group subjects had died vs 12.4% of control group subjects (NS). Two-way ANCOVA adjusting for each baseline score of QoL parameters has not shown significant differences. Total public health care costs over the period in intervention group (2,168,725 yen) were fewer than those in control group (2,291,885 yen) (NS). Long-term care costs in the intervention group (36,001 credits) were higher than in the control group (26,022 credits) (NS), and significantly more elders in the intervention group utilized long-term care services than those in the control group over the period 7-month to 15-month after intervention started. These results suggest that a preventive home visitation program could facilitate earlier use of public long-term care services over two years but might not significantly effect on QoL in the present population.

### WHO IS FRAIL? THE IMPACT OF DIFFERENT FRAILTY MODELS ON CHARACTERISING THE FRAIL POPULATION IN THE IRISH LONGITUDINAL STUDY ON AGEING

Y. Kamiya, V. Timonen, R. Kenny, Trinity College Dublin, Dublin, Ireland

Frailty is a geriatric syndrome which is associated with disability, falls, morbidity and mortality. Numerous definitions have been developed and two main approaches to frailty have emerged. One involves the accumulation of ‘deficits’ across many systems (burden model) and the other identifies frailty as biological syndrome or phenotype characterized by specific set of symptoms (biological model). We use these two models to estimate the prevalence of frailty in a nationally representative sample of 8,400 adults aged 50 and over who participated in the first wave of the Irish Longitudinal Study on Ageing (TILDA). As the burden and biological models have different theoretical foundations, we hypothesize that the factors associated with non-frail versus frail status are different and capture different groups. Eleven per cent of older people are frail according to biologic model, while 19% are frail according to the deficit accumulation model, and 5% were deemed frail when both models were used. People who are frail in the burden model are younger than those in the biological model (mean age 68 years vs. 71 years). They are also less likely to be married, in poorer self-reported health, live alone, and have higher score in the loneliness scale and quality of life. Therefore, frailty models derived from different theoretical approach capture different groups of older people.

### FRAILTY MODELS AND THEIR DISABILITY AND MORTALITY OUTCOMES: THE HEALTH AND RETIREMENT STUDY

Frailty has been modeled in different ways, reflecting different theoretical understandings of the concept. The frailty index (FI) is a measure of an older adult’s cumulative burden of symptoms, diseases, conditions, disability, etc. (Burden model). In contrast, the frailty phenotype is defined in terms of 5 components present in a hypothesized cycle of frailty (Biologic Syndrome model). Although previous research has demonstrated that these models differ in how they identify older adults as frail, we hypothesized that both models would predict substantial future disability and mortality. We analyzed waves 2004-2006 of the Health and Retirement Study, a nationally-representative longitudinal health interview survey. Our study sample included community-dwelling adults >=65 years (n=2,111) in 2004. We operationalized the FI (Burden model) and the frailty phenotype (Biologic Syndrome model) (using physical performance measures). Two-year disability was determined in terms of new dependency in activities of daily living and instrumental activities of daily living. Two-year mortality was determined using HRS data cross-referenced with the National Death Index. We used logistic regression models, which included six demographic characteristics and seven chronic diseases as covariates. Weighted prevalences of frailty were: Burden, 24.7%; Biologic Syndrome, 15.9%. Disability and mortality at 2 years were Burden, 16.8%/13.4%; Biologic Syndrome, 20.8%/19.0%. The unadjusted odds ratio for the association of frailty (Burden model) with disability incidence/progression and/or mortality at two years (the dependent variable in the models) was 4.2 (95% confidence interval: 3.1-5.5), adjusted odds ratio 3.1 (2.3-4.3). The unadjusted odds ratio for the association of frailty (Biologic Syndrome model) with disability incidence/progression and/or mortality at two years was 5.6 (3.9-8.0), adjusted odds ratio 2.5 (1.7-3.5). Significant covariates in all models included age and net worth. Odds ratios for frailty were comparable to or greater than those for chronic diseases. Confirming our hypothesis, although the frailty models differed in identifying older adults as frail, each of the models predicted substantial disability and mortality at two years. Future longitudinal investigation should explore how older adults become frail and how differing trajectories of frailty lead to disability and mortality.
INDEPENDENCE, DEPENDENCE, AND DISABILITY

LATENT CLASSES OF FUNCTIONAL DISABILITY AND THEIR LONGITUDINAL TRAJECTORIES
H. Allore, L. Han, B. Godlove, T.M. Gill, H. Lin, Internal Medicine, Yale Univ., New Haven, Connecticut

Previous longitudinal models of disability (as measured by Activities of Daily Living (ADL)) have used regression models that yield a single trajectory in which risk factors represent increases or decreases in slope estimates. However, this assumes that the population is homogeneous and would follow a single trajectory shifted only by the presence of risk factors. Using data from the Precipitating Events Project, we followed 754 initially nondisabled, community-living persons 70+ years for more than 10 years, with monthly assessments of ADLs and comprehensive assessments at 18-month intervals. We fit latent growth mixture models with random effects adjusted for age, sex, living alone, physical frailty, depressive symptoms, cognitive impairment, presence of two or more chronic conditions to longitudinal measurements of three nominal states of disability (Nondisabled, Mild ([1-2 disabled ADLs], Severe (3-4 disabled ADLs)) over seven consecutive 18-month intervals. Overall across the seven intervals, five distinct latent classes with corresponding trajectories were identified: (1) “Functionally Intact”, comprising 61.6% of the person-intervals with 3.1% within trajectory mortality; (2) “Intact Declining to Mild”, comprising 11.2% of the person-intervals with 13.3% within trajectory mortality; (3) “Consistently Mild”, comprising 13.6% of the person-intervals with 10% within trajectory mortality; (4) “Mild Declining to Severe”, comprising 7% of the person-intervals with 38.6% within trajectory mortality; and (5) “Severely Disabled”, comprising 6.6% of the person-intervals with 50.6% within trajectory mortality. Trajectories differed by intercepts and nonlinear slopes. Except for Functionally Intact, trajectories displayed both worsening and recovery in each 18-month interval.

MOST REASONS WHY OLDER ADULTS MOVE FROM INDEPENDENCE MAY BE AMENABLE TO REMOTE EARLY DETECTION
J. Kaye1,2, N.C. Mattek1,2, S. Maxwell1,2, T. Hayes1,2, K. Wild1,2, T. Zittelberger1,2, 1. Oregon Health & Science University; Portland, Oregon, 2. Oregon Center for Aging & Technology, Portland, Oregon

To design optimal interventions for maintaining independence that can take advantage of remotely acquired home monitoring data of health related activities and behaviors, we sought to identify incidence rates and reasons for transitions from independence to assisted living or nursing facilities among initially independent seniors. Volunteers were 222 older adults with unobtrusive activity sensors and computers installed in their homes for the Intelligent Systems for Assessing Aging Changes (ISAAC) longitudinal study. Baseline characteristics were: mean age 84 years, 73% female and 54% living alone. After up to 4 years of follow-up, 41 (18%) subjects changed residences; 21 (9%) moved from independence to a care facility due to cognitive decline (n=7), physical health problems (n=9), falls (n=7) and mental health issues (n=1). Age and higher Cumulative Illness Rating Scale scores at baseline predicted future moving from independence (p<0.01). At most recent visit prior to move, 29% of movers were cognitively impaired vs. 13% of others (p<0.10). Subjects who moved from independence also scored higher on the Geriatric Depression Scale (p<0.01). Six percent of partnered subjects moved out of independence; 13% of singles moved out. Overall, moves from independence occurred at a rate of 3%/year. Additionally 22 deaths occurred and 12 subjects withdrew. Subjects who moved to a care facility were more likely to die (p<0.01). These data suggest that among independently living seniors transition to more dependent care settings is infrequent, but secondary to a discrete number of causes that are amenable to early detection with ambient home-based activity sensing methodologies.

TRENDS IN PHYSICAL FUNCTIONING AND DISABILITY AMONG OLDER PERSONS WITH SEVERE VISION IMPAIRMENT
S. Vasunilashorn1, B. Steinman2, 1. Population Studies, Princeton University, Princeton, New Jersey, 2. Brown University, Providence, Rhode Island

In the past decade, considerable research has chronicled change in various dimensions of health over time. Improvements in physical functioning and reduced rates of disability among older adults have been documented; however, fewer studies have examined trends in functioning among persons with specific impairments. The purpose of this study was to examine trends in physical function and disability among older persons who self-reported severe visual impairments. We used data from the US NHANES III (1988–1994; N=5222) and NHANES IV (1999–2008; N=6983) to test the hypothesis that older persons with severe vision impairments experienced similar gains in functioning as persons with normal vision. We compared these groups with respect to the percent reporting difficulty/inability in completing any of 6 functional tasks (e.g., walking quarter mile) and any of 3 activities of daily living (e.g., dressing). Results suggest that a greater proportion of persons with poor vision had functional impairment in NHANES IV (78%) than their poor vision counterparts in NHANES III (47%). Similarly, rates of disability have increased for participants with severe vision impairment across that time period (from 13% to 32%). Among persons with normal vision, a lower proportion had functional impairment over both time ranges. Given the significant strides in policy aimed at addressing disability among society, it is important to investigate whether gains in functioning have affected all population subgroups. As population aging continues, tracking this dimension of health across time has important implications with respect to the needs of older persons who have severe visual impairment.

EFFECTS OF AN OLDER ADULT MULTI-COMPONENT PHYSICAL ACTIVITY PROGRAM ON ADL PERFORMANCE
P.E. Toto1, K.D. Raina1, M.B. Holm1, E.A. Schlenk2, J.C. Rogers1, 1. Occupational Therapy, University of Pittsburgh, Pittsburgh, Pennsylvania, 2. University of Pittsburgh, School of Nursing, Pittsburgh, Pennsylvania

Less than 30% of older adults engage in any form of regular physical activity. Despite best practice recommendations and the known benefits on health, the impact of physical activity programs on older adult participation in everyday life and the performance of activities of daily living (ADL) is not well understood. This study examined the effect of the “First Step to Active Health,” a best practice physical activity program, on ADL performance, physical performance, physical activity, and depression in older adults. Sedentary older adults age 60 years and older, residing in a low-income senior apartment building, participated in a 10-week, group-based, physical activity program 2 times per week for 60 minutes, with an additional home exercise program 1 time per week. The physical activity program incorporated endurance, strength, balance, and flexibility exercises, and self-efficacy activities. Subjects were assessed at baseline, posttest (10 weeks) and post-posttest (14 weeks). Comparison of pretest and posttest scores (N=15) using a one-tailed paired samples t-test resulted in improvement (p<0.05) for 2 of 3 ADL domains on the Activity Measure-Post Acute Care and on all 6 physical performance measures of the Senior Fitness Test. Repeated measures ANOVA (N=14) revealed significant main effects (p<0.05) for 3 of 8 measures using the Yale Physical Activity Scale. The adherence rate was 89.7% and retention was 78.9%. These data support the feasibility and effectiveness of best practice physical activity recom-
ACTIVE GENERATIONS: OLDER ADULT VOLUNTEERS IMPROVING CHILDREN’S PHYSICAL ACTIVITY AND NUTRITION
J. Teufel 1, D. Werner 2, P. Holtegrave 1, J. OASIS Institute, Saint Louis, Missouri, 2. Auburn University, Auburn, Alabama

Background: Obesity, nutrition, and physical activity are important public health issues for children and older adults. Efforts to address these issues often do not integrate both age groups. To address this need, OASIS, in partnership with the University of Texas, developed Active Generations, which is an intergenerational adaptation of the evidence-based Coordinated Approach to Child Health (CATCH) program. Older adult volunteers facilitate Active Generations, which provides opportunities for children, grades 3-5, to eat healthy food, engage in physical activity, and learn about health in an out-of-school community setting. Methods: To evaluate the effectiveness of this older adult-volunteer-led program, children were surveyed before and after the program. Local coordinators also collected process evaluation data from volunteers. Results: Approximately 750 children (47% female, average age of 9 years old, 4th grade) in eight cities completed pre-test and post-test surveys, which were adaptations of the CATCH Kids Club surveys. Based on statistical analyses, child participants reported consuming more servings of fruit and vegetables, decreasing the number of hours watching television, decreasing the number of hours playing video games, and increasing the reading of food labels. Children also reported increased confidence to participate in physical activity three to five times per week, to participate in physical activity in after school programs, to run or bike during the week, and to run at a steady pace for at least 15 minutes. Conclusions: Community-based intergenerational physical activity and nutrition programs led by older adult volunteers can improve health-related attitudes and behaviors among children.

SESSION 1575 (SYMPOSIUM)

ALLOSTASIS, LIFESTYLE AND LIFESPAN: A TRANSDISCIPLINARY PERSPECTIVE
Chair: D.L. Morris, University Center on Aging & Health, Case Western Reserve University, Cleveland, Ohio

This symposium is designed to examine the impact of allostatics on human aging based on based on biological, behavioral and social, and policy and practice perspectives. Allostasis describes adaptive processes which seek to balance the internal and external demands, or stresses, which occur as one ages across the lifespan. Lifestyle has been identified as a major factor that affects the health of all persons. Individuals’ ways of living present multiple demands with cumulative effects that accrue and provide a context for identifying and assessing individuals’ attitudes, values, and behaviors. The cumulative effect of a person’s response to genetic, physiologic, psychological, social and environmental demands is described as allostatic load. Four speakers, each a Fellow representing either Biological Sciences, Health Sciences, Behavioral and Social Sciences, or Social Research, Policy and Practice Sections, will provide a definition of allostatic and a discussion of lifestyle factors affecting allostatic load. The objective of this transdisciplinary approach will be to provide an opportunity for participants to explore allostatic as a basis for understanding processes by which lifestyle choices impact individuals’ lifespans. A second objective will be to synthesize an integrated definition of allostasis that is useful to address applied and basic research to understand the cumulative effect of internal and external life style demands on the lifespan. Further, research findings the potential to inform the design of social and public health programs. It is concluded that the future of promoting lifestyles to enhance healthy lifespans will require interdisciplinary efforts of basic and translational research.

THE BASIC SCIENCE: FOCUS ON THE CARDIOVASCULAR SYSTEM
G.E. Taffet, 1. Medicine-Geriatrics, Baylor College of Medicine, Houston, Texas, 2. The Methodist Hospital, Houston, Texas

The adaptive processes invoked to compensate for stresses come with a price, that the organism, or organ system, may be less able to respond adequately to subsequent challenges. This is clearly true for the cardiovascular system. With aging, a multitude of changes occur that result in the need to call on compensatory responses. Four areas will be described in some detail: fuel source (switching from fatty acids to glucose), heart rate regulation (diminished sympathetic responsiveness), importance of atrial systole (increased reliance on left atrial systole for ventricular filling), and calcium fluxes (increased calcium movement across the sarcolemma) as they all show diminished reserves for subsequent stressors. The end result is that the cardiovascular systems of old people and old animals are adequate at rest, but perform less well when challenged. The potential for interventions, like caloric restriction, to modify processes will also be broached.

ALLOSTATIC LOAD: LINKS BETWEEN BEHAVIOR, SOCIAL, AND ECONOMIC CHARACTERISTICS
E. Crimmins, University of Southern California, Los Angeles, California

Summary indicators of biological risk or allostatic load have been proposed as an indicator of cumulative dysregulation across multiple physiological systems. Increased risk is hypothesized to result not only from large and clinically significant dysregulation in individual systems, but also from more modest dysregulation present in multiple systems. Allostatic load has been shown to be related to risks for a number of health outcomes in older ages. In this presentation we use a longitudinal data set with data over a substantial period of time, the Health and Retirement Study, to examine how allostatic load or biological risk is related to lifetime behaviors, social, and economic circumstances. Allostatic load is measured using blood pressure, pulse, waist circumference, glycosylated hemoglobin, cholesterol, C-reactive protein, cystatin-C, lung peak flow rate, and grip strength.

DO INTERVENTIONS REDUCE ALLOSTATIC LOAD OR BUFFER ITS EFFECTS AT OLDER AGES? REVIEW AND DISCUSSION
S. Robert, School of Social Work, University of Wisconsin-Madison, Madison, Wisconsin

Growing evidence from both clinical and population-based studies indicates that economic, psychosocial, and behavioral risk factors affect dysregulation in many physiological systems, with accumulation of allostatic load occurring across the life span. Given the cumulative allostatic load that people carry with them into older age, what are the program and practice interventions that reduce allostatic load or buffer its effects at older ages? While population-based studies produce recommendations for program and practice interventions, there are few interventions that actually test changes in allostatic load, and fewer still that demonstrate large impact in such changes. In this presentation, I review evidence on the role of program interventions in reducing allostatic load and its impact at older ages. I discuss areas for future research on allostatic load, highlighting what we need to know to better develop and evaluate interventions to improve the health of and reduce health disparities among older adults.

BEYOND BIOMARKERS: HOLISM, ALLOSTATIC LOAD AND THE NURSING SCIENCE CASE FOR A MORE INTEGRATED VIEW
E.R. Beattie, School of Nursing, Dementia Collaborative Research Centre: Consumers and Carers, Queensland University of Technology, Brisbane, Queensland, Australia

Allostatic load is both a theoretical construct and a measure of the cumulative impact of chronic stress on the physiological risk for disease and disability. The perspective posits that allostatic load is expected...
to increase as a function of person-environment action over time. Yet a growing body of evidence suggests idiosyncratic responses to stressors that may confer resilience and well being in late life. Limited efforts have been made to integrate an allostatic load perspective with existing stress-based theories, and the overall utility of the concept for providing an holistic understanding of trajectories of health and aging remains challenging. Existing stress-based mid-range theories from nursing science can be integrated with the allostatic load perspective to create a more holistic view of the aging experience than that provided by allostatic load.

SESSION 1580 (SYMPOSIUM)

BEYOND LONGEVITY: STRENGTH IN NUMBERS FOR GENETIC STUDIES OF HUMAN AGING
Chair: J.M. Murabito, Medicine, Section of General Internal Medicine, Boston University School of Medicine, Framingham, Massachusetts
Co-Chair: D.P. Kiel, Hebrew SeniorLife, Boston, Massachusetts
Discussant: G.J. Tranah, California Pacific Medical Center, San Francisco, California

Animal and human studies suggest that genetic factors significantly contribute to human aging but few genes have been identified to date. In this symposium we will draw on the experience of the Aging and Longevity working group within the Cohorts for Heart and Aging Research in Genomic Epidemiology (CHARGE) Consortium that came together in 2008 to facilitate large scale genetic studies and replication opportunities among longitudinal population-based cohorts in the United States and Europe. This effort currently includes 15 cohorts with >30,000 participants with genome-wide genotyping. Most genetic studies of human aging have focused on longevity, a heterogeneous phenotype that does not take into account health or function, and a limited number of candidate genes. The extensive examination of cohort participants often repeated across adulthood provides a unique and rich resource to define successful aging phenotypes that go beyond longevity to include measures of physical and cognitive function, physical performance and frailty. Dr. Amy Matteini will discuss the challenges of phenotype harmonization across many cohort studies while Dr. Gil Atzmon will review the challenges of genetic association testing and approaches to link promising genetic findings to underlying biology. Finally, Dr. David Karasik will present newly developed methods to identify genes that influence multiple aging phenotypes (pleiotropy). Participants in this symposium will learn about the process of defining aging phenotypes for genetic association studies, state-of-the-art analysis methods, new research directions to identify pleiotropic genes, and collaborations with basic scientists to uncover biologic mechanisms of aging and speed translation of findings.

AGING ASSOCIATED GENES: BEYOND THE CANDIDATE GENE APPROACH
G. Atzmon1, K. Lunetta2, 1. Medicine and Genetic, Albert Einstein college of medicine, Bronx, New York, 2. Boston University School of Public Health, Boston, Massachusetts

Genetic and non-genetic factors interact to determine aging phenotypes. A systematic approach to identify genetic determinants of aging phenotypes in elderly persons is lacking. Genome-wide association analysis (GWAS) identifies common genetic variants through unbiased genomic screening. Meta-analysis of GWAS has become the standard to combine data across cohort studies, that use different genotyping arrays, and to increase power to detect small effects of genetic variants. With ~25K subjects, we had 90% power to detect SNPs that explain ≥0.18% of phenotypic variance with genome-wide significance (GWS, p<5x10-8). Despite large samples, the GWS threshold wasn’t achieved for three aging phenotypes (walking speed, hand grip and lower extremity strength), perhaps due to cohorts heterogeneity and trait complexity. Thus, we applied a systems biology approach to link GWAS genetic signals and emerging biology. After attending this activity participants will be able to discuss the pros and cons of each analysis strategy.

FACING THE CHALLENGE: IS THE MULTIVARIATE ANALYSIS A SOLUTION?
D. Karasik1, Y. Hsu1, A. Matteini1, T. Tanaka2, D.P. Kiel2, K. Lunetta2, J.M. Murabito1, 1. Hebrew SeniorLife, Boston, Massachusetts, 2. National Institute on Aging, Bethesda, District of Columbia, 3. Johns Hopkins Medical Institute, Baltimore, Maryland, 4. Boston University, Boston, Massachusetts

To date, GWAS have already produced relevant data for multiple aging-related traits; however, none of these traits is a proxy for the whole organism’s aging. It can be hypothesized that convergent results from GWAS of multiple aging-related traits will ultimately lead to the identification of genes responsible for aging per se. Here we provide several examples of identifying potentially pleiotropic genetic polymorphisms that would otherwise not have been captured by analyzing only one phenotype. To accomplish this we apply methods such as principle component analysis and a “block-clustering” technique that simultaneously relates multiple phenotypes to multiple genotypes. We conclude that jointly considering multiple aging-related phenotypes when performing GWAS analysis is a powerful approach for genomic discovery, both by reducing the burden of multiple testing and improving statistical power by integrating phenotype information. As a further step in genetic discovery, we propose to combine several muscle strength traits based on shared genetics among them. Participants will be able to define pleiotropy and become familiar with several methods to identify pleiotropic genes.

BEYOND LONGEVITY: PHENOTYPE HARMONIZATION ACROSS COHORTS STUDIES
A. Matteini1, J.D. Walston1, T. Tanaka2, A. Smith3, D. Karasik4, A.B. Newman1, 1. Geriatric Medicine, Johns Hopkins Medical Institute, Baltimore, Maryland, 2. National Institute on Aging, Bethesda, Maryland, 3. University of Iceland, Kopavogur, Iceland, 4. Harvard Medical School, Boston, Massachusetts, 5. University of Pittsburgh, Pittsburgh, Pennsylvania

Success of genetic association analysis in age-related outcomes relies heavily on development of well-defined phenotypes. Phenotypes of physical function (walking speed, hand grip, leg strength) were selected and associations with genome-wide association study (GWAS) results were evaluated. Issues that emerged in developing these phenotypes include: cross-sectional versus longitudinal measures, exclusion criteria (age and comorbidities), covariate adjustment and tests for interaction with genetic variants (e.g., with gender or age). Across 11 studies, availability of relevant measures and data collection protocols vary widely. Walk distances ranged from 3 to 10 meters. Hand grip strength measures differed in number of trials performed and in hand(s) tested. Lower extremity strength was collected in 5 cohorts and varied methodologically. A better understanding of measurement error and cohort heterogeneity is needed to interpret GWAS results for aging-related phenotypes. Participants will become familiar with harmonization issues and learn pros and cons of analytic decision-making regarding these phenotypes.
SESSION 1585 (SYMPOSIUM)

BLUEPRINT FOR AGING WORKFORCE STRATEGY: IOM FUTURE OF NURSING & RETOOLING FOR AN AGING AMERICA REPORTS

Chair: C.R. Shillam, Betty Irene Moore School of Nursing, University of California, Davis, Sacramento, California
Disscussant: H.M. Young, Betty Irene Moore School of Nursing, University of California, Davis, Sacramento, California

Workforce planning efforts are currently underway to meet the demands of our rapidly aging population. Approaches essential to this planning must focus on both the numbers required to deliver care, as well as the quality of the delivery of healthcare services. Two valuable Institute of Medicine reports are resources to guide gerontologists in planning for increasingly complex workforce needs: Retooling for an Aging America (2008) and The Future of Nursing: Leading Change, Advancing Health (2010). This symposium will address how these reports provide a blueprint to create synergy across efforts to advance organizational strategies for assuring a diverse and well-prepared workforce to deliver care for older adults. This symposium will include presentations highlighting the key recommendations of these two landmark reports as they apply to increasing geriatric workforce capacity, followed by an interdisciplinary panel discussion of the major implications. The presenters will discuss the lessons learned from the implementation of the Retooling for an Aging America report and highlight the national strategy and progress for the Future of Nursing implementation. The panel will synthesize recommendations and themes across these reports. They will identify strategic challenges and opportunities for addressing the goal of assuring a well-prepared workforce to develop new knowledge, educate future professionals, and deliver care to older adults. The panel will also address how the interprofessional team can best contribute to new models of care for older adults in the context of these two reports.

THE FUTURE OF NURSING: ADVANCING HEALTH FOR OLDER ADULTS

This presentation will provide an overview of the key recommendations of the Institute of Medicine report The Future of Nursing: Leading Change, Advancing Health, as they pertain to the care of older adults and workforce development. Speakers will present a discussion of the partnership between Robert Wood Johnson Foundation and AARP for developing implementation strategies and the engagement of regional action coalitions. Specifically, the focus will be placed on recommendations regarding implementing nurse residencies in diverse settings, expanding opportunities for nurses to lead and diffuse collaborative improvement efforts, and preparing and enabling nurses to lead change to advance health. Presenters will also pose key challenges and opportunities for implementation of recommendations for discussion by the interdisciplinary panel.

RETOOLING FOR AN AGING AMERICA: LESSONS LEARNED

This presentation will provide an overview of the key recommendations of the Institute of Medicine report Retooling for an Aging America, as they pertain to the care of older adults and workforce development. Speakers will present an update on the implementation of particular recommendations of the report, with a focus on recommendations regarding residencies in diverse settings (both MD and RN/APRN), payer incentives to increase the number of geriatric specialists, development of National Geriatric Service Corps, and creation and dissemination of models of care for older adults shown to be effective and efficient. Presenters will also pose key challenges and opportunities for implementation of recommendations for discussion by the interdisciplinary panel.

SESSION 1590 (SYMPOSIUM)

DESIGNING INFORMATION TECHNOLOGY SOLUTIONS TO PROMOTE AN INDEPENDENT LIFESTYLE FOR OLDER ADULTS

Chair: H.J. Thompson, University of Washington, Seattle, Washington
Co-Chair: G. Demiris, University of Washington, Seattle, Washington
Discussant: D. Parker Oliver, University of Missouri, Columbia, Missouri

The US health care system is facing significant challenges as the aging population increases coupled with an aging and shrinking health care workforce. It is imperative that we explore innovative approaches to managing the health and wellness of older adults, in order to proactively maintain and maximize independence. Innovations in management include the use of information technology (IT) solutions which offer both tremendous opportunities and numerous challenges as dissemination has been limited by technical, ethical, clinical and economic issues to date. This symposium provides guidance for designing IT solutions for older adults, and includes insights into dealing with the complexities of this diverse population, demonstrating how prior experiences, education, health history, and social support affect the strategies and approaches. Designers and interventionists must consider during development, particularly the oldest-old. Despite the growing amounts of health data available through information technologies, this information is often fragmented and the overall well-being of an individual is still difficult to assess. We also discuss the role of comfort and aesthetics in acceptance of telehealth technology. Integrated approaches towards visualization of health data from IT solutions is examined from cognitive design principles to facilitate decision making by different stakeholders (e.g., older adults, family members, health care providers). Lastly, the symposium also addresses how data derived from an in-home wireless sensor-based solution using algorithmic approaches to provide cues and reinforcement can be used to proactively maintain independence and aging in place.

INTERDISCIPLINARY DESIGN APPROACHES: METHODS AND RECOMMENDATIONS FROM APPLIED RESEARCH

O. Zaslavsky, B. Reeder, K. Wlimalowska, G. Demiris, H.J. Thompson, University of Washington, Seattle, Washington

In order to design successful technology interventions that link elders, informal caregivers and health care professionals, an interdisciplinary approach that implements proven design methods and involves all stakeholders in a participatory fashion is required. However, technology to support aging in place breaks new ground and therefore design efforts for new technology inform emergent processes that link daily living and professional work activities. This session will give an overview of participatory and user-centered design methods and relate them to designing for aging populations in community and residential settings. We draw on our experiences from a pilot study in a wellness lab and demonstrate design artifacts in the form of two “personas” as tools to aid in the design for the oldest old. The session will conclude with recommendations informed by these personas that engineers, designers and interventionists should consider when designing new technology interactions.
THE ROLE OF COMFORT AND AESTHETICS IN TELEHEALTH SYSTEM ACCEPTABILITY

N. Charness1, M. Fox1, C.A. Crump2, A. Papadopoulou2, 1, Psychology, Florida State University, Tallahassee, Florida, 2, AFrame Digital, Reston, Virginia

Degree of comfort with and perceived aesthetics of telehealth monitoring devices are potentially important factors for acceptance of home telehealth technology. We outline the results of a pilot study of a remote monitoring system that used a Chumby device to administer health questionnaires daily for two weeks as well as requiring the use of a watch-like wrist device to monitor falls, temperature, and location information in the homes of 9 seniors aged 75+ years. Comfort and aesthetics questionnaires for the wrist device showed little change over two weeks, suggesting that first impressions were maintained for the device. Similar findings occurred for the comfort ratings for the Chumby. We discuss item effects for the questionnaires and their implications for acceptance of remote monitoring technology.

DATA VISUALIZATION TECHNIQUES FOR A HOLISTIC UNDERSTANDING OF OLDER ADULTS’ HEALTH

T. Le1, K. Wilamowska1, H.J. Thompson, G. Demiris1, 1, Biomedical and Health Informatics, School of Medicine, University of Washington, Seattle, Washington, 2, School of Nursing, University of Washington, Seattle, Washington

Over the last decades, there has been an increased focus on developing applications to monitor the health status of older adults. These applications produce large amounts of data that are unfortunately not presented in a meaningful way. Health information can be fragmented, making it difficult to assess the overall well-being of individuals. We have applied innovative visualization techniques to capture wellness over time from measures collected by health monitoring applications. We present several approaches to visualizing wellness guided by cognitive design principles, focusing on (1) a holistic view of wellness, (2) change in status over time, and (3) detailed information display. These visualization techniques provide an integrated view of well-being which can then be leveraged by both older adults and health care providers as a shared decision support tool. Understanding the design principles behind data visualization can help us effectively manage an increasing abundance of information.

TECHNOLOGY CONVERGENCE FOR PROMOTING AN INDEPENDENT LIFESTYLE FOR ELDERS

A. Savvides, Electrical Engineering, Yale University, New Haven, Connecticut

Aging in place involves a plethora of factors from detecting adverse health effects to proactively managing and preserving wellness. Considering the sheer numbers of the aging demographic, it becomes apparent that scalable information technologies have an important role to play in supporting unobtrusive and economically sustainable aging in place. From measuring determinants that may predict and help prevent precipitating events, to keeping elders interactive and connected to society, new technologies are expected to provide a powerful platform for delivering care and services. This symposium will provide an overview of how the convergence of information, communication and sensing technologies can provide such a platform. It will describe methods and tools for measuring wellness determinants and overview novel communication and coordination mechanisms for amortizing the cost and burden of care across multiple individuals and entities, also providing relief to family caregivers.

SESSION 1595 (SYMPOSIUM)

HEALTH, AGING, AND DIVERSITY RESEARCH: HYPERTENSION, DIABETES, EXERCISE, AND HEALTH PERCEPTION

Chair: S. Davarian, Gerontology, University of Southern California, Los Angeles, California

This ESPO sponsored symposium features a multidisciplinary group of Health Science emerging scholars. This impressive group of students in gerontology, sociology, and allied health will present on a diverse array of topics at the forefront of research in health and aging. In keeping with the theme of this year’s conference, lifestyle/lifespan, the student researchers will present on the many social, cultural, and internal factors that influence lifespan both nationally and globally. Hypertension in the 68-and-older population of Japan and the US compares hypertension prevalence rates in two economically similar but demographically different countries. The study demonstrates that hypertension rates in the US and Japan are actually similar though measured hypertension and antihypertension medication usage rates differ. A study of diabetes in Mainland China examines diabetes- and hypertension-related mortality risk among the oldest-old (77 years old or older) in an ethnically diverse Chinese population. The study also addresses urban/rural differences in diabetes prevalence. The presentation on barrier effects to exercise among African-American women is of particular interest to healthcare professionals; by identifying the barriers to exercise, healthcare professionals can work towards increasing participation among African-American women and improving the health of this population. Self-rated health in Mexican-Americans investigates whether social support, religiosity, and self-management behaviors have an effect on health status and self-rated health in older adult Mexican-Americans.

BARRIER EFFECTS TO EXERCISE AMONG AFRICAN AMERICAN WOMEN

C. Brown, Virginia Commonwealth University, Richmond, Virginia

Continued participation in physical activity among aging women continues to be a challenge for healthcare professionals. African American women constitute 52% of women who do not participate in physical activity. A survey administered to a subset of African American women (n=24) examined reported barriers between veteran and first time participants in a group exercise program and identified barrier effects on the number of completed athletic events within the 8 month trial. The four most common scheduling barriers were (1) work (67%), (2) group exercise schedule (53%), out of town/trips (33%) and family (33%). The least common scheduling barriers were running schedule (13%) and social activities (7%). Collectively, first time attendees reported more barriers to exercise and did not complete as many athletic events as veteran participants. The identification and removal of barriers by healthcare professionals may promote continued participation in exercise among older African American women.

A STUDY OF DIABETES IN MAINLAND CHINA

X. Pan, Miami University, Oxford, Ohio

The current study aims to: 1) examine diabetes- and hypertension-related mortality risk among the oldest-old (77+) ethnically diverse Chinese population in Mainland China; 2) examine the epidemiology of diabetes for the same population in urban and rural areas. The hypotheses are: 1) gender, ethnicity, diabetes and interaction of diabetes and hypertension predict the risk of mortality; 2) the prevalence of diabetes among females is higher than males in urban areas. The data come from the 1998-2005 Chinese Longitudinal Healthy Longevity Survey (CLHLS). Results indicated the interaction of diabetes and hypertension significantly predicted mortality for men only; and the risk of dying is 5 times higher for men who have diabetes and hypertension compared to those who have neither condition; females are twice more likely to have diabetes than males regardless of urban or rural areas. Objectives:
After attending this activity, participants will be able to 1) understand the health-related problem among oldest-old Chinese population. 2) discuss the impact of diabetes and diabetes-related hypertension among oldest-old population in Mainland China.

SOCIAL SUPPORT, RELIGIOSITY, SELF-MANAGEMENT BEHAVIORS AND HEALTH STATUS IN HISPANIC POPULATIONS

M. Rivera-Hernandez, Gerontology, University of Houston, Texas, 1. University of Houston, Texas

This study examines links between age, sex, and hypertension in the populations 68 years and older of Japan and the United States (US). Data come from the National Health and Nutrition Examination Survey (NHANES) (n=1,971) and the Japanese Longitudinal Study of Aging (JLSOA) (n=1,893). Sex differences in hypertension were smaller in Japan than in the US. In this country, there was no clear pattern of age differences. The prevalence of hypertension (defined as either measured high blood pressure or antihypertensive medication usage) was similar in both countries. The prevalence of antihypertensive medication use was higher in Japan and the prevalence of clinically significant measured blood pressure was higher in Japan. This study utilizes both self-report and measured blood pressure and focuses on the 68 and older population of Japan and the US, creating a more complete picture of hypertension in two economically similar but otherwise different countries.

SESSION 1600 (SYMPOSIUM)

IMPACT OF SYSTEMIC DISEASES ON ORAL HEALTH, DISPARITIES AND EDUCATION FOR HEALTH CARE PROVIDERS

Chair: B. Wu, School of Nursing, Duke University, Durham, North Carolina
Co-Chair: M.J. Saunders, 1. School of Nursing, Duke University Medical Center, Durham, North Carolina, 2. University of North Carolina at Greensboro, Greensboro, North Carolina, 3. Duke University Medical Center, Durham, North Carolina, 4. University of Michigan, Ann Arbor, North Carolina

This symposium aims to address gaps in the gerontological and oral health literature on the association between oral health and systemic diseases, the impact of cognition on oral health, on oral health disparities across racial and ethnic groups in the U.S., and on how to improve health professionals’ knowledge of these links. The first paper examines racial/ethnic variations in the number of self-reported missing teeth among Americans aged 50 and over. We analyzed five waves of data spanning from 1999-2008 from the Behavioral Risk Factor Surveillance System (BRFSS). The sample included 8,808 American Indians/Alaska Natives (AIAN), 10,043 Asians, 35,371 Hispanics, 51,744 Blacks, and 640,063 Whites. Controlling for socioeconomic status, health behaviors, and chronic diseases, results from multinomial logistic regression analysis showed that compared to Whites, blacks (OR=2.07, 95% CI: 1.75, 2.46) and AIANs (OR = 1.61, CI: 1.07, 2.44) were more likely to have lost 6 or more teeth. No significant differences were found for Asians and Hispanics, relative to white Americans. Older age, lower level of education and income, smoking, overweight, and having chronic diseases such as diabetes and hypertension were also associated with number of teeth missing in older adults (Funded by NIH/NIDCR 1R01DE019110).

ORAL HEALTH STATUS IN NURSING HOME RESIDENTS WITH DIFFERENT LEVELS OF COGNITIVE FUNCTION

X. Chen, J.J. Clark, S. Naureen, Department of Dental Ecology, University of North Carolina Chapel Hill, Chapel Hill, North Carolina

OBJECTIVES: The differences in oral health in nursing home (NH) residents with different cognitive functions remain unclear. The study’s goal was to compare oral health in NH residents with different cognitive functions. METHODS: 902 NH residents were retrospectively examined. Medical, functional, cognitive and dental assessments were abstracted from dental records. ANOVA, Chi-squared test and negative-binomial regression were used to document oral health and associated risk factors for subjects with cognitive impairment (CI), with CI but without a diagnosis of dementia, and with a diagnosis of dementia. RESULTS: Demented subjects arrived with 4.2 decayed/broken teeth, significantly more than 3.3 in those without CI (P=0.02), 40% of residents with CI but not dementia were edentulous. Multiple factors contributed to the poor oral health in NH residents. CI is significantly associated with number of missing teeth in NH residents. CONCLUSION: Oral health is poor but differs in NH residents with different cognitive functions.

TEACHING THE LINK BETWEEN SYSTEMIC AND ORAL DISEASES

M.J. Saunders1, B.M. Hicks1, 1. STGEC-Psychiatry, UTHSCSA, San Antonio, Texas, 2. SA GRECC, STVHCS-VISN 17, San Antonio, Texas, 3. Dent Hyg, UTHSCSA, San Antonio, Texas

Research has shown that older patients have better outcomes when treated by an interdisciplinary health care team. In addition, recent
research has shown a link between oral health and cerebro- and cardiovascular disease. Non-oral health professions students need to learn this information as much as do students in the oral health professions. This paper presents an innovative model for the interdisciplinary training of health professions students that focuses on the link between systemic and oral diseases. Interdisciplinary teams of students, including oral health professions students, rotate through a community nursing facility in which a dental hygienist serves as the Dental Program Director. Trainees learn how to screen NF residents for oral problems and the importance of receiving dental care to maintain or improve the residents’ nutritional and general systemic health. Trainees are administered a survey to assess knowledge gained in both oral health and interdisciplinary team care.

DIFFERENCES IN BASELINE DENTAL STATUS BETWEEN SURVIVORS VS. DECEASED AT 20 YEARS

A. Papas, P. Corrado, Tufts University School of Dental Medicine, Boston, Massachusetts

Athena Papas and Pamela Corrado, TUFTS UNIVERSITY SCHOOL OF DENTAL MEDICINE, BOSTON, Ma. Objective: Determine survival status of subjects who participated in the Nutrition and Oral Health Study, started in 1981. Methods: Death Records were examined to determine cause of death. Data were obtained on number of teeth and root tips present. Results: Survival data on 280 volunteers, age 40-80 at the start of the study, was obtained from The National Death Index and the Massachusetts Death Registry. The deceased included 91% Caucasian, 53% females and on average 12.9 years of education. Survivors included 88% Caucasian, 58% females and on average 13.7 years of education. Deceased subjects had fewer teeth (17.8±7.39) at baseline than survivors (21.55±8.63, mw p≤0.0001). In particular, those who died of cardiovascular disease had fewer teeth than survivors (mw p≤0.0001). However, deceased subjects had more root tips (2.86±3.64 vs. 1.86±2.64 respectively, mw p≤0.046). Conclusion: Good oral health is associated with a longer life span.

SESSION 1605 (SYMPOSIUM)

MUSIC AND THE AGING BRAIN

Chair: A. Balbag, University of Southern California, Los Angeles, California

Discussant: C. Finch, University of Southern California, Los Angeles, California

Music’s influential reach spans a wide spectrum, ranging from anatomical brain differences in musicians to facilitating memory recall in Alzheimer’s disease (AD) patients. Music is a complex process and distinctly unique medium: Not only is it art, or entertainment, but also a prime example of multimodal integration with lasting and beneficial effects on the brain. Given its exceptional impact, how does a musical lifestyle affect aging over the lifespan? This symposium examines the innovative connection between music and the aging brain, discussing the implications musical involvement may carry for long-term cognitive health and plasticity. Do we reap cognitive benefits from a nourished hearing environment or from actively making music, or both? The phenomenal relationship between music and AD will serve as a point of departure for implications on how music may also affect normal aging. While memory loss is the hallmark characteristic of this neurodegenerative disease, recent evidence shows musical memory to be spared in AD. Recent advances in this direction will be explored. A universal and non-invasive medium, music may serve a large and diverse population. Practical benefits of using music therapy to facilitate memory recall in dementia and AD patients will be discussed, along with suggestions for caregivers and families on how to incorporate music for patient well-being. (If possible, these dates are requested to facilitate speakers’ scheduling: November 21 or 22, 2011.)

THE CLINICAL BENEFITS OF MUSIC ON AGING, WELLNESS, AND QUALITY OF LIFE

C.M. Tomaino, Institute for Music and Neurologic Function, Bronx, New York

It has long been observed that music, particularly music of personal importance, can reach and stimulate dramatic responses in persons with Alzheimer’s disease and other forms of dementia. Attention is maintained, fragments of memories unfold, and a true connection to the “self” takes place. Current research in neuroscience indicates that there is a strong connection between the auditory system and key neural networks including the medial pre frontal cortex and limbic system. This biological link makes it possible for sound to be processed almost immediately by the areas of the brain that are associated with long term memory, and emotions. These connections also make music an important tool within the context of music therapy. Specific applications of music can be applied to support short term memory, increased physical function, long term memory recall, improved gait, and overall emotional well-being. Drawing from clinical and scientific research, the presenter will explain how and why music in an essential therapeutic tool to not only maintain aging wellness but to reach and benefit those severely limited by Alzheimer’s disease and dementia.

MUSIC AS A MEMORY ENHANCER IN ALZHEIMER’S DISEASE

N.R. Simmons-Stern,2 A.E. Budson,2 B.A. Ally,1 1. Department of Neurology, Vanderbilt University, Nashville, Tennessee, 2. Boston University, Boston, Massachusetts

There has been a drastic increase in the study of music in the area of aging and dementia. The majority of this work has found behavioral and long-term memory retrieval enhanced with music. Although using musical mnemonics to improve the learning of new information has a history of popular use, this has never been tested in patients with Alzheimer’s disease (AD). In a recent study from our laboratory, AD patients and healthy controls studied unfamiliar children’s song lyrics with either a sung or spoken recording, and were tested for their memory of the lyrics presented visually without any audio. AD patients realized a greater than 40% improvement in recognition of verbally presented lyrics when studied with music. Ongoing studies in our lab are examining whether this music-enhanced newly learned information is retained over longer study-test delays and whether music provides benefit to patients for everyday information, such as medication management.

SESSION 1610 (SYMPOSIUM)

PROMOTING OLDER ADULTS’ WELL-BEING ACROSS CARE SETTINGS THROUGH NURSE LED RESEARCH

Chair: D.F. Mahoney, School of Nursing, MGH Institute of Health Professions, Boston, Massachusetts

Discussant: M. Henderson, School of Nursing, MGH Institute of Health Professions, Boston, Massachusetts

GSA encourages scientists to focus on factors that impact the human health span and lifespan. Accordingly, we will highlight the concept of well-being and its’ constructs by focusing on improving clinical understanding and strategies to promote well being. Mahoney will present findings from focus group research conducted in Independent Living Residences. Her findings highlight the disparate meanings of independence among residents, families, and staff that resulted in the creation of a model of Connected-Disconnections which affects residents’ well-being. Roberge reports on a study of 290 patients in a geriatric primary care practice. She tracked participants over a one-year period and found that they required 451 referrals to the emergency room. In addition, she identifies their characteristics, utilization patterns, and factors that precipitated emergency care. Rosenblum-Brunt presents the key components of a nurse-family partnership for psycho-educational interventions designed to prevent or detect early onset of delir-
Instead, a home-like environment, administrative support and empowerment of staff, and shared decision-making involving family may reduce the use of feeding tubes and increase hand feeding of residents with advanced dementia.

CHARACTERIZING EMERGENCY DEPARTMENT UTILIZATION PATTERNS FROM A GERIATRIC PRIMARY CARE PRACTICE
B.J. Roberge, M. Feldmannova, K.A. Hesse, geriatrics, Massachusetts General Hospital, Boston, Massachusetts

The rate of older adults being admitted to Emergency Departments (ED) is increasing raising concerns about unnecessary utilization. Of interest is whether the frequent repeater pattern noted in the research literature similarly arises when a geriatric primary care practice manages care. Descriptive statistics were used to characterize 303 patients who had 487 referrals from a geriatric practice to the ED over an 12 month time-period. One-half of the sample were over age 85. One quarter were discharge directly home. Close to 1/3 were “repeaters” who ranged from two to seven readmissions. A pattern occurred of quick repeaters, readmitted < 30 days and just prior to death. Findings will guide future qualitative interviews with families and older adults to gain an understanding of their viewpoints about ED transfer. This knowledge is critical to developing interventions to promote wellbeing for older adults in the primary care setting.

SESSION 1615 (PAPER)

SEXUALITY AND SELF PERCEPTION IN LATER LIFE
“I’VE NEVER TALKED ABOUT THIS BEFORE”; THE SOCIAL EXPERIENCES OF OLDER ADULTS WITH GLBTQ FAMILY MEMBERS
K. Scherrer, University of Michigan, Ann Arbor, Michigan

Individuals are increasingly likely to “come out” as gay, lesbian, bisexual, transgender, and queer (GLBTQ) and disclose this identity to their families. Yet little is known about how this news impacts older adults, particularly in their experiences with social others (e.g., family, friends, clergy, medical professionals). In this paper examine how older adults socially experience having a GLBTQ family member and what motivates an interest in talking with others. I use in-depth qualitative interviews with 32 older adults (ages 62-97) who have at least one GLBTQ family member who is “out” to them. Interviews were recorded, transcribed, and analyzed utilizing open and focused coding methods. I found that most participants were reluctant to share about their GLBTQ family member(s) with others, although the motivations for doing this varied greatly. For some, non-disclosure was motivated by shame or embarrassment stemming from negative views about homosexuality. For others, lack of interest in disclosure was motivated by feeling awkward in not knowing how to talk about it, or a desire to avoid negative social repercussions for themselves or for their family member. While most were reluctant to share about their GLBTQ family member(s), a small subset of participants spoke with social others to seek emotional support, to educate themselves, or to advocate on behalf of their family member. Implications for helping professionals will be discussed, as they may usefully dispel negative stereotypes about GLBTQ individuals, cultivate comfort talking about issues of sexuality, or provide emotional support for older adults struggling with this news.

OPENNESS TO DISCUSSIONS OF SEXUALITY WITH A DOCTOR IN LATER LIFE: THE IMPORTANCE OF MARITAL QUALITY
S. Adams, Sociology, Case Western Reserve University, Cleveland, Ohio

Many older adults engage in regular sexual activity and maintain a strong interest in sexuality. The importance of recognizing the sexual health needs of older adults has gained increased attention in recent years, with both scholars and policy makers emphasizing the need for
sexual health to become a regular part of older adults’ conversations with medical professionals. However, both medical professionals and older patients are often reluctant to discuss issues of sexual health. Therefore, this study examines the influence of marital quality on attitudes related to openness regarding discussions of sexuality with a medical doctor using data from the nationally representative National Social Health and Aging Project (NSHAP). This research focuses specifically on the marital dyad since the marital relationship is often the center of one’s social network in later life, and because having a supportive spouse is associated with health promotion behaviors, including the seeking of medical care. Results indicate that higher levels of positive marital quality predict greater comfort discussing sex with a doctor among men, as well as greater approval of such discussions among both men and women. After attending this session, participants will be able to explain (1) the influence that a supportive spouse has on older adults’ openness to sexual health conversations with medical professionals and (2) why attitudes concerning communication about sexuality represent an important facet of well-being in later life.

CORRELATES OF HIV STIGMA IN A POPULATION OF OLDER ADULTS LIVING WITH HIV DISEASE IN ONTARIO, CANADA

BACKGROUND: Evidence suggests that HIV stigma negatively impacts the mental health, quality of life and social experiences of older people with HIV/AIDS (PHAs). The primary objective of this study was to determine sociodemographic, psychosocial and health-related variables that contribute to HIV-related stigma in a sample of older PHAs. MEASURES: This cross-sectional study analyzed data from PHAs who participated in the Ontario Cohort Study, a community-governed, multi-site research study that collects clinical and socio-behavioral information voluntarily from PHAs across Ontario. The present study analyzed data from 377 participants (age 50+) who completed an assessment battery between September, 2007 and March, 2010. Sociodemographic, psychosocial and health-related data were analyzed using multiple linear regression; total HIV stigma scale score was the dependent variable. RESULTS: Emotional and informational social support (p<.001), and mastery (p<.001) served as protective factors against stigma while maladaptive coping (p<.01) and less time since diagnosis (p<.01) were associated with greater stigma. Both older women (p<.05) and heterosexual men (p<.05) had higher scores of HIV stigma as compared to men who have sex with men (MSM). The final model adjusting for all factors simultaneously accounted for more than 30% of the variance (R2 = .31) for HIV stigma. CONCLUSIONS: Findings suggest the importance of healthy internal mechanisms (mastery), and external factors (emotional and informational support) as protective factors against the deleterious effects of HIV stigma in older adults. Interventions designed to reduce the impact of stigma and strengthen protective components among HIV-positive older adults, needs to be examined.

SESSION 1620 (SYMPOSIUM)

“PRACTICING TO SCOPE”: NURSING SCOPE OF PRACTICE AND NURSING HOME RESIDENT QUALITY OF CARE OUTCOMES
Chair: K. Corazzini, Duke University School of Nursing, Durham, North Carolina
Discussant: C. Mueller, University of Minnesota School of Nursing, Minneapolis, Minnesota

The 2010 IOM report, “The Future of Nursing” calls for nurses to practice to their full scope of practice; thus, understanding relationships between regulation of nursing scope of practice and care outcomes for older adults in nursing homes (NHs) is critical. In NHs, licensed practical nurses (LPNs) are predominant, rather than registered nurses (RNs); RNs are the professional nurses whereby LPNs have a directed scope of practice under RN supervision, specifics of which vary by state Nurse Practice Act (NPA). Yet, NH use of LPNs continues to increase while RN presence is declining. Further, presence of advanced practice RNs (APRNs) in NHs is low (12% of NHs have an APRN). Given these staffing patterns, regulation of scopes of practice may affect quality of care, both in terms of blurred scope of practice boundaries, whereby LPNs may be performing care beyond their scope, as well as differences in what states allow APRNs, RNs, and LPNs to do. This symposium will examine relationships between nursing scope of practice and NH quality of care from the perspectives of how RNs and LPNs understand their scope of practice and differences in how states regulate scopes of practice. If nurses are to practice to their full scope for improved quality of healthcare nationally, understanding how nurses currently enact their scopes of practice, the differences between states in the regulation of nursing practice, and the effects of these understandings and differences on quality of care outcomes are fundamental to inform regulatory and policy changes.

LICENSED PRACTICAL NURSE SCOPE OF PRACTICE-SENSITIVE CARE OUTCOMES
K. Corazzini1, R.A. Anderson1, C. Mueller2, E.S. McConnell1, L.R. Landerman3, J.M. Thorpe1, 1. Duke University School of Nursing, Durham, North Carolina, 2. University of Minnesota School of Nursing, Minneapolis, Minnesota, 3. Duke University School of Medicine, Durham, North Carolina, 4. University of Wisconsin School of Pharmacy, Madison, Wisconsin

In the past decade, nursing homes (NHs) have increased use of licensed practical nurses (LPNs) by 20% while decreasing registered nurses (RNs) by 25%. This trend contrasts with the non-substitutability of LPNs for RNs due to scope of practice. This study explored differences between state Nurse Practice Acts in LPN practice and Centers for Medicare and Medicaid Services Quality Measures (CMS QMs). Using mixed models of 2007 data from the Online Survey Certification of Automated Records merged with CMS QMs, (N=13,300 NHs) we related aspects of regulation of LPN practice to quality of care outcomes, controlling for state-level and facility-level factors. Pain, catheterizations, and urinary tract infections were consistently related to LPN scope of practice. State differences in LPN scope of practice related to quality for this set of LPN practice-sensitive care outcomes. Relying on LPNs to deliver licensed nursing care in NHs could lead to poorer quality for certain outcomes.

LOCAL INTERACTION STRATEGIES AND RN AND LPN ENACTED SCOPES OF PRACTICE
R.A. Anderson1, S.R. Hunt1, C. Mueller2, E.S. McConnell1, K. Corazzini2, 1. School of Nursing, Duke University, Durham, North Carolina, 2. University of Minnesota, Minneapolis, Minnesota, 3. Durham Veterans Administration Medical Center, Durham, North Carolina

As derived from complexity science, behaviors used by nurses to exchange information, connect with staff members, and promote cognitive diversity are known as relationship-oriented local interaction strategies (LIS). This paper examines the use of LIS in relation to how nurses in nursing homes enact their scopes of practice (SOPs). While SOPs are the legal parameters of what an RN or LPN can do, they do this in work settings in interaction and in response to each other. Data were drawn from a comparative multiple case study of nursing homes in two states (N=45 homes. 225 RNs and LPNs); interviews were coded for use of LIS in relation to 5 components of SOP, assessment, care planning, care evaluation, delegation, and supervision. Results suggest that...
use of LIS is related to both how nurses understand what their SOP is as well as to how they enact their SOPs.

APRN REGULATION AND POTENTIAL FOR IMPROVED QUALITY OF CARE IN LONG-TERM CARE

Despite evidence of the relationships between use of advanced practice registered nurses (APRNs) in NHs and better resident care outcomes, prevalence of APRNs in NHs remains low. Importantly, differences between states in the regulation of APRN practice have the potential to affect their use and implementation; this paper compares state statutes and regulations of APRN scope of practice applicable to APRN practice in NHs. Data were drawn from all 50 states and the District of Columbia’s Nurse Practice Act and Medical Practice Act statutes and code. A mixed-methods analysis was conducted, in which qualitative coding of statutes and code were transformed to quantitative indicators of the permissiveness and restrictiveness in APRN scope of practice. Findings indicated that variations in permissiveness and restrictiveness in APRN scope of practice provided potential incentives and disincentives to NHs to effectively employ and use APRNs for improved quality of care.

DON TENURE AND UNDERSTANDING DIFFERENCES IN RN VERSUS LPN SCOPES OF PRACTICE FOR NURSING HOME CARE

As clinical leaders in nursing homes (NHs), the director of nursing (DON) is the authoritative voice concerning nurse practice scope enactment. Longer DON tenure has been linked to improved resident care outcomes. The purpose of this cross-sectional, mixed-methods, comparative multiple case study of nursing homes in two states (N=45 DONs) conducted with facility DONs, we found that DONs with longer tenure and understanding of registered nurse (RN) and licensed practical nurse (LPN) practice scopes of practice. Findings indicated that variations in permissiveness and restrictiveness in APRN scope of practice provided potential incentives and disincentives to NHs to effectively employ and use APRNs for improved quality of care.

INCOME SECURITY IN CANADA & OTHER OECD COUNTRIES: WILL INCLUSION IN MILLENIUM DEVELOPMENT GOALS ERADIATE POVERTY IN THE OLD?
G.M. Gutman, Simon Fraser University, Vancouver, British Columbia, Canada

While currently in Canada only 6% of couples aged 65+ are below the poverty line, the proportion among unattached women 65+ is almost 50%. High poverty rates also occur among Aboriginals, and other subgroups. This paper examines how inclusion in the MDGs and a UN Convention on rights of older persons might impact chronic or extreme poverty groups in Canada and other OECD countries. Income inequality will also be addressed. Between mid-1990 and mid-2000 Canada had the 2nd largest increase in gap between rich and poor among similarly developed countries. Income inequality also increased in the USA and Finland but fell in other countries e.g. UK, Netherlands. Poverty indicators focus on the bottom of the income scale. Inequality indicators show how resources are distributed across the society. The distribution of resources in a country can affect the extent and depth of poverty. Inequality is also linked to health and social problems.

THE IMPACT OF POVERTY ON HEALTHY AGING IN A CHINESE COMMUNITY
A.F. Tiwari, The University of Hong Kong, Pokfulam, Hong Kong

Methods: Through in-depth, semi-structured, individual interviews, 98 Chinese women in Hong Kong described the factors that impacted on their healthspan and aging lifespan as well as that of their intimate older partners. Results: The women confirmed the many factors known to impact on human healthspan and lifespan including socioeconomic status, education, social engagement, and coping skills. In addition, the circumstances in which such factors existed were also revealed. Specifically, poverty, discrimination, and poor coping skills co-existed which further diminished their and their partner’s control over healthy aging with adverse health outcomes. Worthy of note is that such circumstances occurred in a seemingly affluent society with inadequate poverty eradication policies. Conclusion: Individual’s control over the factors impacting on healthy aging should be considered in the context of societal response to poverty.

CONFRONTING HOMELESSNESS AMONG TURKEY’S OLDER POPULATION: A HOME FOR THE HOMELESS
I. Tufan, Akdeniz University, Antalya, Turkey

While the Turkish Statistical Institute reports that 14,000 people of all ages are registered as homeless, 2010 data suggests there are really some 283,000 homeless in Turkey. Among the homeless in the province...
of Aydin, 128 are 60+ years of age. Three years ago in Aydin, a housing project began to provide temporary or year round shelter and assistance for such older persons. These prefabricated homes are constructed on Aydin Municipal Government land. Aside from providing refuge from the potentially fatal elements of winter, these homes provide older residents with a new perspective on life. To date, 60 older persons have escaped from the social stigma of life on the streets, and live in dignity. Of these, 21 have accepted assistance and live in ½ room homes. Others have benefited from temporary residency. Sponsors support construction of fully-furnished homes with heating units. Residents receive routine health assessments and dental care.

GLOBALIZATION, POVERTY AND OLD AGE: WHY SHOULD WE CARE?
I. Doron, Haifa University, Haifa, Israel

The experience of ageing is becoming more globalized. Older persons are moving across the world for various reasons: joining their adult children in foreign countries; migrating to big cities or warmer climates; returning to their country-of-origin or distantly caring for other ageing family members. However, from an economic perspective, in many countries, older persons still suffer from poverty. Especially in developed countries, the aged population is characterized by high rates of poverty and deprivation. This general picture hides a more complex socio-economic reality in which minority or weakened social groups, such as women, disabled, or the older old, experience even higher rates of poverty in old age. An ethical argument is presented for the moral duty to eliminate poverty in old age. This principled argumentation will attempt to go beyond the existing general and universalistic reasoning that supports the eradication of poverty as such, and will try to emphasize the uniqueness of the social phenomenon of old age.

SESSION 1630 (SYMPOSIUM)

PERSONALISATION AND PREVENTION IN ENGLAND
Chair: K.C. Jones, Personal Social Services Research Unit, University of Kent, Canterbury, United Kingdom
Co-Chair: J. Forder, Personal Social Services Research Unit, University of Kent, Canterbury, United Kingdom
Discussant: K. Windle, Personal Social Services Research Unit, University of Kent, Canterbury, United Kingdom

Within the political agenda to modernise both health and social care services in England, we have increasingly seen terms such as ‘personalisation’ and ‘prevention’. Both are seen to be central to the aim of encouraging older people to become more involved in service design and how they receive both social care and health care support that meet their new needs. To support the development of interventions around personalisation and prevention, a number of evaluations have been commissioned by the Department of Health in England. The symposium will present findings from three evaluations: the Partnership for Older People’s Project (POPP), the Home Care Re-ablement Study and the Personal Health Budgets Evaluation (PHBE).

THE PARTNERSHIP FOR OLDER PEOPLE PROJECT’S
K. Windle, Personal Social Services Research Unit (PSSRU), University of Kent, Canterbury, United Kingdom

The Department of Health initiated and funded the Partnership for Older People’s Project which ran from May 2006 to March 2009. An independent evaluation was commissioned to run alongside the programme to explore the impact of the projects on user outcomes. The EQ-5D was used to measure, (amongst other outcomes), the changes in health-related quality of life (HRQoL), as compared to a similar sample drawn from the British Household Panel Survey. Through grouping the 62 projects into well-being (primary) and secondary and tertiary preventative categories, we demonstrate the changes in HRQoL. In particular, the perhaps unexpected health improvements found within the lower-level well-being projects, those that provided gardening, shopping and small repairs. The differences found within and across the interventions are also explored; identifying those structures and processes that may be supporting greater improvements. The POPP programme demonstrated that prevention and early intervention, positively affected HRQoL.

THE HOME CARE RE-ABLEMENT STUDY
K.C. Jones, J. Forder, Personal Social Services Research Unit (PSSRU), University of Kent, Canterbury, United Kingdom

Home care re-ablement is a new, short-term intervention in England which helps service users to regain confidence and relaunch self-care skills and aims to reduce needs for longer-term support. The study found that re-ablement was associated with a significant decrease in subsequent social care service use. The costs of the social care services used by people in the re-ablement group during the 12 months of the study (excluding the costs of the re-ablement intervention itself) were 60 per cent less than the costs of the social care services used by people using conventional home care services. However, this reduction in social care costs was almost entirely offset by the initial cost of the re-ablement intervention. At a ‘willingness to pay’ threshold of £30,000 for each increase in health-related quality of life, there is a very high probability (just under 100 per cent) that home care re-ablement would be cost effective.

PERSONAL HEALTH BUDGETS EVALUATION
K.C. Jones, J. Caieis, E. Welch, Personal Social Services Research Unit (PSSRU), University of Kent, Canterbury, United Kingdom

The Department of Health in England is now leading a personal health budget pilot programme and have commissioned a national evaluation that runs from November 2009 to October 2012. Twenty sites from the 70 pilots were selected to be in-depth evaluation sites with the remainder being wider cohort sites. The in-depth evaluation will cover the following conditions: long-term health conditions; mental health; NHS continuing health care; and stroke. An important aspect of the evaluation explores early experiences of implementation within the pilot sites. Interviews were conducted with personal health budget project leads, operational staff, health professionals, commissioning managers and third party budget holders. While the majority of participants were enthusiastic about the potential of personal health budgets and the positive impact of providing more choice and control, there were a number of challenges they faced in implementing the initiative, which all relate to changing the culture of health service delivery.

SESSION 1635 (SYMPOSIUM)

RECRUITING PEOPLE WITH DEMENTIA FOR INTERVENTION STUDIES IN PRIMARY CARE & COMMUNITY-BASED SETTINGS
Chair: R.H. Fortinsky, Center on Aging, University of Connecticut Health Center, Farmington, Connecticut
Discussant: M. Downs, Bradford University, Bradford, United Kingdom

This symposium will report experiences of recruiting community-dwelling people with dementia (PWD) for participation in non-pharmacological intervention studies in the U.S. and England. Presentations will describe lessons learned when recruiting, enrolling, and retaining PWD for studies within primary care practice settings and other health and social care organizations. This topic will become more important as: 1) non-pharmacologic interventions are increasingly tested and disseminated in primary care and community settings to help improve health-related outcomes for PWD and their family caregivers, and 2) efforts increase to improve dementia-related diagnostic and management skills of primary care practitioners. The symposium panel will include four presenters, two from each country, and a discussant, Steve
RECRUITMENT EXPERIENCES IN THE PROACTIVE PRIMARY DEMENTIA CARE PROJECT
R.H. Fortinsky, Center on Aging, University of Connecticut Health Center, Farmington, Connecticut

This presentation will describe progress in implementing and evaluating Proactive Primary Dementia Care (PPDC) in community-based primary care group practice sites. PPDC utilizes a nurse practitioner (NP) with geropsychiatric nursing competencies as the interventionist; the NP affiliated with three Connecticut primary care group practices to provide evidence-based protocol-driven care over 12 months to consenting people with dementia (PWD) and their family caregivers (dyads) referred by physicians. Three other practice sites serve as control group dyad referral sources. Recruitment relies primarily on study invitation letters from physicians to potentially eligible dyads with follow-up contact from practice site staff members. We also must establish capacity to consent in PWD for study eligibility. To date, 18 dyads are enrolled in the study and recruitment continues. This presentation will detail study recruitment strategies, successes, and challenges within the context of busy community-based primary care offices with numerous competing priorities.

RECRUITING PEOPLE WITH DEMENTIA TO AN EDUCATIONAL INTERVENTION IN PRIMARY CARE
S. Iliffe, University College London, London, United Kingdom

The EVIDEM-ED study is an RCT of educational interventions designed to enhance the diagnostic and management skills of primary care physicians and nurses. Its primary outcome is the number of patients identified with dementia in 23 group practices in South East England. Secondary outcomes are the quality of care for people with dementia (based on chart reviews) and caregiver satisfaction with primary care services (based on interviews before and after the intervention). The trial has identified 800 people with dementia at baseline, of whom 192 agreed to take part in the secondary outcomes part of the study. Nineteen patients were excluded at the request of their primary care physician, and five withdrew, leaving a study sample of 168 who agreed to the review of their medical records. Eighty of their carers granted interview views. This presentation will describe recruitment strategies used to recruit this sample, and preliminary findings from the trial.

FACTORS AFFECTING CLINICIAN ENGAGEMENT IN RECRUITMENT FOR DEMENTIA TRIALS
D.P. Lowery, Central North West London Foundation Trust, London, United Kingdom

A randomised controlled trial of tailored walking for the management of Behavioural and Psychological Symptoms of Dementia (BPSD) experienced very poor recruitment despite strong support from stakeholders. From a population exceeding two thousand people with dementia only six participants were recruited in the first six months despite minimal exclusion criteria. Consequently we invited clinicians to facilitate roundtable discussions on their perceptions of research, impediments to their role as recruiters and ways to enhance recruitment. Several impediments to clinicians identifying participants to the study team emerged, including: Clinicians feeling accountable for the research; concerns about overburdening participants; anxiety about participants once the research ended; concern about participants feelings if allocated to the control group; clinicians deciding on behalf of their patients that this research was a low priority and lack of perceived rewards for referring participants. Addressing these concerns led to far better recruitment rates.

RECRUITMENT AND RETENTION OF PERSONS WITH DEMENTIA AND FAMILY CAREGIVERS IN INTERVENTION RESEARCH
C.J. Whitlatch, Benjamin Rose Institute on Aging, Cleveland, Ohio

Research indicates that persons with dementia (PWDs) and their family caregivers (CGs) are able to participate together and benefit from psychosocial interventions. These interventions range in approach, intensity, and duration. Regardless of variation, common to all interventions are the challenges of recruiting, enrolling, and retaining PWDs and CGs throughout the study period. This presentation describes a variety of challenges to recruitment, enrollment, and retention, and provides recommendations for solutions to these challenges. Recommendations are based on five research studies with over 150 PWD-CG dyads recruited from non-primary care settings. Examples of successful and unsuccessful recruitment strategies will be described such as targeted radio advertising, and referrals from social service organizations, geriatric assessment centers, and home health agencies. Also described, and equally important, are successful enrollment and retention strategies which include targeted screening, continuity of interviewer and intervention staff, and regular follow-up contact with participating PWDs and CGs.

SESSION 1640 (SYMPOSIUM)

TRANSFORMING CLIMATE, COMMUNITIES AND ENGAGING ELDERS IN ENVIRONMENTAL STEWARDSHIP
Co-Chair: R. Harrell, Public Policy Institute, AARP, Washington, District of Columbia
Discussant: D. Whitman, US Senate Special Committee on Aging, Washington, District of Columbia

As our population rapidly expands and ages, our communities have choices on how to respond to these changes. One approach is to support public health, well-being and create a healthier environment. Another path can detract from safety and health, promote sprawl, increase air pollution, climate change and offer few transportation choices. Local planning that supports active living through policies such as complete streets and transit oriented development can also increase social engagement, physical activity and decrease greenhouse gas emissions and other environmental hazards. Sustainable communities offer protections from potential health and safety hazards and promote opportunities for community engagement and physical activity. This symposium will discuss federal, state and local policies to create sustainable communities in the public and private sectors. Presenters from HUD and EPA will discuss success with the Partnership for Sustainable Communities. We will also address how smart growth efforts can be successful, if done correctly, and how they can fail to meet the needs of older adults or other goals if done poorly. Research findings from AARP and from the University of Maine will share their results from specific initiatives. After attending the session, participants should be able to...
develop a working knowledge of the best practice strategies for engaging older adults as volunteers and community leaders; identify the motivational factors that influence baby boomers and older adults to become involved in civic engagement and environmental stewardship and describe the health, environmental and other benefits from smart growth.

CREATING LIVABLE AND SUSTAINABLE COMMUNITIES THAT BENEFIT OLDER ADULTS: RESEARCH AND POLICY ANALYSIS
R. Harrell, AARP Public Policy Institute, Washington, District of Columbia

Governments at all levels are promoting the development of “livable” or “sustainable” communities, which can have several benefits for healthy aging. These are compact and feature mixed land uses, and if they are well-designed, they can foster greater engagement among residents, transportation options and may also improve residents’ and workers’ health by encouraging walking and biking and minimizing air pollution from vehicle traffic. Successful mixed-use development and transit-oriented development (TOD) require coordinating several government functions and working with the local community, including the private sector. If not specifically addressed in the planning, the needs of older adults can be excluded from the benefits. This session will discuss the results of a study on TOD and older adults, including the ways that sustainable and livable communities can help support healthy aging (or fail to do so) and introduce the policies needed to ensure that outcome.

THE FEDERAL AGENDA FOR SUSTAINABILITY AND ITS IMPLICATIONS FOR OLDER AMERICANS
R.C. Gray, US HUD, Washington, District of Columbia

An integral feature of a sustainable neighborhood design is mixed-use development that encompasses both residential and commercial uses, one that increases opportunities for physical activity, is safe, inclusive, and provides access to housing, jobs, and valuable community amenities. Developing sustainable communities will require active and ongoing coordination between local and regional governments, fostered and supported by incentives at the federal level. A sustainable community will also require active involvement and partnerships with private and non-profits entities, community development organizations, and advocacy and philanthropic groups—all which are committed to expanding housing choice, improved transportation and infrastructure planning, and promoting green and energy-efficient strategies that protect the environment and conserve natural resources. In order to evaluate how well communities are fulfilling the goals of sustainability, we must first understand how the ways in which we plan impacts the availability of affordable housing; the combined costs of housing and transportation for low- and moderate-income families; access to job centers, health care services, and other essential destinations; and, respond to the needs of a growing, changing and aging population. During this session, participants will discuss how federal programs and policies, such as those administered by the HUD-DOT-EPA Partnership for Sustainability, have assisted communities in pursuit of sustainability goals. The issue is whether these goals include a focus on the challenges faced by older Americans as their needs change.

ENGAGING OLDER ADULTS TO SOLVE COMMUNITY PROBLEMS: EXAMINING MOTIVATIONAL FACTORS AND DEMOGRAPHIC PROFILES OF OLDER ADULTS ENGAGED IN ENVIRONMENTAL STEWARDSHIP
L.W. Kaye, J. Crittenden, D.C. Wihry, A. Chamberlain, UMaine Center on Aging, Bangor, Maine

Encore Leadership Corps is a state-wide volunteer leadership program focused on engaging older adults in the areas of development and housing (N=34 projects); staying active, connected, and engaged (N=74 projects); staying healthy (N=47 projects); and transportation and mobil-ity (N=3 projects). One hundred and forty members, who are between 50 and 85 years (Mean=63 yrs), are working to address community and environmental issues in their respective regions. One such project, the Safe Medicine Disposal for ME Program, has successfully engaged older adults as both participants and volunteers to safely dispose of over 5,000 lbs. of medicine while positively impacting nearly 4,000 households in Maine. This presentation will provide an overview of outcomes data from two novel programs that utilize older adults to solve environmental issues. Demographic profiles of program participants and case study vignettes will be used to illustrate strategic motivational factors that influence baby boomer and older adult volunteers.

CHANGES TO THE BUILT ENVIRONMENT CHANGE CLIMATE CHANGE

Community design is critical for the sustainability of a community, as well as the health and well-being of its residents. By redesigning the built environment, it is possible to create transportation and mobility options that benefit people’s lives. Land use decisions by local planners that promote mixed use policies can better connect people to places that we commonly visit in our daily lives. Motor vehicles generate greenhouse gas emissions in the short and long term. These short-lived greenhouse pollutants (sulfates, carbon, and ozone), are significant risk factors for cardiovascular mortality. Poor air quality, due primarily to ozone and particulate matter (PM), is responsible for premature deaths in older adults who are afflicted by cardiovascular disease or COPD. In 2008, 36% of persons 65 and older lived in counties with poor air quality for ozone and 11% for particulate matter (2.5 microns). Reducing these pollutants can lead to an immediate health dividend.

SESSION 1645 (SYMPOSIUM)

UPDATE YOURSELF ON OLDER WORKER TRAINING AND EMPLOYMENT
Chair: A.A. Sterns, College of Nursing, Kent State University, Kent, Ohio, iRxReminder LLC, Akron, Ohio, The University of Akron, Akron, Ohio
Discussant: A. Sarmiento, Senior Service America Inc., Silver Springs, Maryland

Training adult and older adult workers continues to be a major priority in a changing work environment for older worker employment. Innovations and best practices in employment and training programs need critical attention. This symposium, sponsored by the aging and work interest group, focuses on current research and practice and provides new data and information regarding older worker programs successes and difficulties. The symposium will share the findings of a 2010 AARP study on older worker training. We will share updates on the evaluation of recent partnerships and collaborations among Senior Community Service Employment programs, Workforce Investment Act programs, and the aging network. Finally, we will share recent data on successful training on older adults in the use of new technologies and successful training outcomes. In combination, the symposium presents support for the importance of maintaining a strong interventionist perspective in a period of difficult re-employment for older workers.

INNOVATIONS AND BEST PRACTICES IN EMPLOYMENT AND TRAINING PROGRAMS FOR OLDER WORKERS
P. Cummins, S.R. Kunkel, Miami University, Oxford, Ohio

Older workers are more likely to remain in the workplace longer today than in recent years. The economic downturn has resulted in an increase in the unemployment rate, especially for those 55 and over, reaching levels not observed in the past 60 years. When older workers become unemployed, it takes them longer to find a new job than their younger counterparts, and they are less likely to participate in training.
programs. While older workers are quite capable of learning new skills, training may take longer than younger adults. This paper, describes innovations and best practices in employment and training programs for older workers, including Individual Training Accounts, collaborations between Senior Community Services Employment Programs and Workforce Investment Act programs, and the role of the aging network in fostering effective partnerships. A well-structured, effective, and efficient employment and job training program for older workers is a critical pathway to economic self-sufficiency.

OLDER WORKER TRAINING IN A WORLD OF UNCERTAINTY
S.E. Rix, AARP Public Policy Institute, Washington, District of Columbia

Employer concerns about skills obsolescence and comfort with new technology continue to bedevil older workers and jobseekers. In October 2010, a nationally representative employment survey of 5,027 (1) workers, (2) jobseekers, and (3) recent retirees aged 50+ was undertaken by the AARP Public Policy Institute. This presentation will highlight analyses of questions on recent training by the different categories of respondents, including a subset of retirees who returned to the workforce. It will focus on variations in who received job-related training, its type, why training was undertaken, and how training was paid for. It will also discuss whether workers and jobseekers felt that training helped them in their careers or job search. The unemployed and those who recently left the workforce were least positive, despite the potential importance of training for these groups. The presentation will conclude with a discussion of the finding’s implications for public- and private-sector training policy.

AN UPDATE ON TRAINING, TECHNOLOGY, AND OLDER ADULTS
H.L. Sterns1, A.A. Sterns1,2,4, 1. College of Nursing, Kent State University, Kent, Ohio, 2. iRxReminder LLC, Akron, Ohio, 3. The University of Akron, Akron, Ohio, 4. The University of Maryland, Akron, Ohio

There continues to be ageism regarding the training of older workers. Many training professionals believe that older adults cannot master the use of the latest technologies such as smartphones and the applications they support. Research funded by NIA/NIH has clearly demonstrated that the use of well-established life-span developmental approaches to training can be successful. Examples of successful research with training older adults will be presented. The research using smartphones and computer-based training shows success in utilizing technologies for formal work tasks as well as demonstrations of self-management of health-related tasks that are important and applicable to maintaining employment.

INNOVATIONS AND BEST PRACTICES IN EMPLOYMENT AND TRAINING PROGRAMS FOR OLDER WORKERS
P. Cummins1, S. Kunkel1, 1. Sociology & Gerontology, Miami University, Oxford, Ohio, 2. Scripps Gerontology Center, Oxford, Ohio

Older workers are more likely to remain in the workplace longer today than in recent years. The economic downturn has resulted in an increase in the unemployment rate, especially for the over 55 and over 65-age groups, reaching levels not observed in the past 60 years. Less educated and lower earning older adults have a greater risk of job loss and are more likely to have difficulty finding new employment. The only public employment program dedicated to older workers, the Senior Community Service Employment Program (SCSEP), is underfunded and is not structured to provide training that will be necessary for many older workers to find new employment and remain in the labor force. This paper describes innovations and best practices in employment and training programs for older workers and explores ways in which existing programs might be changed to better meet the needs of older workers.

SESSION 1650 (SYMPOSIUM)

BEST LAID PLANS: THE IMPACT OF UNFORESEEN CHALLENGES ON THE ECONOMIC SECURITY OF OLDER ADULTS
Chair: C.E. Bishop, Heller School for Social Policy and Management, Brandeis University, Waltham, Massachusetts
Discussant: G.A. Mackenzie, AARP, Washington, District of Columbia

Adverse health events, layoffs and changes in family structure (widowhood, divorce, marriage) can shake the firmest foundation for retirement. The Economics of Aging Interest Group is pleased to present a symposium that considers whether and how older adults approaching retirement experience and plan for these risks and then details the impact of these shocks on wellbeing in retirement. First, interview and survey findings for a group of relatively asset-rich older adults anticipating retirement are analyzed to provide insight into how older adults assess and prepare for possible retirement challenges. Especially relevant to current events, our second presentation focuses on the choices and future wellbeing associated with labor market fluctuations near the expected retirement date. Third, analysis of a national sample of retired persons estimates the actual risk of some of these shocks, the distribution of risk for subgroups, and the impact of shocks on economic security in retirement. Finally, the link between health shocks and retirement insecurity is explored in an analysis of the impact of health events and out-of-pocket health spending on unsecured debt with implications for bankruptcy risk.

THINGS THAT GO BUMP IN RETIREMENT: TYPES OF THINKING AND PLANNING STRATEGIES

Effective retirement planning requires building not only a solid foundation of retirement resources but also a flexible strategy for responding to the unexpected: those things that “go bump” in retirement. How do people think about and respond to the unexpected? Researchers at MetLife’s Mature Market Institute and Miami University’s Scripps Gerontology Center studied pre-retirees and recent retirees, conducting fifty interviews with couples and individuals (n=79) and surveying a nationally representative sample (n=1007). Twelve challenges to a secure retirement and ten types of thinking about those challenges were identified with implications for retirement decisions. Responses to imagined risks and consequences of the unexpected are varied and dynamic; that is, individuals may express different types of thinking related to particular challenges and they may change their thinking according to context and circumstances. Finally, couples who don’t share thinking and decision styles may be at risk for reduced confidence in their retirement plans.

RECESSIONS, RETIREMENT, AND SOCIAL SECURITY

We examine how labor market fluctuations around the time of retirement affect labor force withdrawal, Social Security claiming, and subsequent retiree wellbeing. To this end, we use 30 years of data from the March Current Population Survey as well as data from the Census and American Community Surveys. We find support for the notion that workers are more likely to leave the labor force, to collect Social Security earlier, and to have lower income later in life when a recession hits around the time of retirement. The impact is greatest for the less-educated, who are more susceptible to job loss and rely more heavily on

64th Annual Scientific Meeting 437
Social Security to support them in retirement. These findings highlight the importance of focusing on older workers who have lost their jobs in the present recession and may suffer lower income for many years as a result.

**POST RETIREMENT SHOCKS: INCIDENCE AND IMPLICATIONS FOR FINANCIAL WELLBEING**

We use waves 1-9 of the Health and Retirement Study (HRS) to investigate the evolution of assets post-retirement and how this evolution is affected by shocks in family structure, health, and cognition. Our sample is individuals from the initial HRS cohort who claimed OASDI benefits at age 62 or older. Individuals are tracked over time with respect to their exposure to adverse events. During each period post-retirement the level of household wealth is estimated from self-reports of asset values and flows of pension, annuity, and social security income. These data are used to pursue two objectives. The first is to provide a view of what sorts of shocks retirees are exposed to, the rate of exposure to these shocks, and how this rate of exposure differs across individuals. The second objective is to provide evidence on the impact of these shocks on wealth-based measures of retirement savings adequacy.

**THE EFFECTS OF HEALTH SHOCKS AND OUT-OF-POCKET MEDICAL EXPENDITURES ON CONSUMER DEBT**

K.A. Zurlo, H. Kim, W. Yoon, J. School of Social Work, Rutgers University, New Brunswick, New Jersey. 2. University of Kentucky, Lexington, Kentucky

This paper examines two issues related to health and financial burden in mid-aged and older Americans: 1) whether or not new health events affect the accumulation of consumer’s uninsured debt (no collateral in borrowing) including credit card debt, and 2) to what extent do associated out-of-pocket medical expenditures contribute to the accumulation of uninsured debt. We used four biennial waves (1998, 2000, 2006, and 2008) of the Health and Retirement Study (HRS). We find that new health events of severe and mild conditions affect the accumulation of uninsured debt. New severe conditions lead to approximately 50 percent to 60 percent more uninsured debt than new mild conditions in measures of dollars and probabilities of increases in debt. Although those with new health events have uninsured debt of $1,100 to $1,700 more compared to those without health problems, approximately 10 percent is attributed to out-of-pocket medical expenditures.

**SESSION 1655 (POSTER)**

A MULTIDISCIPLINARY PERSPECTIVE ON CHRONIC ILLNESS MANAGEMENT IN THE ELDERLY

**THE RELATIONSHIP BETWEEN HEALTH LITERACY AND HEALTH STATUS AMONG PARTICIPANTS IN A CONGESTIVE HEART FAILURE DISEASE MANAGEMENT PROGRAM**

To better understand the relationship between self reported health literacy and health status among Medicare enrollees with an AARP® Medicare Supplement Insurance (i.e. Medigap) plan insured by UnitedHealthcare Insurance Company (or UnitedHealthcare Insurance Company of New York), we surveyed 649 Medigap members in a Heart Failure (HF) disease management pilot program. The surveys assessed the members’ health status, health literacy, satisfaction with the HF program, and perceptions of how the HF program helped make their health. 410 members (65.8%) responded to the survey. Nearly two-thirds (64.3%) of the respondents were ‘extremely’ or ‘quite a bit’ confident in filling out medical forms by themselves (a measure of health literacy), while the rest were either ‘somewhat’ (23%), ‘a little bit’ (5%), or ‘not at all’ (8%) confident in filling out forms by themselves. Only about 10% reported ‘excellent’ or ‘very good’ health status, while 44% reported ‘good’ and 46% ‘fair’ or ‘poor’ health status. The health status responses were stratified by responses to confidence in filling out medical forms to establish a relationship. As a result, 84% of those in ‘excellent’ or ‘very good’ health were ‘extremely’ or ‘quite a bit’ confident filling out medical forms. Meanwhile, 66% of those in ‘good’ and 58% of those in ‘fair’ or ‘poor’ health were ‘extremely’ or ‘quite a bit’ confident filling out medical forms, respectively (P<0.05; Chi-Square test). Health literacy appears to decline with health status. This is problematic, as those in the poorest of health often require the most extensive care.

**THE EFFECTIVENESS OF EVIDENCE-BASED SELF MANAGEMENT CLASSES IN RURAL OLDER ADULTS**

R.E. McAttee, K.A. Packard, T. Horton, Donald W. Reynolds Institute on Aging, University of Arkansas for Medical Sciences, Little Rock, Arkansas

Background: The Stanford University Chronic Disease Self-Management Program (CDSMP) serves as a model that teaches participants the skills to manage chronic conditions and build their self-confidence so they can be successful in adopting healthy behaviors and enhance their quality of life. A Matter of Balance (AMOB) uses practical coping strategies to reduce the risk and fear of falling by incorporating exercises to improve strength, coordination and balance. Working together to assure prevention programs are part of the nation’s health, state units on aging, the academic health science campus, and the state health departments are full partners in administering the program in AR.

Purpose: To conduct a statewide assessment of CDSMP and AMOB programs and participants while analyzing outcomes. Method: Observation and surveys of CDSMP and AMOB leaders during classes, observation of programs, phone surveys of non-completers, and phone survey of participants regarding their perceived clinical outcomes via self report on factors such as dietary changes, blood test, physical activity changes, emotional well-being, and quality of life. Results: Leaders ensured the fidelity of programs and participants were very satisfied with the programs. Both quantitative and qualitative results indicate self-reported overall improvement in clinical and emotional outcomes. Conclusion: These evidence-based educational programs generated positive outcomes for older adults in rural areas and the next steps will be to follow participants to obtain objective quantitative data on clinical outcomes, hospitalizations, and readmissions.

**BARRIERS TO POSITIVE HEALTH BEHAVIORS AMONG OLDER WOMEN WITH CHRONIC ILLNESS**

C. Warner, K.B. Adams, A.R. Roberts, J. Lee, J.A. Arendt, M. Paek, Case Western Reserve University, Cleveland, Ohio

The importance of positive health behaviors for management of chronic illnesses is emphasized in health literature and practice but less is known about barriers to performing these behaviors. We surveyed 138 women (mean age = 72.6 (6.2)) with one or more chronic illness about their adherence to ten key health behaviors. Behaviors included regular provider visits, healthy diet, regular exercise, medication compliance and pacing themselves. These women reported an average of 3.93 chronic illnesses, with the highest incidence of hypertension, arthritis and diabetes. Those with diabetes, followed by arthritis, reported high levels of interference with daily activities. The majority of the sample reported they regularly performed all ten health behaviors, with positive endorsement ranging from 56.9% to 98.6% for these items. The
three behaviors with the highest non-endorsement by the sample were 1) exercise, 2) researching their health conditions via media, and 3) adequate sleep. Most notably, 43.1% reported they did not get regular exercise or physical activity and 23.2% did not regularly get enough sleep. Fourteen written reasons for not exercising regularly focused on respondents’ pain from exercising (arthritis, foot or knee issues) and other health-related reasons (reliance on oxygen, easily winded). Ten reasons offered for insufficient sleep focused on pain or worry keeping the women from sleep. Findings suggest that barriers to participation in health behaviors are primarily illness-related for these older women. Poor health can restrict older adults from performing healthy behaviors. Implications for strategies to increase positive self-management behaviors are discussed.

LVADS AS DESTINATION THERAPY: BURDEN OF TREATMENT VS. BURDEN OF DISEASE
I. Hupey, L.A. Kikta, Penn State, University Park, Pennsylvania

The number of Americans with heart failure is increasing. Although new interventions have improved survival, 50% of patients will die within 5 years of diagnosis. One intervention, left ventricular assist devices (LVADs), has been shown to improve survival in patients with end-stage heart failure. Initially developed as a bridge to transplantation, LVADs are now implanted permanently as destination treatment (DT) in patients who need cardiac support but are not heart transplant candidates. The number of LVAD-DT implants as a life-prolonging EOL treatment is increasing yet, there remains a paucity of research on the EOL experiences of patients and the impact of living with a device requiring continued care and external battery support. The purpose of this study was to examine changes in perception of burden of disease versus the burden of treatment for patients over the course of the LVAD-DT trajectory. Methods: A cross-sectional sample of 20 older patients 1 month post LVAD implant through two years post-implant were surveyed. Patients were asked to rate their perceptions of the burden of disease and treatment prior to the implant and their present perceptions of burden of disease and treatment post-LVAD implant. Findings: For the majority of patients, the burden of disease dramatically decreased initially, then stabilized. The burden of treatment was significantly higher for all patients initially, but decreased considerably for some, but for others remained elevated. Further research is needed to determine why the level of burden remained elevated for some patients and where interventions could impact this finding.

DIETARY MANAGEMENT AND EMOTIONAL DISTRESS AMONG COUPLES COPING WITH TYPE 2 DIABETES
R.C. Hemphill1, M. Franks2, A. Seidel2, M.P. Stephens3, K.S. Rook1. 1. Psychology, Kent State University, Kent, Ohio. 2. Purdue University, West Lafayette, Indiana. 3. University of California, Irvine, Irvine, California

Individuals with diabetes commonly experience feelings of worry, anxiety, and sadness directly related to their disease and its management. Furthermore, among married couples, patients’ diabetes can be a source of emotional distress for partners without diabetes. Because adhering to a healthy diet is often the most difficult aspect of disease management for patients, as well as the most visible aspect of diabetes management for spouses, both partners may be especially emotionally responsive to patients’ successes and failures in managing their diet. Limited research, however, has attempted to link emotional distress of both marital partners directly to patients’ dietary management. The current study examined setbacks in patients’ adherence to a recommended diet as a predictor of diabetes-specific distress and depressive symptoms among 112 older couples in which one partner (the patient) was diagnosed with type 2 diabetes and the other partner (the spouse) was not. In-person interviews were conducted three times over the course of one year. Concurrent analyses showed that each partner’s reports of patients’ dietary setbacks were positively associated with their dietary setbacks were positively associated with their diabetes distress, but were unrelated to their depressive symptoms. Additionally, in longitudinal analyses, only spouses’ reports of patients’ dietary setbacks predicted increases in their diabetes distress and depressive symptoms six months later. Findings highlight the need to consider the short- and long-term emotional consequences of patients’ difficulties maintaining a healthy diet, not only for patients with diabetes, but also for their spouses.

SUBJECTIVE HEALTH AND BIOLOGICAL DYSREGULATION IN THE CONTEXT OF PHYSICAL ILLNESS IN OLDER ADULTS
V. Racine, J. Jobin, C. Wrosch. Psychology Department, Concordia University, Montreal, Quebec, Canada

Self-rated health has been shown to be a significant predictor of declines in physical health and subsequent mortality even when controlling for objective indicators of physical health (Mossey & Shapiro, 1982). The mechanism by which self-rated health predicts mortality remains ambiguous, though one proposed mechanism may be the adaptive use of health engagement control strategies (Wrosch & Schulz, 2008). High self-rated health may lead to engagement in health engagement control strategies when individuals face high levels of chronic illness which may translate to adaptive biological regulation of the immune system (e.g., low levels of C-Reactive Protein, CRP); Jylhä, Volpato, & Guralnik, 2006). It was hypothesized that the interaction between self-rated health and objective health would significantly predict CRP. It was further expected that this relation would be mediated by the use of health related control strategies. The Montreal Aging and Health Study (N = 111) was used to test this hypothesis using a cross-sectional design. The interaction between self-rated health and objective health significantly predicted CRP levels. Specifically, individuals with high levels of chronic illness and high self-rated health showed significantly lower levels of CRP compared to those with high chronic illness and low self-rated health [F(6, 111) = 2.30, p = 0.04]. However, the adaptive use of health-related control strategies was not found to significantly mediate this relation. The results indicate that high levels of self-rated health may be protective against systemic inflammation in the face of chronic illness. Implications are discussed.

THE DUALITY OF OPTIMISM AND PESSIMISM IN ELDERLY AFRICAN AMERICAN PATIENTS WITH HEART FAILURE
C.J. Burant1,2, G. Graham3, R.A. Siders1, R.S. Boxer1. 1. Case Western Reserve University, Cleveland, Ohio. 2. Louis Stokes VA Medical Center, Cleveland, Ohio

African Americans (AA) have higher morbidity, mortality rates, more functional decline, and more hospitalizations associated with heart failure (HF) as compared to other races. Self-care, such as adherence to medication and low sodium diet are important to controlling symptoms and improving quality of life. The current study examined the dual nature of optimism and pessimism in AA patients with HF. Specifically, how optimism and pessimism may impact self-care issues and health outcomes differently. Data were collected from 35 older AA subjects at a HF clinic at a large Midwest university affiliated hospital. A medium effect size of <.30 for correlations was used to determine potential relationships among the variables of interest. The mean age of the cohort was 76 years (SD=7.8), 72% women, 57% were New York Heart Association (NYHA) class II, and 37% NYHA class III, 83% had systolic HF with a mean ejection fraction of 41%. Higher levels of optimism were positively correlated with self-care issues including: KCCQ self-efficacy score (r=.31), frequency of adherence (r=.31) and negatively correlated with higher levels of difficulty in adherence (r=-.31). Conversely, pessimism showed no relationship with these outcomes. Higher scores on pessimism were associated with poor health outcomes, such as the KCCQ symptom stability score (r=.34), KCCQ quality of life score (r=-.35) and positively correlated with the NYHA heart failure.
classifications \((r=.35)\). Optimism was not associated with any of these measures. Preliminary findings suggest that in AA patients with HF, optimism impacts self-care issues while pessimism impacts health outcomes.

**LIKELIHOOD OF USE OF THE SPANISH VERSION OF STANFORD’S CDSMP BY THE OHIO HISPANIC POPULATION**

J.K. Chahal, S. Kunkel, *Sociology & Gerontology, Miami University, Oxford, Ohio*

High prevalence of chronic conditions among Hispanics combined with the aging of the population reinforces the need for preventative programs within this community. Previous studies on Hispanic utilization of prevention programs have been predominantly conducted in the southwestern region of the United States. In order to expand knowledge in less Hispanic populated regions, this study aimed to understand factors influencing the Hispanic population’s potential use of preventative services. This research was conducted to determine if the Ohio Hispanic population would be likely to use the Spanish version of Stanford’s Chronic Disease Self-Management Program (CDSMP), and to identify factors associated with successful implementation. The study was divided into two phases (key informant interviews and distribution of surveys to potential clients) and was conducted at a total of four site locations, one in each major metropolitan area of Ohio. Results show that the major factors important for successful implementation of the CDSMP are: building a context of trust for the program, expanding and creating community collaborations, and providing financial and infrastructure support for organizations and their clients. These findings suggest that improving partnerships within the community will provide appropriate resources and support systems for implementing a new program, while ensuring to avoid budgetary concerns associated with providing overlapping services. Future program implementation should focus on creating established and trusted community collaborations in order to minimize barriers to preventative services and increase utilization among the surrounding Hispanic community.

**TYPE 2 DIABETES CARE: THE IMPORTANCE OF OLDER PATIENTS’VALUES**

C.L. LaCoe\(^1\), E.A. Beverly\(^2\), M. Scanze\(^1\), R.A. Gabbay\(^1\), L.A. Wray\(^1\), J. Psychology, University of Massachusetts Dartmouth, North Dartmouth, Massachusetts

Although type 2 diabetes is increasing in prevalence and costs, effective care may reduce the physical, emotional, and financial toll of the disease and its complications. Recent diabetes guidelines recommend individualized care based on patient characteristics; patients’ values for care were identified as important components of individualized care. Values represent an enduring belief that a specific behavior or ideal is personally or socially preferable. Given limited research on the topic, we examined older adults’ values: (1) values for diabetes care by age category; (2) perceptions of how often their doctors asked about their values for care; and (3) the relationship between perceived doctors’ concern for values and blood glucose levels (HbA1c). Following on our qualitative study of older adults’ values for diabetes care, we conducted telephone interviews with 91 older adults living in Central Pennsylvania, collecting data on demographics, health status, values for diabetes care, and attitudes about diabetes. Leading values for desired diabetes outcomes included “staying as healthy as possible” and “having an enjoyable quality of life” in both the younger and older age category. Leading values for desired diabetes lifestyles included “being thankful for current health” and “living life as one wants to” in both the younger and older age category. Nearly half (49%) of the participants reported that their doctors almost never or generally did not ask about their values for care. These same adults also reported significantly lower HbA1c levels (\(R^2=0.1969, p=0.0163\)). After controlling for covariates, this relationship remained significant.

**BENEFITS OF GROUP DIABETES EDUCATION FOR OLDER ADULTS**

E.A. Beverly\(^2\), Y. Lee\(^1\), K.M. Brooks\(^1\), B.A. Hultgren\(^1\), J.S. Bishop\(^1\), O.P. Ganda\(^1\), M. Munshi\(^1\), K. Weinger\(^1\)

1. Behavioral Research, Joslin Diabetes Center, Boston, Massachusetts, 2. Harvard Medical School, Boston, Massachusetts, 3. Beth Israel Deaconess Medical Center, Boston, Massachusetts

To examine the value of group diabetes education for older adults with type 1 and type 2 diabetes who have not reached A1c targets, we compared older patients (>60 years old) who attended group education classes to younger patients (<60 years old). In our ongoing study, we measured glycemic control, self-care behaviors, and psychosocial factors (diabetes distress=Problem Areas in Diabetes; frustration with diabetes treatment=Self-Management Questionnaire; frequency of self-care=Self-Care Inventory-Revised) at baseline and 3, 6 and 12 months post education. To date, 194 patients have completed the 3-month assessment (38%/>=60 years, 87% White, 48% female, 63% type 2, 55±12 years old, 15±2 years of education, 17±11 years with diabetes, A1c=9.0±1.2%). Wilcoxon t-tests found that groups did not differ on demographic characteristics; however, baseline levels of A1c and frustration with diabetes treatment were higher in younger patients (9.2% vs 8.6%, \(p=0.001\); 52 vs 42, \(p=0.004\)) and self-care behaviors were higher in older patients (64 vs 54, \(p<0.001\)). At 3 months post education, both older and younger patients improved A1c levels (delta -0.4% vs -0.6%, \(p=0.5\)), self-care behaviors (delta 2.5 vs 6.4, \(p=0.04\)), diabetes distress (delta -6.4 vs -5.7, \(p=1.0\)), and frustration with diabetes treatment (delta -6.9 vs -9.5, \(p=0.1\)). Older and younger patients only differed on self-care behaviors with younger patients showing greater improvement at the 3-month assessment. These preliminary data suggest older patients receive equal benefit to participating in group education as do younger patients. Clinicians can recommend group diabetes education classes to older patients struggling with glycemia.

**CARDIOVASCULAR DISEASE RISK FACTORS AND SOCIAL SUPPORT ON COGNITIVE DECLINE IN OLDER ADULTS**

A.M. Couto, A.J. Revel, Psychology, University of Massachusetts Dartmouth, North Dartmouth, Massachusetts

The influence of cardiovascular disease risk factors on cognitive decline was investigated in middle-aged and older adults. Longitudinal research (Kivipelto et al., 2001) has demonstrated mid-life blood pressure and serum cholesterol concentrations are indicative of cognitive decline in later life. Relative to blood pressure, this relationship is moderately attenuated with anti-hypertensive treatment (Launer et al., 2000), suggesting better control of early cardiovascular risk factors may reduce the occurrence of late life cognitive decline. Pearson (1986) also purported the inestimable importance of socially supportive relationships and effective social networks in mental and physical health. Lack of social networks or support systems has been linked to higher mortality, cardiovascular disease, and psychiatric issues. In our investigation of community-dwelling adults (Mage=68.36, range 53-90 years), global cognitive status (MSBDT=5.87, range=0-28), self-reported vascular health, and blood pressure were assessed. Of those tested (N=42), 38 indicated having a history of vascular health issues. Results indicated a statistically significant relationship between living arrangement (residing alone or with family members who might potentially serve as caregivers) and systolic blood pressure. F(3, 37)=3.42, \(p=0.03\), diastolic blood pressure, F(3, 37)=6.82, \(p=0.00\), and mean arterial pressure, F(3, 37)=5.93, \(p=0.02\). In addition, persons who scored at or above 24 on the MMSE perceived more social support (M=6.17; range=1-7) from friends than persons who scored below 24 (e.g., clinical dementia) on the MMSE (M=4.42). These associations suggest preliminary evidence of cardiovascular risk severity as important in the assessment of social support and cognitive status.
COMORBID CHRONIC DISEASES AND MENTAL HEALTH DISORDERS IN OLDER ADULTS: RISK AND PROTECTIVE FACTORS

J.D. Flatt, S. Albert, D. Musa, M. Silverman, Behavioral and Community Health Sciences, University of Pittsburgh, Pittsburgh, Pennsylvania

Objectives: Guided by the life-span theory of control, we explored the risk and protective factors for comorbid depression and anxiety in older adults with two chronic diseases: osteoarthritis and ischemic heart disease. The life-span theory suggests that optimal primary and secondary (OPS) control strategies help older adults with managing their health problems.

Methods: Data are based on a population-based sample of older African Americans (N=443) and whites (513) who reported on self-care practices. Multiple linear regression analysis was used to assess whether constructs of the life-span theory of control were associated with depression and anxiety symptomatology independently and jointly. Results: Those with ischemic heart disease and females were at greater risk for comorbid depression and anxiety. After adjusting for age, race, and health conditions, memory impairment and pain remained a significant risk factors for depression, whereas memory impairment was not a significant risk factor for anxiety or comorbid depression-anxiety. Higher levels of OPS control strategies were associated with less risk for depression, anxiety, and comorbid depression-anxiety (B=-1.53, p < .001; B=-2.16, p < .001; B=-3.69; p < .001, respectively). Implications: Research has suggested that control strategies are important for managing health threats and quality of life. Our findings suggest that older adults with higher levels of control strategies are at a decreased risk of mood disorders. Interventions for increasing self-care strategies in older adults with comorbid chronic illness and depression-anxiety may help to alleviate these psychological problems, improve adaptation to health stresses and increase overall quality of life.

CONTRIBUTION OF SATISFACTORY SUPPORT TO SELF CARE IN PERSONS WITH CARDIAC DISEASE

M. Sebern, Nursing, Marquette University, Milwaukee, Wisconsin

Although the literature emphasizes the importance of social support and health, little attention is directed to relationship processes that foster or inhibit the expression or receipt of support. In prior work, Shared Care was identified as a system of three relationship processes (communication, decision making, and reciprocity) used to exchange satisfactory support between cardiac patients and family members who provide unpaid assistance to them. The purpose of this study was to examine the association between cardiac patients’ and family caregivers’ perception of Shared Care and the patient’s self care and health. A cross-sectional design was used. Survey data was collected from 91 patient/family caregiver dyads (182 participants). Factor correlation models were used to validate associations between patients’ and caregivers’ Shared Care, and patients’ self care and health. The typical patient was a 67 year old Caucasian male with a high school education. The typical caregiver was a 59 year old Caucasian female, spouse, with a high school education. Correlations between dimensions of patient Shared Care and dimensions of their self-care were moderate and significant (r = 0.24 to 0.36, p < .05). The correlations between dimensions of patient’s Shared Care and their mental health were also significant (r = 0.35, p < .007). All 3 dimensions of caregiver Shared Care correlated positively with patient mental health (r = 0.36 to 0.39, p < .003). In conclusion the data supported associations between Shared Care and self care and mental health. Interventions to enhance Shared Care may improve health outcomes for cardiac patients.

USES OF HEALTH CARE SERVICES AMONG OLDER ADULTS THAT HAVE BEEN DIAGNOSED WITH CANCER IN MEXICO

M. Rivera-Hernandez, Gerontology, Miami University, Oxford, Ohio

The prevalence of cancer in Mexico has steadily increased in the past decade, and this condition is now one of the major causes of death in Mexico. Despite the medical advances, cancer cases still increased. The aim of this study is to determine the use of conventional health care services and complementary and alternative medicine (homeopath or folk healer) in a national sample of Mexican older adults that have been diagnosed with cancer. The Mexican Health and Aging Study (MHAS) is a longitudinal representative study of older adults. There were 299 people who were diagnosed with cancer or malign tumor excluding skin cancer 50 years and older. The most commonly used treatments included chemotherapy, surgery/biopsy, radiation/X-ray, and medication/treatment for side effects of treatment. This study uses linear regression models to analyze the relationship between demographic characteristics (age, sex, education, and ethnicity), comorbidities (high blood pressure, heart disease, stroke, arthritis, and vision problems), urban/rural residency, and health insurance. The findings suggest that the number of visits to homeopaths and folk healers is related to the sex of the patient and whether the patient lives in rural/urban areas, and have been diagnosed with diabetes. Also, the number of visits to the physician appears to be related to the sex of the person and comorbid conditions, insurance coverage, and rural/urban environment. These findings may help us to understand the problems with access to conventional treatment and traditional therapies.

GEO- NARRATIVE: UNDERSTANDING THE ROLE OF PLACE AND SOCIAL SUPPORT IN THE SELF- MANAGEMENT OF CHRONIC CONDITIONS

I.S. Harvey, D. Hudson, M. White, Kinesiology and Community Health, University of Illinois Urbana Champaign, Champaign, Illinois

Social support is a complex multidimensional construct which can be beneficial to individuals with chronic health conditions. Understanding the relationship between social support system and self-management practices depends on ascertaining the role of the physical environment. This study integrated Geographic Information System (GIS) and narrative analysis to visualize and understand the complexity of self-management practices among older adults residing in senior homes and the strategies they adopt maintain their health and wellbeing. The GIS-based narrative analysis used narrative analysis as the qualitative approach, 3D GIS-based time geographic methods as the representational framework, and 3D-VQGIS as the computer-aided qualitative data analysis component. Using life path as the representational tool, the respondents’ narratives about their experience and events were chronologically organized, visualized, and interpreted. As qualitative materials were incorporated into GIS through hyperlinks, they were linked to specific geographic features in the GIS database. Based on 30 interviews, the study mapped the route of the older adults and found that African American women self-management practices were much more spatially restricted compared to non-Hispanic white women. By studying the social support systems, the study found that both men and women residing in the senior homes considered friendships as an important social predictor in their daily self-management practices. The study shed light on the complex relationships between the social and physical environment, and self-management practices among residents of a senior housing complex. The results have implications in designing specific support programs within senior housing.

SESSION 1660 (POSTER)

ACROSS BORDERS: CROSS-CULTURAL AND CROSS-NATIONAL STUDIES OF AGING

EXPLORING THE RELATIONSHIP BETWEEN QUALITY OF LIFE AND MORTALITY IN OLD AGE: A COMPARATIVE STUDY

C. Li1, P. Bath2. 1. Kainan University, Taipei, Taiwan, 2. The University of Sheffield, Sheffield, United Kingdom

Introduction: Lower quality of life may increase the risk of mortality in old age. Although previous research has suggested that predic-

64th Annual Scientific Meeting 441

Downloaded from https://academic.oup.com/gerontologist/article-abstract/51/suppl_2/1646194 by guest on 30 April 2018
tors such as health, social relationship, and depression can affect mortality among older people, little research has explored the relationship between quality of life (QOL) and mortality. Therefore, the purpose of this research was to determine the relationship between QOL and long-term mortality among older people in the UK and Taiwan. Methods: Data were derived from the 1989 waves of two nationally-representative samples of older people: the Nottingham Longitudinal Study of Activity and Ageing (NLSAA) in the UK, and the Survey of Health and Living Status of the Elderly in Taiwan (SHLSET). Kaplan-Meier analysis and the log-rank (Mantel-Cox) test were used to explore the relationship between levels of life satisfaction (low versus high) and 14-year mortality in old age in the two studies. Results: There was a significant difference in the mean survival time for people with high and low levels of life satisfaction over the 14-year period in unadjusted models in both studies. There was not a significant difference in survival for people with high life satisfaction between the two countries ($p=0.588$). However, people with low life satisfaction in the SHLSET study (Taiwan) lived significantly longer than people with low satisfaction in the NLSAA study (UK). Conclusion: Older people with higher reported QOL had lower long-term mortality than people with low reported QOL. Whether this is due to QOL per se, or due to mediating factors, is not clear. There was some evidence of a cross-national difference among people with low QOL. Further analyses will explore the QOL-mortality relationship further whilst controlling for potential explanatory factors.

THE CES-D IN CROSS-NATIONAL AND LONGITUDINAL PERSPECTIVE: DOES THE GENDER GAP IN DEPRESSIVE SYMPTOMS PERSIST OR NARROW ACROSS TIME IN THE UNITED STATES AND JAPAN?
A. Tiedt, Sociology and Anthropology, Fordham University, Bronx, New York

Past research has described the gender gap in depressive symptoms as one of the most persistent mental health phenomena of recent decades. However, few cross-national studies have compared the gender gap in longitudinal perspective. This research used data from the University of Michigan’s Health and Retirement Study (HRS) and the Nihon University Japanese Longitudinal Study of Aging (NUJLSOA) to examine fluctuations in depressive symptoms, as captured by the CES-D, over two survey waves. The study posited that social support would mediate the relationship between gender, somatic health and depressive symptoms and that the correlates of depressive symptoms for Japanese elders would be contingent on multigenerational living arrangements. Results confirmed the existence of the gender gap across cultures and the importance of family support variables in Japan. In the United States, marital status, rather than support from adult children, was the key social determinant of depressive symptoms. At the same time, continued marriage and community contact had a protective effect on depressive symptoms among men in either nation. The analyses also revealed that disability and chronic illness had a direct relationship with depressive symptoms among most U.S. elders, while increases in chronic conditions were problematic for Japanese women. These results imply that despite contemporary preferences for independent living among Japanese, family support relationships centered on filial piety continue to have consequences for elder mental health. In contrast, spouses are the main buffers against depressive symptoms in the United States.

THE EFFECTS OF LIFESTYLE ON PROCESS OF AGING IN CHINA
K. Huang, Y. Zhu. 1. Sociology Department, Peking University, Beijing, Beijing, China, 2. Social Work & Social Administration, Hong Kong, Hong Kong, China

Existing studies believed that lifestyle affects deterioration, particularly the senescence of the elderly population. But to what extent does lifestyle affect the process of aging? This study retested this assumption in case of China and explored a more specifically quantitative result based on the follow-up data from the five waves Chinese Longitudinal Healthy Longevity Survey (CLHLS). This study made a cross-sectional study in the 2008 data to examine the differences among the elderly population who have lifestyle disparity and also does a longitudinal research on the elderly people aged 65 above, firstly observed in 1998 and followed up in 2000, 2002, 2005, and 2008, and the middle-aged adults aged 35-64, firstly observed in 2002 and followed up in 2005, and 2008, in order to distinguish diverse aging processes for people having various lifestyles. The process of aging (dependent variable) was defined by the behavior and cognitive ability and classified into several steps of deterioration. The lifestyle (independent variable) was measured by smoking, physical exercise and diet. This study used Ordered Logit regression model and our findings from this study demonstrated as follows: Firstly, the elderly people who own different lifestyles have significantly different aging features; Secondly, the effect of smoking on aging process is considerably significant for both the middle-aged adults and the elderly people while the impacts of physical exercise and diet on aging process is remarkably significant for the middle-aged adults but slightly for the elderly people.

THE EFFECT OF ACCULTURATION ON DEPRESSION OF KOREAN IMMIGRANT ELDERS LIVING IN CANADA AND U.S.

Korean immigrant elders experience high levels of depressive symptoms. In current literature, often adjustment (or acculturative) stress has been assumed to be a source of depression among immigrants, including immigrant elders. However, the correlates of depression may not be uniform across different migration environments. The purpose of this study was to examine and compare factors that influence the level of depression among Korean immigrant elders living in Canada and the U.S. by combining data from two separate studies in Arizona State (Tucson & Phoenix), the U.S., and the metropolitan area of Toronto, Canada. Original variables from both studies were compared and the common variables were extracted to build a single dataset. A total of 245 participants ages 65 or older (mean age: 73.5, SD=6.67) from Arizona (n=117) and Toronto (n=128) were used for regression analysis of depressive symptoms (Geriatric Depression Scale-Short Form: GDS-SF). Results showed similarities between two groups in demographic characteristics including gender composition, marital status, and educational level and the level of depression. However, regression analyses revealed distinctive patterns between two groups. Acculturation variables, such as years since immigration and English proficiency, were negatively associated with GDS-SF in Arizona, where the Korean population is small, but not significant in Toronto, where Korean community is well developed with many services available in ethnic languages. The results suggest that the capacity of ethnic community Korean immigrant elders may have played a role in the differential development of depression. Implications for practice, education, and future study were discussed.

THE IMPACT OF OLDER ADULTS’ QUALITY OF LIFE ON AGING: RESULTS FROM SF-6D
S.V. Humboldt, I.P. Leal, Instituto Superior de Psicologia Aplicada (ISPA), Lisbon, Lisbon, Portugal

Objective: The increase of older adults in the population has emphasized the need for consideration of what it takes to live this phase of life with a sense of quality and satisfaction. This research aims at examining the relationships between older adults’ quality of life (QoL) and aging. Methods: For the purposes of this study, the Health Survey Questionnaire (SF-6D), one measure of cognitive functioning - the Mini-Mental State Examination (MMSE) and demographics, were included. Measures were completed using a variety of culturally appropriate meth-
TWO DIFFERENT CONTEXTS, THE US AND COSTA RICA
SUBJECTIVE SURVIVAL EXPECTATIONS AND OBESITY IN LIFE; SUCCESSFUL AGING.

Background: Except for few exceptions, there is no research done on subjective survival expectations related to excess body weight in developed countries; for developing countries, research on this topic is scant. Objective: To study the determinants of subjective survival expectations in two different contexts, the US and Costa Rica. Given the relationship found between obesity and mortality, the focus is put on the effect of excess body weight on these expectations. Data: 2004 Health and Retirement Study (HRS) and 2004-2006 Costa Rican Study on Longevity and Healthy Aging (CRELES). Both studies are fully compatible. Subjects: Individuals aged 60–90. The sample size is 10531 for the HRS study and 1206 for the CRELES study. Method: Ordered Logistic Regressions. In the CRELES study the answer to the subjective survival question is a 4-point Likert scale ranging from “Very Likely” to “Very Unlikely.” In the HRS study it can be any integer between zero (“Absolutely no Chance”) and 100 (“Absolutely Certain”). The subjective survival answers given by HRS respondents were transformed to the mentioned 4-point scale. The analysis stratifies individuals by age (60–69 and 70–89). Results: Results show similarities between the HRS and CRELES studies in the determinants of subjective survival expectations. Health-related variables seem to mediate the relationship between obesity and subjective survival expectations among individuals in the younger age group in the CRELES study and among individuals in both age groups in the HRS study. Among older individuals in the CRELES study obesity has an independent effect on these expectations.

KOREAN BABY BOOMERS PANEL STUDY: KOREAN BABY BOOMERS AS A SANDWICH GENERATION?
G. Han1, H. Choe1, K. Eun1, J. Lee1, S. Joo1, J. Kim1, I. Seoul National University, Seoul, Republic of Korea, 2. Chonnam National University, Kwangju, Republic of Korea, 3. Ewha Womans University, Seoul, Republic of Korea

The Korean baby Boom, comprising 7,125,000 persons and 14.7% of Korea’s current population, are often characterized as a “Sandwich Generation” squeezed between care responsibilities to elderly parents and a duty to support dependent children. However, no systematic empirical data has been provided regarding this assertion. This study examined generational position of Korean Baby Boomers within the family and Identified Boomers’ supports that they provided up to their elderly parents(G1) and down to their children(G3). Data used in this study are from the 1st wave of Korean Baby Boomers Panel Study. A total of 4,668 respondents born between 1955 and 1963 were surveyed in face-to-face interviews using structured questionnaires, from May till August in 2010. 1) About 27% of respondents have demographic potential to be “sandwiched”, having at least one living parents and dependent children age 18 and younger. When we expand the definition of dependent family members to include the adult children who are not married, and also the care of in-law relations to reflect cultural expectations to support children until they marry and also provide care to parents-in-laws, proportion of Sandwich Generation climbs to 75.3%. 2) When we examined actual support behavior, only 23% of respondents are identified as having double burden of supporting unmarried children and providing regular supports to elderly parents. As parents of Boomers will soon enter “very old” stage, Boomers’ burden of caring for their elderly parents will increase. These results suggest that Boomers’ burden as a sandwiched generation will increase for the time being.

AGING TRAJECTORIES AMONG IMMIGRANT MIDDLE-AGE FILIPINO WOMEN IN AMERICA
K.J. Kalaw, Sociology and Gerontology, Miami University, Oxford, Ohio

Middle adulthood is significant in one’s life course towards becoming an older adult yet has received little attention. Midlife studies remain to be at the periphery in contrast to older adult studies. Thus, this study attempts to contribute to the slowly emerging literature on the intersection of middle adulthood with ethnicity and gender in the United States and its increasing diversity over time. A qualitative case study was conducted in North Carolina among four middle-age married Filipino immigrant women to explore their perceptions of later life. In the study, it aimed to understand how identity was created in relation to women’s perceptions on their aging trajectories. The findings showed that essential in knowing their perception is knowledge on their identities. More so, the study affirms past researches that identity is a product of one’s past and present self. Once established, perception on their future selves is created and their aging trajectories will follow. The themes identified on their perceptions on aging were: concept of home, sense of Filipino identity and meaning of the American dream. Each woman gave different meanings on how their experiences then and how shaped their future selves align with their aging trajectories. In sum, these women’s aging trajectories are products of the interplay of self and society across time and space.

INTERGENERATIONAL FAMILY TRANSFERS IN LATIN AMERICA: EFFECTS OF ECONOMIC AND SOCIODEMOGRAPHIC CHANGE
E. Storelli, Boston College, Chestnut Hill, Massachusetts

Current debates on families and aging in Latin America have raised concerns that the region’s rapid demographic, economic, and cultural changes will lead to inadequate care and support for the region’s rapidly growing aging population. To date, there is little empirical evidence on the ways these changes, such as decreasing fertility and increasing rates of divorce, migration, and women’s labor force participation, for example, are affecting intergenerational family transfers in the region. This paper utilizes data from the Survey on Health and Well-Being of Elders (SABE), a cross-national seven-country representative study, to investigate the structure and content of intergenerational exchanges between older adults and their children in Latin America, and to assess whether demographic, cultural and economic factors are linked to intergenerational support given to older adults by their children. Results suggest that all three forces are tied to intergenerational family transfers in significant and important ways. For example, higher rates of child migration reduce the odds of older adults receiving instrumental and emotional care. Having employed daughters reduces the odds of older adults receiving supportive services, but increases the odds of receiving financial support, goods, and emotional companionship. Furthermore, fewer children and higher proportions of non-biological children, often due to divorce and remarriage, reduce the odds of receiving all forms of support. These and other findings will be discussed in context of future changes to intergenerational support and policy alternatives.
Population aging in less developed countries is likely to result in large increases in family caregiving demands, which may differentially affect women. However, we lack nationally representative estimates of the prevalence or gender balance of old-age caregiving in lower- and middle-income countries. Methods: Using data from the Study on Aging and Adult Health (SAge), we estimated prevalence of family caregiving for and by adults aged 50+ in 4 lower-income countries: Ghana, South Africa, Russia, and India. We define caregiving as providing care to a family member in the same household with health tasks or activities of daily living. We estimate crude and age-standardized country-specific prevalence of caregiving. We also test whether women are more likely to provide care in each country. Results: The crude prevalence of caregiving was highest in India (11.0%), where age adjusted prevalence was 6.9%. Similar patterns were seen between crude and age adjusted estimates in Ghana (4.1% v. 2.5%), South Africa (2.9% v. 1.3%), and Russia (8.5%, 7.4%). We found women were at increased odds of providing care than men when adjusting for age (e.g., Russia OR: 1.55, 95% CI: 1.27, 1.89). More importantly, path analyses indicated that the hypothesized correlates of worry differentially contributed to the prediction of worry across the two cultures and across the two age groups. That is, with one minor exception, the hypothesized correlates did not predict worry within the German sample, but did predict worry within the American sample. Among the younger adult sample, endorsement of chance control and life events predicted worry, but among the older sample, endorsement of internal locus of control and powerful others locus of control predicted worry.

GENDER DIFFERENCES IN CAREGIVING FOR THE ELDERLY IN LOWER- AND MIDDLE-INCOME COUNTRIES

B.D. Capistrant, L.F. Berkman, D. Bloom, M. Glymour, Harvard School of Public Health, Boston, Massachusetts

Background: Population aging in less developed countries is likely to result in large increases in family caregiving demands, which may differentially affect women. However, we lack nationally representative estimates of the prevalence or gender balance of old-age caregiving in lower- and middle-income countries. Methods: Using data from the Study on Aging and Adult Health (SAge), we estimated prevalence of family caregiving for and by adults aged 50+ in 4 lower-income countries: Ghana, South Africa, Russia, and India. We define caregiving as providing care to a family member in the same household with health tasks or activities of daily living. We estimate crude and age-standardized country-specific prevalence of caregiving. We also test whether women are more likely to provide care in each country. Results: The crude prevalence of caregiving was highest in India (11.0%), where age adjusted prevalence was 6.9%. Similar patterns were seen between crude and age adjusted estimates in Ghana (4.1% v. 2.5%), South Africa (2.9% v. 1.3%), and Russia (8.5%, 7.4%). We found women were at increased odds of providing care than men when adjusting for age (e.g., Russia OR: 1.55, 95% CI: 1.27, 1.89). More importantly, path analyses indicated that the hypothesized correlates of worry differentially contributed to the prediction of worry across the two cultures and across the two age groups. That is, with one minor exception, the hypothesized correlates did not predict worry within the German sample, but did predict worry within the American sample. Among the younger adult sample, endorsement of chance control and life events predicted worry, but among the older sample, endorsement of internal locus of control and powerful others locus of control predicted worry.

SESSION 1665 (POSTER)

ADDRESSING FALL PREVENTION AND ENHANCING MOBILITY AMONG OLDER ADULTS

CHANGE IN LEISURE INVOLVEMENT AMONG OLDER ADULTS AFTER FALLING
T. Chen1, M. Janke2. 1. University of South Florida, Tampa, Florida, 2. University of South Florida Polytechnic, Lakeland, Florida

Leisure activities occupy more time on a daily basis during older adulthood (AARP, 2010). Research has identified a relationship between activity participation and falls, suggesting that falls can lead to reduced activity participation which in turn increases the likelihood of falls. While the high prevalence of falls in the aging population and the resulting physical and psychological effects have been studied extensively, less is known whether or how participation in leisure activities changes after falling. Using the Health and Retirement Study (HRS, 2004-2006) and two waves of data from the Consumption and Activities Mail Survey (CAMS, 2005-2007), we investigated the patterns of energy expenditure on leisure activities after falling among older adults. The sample included adults aged 65 and older (N = 6083) and was predominantly white (86%) and female (61%). The total energy expenditure (TEE) was calculated for each respondent as well as a total number of leisure activities in each wave. We used independent t-tests, Chi-Square analyses, and regression analyses to examine the variation of leisure patterns and TEE among older population. Our findings indicated that older adults who fell engaged in significantly fewer leisure activities than those who did not fall; however no significant difference in TEE was found between these two groups. Moreover, fall status was a significant predictor for the number of leisure activities but not TEE in subsequent waves.

N’BALANCE®, A COMMUNITY-BASED FALL PREVENTION INTERVENTION THAT MAY IMPACT LEISURE SELF-EFFICACY FOR OLDER ADULTS
C.M. Headley1, L.L. Payne2, C. Katzmennder1. 1. Exercise & Sport Science, Judson University, Elgin, Illinois. 2. University of Illinois, Champaign, Illinois. 3. Metropolitan State College, Denver, Colorado

Leisure activities positively impact the health and well-being of older adults and promote higher quality and successful aging. Older adults often perceive leisure as relaxing and enjoyable, yet a recent study found only 4% of older adults engage in leisure time physical activity (Americans Tim Use Survey, 2008; Rowe & Kahn, 1998). Falls and fear of falling can have a negative impact on older adults’ perception that they are able to participate in leisure activities. Fortunately, multi-factorial, multidimensional community-based fall prevention programs have been shown to have a decrease in the risk of falls in older adults and can have a greater reach within a community. The purpose of this study was to examine the effects and influence of N’Balance®, a community-based fall prevention intervention for older adults and better understand its implications for leisure self-efficacy among older adults. This was a community-based intervention trial with a control group using two sites. A two-way (group x time) ANOVA was used to examine differences in the dependent variables within each group over time (from pre- to post-test) and between groups (intervention vs. control). Results of pre- and post-test assessments indicated that N’Balance® was associated with improved balance (.00) and the fear of falling (.04). Leisure self-efficacy approached significance (.06) as a result of participation in N’Balance®. Leisure is an important factor for successful aging and the perception that falling may occur can reduce active leisure participation.

EFFECTICITY OF A FALL PREVENTION PROGRAM DELIVERED TO MONOLINGUAL KOREAN- AND SPANISH-SPEAKING SENIORS
D. Rose1, M. Moutapap1, T. Hummel2, R. Saborio3. 1. California State University, Fullerton, Fullerton, California. 2. St. Barnabas Senior Services, Los Angeles, California

The purpose of this study was to establish the short-term efficacy of a fall prevention (FP) program with monolingual Korean-Speaking (KS) and Spanish-Speaking (SS) older adults at moderate-to-high risk for falls. A total of 29 SS (M = 74.7 yrs, SD = 6.4) and 37 KS (M = 75.9 yrs, SD = 5.6) older adults completed a 12-week program that included a medical risk assessment (and follow-up), group exercise, and a home assessment and modification component. Each of 3 program rotations was limited to 10 to 12 participants from the same ethnic group. A social
worker conducted the medical risk assessment and home assessment components and an English-speaking Occupational Therapist (with minimal assistance of a translator) delivered the exercise component. All participants completed the medical risk assessment and the majority (93.3%) discussed the results of their Health Activity Questionnaire (HAQ) checklist with their doctor as directed. Significant improvements in balance (p < .001), lower body strength (p < .001), and functional mobility (p < .002) were also observed for the total sample post-completion of the exercise component. Only 38 (KS = 24, SS = 14) of the 66 participants had their homes inspected; 8 subsequently refused service to make recommendations; 1 participant did not need service. Moreover, only 44.1% indicated that recommended home modifications were completed at follow-up. The translated FP program was delivered with generally good fidelity when compared to the original InSTEP model and participants reported high levels of satisfaction with the program as delivered.

ACTIVITY, BALANCE, LEARNING, AND EXPOSURE (ABLE): A NEW INTERVENTION FOR EXCESSIVE FEAR OF FALLING
J. Wetherell1,2, K.M. Johnson1, S.R. Ward1, D. Chang1, A. Petkus1, I. Dept. of Psychiatry, UCSD, La Jolla, California. 2. VA San Diego Healthcare System, San Diego, California. 3. University of St. Augustine, San Marcos, California. 4. UCSD/SDSU Joint Doctoral Program in Clinical Psychology, San Diego, California

Approximately 10% of older adults living independently in the community, including more than 5% of those who have never fallen, experience moderate to severe fear of falling (FF) and avoid multiple activities as a result. Excessive FF leads to decreased physical activity, disability, loss of independence, depression, anxiety, reduced social engagement, poor quality of life, and falls. Interventions targeting FF, typically delivered in groups and incorporating cognitive restructuring, education, and exercise, increase fall-related self-efficacy. Unfortunately, behavioral avoidance is resistant to treatment, and older adults with high levels of FF are least likely to attend these interventions and most likely to drop out prematurely. This suggests that avoidance should be targeted more directly and that interventions should be designed to reach those with severe fear and avoidance who are most likely to drop out of traditional FF programs. Despite the similarities between excessive FF and anxiety disorders, and the fact that the most effective behavioral treatment for most anxiety disorders is exposure therapy, no FF interventions to date have incorporated an exposure component. We have developed and are piloting an in-home, physical therapist-delivered intervention that integrates exposure therapy with exercise, a home safety evaluation, and a medication review for older adults with excessive and disabling FF. Preliminary data suggest that the intervention reduces avoidance as well as concerns about falling. We will present data from the first six patients who have completed the intervention.

SOCIODEMOGRAPHIC CHARACTERISTICS AND FALLS RISK FACTORS AMONG INDEPENDENT-LIVING OLDER ADULTS
R. Ellis1, M. Kosma2, J. Fabre2, D.S. Moore2, I. Antikainen1, C.A. Baptiste1, T. Kim1, R.H. Wood1, 1. Kinesiology and Health, Georgia State Univ, Atlanta, Georgia. 2. Louisiana State University, Baton Rouge, Louisiana. 3. New Mexico State University, Las Cruces, New Mexico

We examined sociodemographic characteristics and falls risk factors in 326 Black (n = 318) and White (n = 308) residents (M age = 72.6, SD = 9.3) of Louisiana (n = 411), Georgia (n = 182), and New Mexico (n = 33). Income groups were low (<$1306 monthly; n = 271), medium ($1307-$1836 monthly; n = 74), and high (>=$25,000 annually; n = 179). Education groups were low (high school degree or less; n = 381), medium (some college or associate’s degree; n = 132), and high (bachelors degree or more; n = 104). The Comprehensive Falls Risk Screening Instrument assessed the falls risk factors of history, physical functioning, medication, vision, and home environment, and produced an average total falls risk score. A 3 x 3 x 2 MANCOVA (covariates were state and age) showed main effects for income (F = 2.34, p = .006) and race (F = 2.67, p = .02). Pairwise comparisons revealed that low income participants had greater falls risk scores for history (p = .002), physical functioning (p = .001), medication (p = .02), vision (p = .04), and total falls risk (p < .001) than high income participants. Similarly, Black participants had greater falls risk scores for history (p = .02), physical functioning (p = .003), medication (p = .02), and total falls risk (p < .001) than White participants. Low income and Black race are associated with greater falls risk and professionals should consider these differences when designing falls prevention programs.

ATTITUDES IN JAPAN TOWARDS OLDER ADULTS’ FALLING AND BATHTUB DROWNING, AND PREVENTION MEASURES
F. Toyota, T. Ikeuchi, H. Osada, J. F. Oberlin University Graduate School, Tokyo, Japan

This study utilized an analytical model of four “M” factors to evaluate attitudes of older adults toward falling at home and drowning in their Japanese bathtub, and about measures for preventing such accidents. The 4M factor – Man, Machine, Management, and Media – model was originally used by the U.S. National Transportation Safety Board (NTSB). Our sample included 85 men and 65 women (N = 150), ages 60 years and older (M = 66.51, SD = 3.75). Participants completed questionnaires seeking to assess their attitudes about methods of preventing falls and drowning. We asked if they would consider methods in fall prevention as being practical, by referring to the attitudes of the 4M analysis, such as taking the specific action of keeping electric cords away from pathways. The answers were rated on a scale of 1=strongly disagree to 4=strongly agree. We also asked if they had taken preventive actions on the same 4M factors, and to rate on a three-point scale (1=done already, 2=not yet, but will consider in future, and 3=not done and no plans in future). From 77.9% to 91.0% of participants reported they saw fall prevention measures as being practical, and 69.0% to 85.3% reported believing that drowning prevention measures were also practical. However, 28.3% to 40.8% reported having taken no actions to prevent falling, while 41.0% to 58.2% reported taking no preventative steps to prevent drowning. Findings suggest that there are discrepancies between older adults’ attitudes toward falling and drowning and the measures they actually take to prevent these accidents.

FALL RISK AMONG OLDER ADULTS WITH VERY EARLY (PRECLINICAL) ALZHEIMER’S DISEASE
S. Stark, C.M. Roc, E. Grant, J.C. Morris, Washington University, St. Louis, Missouri

Background: Falls are prevalent in persons with Alzheimer’s disease (AD). To explore whether motor changes precede cognitive changes in persons who ultimately develop symptomatic AD, we examined the rate of falls among healthy older adults with and without preclinical AD based on their PIB PET imaging studies and molecular biomarker profile. Methods: We conducted prospective cohort study (to examine the cumulative incidence of falls among community-dwelling cognitively normal older adults. Falls (unintentional movement to the floor, the ground, or an object below knee level) were reported monthly. A Cox proportional hazards model was used to test whether time to first fall was associated with MCBP at baseline, after adjustment for age, gender, education, and race. Results: The sample (n=125) was predominately female (63.9%) and white with a mean age of 74.5 years. The response rate was 100% with an average of 191 days of data available. There were 49 participants who experienced a fall. With the exception of CSF Aβ42, higher levels of each biomarker were associated with a faster time to first fall. A positive PIB PET

64th Annual Scientific Meeting
image resulted in a 2.72 times greater chance of experiencing a fall among healthy older adults. Conclusion: Preclinical AD is a risk factor for falls in older adults. This study points to the importance of understanding the motor changes that appear to precede cognitive changes.

WHO ATTENDS FALL PREVENTION PROGRAMS?
J.D. Flatt, J. King, E. Lukish, A. Swailes, S. Albert, Behavioral and Community Health Sciences, University of Pittsburgh, Pittsburgh, Pennsylvania

Background: Falls result in devastating problems for older adults and lead to increased morbidity, mortality and health care costs. One in three community-dwelling older adults fall each year, and close to half of older adults aged 80 and older fall each year. Several community-based fall prevention programs have been shown to reduce fall risks and fall-related injuries. Purpose: Describe the personal characteristics of participants who attend two statewide fall prevention programs in Pennsylvania. Methods: Participants were recruited from local Area Agencies on Aging and partnering senior centers that offer fall prevention programming to seniors. Results: Currently, 193 participants have been recruited from 33 senior centers/providers in eight counties in Pennsylvania. The mean age is 78, 45% of participants are 80 years or older, 82% female and 18% are African American. Seventy-eight percent live in a home or apartment in the community and only 6% receive homemaker or nursing services at home. In regards to participation in fall prevention programming, approximately 43% of participants had taken one of the two fall prevention programs. Seventy-eight percent of people completing either falls prevention program were less than 80 years old compared to 32% among those 80 or older, (p < .01). Conclusion: This finding has important implications for recruiting and engaging adults 80 years of age or older in community-based fall prevention programming. Fall prevention programs should consider the specific needs of this high risk group and employ strategies to further engage this population in fall prevention programs.

FALLS AND DEPRESSIVE SYMPTOMS IN OLDER JAPANESE WORKERS
F. Togo1, A. Ohnishi, K. Ishimatsu, 1. The University of Tokyo, Tokyo, Japan, 2. National Institute of Occupational Safety and Health, Kawasaki, Japan

Falls are a leading cause of work-related injuries among Japanese workers who are over 50 years old. It has recently reported that there is a close association between depressive symptoms and fall risk in older people, but links between falls and depressive symptoms are still unclear in older workers. The present study examined the associations between falls and depressive symptoms in 54 male volunteers, aged 50-69 years, and in 41 female volunteers, aged 51-72 years. All subjects were building cleaning and support services workers. The number of falls suffered by the subjects in the 12 months before the assessment was recorded. A fall was defined as “an event which resulted in a person coming to rest unintentionally on the ground or other lower level, not as the result of a major intrinsic event or an overwhelming hazard”. Subjects completed the Center for Epidemiological Studies Depression Scale (CES-D), a 20-item, self-report, rating scale developed to measure current level of depressive symptoms in community populations. Difference between subjects with and without a history of falls (fallers and non-fallers, respectively) was tested by using non-paired t-test. The respective numbers of male and female fallers were 7 and 11. Score of CES-D was significantly higher in fallers than non-fallers in men, but did not differ between fallers and non-fallers in women. These results indicate that depressive symptoms might correlate with falls in older male workers, but not in older female workers.

SESSION 1670 (POSTER)
CARE SUPPORTS, SERVICES AND PROGRAMS

EARLY ALZHEIMER’S INTERVENTION: A HOLISTIC APPROACH TO CARE
N. Blume, Nursing, Lamar University, Beaumont, Texas

Early Alzheimer’s disease intervention reveals that maintaining cognitive function can be supported and maintained for longer periods when a holistic approach to both care partners is implemented. The purpose of the current study was to determine if a baseline cognitive functioning level can be maintained over time using a holistic intervention approach. Instruments used to measure functioning in the care partner dyads were (1) Beck Depression Inventory, (2) Department of Veteran’s Affairs (VA) St. Louis University Mental Status (SLUMS), (3) Instrumental Activities of Daily Living (4) Caregiver Support and Satisfaction Inventory and a qualitative questionnaire of open ended questions about the caregiver’s perceptions of care. Seven early Alzheimer’s diagnosed persons and their caregivers were participants in a series of six intervention strategies over a three month period. Cognitive functioning was assessed for the persons with Alzheimer’s at the beginning and ending of the series to determine if functioning was maintained. The series of interventions was repeated after a 3 month time in a time-series design. Caregivers were trained in communication methods similar to validation therapy and relaxation methods while their early diagnosed family member or friend worked at a cognitive/memory strategy. The care partner dyads interacted using the strategies taught and the level of functioning apparent. Cognitive or thinking ability was maintained over the first three month period, diminished the second three months and rose again with the next set of interventions for the early Alzheimer’s diagnosed persons. The caregiver partner maintained with fewer depressive symptoms reported.

CAREGIVER BURDEN, HEALTH UTILITIES, AND INSTITUTIONAL SERVICE USE IN ALZHEIMER’S DISEASE
E.A. Miller1, L. Schneider2, R. Rosenheck3, 1. Gerontology, Univ. of Massachusetts Boston, Boston, Massachusetts, 2. Univ. Southern California, Los Angeles, California, 3. Yale University, New Haven, Connecticut

This study examines the moderating effect of caregiver burden on the relationship between the health status of Alzheimer’s disease (AD) patients and use of institutional services (hospital, nursing home, and residential care). Data were obtained at baseline and 3-, 6-, and 9-months following study entry on 421 community-dwelling AD patients in the CATIE-AD trial. The outcome variable includes any institutional services use. Logistic regression was employed to estimate the interaction of Health Utility Index (HUI-III) score (a general health status measure) at outcome and four caregiver burden measures. Marginal effects were calculated and plotted using random effects models for observations at multiple time points per individual. Average effects were calculated across all observations using models without random effects. Random effects results suggest that caregiver burden weakens the inverse relationship between health utilities and institutional service use, leading to greater likelihood of institutional use than would be expected at a given level of health. This is indicated by positive, significant signs on the HUI-III caregiver burden interaction when burden is measured using the Caregiver Distress Scale, Beck Depression Inventory (BDI), and Caregiver Assessment Survey (all p<.05). It is reinforced by positive, significant average effects deriving from Caregiver Distress and BDI models without random effects (both p<.10). Results deriving from the Burden Interview Scale, though positive, were non-significant and weak by comparison. Caregiver support interventions should be offered to individuals caring for less advanced AD patients. Otherwise healthy
patients may be at increased risk for institutionalization when caregivers experience high levels of burden.

PERSON-CENTERED IN-HOME CAREGIVING FOR PERSONS WITH ALZHEIMER’S DISEASE
M.J. McClendon, K.A. Smyth, Case Western Reserve University, Cleveland, Ohio

Research on in-home caregivers of persons with dementia has found that training in coping skills and avoidance of emotion-focused coping characterized by wishful thinking or fantasizing increased the survival time of care recipients. We hypothesized that caregiver coping is linked to care-recipient survival because coping is related to person-centered care. Research has also shown that caregivers with neurotic personality types are more likely to use emotion-focused coping. Thus, we hypothesized that caregiver personality may also be linked to person-centered caregiving. To investigate the relationships between caregiver personality, caregiver coping, and person-centered care, we conducted a mail survey of 128 in-home dementia caregivers. Measures of person-centered care consisted of 35 items from existing scales (Exemplary Caregiving, Environmental Support, Frustrations with Caregiving, and Criticism of Care-Recipient), plus six new environmental items. Coping was measured with sixteen items from an existing scale, and personality was measured with 44 items from the Big Five Inventory. Factor analysis revealed six reliable dimensions of person-centered care (Personalized, Punitive, Respectful, Controlling, Compensatory, and Withdrawal). Personalized and respectful caregiving were related to non-wishful coping and to open, agreeable, neurotic, and/or non-extraverted personalities. Punitive, controlling, and withdrawal caregiving were related to wishful and/or fantasy coping and to extraverted, non-agreeable, and/or non-neurotic personalities. To generalize, agreeable, open, neurotic, and non-extraverted caregivers who did not use wishful or fantasy coping were better at person-centered care. Research is needed to determine whether or not training in person-centered care needs to be individualized in terms of caregiver personality and coping style.

TRAINING FOR TELEPHONE ADMINISTERED DEMENTIA CARE COORDINATION: LESSONS LEARNED

Partners in Dementia Care (PDC) is a multi-site study of a telephone care coordination model for veterans with dementia and their family caregivers. Key features of PDC include: formal partnerships between VA Medical centers and the Alzheimer’s Association, a multidimensional assessment and treatment approach, ongoing monitoring, and a shared computerized system to guide service delivery. Care coordinators assist families by offering: dementia education, emotional support and coaching, linkage to services and resources, and mobilization of informal care. Two study sites (Houston, TX and Boston, MA), and three control sites (Oklahoma City, OK, Providence, RI and Beaumont, TX) enrolled a total of 508 veterans, 486 of whom had a family caregiver participate as well. The project findings presented are relevant for design and delivery of dementia care coordinator training. A total of 313 computerized intervention records were analyzed to highlight common areas of assessed need for veterans and caregivers across medical and non-medical domains. This analysis underscored the breadth of service knowledge and clinical skills which need to be addressed in training. Themes were also drawn from semi-structured debriefing interviews conducted with 6 of the study care coordinators with social work, nursing, or counseling backgrounds. Primary challenges for providing this type of intervention were stated, including: forming a professional partnership across sites and establishing rapport and trust with participants over the phone. Potential training strategies suggested included: team building activities, communication techniques and case reviews. Detailed lessons learned and recommended training practices will be shared to improve dementia care service delivery.

ASSESSING THE NEEDS OF INFORMAL CAREGIVERS OF OLDER ADULTS FOLLOWING HOSPITAL DISCHARGE
D.A. Menio, M. Mathes, M. Cuciurean-Zapan, Center for Advocacy for the Rights and Interests of the Elderly, Philadelphia, Pennsylvania

National studies have documented the financial, emotional and clinical importance of family caregivers (Gibon and Houser 2007; Colvin et al. 2004). The impact of caregiver burden on the health and well-being of the caregiver has also been reported (National Alliance for Caregiving and AARP 2004). Substantial declines in the length of hospital stay for patients age 60 and over have sharpened concerns about the adequacy of discharge planning (Manon et al. 1992). Moreover, as one study noted, “[f]amily caregivers encounter the home care system at a time of great stress and need. They understand little about the system when the case is opened and not much more when it ends six or seven weeks later” (Levine et al. 2006). During the Summer of 2010, the Center for Advocacy for the Rights and Interests of the Elderly conducted a study to assess the needs of caregivers of older adults who have been discharged from the hospital in the Philadelphia area, as well as caregivers’ perceptions of the effectiveness of available resources and the accessibility of existing supports. The study used semi-structured qualitative interviews as well as two focus groups with individuals who care for family members with Alzheimer’s Disease. The data was analyzed using standard qualitative methods. These include field notes, transcription, theme development and analysis, coding, and synthesis. This session will present study findings, conclusions and directions for future work.

STAKEHOLDER INPUT INTO A TOOL TO INVESTIGATE CAREGIVING ISSUES FROM THE PERSPECTIVE OF FAMILY PHYSICIANS
C. Gibbons1, M. Bedard1,2, A. Lambert-Belanger2, J. Riendeau2, I. Research, St. Joseph’s Care Group, Thunder Bay, Ontario, Canada, 2. Lakehead University, Thunder Bay, Ontario, Canada, 3. Northern Ontario School of Medicine, Thunder Bay, Ontario, Canada

Background: Many seniors with dementia are supported to “age in place” by unpaid caregivers, many of whom are seniors themselves. Family physicians (FPs) are uniquely positioned to play a critical role in caregiving situations. Unfortunately, we have little knowledge of caregiving issues from the perspective of FPs, which limits opportunities to effect change of benefit to care recipients, caregivers, and FPs. Objectives: Our objectives are to develop a survey to: better understand FPs’ knowledge of caregiver issues; assist health planners/decision-makers in optimizing the role of FPs in supporting caregivers’ health and well-being; and indirectly maximize the health status and quality of life of care recipients. Methods: After completing a literature review, three domains were identified – health outcomes and accountability, preparation, and the accessibility of existing supports. The study used semi-structured qualitative interviews as well as two focus groups with individuals who care for family members with Alzheimer’s Disease. The data was analyzed using standard qualitative methods. These include field notes, transcription, theme development and analysis, coding, and synthesis. This session will present study findings, conclusions and directions for future work.

64th Annual Scientific Meeting
experiences with caregivers and identified relevant questions. Conclusions: The comments from health planners/decision makers and FPs were incorporated into a revised version to be presented. This survey could be used for healthcare planning to develop targeted interventions to ultimately improve the health of caregivers and care recipients.

DESIGNING MEMORY CARE COMMUNITIES TO PROMOTE WAYFINDING: THE UTILITY OF SHADOW BOX INTERVENTIONS

A. Jay, L. Feliciano, Psychology, University of Colorado at Colorado Springs, Colorado Springs, Colorado

There is a growing population of older adults with dementia residing in long-term care settings. These individuals commonly experience difficulty locating their bedroom as a result of cognitive impairment, limited learning histories in the care facility, and ineffective cues to help distinguish individual bedrooms. Ineffective room finding abilities may expose elders to safety hazards and create problems for other residents and staff. The current study is being conducted in a series of three experiments to determine what types of memory box items improve the room finding abilities of older adults with moderate to severe dementia. In Experiment One, a recognition assessment was administered in which the participant’s ability to meaningfully identify various self-referent stimuli was measured (i.e., young adulthood, middle adulthood, late adulthood photographs, and printed name). Participants who moved onto Experiment Two participated in a preference assessment to identify highly preferred items. In Experiment Three, a room finding intervention was introduced in the form of memory boxes hung outside participant bedroom doorways. After exposure to an empty baseline memory box, participants received either a personalized memory box (i.e., features best recognized stimulus from Experiment One and top preferred items like a military medallion from Experiment Two) or a general memory box (i.e., features neutral items like seashells not personally relevant to the participant, but simply served as a landmark). Wayfinding probes assess room finding abilities via direct observation techniques. Data collected are presented as accuracy and latency to room finding. Implications and future directions for research are discussed.

ASSESSING VETERAN PREFERENCES IN THE COMMUNITY LIVING CENTER (CLC)

K. Curyto1, K. Van Haitsma1, M. McCulloch2, 1. VA Western NY Healthcare System, Batavia, New York, 2. Polisher Research Institute, North Wales, Pennsylvania

Psychosocial preferences (e.g., social contact, activities, control and independence, caregiver characteristics, routines) are related to satisfaction and quality of life and not assessed comprehensively in long-term care. This project aimed to revise the original Preferences for Everyday Day Living Inventory (PELI) to include the language that CLC Veterans use and understand based on 31 Veteran interviews. Average age was 74.3 (59-92 years), 96.8% were male, 83.8% were Caucasian, and 16.3% were African-American. Seventy-eight PELI items were excluded because they had been through cognitive interviewing and included in the MDS 3.0 Preference Assessment Tool. Thirty-one participants were interviewed about their comprehension, interpretation, and reactions to the content and language of PELI items, with a minimum of 5 responses per item. Responses were summarized for content, wording, and meaning. Based on team reviews, one of four decisions was made about each item: retain with no further testing, keep testing, reword and keep testing, or delete. Out of these 78 PELI items, thirty-nine items were retained with no changes. Twenty-nine items were reworded, with an average of 1.75 changes per item. Reasons for wording changes included difficulties reading the item, item meaning, assumptions made, knowledge or cognitive ability needed, and sensitivity or bias. In addition, 10 items were added for cognitive interviewing in response to team reviews of cognitive interviews. Future studies will focus on the stability of Veteran preferences as measured by the PELI and designing interventions to improve mood, behavior and quality of life.

A FAMILY-FOCUSED “NEW PARADIGM” INTERVENTION FOR ALZHEIMER’S DISEASE

D.A. Chiriboga, S. Rhew, K. Kwag, L.M. Brown, Y. Jang, V. Molinari, S. Wang, Aging and Mental Health Disparities, University of South Florida, Tampa, Florida

This poster will present results of a four-year evaluation of a Medicaid Alzheimer’s Program (MAP) waiver. Designed to keep persons with Alzheimer’s disease out of nursing homes, the program provided 11 services tailored to the needs of each care giver-recipient dyad. Costs and risks of nursing home placement were compared with those for four other Medicaid programs: the Aged and Disabled Waiver (ADW), Assisted Living for the Elderly (ALE), Channeling (CH), and Nursing Home Diversion (NHD). MAP costs were significantly greater than costs than all programs except NHD. A survival analysis of long term placements into nursing facilities was then performed. Only Medicaid recipients who had participated in one of the programs for five months or more were included in the analyses, and placement was defined as a consecutive stay of three or more months in a nursing home. It was found that MAP reduced the risk of long term placement by 31.6% relative to the risk of placement faced by the total group of those enrolled in the other programs. When MAP was compared separately to each of the other programs, the risk of placement was significantly reduced when compared to ADW and ALE. While the risk of placement was lower for MAP than it was for the other two programs, the differences were not significant. Discussion focuses on the value of a new paradigm of care that focuses on the family as a unit, as opposed to either the care giver or the care recipient.

THE IMPACT OF PSYCHOEDUCATIONAL INTERVENTION PROGRAM ON FAMILY CAREGIVER BURDEN AND DEPRESSION FOR FAMILY CAREGIVER OF KOREAN RESIDENTS WITH DEMENTIA IN THE NURSING HOME

S.K. Han, Bergen Regional Medical Center, Paramus, New Jersey

This study examines the impacts of the Psychoeducational Intervention Program (PIP) that strives to eliminate family caregiver burden and depression while increasing family involvement in the caring of Korean residents with Dementia in the nursing home. The data was collected through quantitative methods with semi-structured and close-ended questions from the family caregiver with the use of Zarit’s family caregiver burden scale and geriatric depression scale (GDS). The study uses T-Test with SPSS to show the effect of PIP. Results indicated that PIP, a treatment in which a social worker conducts a 3-hour, one session interview with the family caregiver, designed for articulating the causes of stress, reframing the family caregiver’s role, and teaching basic relaxation skills and Dementia information with behavior disturbance, reduced the family caregiver’s burden and depression. According to a pre-test and a post-test 6 months before and after PIP, the family caregiver’s burden was significantly lower with the application of PIP, showing improvements in feeling time limitation (p<.05), being stressed (p<.01), strained (p<.01), afraid (p<.01), and feeling overwhelmed (p<.05). The family caregiver’s depression was also significantly lowered (p<.001). The PIP encouraged the family caregiver to be more involved in caring for the resident with visible increases in the frequency of visits, positive interaction with the staff, and willingness of medical health care decisions. The study suggests that PIP reduces family caregiver burden and depression through education and counseling session upon the time the resident is first admitted. The study also shows that PIP with a bilingual and bicultural social worker increases the effectiveness and receptiveness of the treatment.
ADAPTING THE REACHII PROGRAM COMPONENTS TO COMMUNITY CONTEXTS: LESSONS LEARNED IN NORTH CAROLINA

A midcourse evaluation was conducted to assess the REACH II Caregiving program components implemented by agency-based interventionists in 14 counties in North Carolina. An iterative mixed methods approach was used with an online survey of 6 interventionists and coaches, followed by an in-person group discussion. Questions were guided by the RE-AIM framework and addressed program components, including: the pre-intervention meeting; intervention training; participant recruitment; initial risk assessment and individualized treatment plan; daily implementation; coaching and technical assistance; certification requirements; and program operations and protocols. Additional input was gathered on: perceived value of REACH II; program maintenance; and any unanticipated outcomes for clients or interventionists. There was overall satisfaction with the program, but there were many suggestions for adapting specific components. Chief among these were: 1) redesign interventionist training: gauge to the level of trainee experience and create a streamlined summary of intervention; 2) modify forms; create 1 fidelity checklist, delete the Screener, make the Stress Diary and Brainstorming forms optional; 3) rename “Behavioral Prescription” to “action planning”; 4) revise Interventionist Notebook for flow and uniformity; 5) reduce Caregiver Notebook by one-third; 6) change technical assistance monthly calls to quarterly. All of the adaptations were proposed to the AoA and approved. The mid course review is integral to a systematic implementation process to assess feasibility and to make recommendations for adaptations to strengthen the intervention while maintaining fidelity. What we learned may contribute to the development of a science of translation from research to practice.

IMPLEMENTING PLEASANT EVENTS WITH ASSISTED LIVING DEMENTIA RESIDENTS

This study describes the use of pleasant events with assisted living dementia residents with challenging behaviors. Forty-eight direct care workers (DCW)-resident dyads participated. DCWs were 44 years of age (range=21-73), female (90%), diverse (29% identified as Asian), and born outside of the U.S. (85%). Residents were 87 years of age (range=77-100), female (75%), Caucasian (90%), had a mean MMSE of 11.6 (SD=7.1), and were identified as having challenging behaviors. As part of the STAR (Staff Training in Assisted-living Residences) intervention, DCWs participated in four individual consultations where they identified pleasant events to implement with residents. One-hundred percent of DCWs participated in at least two consultations and 81% participated in all four. Pleasant events were coded in five categories: one-to-one activity, group activity, exercise, outings, and other. DCWs were able to identify pleasant events to implement with residents at 100% of the consultations. DCWs predominantly implemented one-to-one activities (89%), with group activities (39%) and exercise (29%) also widely implemented. The majority of staff identified and implemented multiple pleasant events (69%) at each consultation. Pleasant events included: conversation, looking at photo albums, applying lipstick, going for a walk, giving a compliment, having coffee, supporting hobbies, and group activities with residents. These findings have clinical implications as DCWs, with their extensive contact with residents, are in a unique position to implement interventions. Providing training to DCWs on how to incorporate pleasant events into their work routine may be a promising approach to reduce challenging dementia behaviors, such as depression and anxiety.

CHANGES IN EMOTIONAL SUPPORT OF DEMENTIA CAREGivers AT PLACEMENT AND BereavEMENT
K. Kim, S.H. Zarin, Human Development and Family Studies, The Pennsylvania State University, University Park, Pennsylvania

Emotional support (ES) is an important personal resource for caregivers coping with stressful events and stressors. Prior studies have generally found that ES is stable over time, but this work has not considered how major transitions in the caregiving career might affect ES. The current study examines how ES changes in relation to two important caregiving transitions, placement and death of the care receiver. We analyzed longitudinal data from 408 caregivers of persons with dementia in the Caregiver Stress and Coping Study which interviewed people annually over a 5-year period, resulting in up to 6 waves for each caregiver. At baseline, all caregivers were caring for individuals with dementia in the community. Placement and death of the care receivers were identified during the subsequent follow up interviews. Multi-phase growth curve models based on two time metrics (time-to-from-placement and bereavement) were applied to the longitudinal data. ES remained stable on average in relation to placement, but there was significant between-person variability in the response to placement, which is associated with family closeness and duration of care. In contrast, ES increased following death of the care receiver. These findings following bereavement may reflect the many rituals and norms surrounding death. By contrast, the effect of placement on ES tends to be conditioned by the caregiving context, such as family relationships and caregiving history. Although placement is a difficult transition for caregivers, they cannot depend on family and friends to provide increased support for adapting to the transition.

THE FIT KITS STUDY: DEVELOPING INTERACTIVE ACTIVITY MATERIALS FOR PEOPLE WITH DEMENTIA AND THEIR FAMILY CAREGivers
B. Wright1, E. Femia2, 1. The Lewin Group, Falls Church, Virginia, 2. FIT Interactive, Falls Church, Virginia

This study, funded by an Institutes of Health Small Business Innovation Research (SBIR) grant, tested the use of FIT (Families Interacting Together) Kits for people with Alzheimer’s disease or other dementia and their family members. The first phase of the project involved four focus groups with family caregivers to explore the feasibility of the kits and how they could benefit families. The second phase tested the use of FIT Kits by caregivers with their family members over one month. Findings highlight the challenges with engaging people with dementia in activities and the need for resources to assist caregivers with this challenge. Caregivers expressed interest in using the FIT Kits as a way to give their family member something enjoyable to do, enhance visits with family members, or provide the caregiver some respite. Of importance is that activities be appropriate for adults and provide the person with dementia with a sense of purpose (pencil sharpening, sorting coins). Caregivers expressed interest in activities customized based on their family members’ stage of dementia, activity interests (brain stimuli, sports, babies, animals), or occasion (birthday, Christmas). Results also indicated the importance of educational materials, including tips and ideas for engaging family members with dementia (trying multiple activities to see what works, using activities in non-traditional ways, and using humor). Caregivers wanted guidance on how to introduce an activity for the first time and a list of creative ideas to try with items they already have (folding napkins, looking at photo album).
PREDICTORS OF TREATMENT PREFERENCE AGREEMENT AMONG OLDER PATIENTS, SURrogATES, AND PHYSICIANS

E. Woodhead1, T. English2, M. Goldstein3, A. Garber1, L. Carstensen1, 1. VA Palo Alto, Palo Alto, California, 2. Stanford University Department of Psychology, Stanford, California, 3. Stanford University Center for Primary Care and Outcomes Research, Stanford, California

Past research suggests that there are moderate levels of agreement about treatment preferences between patients and surrogates and between patients and physicians. There is limited research on agreement between physicians and surrogates, and whether characteristics of the patient predict agreement among patients, surrogates, and physicians. The objectives of the current study were to examine level of agreement between patients, surrogates, and physicians, and to determine whether patient variables and aspects of the decision differentially predicted agreement among all pairings of individuals (patient-surrogate, patient-physician, and physician-surrogate). Participants included 77 patients over age 60 recruited from a low-income community medical center, as well as physicians at the clinic and the patient’s elected surrogate. We used the Life Support Preferences Questionnaire to assess treatment preferences. Patients indicated their own preferences; the physician and surrogate were asked to indicate the patient’s preferences. We used linear regressions to examine the predictive utility of patient demographics, mental and physical health, and performance on a brief cognitive battery on agreement. Physician-surrogate agreement was moderately high (M = 0.65, SD = 0.20) and was not significantly different from the other pairings. When examining the influence of patient variables on agreement, preference for less treatment predicted higher patient-physician agreement and higher agreement among all three individuals (b = -0.44, p < 0.001; b = -0.24, p = 0.04, respectively). Rates of agreement for all pairings were highest for preferences about current health. Future research should explore physicians’ understanding of patient treatment preferences when higher levels of intervention are desired.

INITIAL FINDINGS: FEASIBILITY TESTING OF THE CAREGIVER SELF-MANAGEMENT OF UNMET NEEDS INTERVENTION

S.W. Morgan, University of Wisconsin - Milwaukee, Milwaukee, Wisconsin

Almost 11 million Americans provide unpaid care to persons living with dementia. Persons with dementia may be unable to communicate their needs in a way that their caregivers can recognize leaving those needs unmet. The inability to recognize unmet needs can result in deleterious health outcomes for the care recipient. The (C-SUM) was designed to teach family caregivers to self-manage the needs of persons living with dementia thereby leading to reductions in family member discomfort, agitation, and stress and caregiver burden and stress. The aim of this feasibility phase was to evaluate the use and usefulness of the study measures and components, describe the sample, evaluate recruitment and retention and gain insight into the self-management process. Sixteen caregiver/family member dyads completed feasibility testing. The study involved pre and post measures of stress and burden in the family caregiver and stress, pain and agitation in the family member living with dementia. Additional measures included demographics, caregiver sleep and health. The caregivers are primarily female (n = 13), diverse, African American (n = 6) Hispanic (n = 2), and low-income (>50% have a household income of <$39,000). The caregivers (n = 16) reported poor sleep quality, poorer health quality relative to bodily pain, vitality, and role emotional state when compared to population norms. Preliminary findings relative to self-management indicate that the C-SUM impacts the process components of self-efficacy, outcome expectancy, self-regulation skills and abilities, decision-making, planning and action. There is little literature about self-management and caregivers of persons with dementia so these initial findings provide important insights into this process.

PROGRAM SATISFACTION AND STRESS REDUCTION AMONG REACH II CAREGIVER PARTICIPANTS: FINDINGS FROM NORTH CAROLINA

The majority of extant research on caregiving focuses on psychosocial and physical outcomes, such as depression, health, and stress. It is important to examine such outcomes within an intervention context to better understand how they may affect program efficacy and participant satisfaction. This analysis examined the relationship between stress reduction and program satisfaction in a sample of family caregivers (CG) for individuals living at home with a diagnosis of Alzheimer’s disease (AD) or related dementia. Data came from measures used in the original multi-site intervention Resources for Enhancing Alzheimer’s Caregiver Health II (REACH II) that is being tested for feasibility in North Carolina. The sample currently consists of 12 caregivers with an average age of 68.11 years (SD = 10.71, range = 45-79). Results indicate that moderate to strong trend relationships exist between baseline risk appraisal, stress, race and program satisfaction, with White caregivers reporting substantially lower levels of satisfaction as compared to African-American caregivers as determined by an independent-samples T-test. Greater baseline risk was associated with lower overall satisfaction (r = -.37), whereas lower levels of baseline stress were associated with greater satisfaction (r = .32). Further analyses indicated that for caregivers with higher levels of baseline risk, lower levels of satisfaction were more strongly related to lower levels of understanding regarding the need for self-care and care-recipient needs (r = .60). Discussion will further explore specific intervention components and participant characteristics that may or may not contribute to overall program satisfaction and reduction of caregiver stress.

PREDICTORS OF THE IMPACT OF NONPHARMACOLOGICAL INTERVENTIONS FOR AGITATION IN NURSING HOME RESIDENTS

J. Cohen-Mansfield1,2, K. Thein1, M.S. Marx1, M. Dakheel-Ali2, 1. Herzeg Institute, Tel Aviv Univ, Tel-Aviv, Israel, 2. Research Institute on Aging, Rockville, Maryland

While the most common treatment approach for agitated behaviors in nursing home residents with dementia is pharmaceutical, there is a growing movement to use nonpharmacological interventions. However, research is needed to determine specific factors that contribute to the success of nonpharmacological interventions. In this presentation, we describe the influence of person characteristics (e.g., demographic, medical, functional variables) on the efficacy of nonpharmacologic interventions to reduce agitation. Agitation was systematically observed at baseline and during intervention stages using the Agitated Behavior Mapping Instrument (ABMI) in a sample of 89 residents from 6 Maryland nursing homes. Their mean age was 85.9 years, 73% were female, 81% were Caucasian, over half were widowed, and 42.7% had a college, technical school of graduate degree. Their mean MMSE score was 7.6. Each participant received interventions based on an individualized algorithm (TREA–Treatment Routes for Exploring Agitation) which identifies unmet needs and matches interventions to needs and to the participant’s sensory, cognitive and functional abilities as well as to self-identity and preferences. Analysis revealed that higher levels of
cognitive function, ADL function, and speech correlated significantly with decreased levels of agitation during intervention. The presence of staff barriers (e.g., refusals, interruptions) correlated significantly with less reduction of agitation during intervention. In order to maximize the success of nonpharmacological interventions for agitation, nursing home staff need to consider the role played by person characteristics and staff-related barriers. This study was supported by grant #SR01 AG010172-14

SESSION 1675 (POSTER)

CAREGIVING, CAREGIVING RELATIONSHIPS, AND WELL-BEING

‘WHAT’S AGE GOT TO DO WITH IT?’: CLINICAL BARRIERS, SOCIAL OBSTACLES AND INTERACTIONAL TENSIONS OF LIFE WITH EARLY-ONSET ALZHEIMER’S

Although Alzheimer’s commonly occurs in seniors, a growing number of individuals are being diagnosed younger, with what is called early-onset. This paper draws on in-depth qualitative interviews (N=17) to learn about the experiences of early-onset, from both the perspective of those diagnosed and family members. Grounded theory methods were used to collect, code and analyze data into common themes. These narratives highlight the unique experiences of living with dementia at earlier biographical stages. Age-based differences reveal clinical barriers, social obstacles, and interactional tensions. These distinctions complicating personal, intimate and social relationships for younger people with AD engage core sociological debates about the relationship between biography, identity and narrative. As both a ‘disruptive’ and ‘reconstructive’ force, the case of early onset Alzheimer’s builds on existing biographies, identity and narrative. As both a ‘disruptive’ and ‘reconstructive’ force, the case of early onset Alzheimer’s builds on existing biographical stages. Age-based differences reveal clinical barriers, social obstacles, and interactional tensions. These distinctions complicating personal, intimate and social relationships for younger people with AD engage core sociological debates about the relationship between biography, identity and narrative. THE RELATIONSHIPS BETWEEN STRESS PERCEPTIONS AND STRESS BIOMARKERS OF FAMILY CAREGIVERS IN NORTHERN TAIWAN

Y. Chiu, K. Cheng, C. Li, S. Lee, S. Liao, School of Nursing, Chang-Gung University, Taoyuan, Taiwan

Background: Family caregivers (FCGs) of persons with dementia (PWDs) are under chronic stress. However, their stress has often been assessed by their distress without physiological indicators. Furthermore, studies to date have rarely documented the relationships between FCG distress and stress biomarkers. Purpose: The aims of this study were to describe the distress and stress biomarkers of FCGs for PWDs in northern Taiwan and to explore the relationships between FCGs’ distress and stress biomarkers. Methods: This secondary data analysis study included 113 dyads of PWDs and their FCGs who donated blood samples. The original study sites were located in northern Taiwan. FCGs' distress was assessed by the Chinese Neuropsychological Inventory-Caregiver Distress Scale (CNI-CD), and stress biomarkers included interleukin IL-1ß, IL-6, IL-10, cortisol, C-reactive protein (CRP), and albumin. Results: The greatest FCG distress was found toward PWD’s appetite & eating behavioral change (mean = 2.75 ± 1.29). Levels of the stress biomarkers were not correlated with FCGs’ overall distress toward PWDs’ neuropsychological problems. However, IL-1ß, IL-6, IL-10 and albumin levels were correlated with FCGs’ specific distress toward specific PWDs’ neuropsychological symptoms: levels of IL 10 was related to PWDs’ agitation/aggression, levels of IL-1ß, IL-6 and albumin were correlated with PWDs’ delusion. Conclusions: In this study, we found some stress biomarkers (IL-1ß,IL-6, IL-10) were associated specific PWDs’ neuropsychological symptoms (p <.05). Further longitudinal research is needed to clarify the causal relationships between subjective distress and objective stress biomarkers to better comprehensively evaluate FCGs’ stress levels.

PSYCHOLOGICAL WELL-BEING IN DEMENTIA CAREGIVERS

C.K. Holley1, B.T. Mast2, 1. Behavioral Health, Stratton VA Medical Center, Albany, New York, 2. University of Louisville, Louisville, Kentucky

Although there is an abundance of literature examining the negative effects of dementia there is relatively little research examining resiliency in caregiving. The purpose of this study was to determine which aspects of psychological well-being predict low levels of burden and grief. Eighty dementia caregivers completed a survey related to their experiences, including measures of burden, anticipatory grief and psychological well-being. Independent sample t-tests were used to examine mean level differences on the subscales of the Ryff Scales of Psychological Well-Being in caregivers reporting high and low levels of burden and grief. Examining the subscales revealed that those with low levels of burden had significantly higher levels of positive relations with others (t82= 2.27, p = .03), self-acceptance (t82 = 2.56, p = .01), and environmental mastery (t82 = 5.51, p < .01), but there were no differences in autonomy, purpose in life, and personal growth. Similarly, those with low levels of anticipatory grief reported significantly higher levels of positive relations with others (t82 = 2.31, p = .02), self-acceptance (t82 = 2.12, p = .04), and environmental mastery (t82 = 2.83, p < .01) with no differences in the remaining subscales. High levels of psychological well-being were associated with avoiding caregiver burden and grief. However, not all aspects of well-being are equally important in this regard. Specifically environmental mastery, self-acceptance, and positive relations with others, may serve a protective function against some of the deleterious effects of caregiving such as burden and grief.

LIFE EVENTS, DAILY STRESSORS, AND CORTISOL RESPONSE IN MOTHERS OF ADOLESCENTS AND ADULTS WITH ASD

Recently, literature has emerged linking the stress of parenting a child with developmental disability to a pattern of hypocortisolism. The current paper extends the work of Seltzer and colleagues (2010) by focusing on the cortisol response of mothers of adolescents and adults with Autism Spectrum Disorders (ASD) under stressful conditions that are not specific to the child’s ASD symptoms. This study examines how negative life events and daily stressors are associated with maternal awakening cortisol level. Participants were selected from the Adolescents and Adults with Autism Study (AAA; Seltzer et al., 2003). In addition to completing a set of questionnaire and in-home interview, the 82 mothers participated in the AAA Daily Diary Study. Based on the paradigm from the MIDUS study, the Daily Diary Study consisted of telephone interviews over eight evenings and saliva collection across four days. Controlling for a set of mother and child characteristics, results from the 2-level multilevel models revealed an interactive effect of number of daily stressors (previous day) and number of negative life events
for log awakening cortisol. On days following a greater number of daily stressors, mothers who had previously experienced more negative life events had lower awakening cortisol level than mothers who reported fewer negative life events. Findings also showed a significant interaction between previous day stressor severity and number of negative life events for awakening cortisol level. These findings highlight the toll that global and everyday stressors have on the cortisol response of mothers of adolescents and adults with ASD.

POSITIVE ASPECTS OF CAREGIVING: EXAMINING RACIAL DIFFERENCES ON THE SELF-AFFIRMATION AND OUTLOOK ON LIFE SUBSCALES
J.I. Alva, T. McCallum, Case Western Reserve University, Cleveland, Ohio

Past research on caregiving has focused on the negative consequences of providing care for a family member with dementia. More recently, research on rewards and more positive aspects of caregiving has emerged. The Positive Aspects of Caregiving (PAC) scale (REACH I, 1995) measures the positive appraisals attributed to the caregiving experience. Research on factors related to increased PAC may help explain why some caregivers derive satisfaction from the challenging caregiving task. Past research has identified racial differences in this area. For example, African American caregivers report higher levels of PAC compared to White caregivers (Roff et al., 2004). Preliminary research on the PAC measure identified two components through factor analysis: Self-Affirmation and Outlook on Life (Tarlow et al., 2004). Differences in these two factors have yet to be explored. The current study examines racial differences in these factors to determine if different racial groups identify more strongly with different components of PAC. The sample used in this secondary data analysis from the REACH II (2001) dataset included 642 Alzheimer’s caregivers. Three racial groups were represented: White (n = 220), African American (n = 211), and Latino (n = 211). A one-way between groups multivariate analysis of variance was performed resulting in no statistically significant results. Possible reasons for the absence of racial differences in Self-Affirmation and Outlook on Life factors are discussed.

THE GRIEF PROFILE FOR CAREGIVERS OF PERSONS WITH DEMENTIA

This study examined the relationship between caregiver depression and the experience of grief and burden. We assessed anticipatory grief and burden in 80 dementia caregivers using the Marwit-Meuser Caregiver Grief Inventory, Anticipatory Grief Scale, Zarit Burden Interview, and Montgomery Burden Scales. Whereas the total scores for each of the grief and burden measures did not differ between clinically depressed and non-depressed caregivers, depression did affect the pattern of item endorsement. Chi-Square analyses demonstrated that depressed caregivers were significantly more likely to endorse items concerning changes in their own life including loss of freedom and control than did non-depressed caregivers. Eleven items differed significantly between groups (p<.05) and four more items showed statistical trends. For example, depressed caregivers endorsed “I feel I am losing my freedom” (p=.002) and “Do you feel that your social life has suffered because you are caring for your relative?” (p=.007) more than non-depressed caregivers. There was no difference in item endorsement patterns on items concerning other aspects of life (e.g., caregivers support network). For example, there was no difference on items such as, “I have nobody to communicate with” and “My extended family has no idea what I’m going through” (p>.10). These findings are consistent with prior literature demonstrating that people with depression exhibit greater self-focused attention, and suggest that depression influences the way burden and anticipatory grief are experienced even when the overall levels of burden and grief are similar to those of caregivers without depression.

DISCREPANCY IN PERCEPTIONS OF VALUES OVER TIME: INDIVIDUALS WITH DEMENTIA AND FAMILY CAREGIVERS

Cross-sectional evidence suggests that there are discrepancies in reports between individuals with mild to moderate dementia (IWDs) and their family caregivers when reporting on the values and preferences held by IWDs regarding their daily care. Caregivers consistently report less importance of IWDs’ care values and such discrepancy is primarily associated with caregivers’ beliefs about IWDs’ involvement in decision making. However, research has yet to address how these relationships change over time and how they are related to wellbeing. Using a sample of 216 dyads, where one person has mild to moderate dementia and the other is a family member providing assistance and supervision, we used linear growth curve modeling to investigate how discrepancies in report on IWD’s values and preferences in daily care change over four years. Results indicate significant increases in discrepancies over time due to caregivers reporting less perceived importance with time, as well as significant interindividual differences in discrepancies over time. Baseline caregiver beliefs remained a significant predictor of level of discrepancy along with IWD depression and quality of life at baseline. While caregiver depression was not associated with discrepancy, caregiver quality of life at baseline was significantly associated with the change in discrepancy over time. These findings identify differential effects of individual characteristics on understanding discrepancy in perceptions over time. They also demonstrate a need to investigate further the influence of wellbeing and other factors on perceptions of values, particularly as ongoing discrepancies may represent a challenge when caregivers become surrogate decision makers for their relatives.

PREDICTORS OF DEPRESSION AMONG HIGHLY BURDENED DEMENTIA CAREGIVERS
G. Tremont1,2, J. Davis1,2, K.E. O’Connor, R.H. Fortinsky3, C. Grover2, 1. Brown University, Providence, Rhode Island, 2. Rhode Island Hospital, Providence, Rhode Island, 3. University of Connecticut Health Center, Farmington, Connecticut

Highly burdened dementia caregivers are at heightened risk for depression, but not all of these caregivers report significant depression. The purpose of this study was to identify factors that explain why burden is associated with depression in some caregivers but not in others. Participants were 114 dementia caregivers (M age = 61.89, SD = 12.10; 53.5% spouse, 41.2% adult child, 5.5% other) enrolled in an intervention study who were providing a minimum of 4 hours of daily care for at least 6 months (M length 48.13 mo, SD = 38.48). Caregivers were selected if they endorsed a significant level of perceived burden on Zarit Burden Interview (score >24). They were divided into two groups based on their self-reported depression on the Center for Epidemiologic Studies Depression Scale (high = 16 or higher [n=56] versus low = less than 16 [n=58]). Individuals with low self-reported depression had significantly higher self-efficacy for managing dementia symptoms and higher relationship satisfaction compared to those with high levels of depression (both p<.05). Differences were not seen for ADL impairment or behavior problems in the patient, caregiver age or education, or length of caregiving. Regression analysis showed that self-efficacy for symptom management accounted for significant variance in depression even after controlling for perceived burden (ΔR2 = .03, p = .025). Findings suggest that confidence in managing dementia symptoms and a positive view of the caregiver-patient relationship may protect burdened caregivers from depression.
POSITIVE AND NEGATIVE CAREGIVING EXPERIENCES: CONSIDERING DYADIC INFLUENCES

E. Tov, S.M. Moorman, Sociology, Boston College, Chestnut Hill, Massachusetts

While much caregiving research has focused on caregiver burden and the rewards of caregiving, little of this work directly considers the influence of a caregiver’s relationship with the care recipient. This study examines the factors that contribute to positive and negative caregiving experiences among over 1,000 family caregivers of older adults who participated in the 2004 National Long Term Care Survey. Using ordinary least squares (OLS) regression, we assessed the effects of positive influences of the relationship (e.g., helpful care recipient behaviors), detrimental influences (e.g., family conflict), and care recipient perceptions, which included self-reported socioemotional well-being measures. Positive and dyadic relational factors were associated with positive caregiving experiences; social support, helpful care recipient behaviors, and care recipient happiness increased positive caregiving experiences while negative recipient behavior decreased them. Relationship factors had less to do with negative caregiving experiences; rather, the most important contributors were financial hardship, poor caregiver health, and gender, with women being more likely to report negative experiences than men. These results suggest that the mechanisms behind positive and negative caregiving experiences may differ. Interventions that may lessen caregiver burden, therefore, will not necessarily pave the way for positive caregiving experiences. Nevertheless, some indicators, such as recipient behavior, are fundamental in creating both positive and negative experiences. Efforts aimed at alleviating caregiver burden or enhancing positive aspects of caregiving should thus be sensitive to the caregiver / care recipient relationship.

NEIGHBORHOOD SOCIO-ENVIRONMENTAL INFLUENCES ON PSYCHOLOGICAL HEALTH AMONG INFORMAL CAREGIVERS

T. Wakui1,2, E.M. Agree1, T. Saito1, I. Kai3, I. Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland, 2. Japan Society for the Promotion of Science, Tokyo, Japan, 3. School of Public Health, the University of Tokyo, Tokyo, Japan

The role of neighborhood social cohesion, collective efficacy, and social capital for elder health has received much attention. However, the effects of neighborhood socio-environmental factors on caregivers’ well-being remain overlooked, despite the known importance of social support for alleviation of caregivers’ burden and psychological health. In this research we examine the relationship between neighborhood trust and reciprocity, and caregivers’ psychological health, and whether these factors have a buffering effect among caregivers who have greater care demands. In 2010 we conducted a mail survey of family caregivers from 17 municipalities in Japan. Neighborhood social cohesion was assessed with questions on community social trust and reciprocity. The Zarit Burden Inventory and Center for Epidemiological Studies Depression Scale were used to assess psychological health. Information on help provided, recipient dementia symptoms, and actual social support from community and other caregiver and recipient characteristics was also collected. The final analytic sample comprises 2,511 informal caregivers, whose mean age was 63. In multiple regression analysis, those who trusted their neighbors or reported higher reciprocity had lower burden and depression, even controlling for actual support received from the community. For ADL caregivers, neighborhood trust and reciprocity were important regardless of care demands, but reciprocity was more important for dementia caregivers. Findings suggest that the perception that help is available may be important over and above actual help received from the community. This is particularly true for dementia caregivers, for whom back-up care is a more critical day to day concern.

THE ASSOCIATION BETWEEN SLEEP QUALITY AND FATIGUE IN DEMENTIA CAREGIVERS

Y. Chang1,2, L.O. Wray1, P. Chang1, S. Lai1, I. School of Nursing, The State University of New York, University at Buffalo, Buffalo, New York, 2. Center for Integrated Healthcare VA Western New York Healthcare System, Buffalo, New York, 3. Alzheimer’s Association Northern California & Northern Nevada, Mountain View, California

Background: Family caregivers often experience sleep disturbances due to overwhelming caregiving task provided to their loved ones with dementia. Insufficient sleep may cause serious consequences that can affect the immune system, daily functioning, and psychological and physical health. The association between sleep and fatigue has been established in other populations. However, little is known about fatigue and its association with sleep quality in dementia caregivers. Purpose: This study aimed to examine the association between sleep quality and fatigue in dementia caregivers. Methods: This study used a cross-sectional design. Participants were recruited from San Francisco Bay Area and the Alzheimer’s Association Northern California and Northern Nevada chapter. Measures included the Pittsburgh Sleep Quality Index (PSQI), the Lee Fatigue Scale (fatigue and energy scales), and a demographic questionnaire. Descriptive statistics and Pearson’s correlation were utilized for data analysis. Results: A total of 60 family caregivers participated in the study. Preliminary findings indicated that 75.5% of participants reported poor sleep quality (PSQI > 5). Participants reported experiencing a moderate level of fatigue (mean 4.72) and a moderate level of energy (mean 5.01). Significant associations were found between sleep quality and fatigue (r = .553; p <.000) as well as sleep quality and energy (r = -.245; p <.05). Conclusions: The findings revealed that caregivers who had a poorer sleep quality reported a higher level of fatigue and a lower level of energy. Our findings indicated a need to develop interventions for dementia caregivers to improve sleep quality and decrease fatigue.

PSYCHOTROPIC MEDICATION USE IN A POPULATION STUDY OF DEMENTIA CAREGIVER DEPRESSION

K.W. Piercy1, E.B. Fauth1, M.C. Norton1, P. Rabins1, R. Pfister1, J. Olson1,3, C. Lyketsos1, J. Tschanz2,1, J. Utah State University, Logan, Utah, 2. Johns Hopkins University, Baltimore, Maryland

Research suggests that caregivers of persons with dementia (PWD) are at increased risk for depression. Most of what is known about psychotropic medication use (anti-depressant, anti-anxiety, and sedative hypnotics) in carers has been studied in clinical samples. The Cache County Dementia Progression Study is a population study of dementia caregivers (n=256) seen up to four times in two years (M=2.5 visits, SD=1.08). This sample reports low levels of depressive symptoms (M=7.98, SD=7.8 on the Beck Depression Inventory; BDI) with no significant average change over time. Using linear mixed models, we tested if time varying psychotropic medication predicted differential rates of change in depressive symptoms. Persons with dementia were 61% women, averaged 85 years old (SD=5.53), with average dementia duration of 3.68 years (SD=1.91). Caregivers averaged 67 years old (SD=14.34): were 76% women, 50% adult children, and 45% spouses. Twenty percent of the sample reported psychotropic medication use at baseline. Psychotropic users did not differ from non-users in age, relationship to the PWD, or self rated health, although male caregivers were less likely to use psychotropics than female caregivers (p=.08). The subsample of psychotropic users had significantly higher average BDI scores over the course of the study (p<.001) and showed significant decreases in BDI scores over time (p=.04) compared to caregivers not taking psychotropics. While this population-based sample reports lower levels of depression than clinical samples, depressive symptoms were stable over time. The subset using psychotropic medications experienced a decrease in depression scores over time compared to caregivers not using them.
CAREGIVING EFFICACY COMPLETELY MEDIATES THE RELATIONSHIP BETWEEN BEHAVIORAL SYMPTOMS AND DEPRESSION OF CAREGIVERS OF ALZHEIMER DISEASE
S. Cheng, Department of Psychological Studies, Hong Kong Institute of Education, Tai Po, Hong Kong

Objective: To investigate whether caregiving efficacy mediates the relationship between patients’ behavioral symptoms, cognitive impairment, and functional impairment on the one hand, and caregivers’ burden and depression on the other. Methods: 135 caregivers of family persons with Alzheimer disease participated in a 4-wave longitudinal study. This study reports cross-sectional findings at Wave 2 in which a measure of caregiving efficacy was administered. Also assessed were, in patients, behavioral and psychological symptoms of dementia, Mini-Mental State Examination, and impairments in activities of daily living. Caregiver burden and depression were assessed by the Zarit Burden Scale and the Hamilton Depression Rating Scale. Data were analyzed using structural equation modeling. Results: Behavioral symptoms were more predictive of burden and depression, than cognitive or functional impairment. However, all pathways between patient problems and caregiver distress were fully mediated by caregivers’ sense of efficacy. Conclusion: Caregiving efficacy is a powerful attribute of caregivers. However, what contributes toward efficacy among dementia caregivers is not at all clear. Future research should investigate the basis for caregiving efficacy.

CAREGIVING AS A REWARDING EXPERIENCE: DOES SPIRITUALITY MATTER AMONG ALZHEIMER’S FAMILY CAREGIVERS?

Purpose: Caring for an Alzheimer’s relative can engender physical, emotional, and psychosocial stress. Although research has largely focused on the negative effects of stress on caregiving, a growing literature has begun to examine the positive aspects of caregiving (PAC), defined as the rewards or gains derived from the caregiving experience. This study tested Pearlin et al.’s stress process model in explaining PAC among Caucasian (n=220), African-American (n=211) and Latino (n=209) Alzheimer’s family caregivers; and examined the role of spirituality in predicting PAC for each ethnic group. Methods: A secondary data analysis was performed using baseline data from the Resources for Enhancing Alzheimer’s Caregiver Health (REACH) II project. Latent constructs included: objective and subjective stressors, social support, spirituality, and PAC. Structural equation modeling (SEM) was performed using LISREL 8.80. Results: Acceptable model fit was found for each group, suggesting that Pearlin et al.’s stress process model is a valid model for explaining PAC across these three groups. The results indicated a direct effect of spirituality on PAC for Caucasians, no effect for African-Americans, and both a direct and a partial mediation effect of spirituality for Latino CGs. Discussion: This study suggests: 1) the constructs in Pearlin et al.’s model are useful in explaining PAC for Caucasian, African American, and Latino caregivers and 2) spirituality plays a positive role in facilitating PAC among Caucasian and Latino caregivers, but not among African American caregivers. In the latter case, the non-significant finding may be explained by the minimal variance in spirituality observed among African-American caregivers.

THE INFLUENCE OF SOCIAL-RELATIONAL INVOLVEMENT ON DEPRESSIVE SYMPTOMOLOGY-FOCUSED ON INTERMEDIATING EFFECT OF CAREGIVING BURDEN
Y. Oh, M. Paek, MSASS, Case Western Reserve University, OH, OHIO

The purpose of this study is to investigate the mediating effect of burden in caregivers of impaired older adults on the relationship between social-relational involvement and depressive symptoms. Many studies show that social-relational involvement is an important predictor of caregiving burden and depression among caregivers of vulnerable people. Several studies demonstrated that caregiving burden also plays a significant role in predicting depression among family caregivers. There is little known about the mediating relationship between social-relational involvement and depression among family caregivers. METHODS To achieve the purpose of the study, we selected family caregivers who live with elderly people from the first wave (2008) of Seoul Welfare Panel Study (SWPS). The sample included 297 Korean family caregivers. Depressive symptomology was measured by the CES-D, a 5-point Likert-type self-report scale. Social relational involvement was assessed by the degree of participation in social activities. Caregiving burden was measured by six items which reflect financial, physical, psychological, employment, time constraints burden, and insufficient knowledge. RESULTS There are two major findings: First, caregiving burden, as a mediating variable, has effect on the relationship between social-relational involvement (β= -.13, p < .05) and depressive symptoms (β=.15, p < .01). Second, the negative effect of social-relational involvement on depressive symptoms still exists (β = -.30, p < .01), after adding caregiving burden into the analysis model (CFI= .987, RMSEA=.43). These results suggest that attention should focus on providing interventions to promote social interaction and to alleviate caregiving burden for family caregivers with older adults.

CAREGIVER-REPORTED PATIENT BEHAVIOR PROBLEMS ONE-YEAR AFTER A STROKE EVENT
M.M. Perkins1, J. Goldstein2, 1. Psychology, University of Alabama at Birmingham, Birmingham, Alabama, 2. Sanford University, Birmingham, Alabama

Stroke is the third leading cause of death in the United States and depending on the severity of the stroke, survivors can experience significant physical and mental disability. It is important to understand how caregivers view the behavior changes of the stroke survivor because it can ultimately impact the caregiver’s health. Haley and colleagues (2009) found mood disturbances of the stroke survivors to be one of the most stressful problems faced by stroke caregivers. The current study used data collected from spouse caregivers of male stroke patients at the Lakeshore Rehabilitation Hospital in Birmingham, AL. The baseline interview was conducted between 12 and 18 months after the stroke event. Caregivers participated in a telephone survey that measured changes in psychological, emotional, and physical health, family involvement, and financial status since the stroke incident. Problems with the stroke patient’s behavior were assessed using 11 caregiver-reported items that also included the degree to which these problems were occurring or unpleasant. Data was provided on 35 female spousal caregivers who were, on average, 67.9 years old. The caregivers reported an average of 4.1 patient behavior problems, with 32 indicating at least one problem (91.4% of the sample). The most frequently reported problem was the husband’s ability to communicate with speech was worse now than it was before the stroke, and caregivers felt that the problem happened for several words or phrases. The relationship between caregiver health and stroke patient recovery will be discussed.

SESSION 1680 (POSTER)
COMMUNITIES, SUPPORT, AND RESILIENCE
THRESHOLDS OF CULTURAL RENEWAL IN ONE RETIREMENT COMMUNITY: THE SIGNIFICANCE OF NEW DOORS
S.A. Eisenhandler, Sociology, University of Connecticut, Waterbury, Connecticut

During six years of qualitative study [2005-2011] the small retirement community of Kahehtiyoh in a rural pocket of northwestern
Connecticut has yielded flowers, veggies, a stable community, and a good quality of life for its residents. Analytically the Kahehtiyoh study has provided new insights and confirms findings derived from other research about the kinds of group interaction and communal features that are strongly associated with social well-being for older people. The research study has documented a culture created by long-term residents and staff as well as changes that have emerged within the community as residents and staff members have moved on or have died. This poster examines observable, material changes that are now present in the ‘bones’ or physical infrastructure of the retirement community. Specifically the poster addresses external or structural elements (such as the recent availability of outside funding for renovation of housing units) that play a crucial part in shaping the direction of cultural change and in setting the pace for change. Moreover, in a recent ceremony marking an important transition in the community, the role of multiple social actors and larger contexts, i.e., the political landscape in the local community and the state underscores the power and influence of larger social forces. A threshold is both a point of entry and exit, of farewells and welcomes; the symbolic significance of changing thresholds with new doors says much about the renewal of a retirement community and its culture.

INTERGENERATIONAL EQUIVALENCE OF A MEASURE OF COMMUNITY SATISFACTION AMONG BLACK AMERICANS
A. Schwartz, Boston College Graduate School of Social Work, Chestnut Hill, Massachusetts

This paper examined generational equivalence of measurement properties of a measure of community satisfaction between young and older African Americans. Data was from the National Study of Black Americans: Wave 4, 1992. The sample included 659 participants (young group n=317, older group n=342), with a mean 1991 income of $34,255, and mean age of 53 years. Within group confirmatory factor analyses (CFA) revealed that the measurement model of community satisfaction models had excellent fit in both generations (younger group χ²=7.11, DF=28, p < 0.53; older group χ²=10.58, DF=8, p=0.23). The subsequent multi-group CFA indicated that the measurement equivalence hypotheses were supported suggesting the community satisfaction scale had cross-generational measurement equivalence. The findings confirm that this scale can be used in intergenerational comparison research to help promote the quality of life of Black Americans.

A WAR WITHIN A WAR: AN AFRICAN-AMERICAN VETERAN’S STORY
H.K. Black, Behavioral Research, Arcadia University, Glenside, Pennsylvania

Many histories of World War II distorted African American soldiers’ contributions. Research on suffering in elders revealed that lack of government acknowledgement of their efforts angered and pained African-American veterans. Our use of one case illustrates how the case study shows a phenomenon, such as racism in World War II, in depth. Mr. Thompson, a 90 year old combat veteran, was drafted in 1942, sent to Italy, and saw the irony of racism in war. His all-Black infantry division liberated a seaside resort town, Virregio, in Tuscany. They could not even visit Virregio after liberation because the American General in charge “did not want Blacks coming in.” A key finding is: life course development theories do not fit African American elders’ experiences. Our case: 1) shows the need for alternative human development models; 2) reveals how elderly veterans interpret experiences of racism and war and 3) acknowledges that DuBois’ ‘double consciousness’ persists as a function of self-protection.

FAMILIES AND CARING IN SOUTH ASIAN COMMUNITIES IN THE UK: KEY THEMES AND CRITICAL CHALLENGES
C. Victor, W. Martin, M. Zubair, Brunel University, Uxbridge, United Kingdom

Introduction: Within the UK we have a limited evidence base about the experiences of growing old for Bangladeshi and Pakistani communities, especially in terms of their need for and expectations of care and support. Methods: We draw on our experiences of the fieldwork for and utilize the data generated by 110 semi-structured interviews conducted with a diverse group of Bangladeshi and Pakistani men and women aged 50+ years for our ESRC New Dynamics of Ageing project; Families and Caring in South Asian Communities. All participants were resident in the local community and were not recruited from specific care provision agencies. Interviews were either recorded, transcribed and reviewed by the research team according to participants’ preferences. Findings and Conclusions: In this paper we offer a preliminary data analysis and the substantive findings. We explore critical methodological issues from the fieldwork focusing in particular upon the age and gender of our researcher was linked to the creation of the researcher identity and the influence this had upon access and recruitment of study participants. We examine the complex interplay between these factors and challenge the duality of the ‘insider/outsider’ concept from our fieldwork experience. In terms of our empirical data we focus upon the expectations of receipt and provision of care and support expressed by participants in terms of both locally and transnationally based caring networks and the links between family and formal caring solutions.

OLDER RV RETIREMENT PARK RESIDENTS: WHO ARE THESE PEOPLE AND ARE THEY AGING SUCCESSFULLY?
E. Sikorska Simmons, A. Gens, A. Hartman, L. Lei, M. Lopez-Perez, B. Stevens, Sociology, University of Central Florida, Orlando, Florida

RVing, as an alternative form of housing and lifestyle, can accommodate a variety of older people’s needs. There is a growing number of RV retirement parks that are specifically designed for older adults. Little, however, is known about older people who live in these parks. This study examined characteristics of RV retirement park residents and their lifestyle. The sample included 110 residents of an RV retirement park in Florida. Data were collected, using a self-administered questionnaire. Of the 110 participants, 46% were women, 99% were white, and 68% were married. Almost all had children (95%), close friends (91%) and were in frequent contact with them. The mean age was 76, and 25% were 80 or older. More than half (56%) assessed their health as “excellent” or “very good.” Almost all (96%) reported high levels of life satisfaction. Snowbirds constituted the largest group (58%), followed by part-timers (29%), and full-timers (12%). The length of RVing varied from 1.5 to 62 years, with a mean of 30 years. The most common type of RV was a travel trailer (72%). During a typical week, most residents participated in at least three activities, including visiting friends, walking, and sightseeing. “Feelings at home, regardless of place” and “traveling and meeting people” were the most appealing aspects of RVing. Most residents were resident in the local community and were not recruited from specific care provision agencies. The experiences of growing old for Bangladeshi and Pakistani communities, especially in terms of their need for and expectations of care and support. Methods: We draw on our experiences of the fieldwork for and utilize the data generated by 110 semi-structured interviews conducted with a diverse group of Bangladeshi and Pakistani men and women aged 50+ years for our ESRC New Dynamics of Ageing project; Families and Caring in South Asian Communities. All participants were resident in the local community and were not recruited from specific care provision agencies. Interviews were either recorded, transcribed and reviewed by the research team according to participants’ preferences. Findings and Conclusions: In this paper we offer a preliminary data analysis and the substantive findings. We explore critical methodological issues from the fieldwork focusing in particular upon the age and gender of our researcher was linked to the creation of the researcher identity and the influence this had upon access and recruitment of study participants. We examine the complex interplay between these factors and challenge the duality of the ‘insider/outsider’ concept from our fieldwork experience. In terms of our empirical data we focus upon the expectations of receipt and provision of care and support expressed by participants in terms of both locally and transnationally based caring networks and the links between family and formal caring solutions.

THE SIGNIFICANCE OF ETHNICITY IN PENSIONS: A QUANTITATIVE OVERVIEW
O. Gough1, R. Adami1, A. Sharma1, A. Carosi2, 1. Westminster Business School, London, United Kingdom, 2. University of Bologna, Bologna, Italy

The research provides an overview of the variation in employment patterns, pension participation and poverty levels at retirement between

Looking for Meaning, a Preventive Life Review Course for Long-Term Care Residents

L.F. van Asch, J.D. Lange, M. Smalbrugge, A. Pot

Program on Aging, The Netherlands Institute of Mental Health and Addiction, Utrecht, Netherlands, 2. VU University, Amsterdam, Netherlands, 3. VU University Medical Center, Amsterdam, Netherlands

Background: Older Adults Living in Long-Term Care Facilities Have a Higher Risk to Become Depressed. “Looking For Meaning” is an Evidence-Based Preventive Life-Review Course for Community-Dwelling Older Adults with Depressive Symptoms. The Purpose Of the Current Pilot Study was to Evaluate if This Course Is Suitable for Long-Term Care Residents. Another Aim Was to See if The Course Has an Impact on Depressive Symptoms, Psychological Wellbeing, and Quality of Life. Method: The Pilot Project Was Conducted in Eight Long-Term Care Facilities in The Netherlands. The Residents Participated in Eight Different Groups, Each Consisting of 5-8 Persons. Exclusion Criteria Were Clinical Depression and/or Cognitive Impairments. The Intervention Was Carried Out by a Psychologist and an Activity Therapist. To Evaluate The Effects Of the Intervention on Depressive Symptoms, Psychological Wellbeing, and Quality of Life, Three Questionnaires Were Used: the Geriatric Depression Scale-8 (GDS-8), Philadelphia Geriatric Center Morale Scale (PGCMS) and the Euroqol-5 (EQ-5D). Data were Collected at Baseline and One Week After the Last Session. Results: At Baseline the Sample Consisted of 42 Females and 13 Males. Due to Death and Physical Illness 44 Participants Completed the Course. Results of the Pilot Study Show That the Intervention Had a Significant Effect on the GDS-8 (P < 0.001) and the PGCMS (P < 0.001), but no Significant Effect on the Thermometer of the EQ-5D (P = 0.186). Which Subgroups Benefit More or Less From This Course Was Also Investigated. Discussion: “Looking For Meaning” Seems To Be Suitable for Long-Term Care Residents. It Also Seems to Have an Impact on Depressive Symptoms and Psychological Wellbeing.

Older African American Men and Manhood: A Lifespan Perspective

B. Sellers, W. Powell Hammond

1. Ivory Tower Insights, Decatur, Georgia, 2. University of North Carolina, Chapel Hill, Chapel Hill, North Carolina

With an increasing focus on US health disparities, psychosocial issues impacting African American men throughout the lifespan are receiving greater attention. Specifically, research is focusing on how African American men view their social roles as men. The current study investigates perceptions of manhood among African American men who are aging successfully, e.g., low incidence of disease, high physical and cognitive functioning, engaged socially. The sample consists of thirteen African American men aged 70 years and older (M = 79.6 years) residing in the greater Pittsburgh area who participated in a mixed methods interview regarding manhood, health, discrimination, and social support. Manhood meaning was assessed by asking participants a series of open-ended questions, “what does manhood mean for you?” (Hammond & Mattis, 2005). Retrospective accounts of manhood meaning and influences on manhood meaning were also collected. Among the participants, there was variability in specific meaning of manhood, with themes of being a provider, being independent, caring for children/grandchildren, and being fair/social responsibility emerging throughout the interviews. Participants also acknowledged changes in their perceptions of manhood across their lives from experiences with friends/family and observations of other men. These data were then compared with published qualitative studies conducted with younger groups of African American men. Results suggest that while previous studies found similar emergent themes regarding social responsibility and being a provider, findings differ with regard to older men’s usage of reflection and past experience, and their perceptions of discrimination. Implications for improvement of men’s well-being across the lifespan will be discussed.

Challenges Faced and Lessons Learned from Sustaining Community-Based Participatory Research Partnership in Chicago Chinatown

E. Chang, M.A. Simon, W. Hammond, B. Wong, W. Wong, X. Dong

Background: Community-academic partnership is among the most commonly practiced collaborations in community-based participatory research (CBPR) projects. Despite growing interests and demands in partnerships, less attention is given on partnership sustainability—a critical issue to the management of successful community health initiatives. Methods: Our community-academic partnership is a synergistic effort between Rush University Medical Center and Chinese American Service League to conduct a CBPR project with older Chinese population in the Chicago Chinese community. Based on a well-accepted sustainability conceptual framework, this study presents challenges faced and strategies learned throughout the initial steps, midterm actions, and long-term goals pertaining to partnership sustainability. Results: Our experience in this ongoing collaboration shows that partnership sustainability goes beyond program-based evaluation. Rather, the social, environmental, and cultural contexts within which the partnership operates serve as critical forces for long-term sustainability. In particular, we have learned that working with Chinese elderly community requires trust and respect for its unique cultural values and linguistic diversity. With a committed attitude to mutual learning, both community and academic partners will be able to better explore, comprehend, and appreciate each other’s standpoint, thereby contributing to sustaining meaningful partnerships. Conclusion: Our results indicate the need to develop evidence-based, impact-driven health partnerships with culturally appropriate strategies critical for advancing social change. Furthermore, we believe our partnership experience with Chinese population provides implications for expanding CBPR model to fully address the needs of diverse populations.

In the Path of Progress: The Impact of Zoning Policy on Aging-In-Place and Age-Friendly Planning

A.W. Costley, York College-CUNY, Queens, New York

Background: While many U.S. cities work to become more “age-friendly” by transforming commercial and physical environments, urban renewal projects can often work against these efforts. This mixed-method study in New York City explored the impact of a major rezoning plan on minority older adults, aging-in-place and the potentially negative impacts on the area’s age-friendly status. Methods: Survey data from 60 residents (ages 60-90 m/sd = 74.7/7.7) were collected at senior centers in the rezoning area. Items assessed income, housing status, ADLs/IADLs, attitudes toward essential age-friendly features (WHO...
EXPLORING THE LONG-TERM CARE NEEDS OF ALASKA NATIVE ELDERS IN RURAL ALASKA

J.P. Lewis, K. Boyd, University of Alaska Fairbanks, Fairbanks, Alaska

The current trend in long-term health care service delivery includes placing older adults in long-term care or skilled nursing facilities. Many of the rural villages in the State of Alaska have little to no access to routine health care services let alone a long-term care facility. When an Elder begins to need more assistance or medical care than family members are able to provide, many of them are sent to a long-term care facility in an urban location. Previous research with Alaska Native Elders has given voice to the Elders’ preference of remaining in their home community as they grow old (Lewis, 2011). We were approached by a community in the Northwest region of Alaska to conduct a needs assessment with the Elders in the area to determine the most effective, efficient, and culturally congruent way to serve the Alaska Native Elders in their communities. Working collaboratively with the 5 participating villages we conducted a quantitative needs assessment employing the use of the Indian Health Service “Identifying our Needs” survey instrument. This phase consisted of interviews with 134 Alaska Native Elders aged 60 years and older, and was followed by a qualitative phase in which selected elders were interviewed to help gain a deeper understanding of their wants and needs. The results provide strong support for a much needed paradigm shift in the way long-term care is delivered in Alaska.

A DEMOGRAPHIC AND SOCIAL PROFILE OF MIDDLE-AGED AND OLDER HMONG FROM THE AMERICAN COMMUNITY SURVEY

M.S. Yang, J.A. Burr, J.E. Mutcher, Gerontology, Univ. of Massachusetts Boston, Boston, Massachusetts

Following the Vietnam War, two waves of Hmong refugees from Southeast Asia migrated to the US, settling primarily in California, Minnesota and Wisconsin. This paper is among the first to provide a quantitative analysis of some of the key characteristics of middle-aged and older Hmong people that reflect their unique cultural heritage, their immigrant status, and their vulnerability. We analyze three-year pooled data (2006-2008) from the American Community Survey for persons 50 years old and older. In demographic terms, only 3.5% of the population is 65 years old or older (compared to 13% of the total US population). In terms of family characteristics, 53% are married, 20% are widowed, and more than 9-in-10 middle-aged and older Hmong persons live in a multigenerational household (with 42% living in a household with at least one grandchild and more than 5% raising a grandchild). Only 1-in-4 Hmong in this age group have completed high school and median personal income is under $10,000 per year (median household income is more than $50,000). Yet, nearly 60% live in an owned home, a rate that is considerably higher than for some other immigrant groups. These statistics and others provide a picture of a relatively economically poor but family rich ethnic group. Findings from this study help us to understand better how this refugee population transitions into later life. The findings are also discussed in terms of the unique culture and history of the Hmong people.

LINKS AMONG HOPE, GRIT, AND PERCEPTIONS OF COMMUNITY FOR OLDER AND MIDDLE-AGED ADULTS

K.N. Erickson, B.A. Randall, North Dakota State University, Fargo, North Dakota

Theories of successful aging emphasize that resource availability, social support, and psychological characteristics affect older adults’ well-being. Older adults tend to be strongly committed to aging in place, and have strong bonds to their community. Research has emphasized the importance of services (e.g., transportation). However, a focus on services ignores the broader reality of successfully aging in place, as multiple community features and psychological characteristics likely contribute. Of particular interest is the perception of a match between the importance and availability of community features, as greater perceived match should enhance well-being. Psychological characteristics may impact the perceived level of match. Hope Theory suggests variability in individuals’ ability to cope with goal blockage. Similarly, grit influences perseverance in striving toward goals. Individuals low in hope and grit may perceive greater mismatch, as people high in these characteristics would work to resolve obstacles. Those high in hope and grit may also generally be more satisfied with and engaged in their communities. A community sample of upper-Midwest adults (aged 37-89, N=198, 51 were age 65+) will be used to compare middle-aged and older adults on the links between hope, grit, and multiple variables measuring community perceptions. Regression analyses showed that hope was not significant, though high grit predicted less mismatch between important and available community features for older adults, but not for middle-aged. Older and middle-aged adults with higher hope scores reported greater community satisfaction. Additional analyses will explore the relations of hope and grit to other aspects of community for both groups.

THE EFFECT OF ACCULTURATION ON ALCOHOL CONSUMPTION AMONG HISPANIC AND ASIAN ELDERS

A.N. Bryant, G. Kim, Psychology, Univ Alabama, Tuscaloosa, Alabama

Alcohol use by older adults is occurring more frequently, while simultaneously the number of older adult minorities is growing. It is important to identify drinkers as unhealthy drinking often goes unnoticed in older adults. Identifying risk factors for older adult alcohol use is an area that warrants attention. Previous studies have found that higher levels of acculturation may be related to an increase in alcohol consumption among both Hispanics and certain subgroups of Asians. However, such an examination has not been conducted among older adults. Using data obtained from the 2009 California Health Interview Survey (CHIS), 1,088 Hispanics and 1,536 Asians aged 60 and older were selected for analyses. Results show that there was no significant difference in prevalence of past year alcohol consumption between Hispanics (43%) and Asians (44%). Results from regression analyses show that percent of life spent in the US was a significant predictor for Asians’ alcohol consumption (p<.01), indicating that those who had spent a greater percentage of their life in the US were more likely to have consumed alcohol in the past year. The absence of limited English proficiency was a significant predictor for alcohol consumption in Hispanics (p<.01). While neither one of the significant acculturation related variables fully encompasses the concept of acculturation, it is reasonable to view these variables as proxies of acculturation, suggesting that acculturation may be related to alcohol consumption for both older Asians and Hispanics. Such information may be useful in identifying individuals in need of...
SESSION 1685 (POSTER)

COPING, CONTINUING, AND CARE: CANCER IN LATER LIFE

VITAL INVOLVEMENT THEMES OF CANCER COPING IN ELDER KOREAN AMERICAN AND CAUCASIAN AMERICAN SURVIVORS

H.Q. Kivnick, H.Y. Lee, School of Social Work, University of Minnesota, St. Paul, Minnesota

Although cancer is the leading cause of death among Asian Americans (AA) and cancer disparity is visible in AA communities, research focused on these areas is scarce. Available literature attributes disparities primarily to obstacles posed by AA’s culture-based interpretations, beliefs and attitudes towards the disease, cultural associations about psychosocial support, coping behaviors and the entire continuum of cancer care. This exploratory study begins to identify culturally-based themes of vital involvement (VI) that also come into play as older Korean- and Caucasian-American cancer survivors cope and then continue to live with cancer. Using a semi-structured interview guide, researchers conducted face-to-face interviews with five elder Korean- and five Caucasian-American cancer survivors (aged 55-83). Lasting from 1-2 hours, each interview was audio-recorded and transcribed verbatim in its own language. Data from the two cultural groups were analyzed separately, using grounded theory to identify thematic categories and dimensions, and to integrate these categories into theory. Seven major themes emerged, for VI of cancer coping: (1) Support; (2) Outlook; (3) Personal responsibility for treatment management; (4) Care quality; (5) Religion/spirituality; (6) Ongoing life; and (7) Other cancer people. Within themes, some dimensions are shared between the two cultural groups; others are not. Not surprisingly, Korean American participants need to overcome the additional obstacles that confront many immigrants seeking cancer care (e.g., language; economic disadvantage; unfamiliarity with American health care). Implications are discussed, for developing culture-specific cancer-coping intervention strategies around identified VI themes.

DO MILITARY VETERANS IDENTIFY CANCER AS A TRAUMATIC STRESSOR?

E.A. Mulligan1-3, J. Schuster4, A.D. Naik5, J. Gosian1, K.M. Doherty1, J. Moyer1,2. VA Boston Healthcare System, Boston, Massachusetts, 2. Harvard Medical School, Boston, Massachusetts, 3. Washington University, St. Louis, Missouri, 4. National Center for PTSD Women’s Health Sciences Division, Boston, Massachusetts, 5. Michael E. DeBakey VA Medical Center and Baylor College of Medicine, Houston, Texas

Given the lifetime risk of cancer (40%) in combination with advances in treatment, cancer survivorship is increasingly common, especially among older adults. Various aspects of the cancer experience may be traumatic (e.g., diagnosis, recurrence), which is in keeping with the inclusion of life threatening illness as a stressor that can elicit post-traumatic stress disorder (PTSD) symptoms in DSM-IV. The majority of cancer-related PTSD research does not explicitly assess if survivors view cancer as a traumatic stressor (PTSD Criterion A). The purpose of the current analyses was to investigate the prevalence of cancer-related Criterion A as well as the relationships between Criterion A endorsement, other PTSD symptoms, and survivor characteristics. A sample of 73 primarily male (96%) military veterans were interviewed 6 months after receiving a diagnosis of head and neck, colorectal, or esophageal/gastric cancer. Eighty-six percent of the sample identified cancer as a threat of death, serious injury, or loss of physical integrity (Criterion A1) and 74% reported that they responded to cancer with fear, helplessness, or horror (Criterion A2). Taken together, 66% of participants endorsed both A1 and A2 (overall Criterion A). However, fewer veterans met full diagnostic criteria for cancer-related PTSD (16%).

The Gerontological Society of America
Veterans who identified cancer as traumatic endorsed significantly more overall PTSD and reexperiencing symptoms on the PTSD Checklist-Civilian Version. Additionally, participants who met Criterion A1 were significantly younger than those who did not. Many veterans viewed cancer as a traumatic stressor, but future research is needed to determine which survivors are most susceptible to cancer-related PTSD.

INFLUENZA IMMUNIZATION AMONG OLDER ADULTS WITH AND WITHOUT CANCER
M. Kilgore1, J.L. Locher1,2, A.C. Rucks1, S.A. Spencer1. 1. Health Care Organization & Policy, UAB School of Public Health, Birmingham, Alabama; 2. UAB School of Medicine, Birmingham, Alabama

Context: Older adults and cancer patients are at increased risk for influenza infection and, once infected, are at increased risk for adverse complications. Thus both older adults and, especially, cancer patients should receive influenza vaccinations. Objective: The purpose of this study was to compare the likelihood of receiving an immunization for influenza among older adults following a cancer diagnosis with older adults not diagnosed with cancer. Design, Setting, and Participants: We conducted a retrospective analysis using the Surveillance, Epidemiology, and End Results (SEER)-Medicare Data, a linkage of the NCI’s tumor registry data and Medicare Claims. Data on Medicare beneficiaries diagnosed with breast, colon, or prostate cancers in the year 2001 (n=35,257) and also data for a 5% sample of Medicare beneficiaries without a cancer diagnosis residing in the areas covered by the SEER registries (n=203,124) were included in the analyses. Main Outcome Measure: Influenza immunization. Results: We found that immunization rates increased over time for persons diagnosed with cancer in 2001 (from a pre-cancer diagnosis rate of 46.8% to a post-diagnosis rate of 50.8%), but the increase was much greater among Medicare beneficiaries who did not receive a cancer diagnosis (42.6% to 79.7%) (p < 0.00001; 95% CI 0.320 – 0.324). Conclusions: Older adults recently diagnosed with cancer receive influenza immunizations at much lower rates than older adults who have not been diagnosed with cancer. Opportunities exist to improve influenza immunization among this population who are at increased susceptibility to influenza because of compromised immune systems.

SURVIVORS’ BODY SATISFACTION AND SELF-ESTEEM: THE INFLUENCE OF FUNCTIONAL LIMITATIONS AND CANCER SYMPTOMS AMONG LONG-TERM ADULT CANCER SURVIVORS
H.T. Renzhofer, S. Brown, C. Cronin, G. Deimling. Case Western Reserve University, Cleveland, Ohio

Cancer is an illness with implications for an individual’s sense of self, including specific issues such as body satisfaction and self-esteem. This study examines how older adult long-term cancer survivors’ reports of functional limitations and cancer symptoms influence their body satisfaction and self-esteem. It also examines whether these relationships are influenced by stigma perceived by cancer survivors. The data used in this research is from a longitudinal study of 321 older adult, long-term survivors of breast, colorectal and prostate cancer. Participants were randomly selected from a tumor registry of an NCI designated comprehensive cancer center. Survivors selected for the study were aged 60+ years, and had survived cancer at least five years since diagnosis. Our analyses indicate that African Americans have higher body satisfaction, when compared to whites (β = -1.66). Respondents with higher functional difficulties (β = -2.02) and current cancer symptoms (β = -1.18) report a lower body satisfaction. In addition, our analyses indicate that survivors who were diagnosed later in life have higher self-esteem than those diagnosed younger (β = -2.37). Whereas, respondents with more functional difficulties (β = -2.07), report lower self-esteem. Overall, these findings suggest that race, cancer-related functional difficulties and current cancer symptoms are key factors in the body satisfaction and self-esteem of cancer survivors. This research has implications for clinicians and mental health professionals who may address how cancer-related functional difficulties and symptoms affect the quality of life of older adult survivors.

THE IMPACT OF CANCER ON IDENTITY-RELEVANT FACTORS AND THE SOCIAL SELF
G. Deimling, S. Brown, H.T. Renzhofer, C. Cronin. Case Western Reserve University, Cleveland, Ohio

Research on life-threatening or serious chronic illness identifies the impact they can have on the individual’s sense of self (Fran, 1991; Thoits, 1991). Our research examines a multivariate model of the relative impact of cancer factors and other health problems on cancer-related aspects of identity and the social self. Data from in-person interviews with 321 older-adult cancer survivors in a NIH funded research project at an NCI comprehensive cancer center are utilized to test a conceptual model on the key predictors of identity-relevant outcomes. Regression analyses show that cancer-related health worries (β = -.19) and perceived cancer stigma (β = -.25) are significant predictors of lower self-esteem among cancer survivors, and stigma is a strong predictor of poor self-continuity (β = -.28). However, non-cancer factors, such as co-morbidities (β = -.16) are also significantly related to lower self-esteem. Cancer-related factors, such as continuing cancer symptoms (β = -.15) and perceived stigma (β = -.21), are significant predictors of body satisfaction, which is correlated with self-esteem. These results suggest that both cancer and non-cancer health factors play an important role in the individual’s cancer-linked identity and the broader social self. These results suggest that psycho-social practitioners and health care providers need to be aware of the role that cancer, even in the distant past may have on important aspects of identity. These include aspects of identity that are both cancer-linked and more general aspects of self and identity, such as self-esteem, body image, and continuity of self.

ADULT DEVELOPMENTAL PERSPECTIVES ON COPING WITH CANCER: LIFE ACTIVITIES, SATISFACTION, AND DEPRESSION

Cancer diagnosis and treatment may affect functioning in multiple life domains, with variable psychosocial consequences for individuals. This study examined functional and mental health outcomes in military veterans, six months after treatment for head and neck (N=32), colorectal (N=33), or esophageal /gastric (N=8) cancer. 73 mostly male (96%) and mostly older veterans (M age 63.68, SD = 10.16, range 27-87, 67% over age 60), completed in-person interviews that included measures of community integration, illness intrusiveness, and depression. Participants reported that the most important areas of life activity were: relationships (with family/relatives, friends, spouse/partner), using transportation, and recreation/leisure. Areas of life most frequently reported as interfered with by cancer and its treatment include: the feeling of being healthy (74%), eating/drinking (68%), recreation/hobbies (67%), and work/chores/errands (63%). A significant minority of veterans reported that relationships with one’s spouse/partner (40%) or other family (41%), or friends (41%) were interfered with by cancer. A minority of veterans reported major (14%) or minor (18%) depression on the PHQ-9. Older veterans reported lower levels of depressive symptoms (r=0.356**). Older veterans were more likely to report satisfaction with important life domains (e.g., r=0.309* regarding satisfaction with relationships with friends, and r=0.346** regarding satisfaction with recreation/leisure). Veterans with greater depressive symptoms reported more interference in life activities by cancer and its treatment.
DAILY WELL-BEING OF CANCER SURVIVORS: THE ROLE OF SOMATIC AMPLIFICATION

M. Barrineau1, H. King1, E. Costanzo2, D. Almeida3, 1. Penn State University, University Park, Pennsylvania, 2. University of Wisconsin-Madison, Madison, Wisconsin

Cancer survivors may experience similar symptoms and emotions to those of the acute cancer phase, and previous discussions have noted that understanding somatization in cancer patients is critical. Somatic amplification, the sensitivity to bodily concerns and sensations, may contribute to continued suffering and impact the intensity of future treatment in individuals with a cancer history. The present analyses examine how somatic amplification is associated with daily well-being, specifically daily reports of physical health symptoms and positive and negative affect in cancer survivors. Participants were drawn from the second wave of the National Study of Daily Experiences (part of the MIDUS survey) and included 111 cancer survivors (mean age = 65, range = 38-82; 63% female). Participants completed a baseline assessment containing a measure of somatic amplification as well as eight consecutive evening telephone interviews, which included questions regarding daily experiences (i.e., physical health symptoms and positive and negative affect). Results from a series of linear regression models revealed that among cancer survivors, higher scores on somatic amplification were associated with greater negative affect, less positive affect, and more severe ratings of physical health symptoms. Preliminary analyses suggest that somatic amplification contributes to the daily well-being and experiences of cancer survivors. Additional analyses will compare cancer survivors to matched controls in an effort to understand how the role of somatic amplification may differ across groups.

SpiriTuridity and Functional Status in African American Breast Cancer Survivors

C. Talley, College of Nursing, Michigan State University, East Lansing, Michigan

Purpose: The purpose of this study was to examine the relationship between spirituality and functional status (physical and social functioning) in African American breast cancer survivors that were 2, 5, and 10 years post diagnosis. Methods: This secondary analysis included 170 female African American breast cancer survivors that were 55 years of age or older at time of diagnosis. The mean age was 65.2 (SD=8.2); most of the participants were widowed. Spirituality was examined with the Functional Assessment of Chronic Illness Therapy-Spiritual Well-Being (FACIT-sp); physical and social functional was examined with the Medical Outcomes Study 36-item Short Form (physical and social functioning subscale). Spiritual meaning/peace was found highly significant positively related to physical function (beta=0.51, p<0.0054 adjusted by co-morbidities and other covariates) and social function (beta=0.96, p<0.0001 adjusted by co-morbidities and other covariates). Number of co-morbidities was found to be significantly negatively related to physical function (beta=-1.96, p<0.00002 adjusted by spiritual meaning/peace and other covariates. beta=-2.03, p<0.0001 adjusted by spiritual well being and other covariates) and marginal significant negative related social function. Spiritual well-being and meaning/peace as defined by the FACTIT-sp, may influence some aspects of functional status (physical and social functioning) in older African American long-term breast cancer survivors. These findings highlight the need for assessing spirituality needs in this population. Spirituality may be a protective factor. Future studies should include a longitudinal design.

Decision-Making and Involvement in Older Adult Cancer Survivors: Race and Psychosocial Factors

C. Cronin, G. Deimling, S. Brown, H.T. Renzhofer, Case Western Reserve University, Cleveland, Ohio

An important aspect of cancer treatment is the patient’s involvement in treatment and care decision. This research examines the role that race and psychosocial factors play in decision-making involvement at the time of treatment as well as in the decades that follow. Data were taken from an ongoing longitudinal research project funded by the National Cancer Institute (grant #R01-CA-78975). The sample was randomly selected from a tumor registry (n=321) and includes survivors of breast, colorectal, and prostate cancer, aged 60 years or older during the initial interview, who had survived cancer for five or more years and were in remission. Multivariate regression analysis indicates a strong predictive pattern between being involved in medical decision-making at the time of treatment and medical involvement later in life (Beta=0.697). When considering an older adult cancer survivor’s role in decision-making, race (Beta=0.184) is a predictor, even when psychological traits such as dispositional optimism and social traits such as self-esteem, are controlled. Patient’s perception of choice in their treatment option at the time of treatment is not a significant predictor of involvement and decision-making in the future (Beta=0.059). These findings have long-term implications concerning the importance of older patients’ involvement in their cancer treatment and medical decision-making; they show providers’ encouragement of involvement in decisions at time of treatment has the potential to create a pattern of future involvement in medical decisions. Furthermore, these findings show that there are differences across races in involvement in medical decision-making.

Family Dynamics, Involvement in Health Care, and Health of Older Adult Survivors of Cancer

S. Brown, G. Deimling, C. Cronin, H.T. Renzhofer, Case Western Reserve University, Cleveland, Ohio

This study examines the role of family dynamics during the experience with cancer as it affects involvement in health care by family members and physical health among older adults who are cancer survivors. Data were collected from a sample (n=230) of older adult (M age=70), long-term (5+ years) cancer survivors identified using a tumor registry from an NIH funded project at a major comprehensive center. Findings from this study reveal that at the bivariate level both family communication and family involvement in health care are correlated with health outcomes. While the relationship between family involvement in health care are minimized at the multivariate level, family communication during the diagnosis and treatment of cancer survivors remains a consistently strong predictor of health outcomes. More specifically, the effects of open family communication during cancer diagnosis and treatment help to explain current self-rated health (β=.20), functional difficulties (β=-.32), and co-morbidities (β=-.21). In addition, being married (β=-.19) and the disclosure of information about one’s cancer experience with family members during diagnosis and treatment is shown to influence family involvement during remission. These findings clearly indicate that family dynamics is an important predictor of health during a time of chronic illness, and for family involvement in health care to occur during remission. This has important implications for health care practitioners working with cancer survivors. Inclusion of family members during diagnosis and treatment of cancer patients may be a key determinant of later health.
SESSION 1690 (POSTER)

DEATH, DYING AND GRIEF

ATTITUDES AND BELIEFS ABOUT HOSPICE AND PALLIATIVE CARE AMONG SEXUALLY DIVERSE WOMEN
A. June, D.L. Segal, University of Colorado at Colorado Springs, Colorado Springs, Colorado

The purpose of the present study was to explore differences in end-of-life health care attitudes and beliefs among lesbian and heterosexual old and middle-aged women. Self-identified lesbian older adults (n = 30; 90% White, M age = 66 years, SD = 5.5 years), heterosexual older adults (n = 31; 87% White; M age = 64.8 years, SD = 4.6 years), lesbian middle-aged adults (n = 35; 97% White; M age = 50 years, SD = 7.3 years), and heterosexual middle-aged adults (n = 49; 88% White; M age = 50.5 years, SD = 5.5 years) anonymously completed the Beliefs about Pain Management scale and the Hospice Beliefs and Attitudes scale of the End-of-Life Care Questionnaire. Two-way (age X orientation) ANCOVAs, controlling for group differences on having completed a Living Will and Durable Power of Attorney for health care, revealed significant differences for age on comfort discussing pain management, F(1, 138) = 12.37, p < .05. Older adult women reported more comfort discussing pain management than middle-aged women. Significant differences were also found on hospice beliefs and attitudes for age, F(1, 138) = 5.43, p < .05, and for sexual orientation, F(1, 138) = 6.06, p < .05. Results showed that older adult women held more positive beliefs about hospice care than middle-aged women and lesbian women held more positive beliefs than heterosexual women. None of the interactions were significant. Implications of these findings are discussed.

GENDER ROLES, AGE, AND GRIEF IN ADOLESCENCE AFTER PARENTAL LOSS
K. Schiffner, B. Hayslip, University of North Texas, Denton, Texas

While parent-child relationships are significant throughout life, personal and vocational changes as children grow may impact the nature of such relationships. Relationships are further influenced by differences between mothers and fathers, as well as between daughters and sons. For most adults, the death of a parent is a significant event, and grief may be influenced by such variables as age, relationship quality, and gender roles. The current study sought to examine how changes in the parent-child relationship as both generations age affect grief after the death of a parent, while taking into account time since the death. We also utilized the Scanzoni (revised from 1975, 1976) scale to examine how traditional or egalitarian gender roles might affect the course of grief in the context of the death of a parent. Adults (M age = 23.37) were assessed with the Texas Revised Inventory of Grief, the Hopkins Symptom Inventory, and a short form of the Bereavement Experience Questionnaire. After controlling for time since the death and sex role preferences, gender of the child was significant (p < .05) for total BEQ scores, as well as for several specific dimensions of grief (BEQ-Blame/Guilt/Anger, BEQ-Preoccupation, TRIG-Present). Age of the deceased parent (older adults vs. younger adults) did not impact expression of grief.

“A ROOM FULL OF CHAIRS AROUND HIS BED”: BEING PRESENT AT THE DEATH OF A LOVED ONE IN VA MEDICAL CENTERS
B.B. Williams1, 2, A. Wittich1, L.L. Woodby2, K.L. Burgio2, 1, VA Medical Center, Birmingham, Alabama, 2. University of Alabama at Birmingham, Birmingham, Alabama

PURPOSE: Americans express a preference for dying at home with loved ones, yet hospital deaths remain the norm. We explore next-of-kin experiences of being present at the moment of a loved one’s hospital death. METHODS: In 2005-2010, we conducted interviews with 78 next-of-kin of deceased veterans in 6 VA Medical Centers in the South- east U.S. We used content analysis to explore respondents’ experiences with hospital deaths of loved ones, characterizing the underlying social process. RESULTS: A majority of respondents were female (78%) and white (60%). Forty percent were surviving spouses, 31% adult children, and 17% siblings of the deceased. Location of death included ICU/CCU/SICU (42.3%), acute care (38.5%) hospital long-term care (10.2%), and palliative care unit (8.9%). 42.3% of respondents were present in the hospital room at the time of death. Those present were disproportionately female (84.8%), white (78.8%), surviving spouses (54.4%), and had patients dying in the ICU (51.5%). Being present at the time of death was part of a larger family process of keeping vigil at the bedside. Family presence at the moment of death often took the form of family prayer circles around the patient’s bed, enhancing family unity and promoting spiritual bonds with the deceased. CONCLUSIONS: This research characterizes personal, interpersonal, and institutional factors related to family presence during the death of hospitalized loved ones. It also sensitizes us to the role of death bed vigils in bringing together family members during a time of crisis and providing survivors with a spiritual bond to the deceased.

MEASURING PREDEATH GRIEF IN FAMILY CAREGIVERS OF PERSONS WITH DEMENTIA
E.A. Mulligan, J. Washington University, St. Louis, Missouri, 2. VA Boston Healthcare System, Boston, Massachusetts, 3. Harvard Medical School, Boston, Massachusetts

Research suggests that family caregivers of persons with dementia may experience grief prior to the death of their care recipients, in part because of the series of losses they experience and the chronic nature of caregiving. The purpose of the current study was to compare two self-report measures of predeath grief, one adapted from the postdeath literature (the Prolonged Grief Disorder Inventory; Prigerson, Vanderweerker, & Maciejewski, 2008) and one designed specifically for use with dementia caregivers (the Marwit-Uscker Caregiver Grief Inventory-Short Form; Marwit & Meuser, 2005). A total of 202 spousal (63%) and adult child (37%) caregivers of persons with dementia completed questionnaire packets. Results from this study suggest that grief is an important component of the caregiving experience that is related to but distinct from depression. Based on information about psychometric properties and confirmatory factor analyses, both measures are appropriate for use with dementia caregivers. In correlational and regression analyses there were several areas of overlap between the measures, including significant associations with characteristics of caregivers (e.g., spousal relationship). However, these associations varied somewhat across subscales. One clear area of discrepancy was the number of caregivers identified as potentially in need of intervention by each measure, as the Prolonged Grief Disorder Inventory was more conservative (7% of caregivers versus 27%). Future research is needed to determine if predeath grief as measured by each instrument is predictive of long-term distress and dysfunction in the context of longitudinal studies.

BEREAVEMENT AMONG HOSPICE CAREGIVERS ONE YEAR FOLLOWING LOSS: PREDICTORS OF GRIEF, COMPLICATED GRIEF, AND DEPRESSIVE SYMPTOMS
J.Y. Allen, W.E. Haley, B. Small, S. McMillian, University of South Florida, Tampa, Florida

Although bereavement is described as an experience to which most individuals are resilient, subgroups may have heightened risk for physical and mental health morbidities and mortality (e.g. Prigerson et al., 2009). Some individuals have clinically significant grief outcomes, so inclusion of complicated (pathological grief) in the DSM-IV has been proposed (e.g. Prigerson et al., 2009). Therefore, the purpose of this study was to identify predictors of normal and complicated grief in a sample of older caregivers. Because persistent duration is proposed as a criterion for complicated grief (Prigerson & Jacobs, 2009), outcomes

64th Annual Scientific Meeting 461
1-year post-loss were investigated. Predictors of depressive symptomatology were also explored. Regression analyses were conducted using data from 188 hospice caregivers residing in Florida. Models included demographic, physical impairment, caregiver baseline depression and resource factors. Less social support, more nursing staff visits, and more symptoms of baseline depression were predictive of higher complicated grief scores, indicating worse bereavement, and risk for clinically significant complicated grief. Older age was also predictive of greater risk for clinically significant complicated grief. Lower education and more depressive symptoms predicted better “normal” grief and depression outcomes at follow-up. Finally, better palliative performance predicted fewer symptoms of depression. Findings suggest an important role of caregiver education levels, received social support, and baseline depression in complicated grief. These results may aid clinicians seeking to target individuals who may benefit from services. Further, findings that increased nursing staff visits are predictive of complicated grief may indicate other underlying factors, such as patient clinical variables, at work.

BOOMER LATINAS REMEMBER THEIR MAMAS: MOTHER-DAUGHTER ATTACHMENT AND LOSS AFTER A MOTHER DIES

C.A. Gosselink, A.L. Hoover, Psychology, Missouri State U, Springfield, Missouri

Negligible literature exists examining the depth of bereavement experienced by middle-aged boomer women when their mothers die. In this research project, Bowlby’s (1969) Attachment Theory served as a guiding framework to study how boomer daughters characterized their relationships with their deceased mothers and how they coped with their grief. Twenty-five Latinas born between 1946 and 1964 were interviewed in face-to-face, audiorecorded sessions that lasted from two to four hours. Content analysis was performed on the daughters’ narratives. The vast majority of respondents expressed deep attachment to their mothers. “Regina” recalled the deep affection she felt toward and received from her dying mother: “I had so much love… Mama told me, ‘You don’t know how much I love you.’ I would say, ‘I do, and I love you too.’ And she said, ‘I love you more.’” Similar sentiments were expressed even by Latinas who reported childhoods that included abuse, neglect, or abandonment. Many of the respondents still felt bereft years after the demise of their mothers. Implications of these findings include a greater need for culturally-aware bereavement and counseling services for a group of women whose grief is frequently overlooked. Suggestions and recommendations for addressing this need will be discussed.

SESSION 1695 (POSTER)

DRIVING AND TRANSPORTATION ISSUES FOR AGING ADULTS

DISEASE SEVERITY AND DRIVING CESSION: FINDINGS FROM THE HEALTH AND RETIREMENT STUDY

E. Dugan, C. Lee, F. Powell, Gerontology Dept, University of Massachusetts Boston, Boston, Massachusetts

Driving a personal vehicle is the preferred means of transportation for most Americans. The transition from driver to passenger is not well-understood. Our previous research identified biopsychosocial risk factors for driving cessation. This study extends that work by exploring the impact of chronic disease (diabetes, stroke, arthritis) severity and cognitive function on driving transitions. This paper pooled data from the 1998, 2000, 2002, 2004, 2006, & 2008 waves of the Health and Retirement Study (HRS). The HRS is a nationally representative longitudinal survey of community dwelling adults in the United States. The analytic sample was restricted to adults age >65 who answered all of the driving questions in the HRS survey (N=43,532). Expected demographic factors (age, gender, education, income, race/ethnicity) were related to driving cessation. In addition, we found that indications of severity of the chronic conditions were associated with driving status. Increased risk for driving cessation was associated with: taking insulin for diabetes; having seen a doctor in the past 2 years because of a stroke; reporting that arthritis limited usual activities; lower summary cognitive score (p<.05). These findings support the approach of assessing disease severity rather than relying on a diagnosis alone when evaluating driving fitness.

SELF-REPORTED DRIVING BEHAVIORS AMONG OLDER ADULTS WITH CLINICALLY DIAGNOSED MILD COGNITIVE IMPAIRMENT: DO THEY AVOID DIFFICULT SITUATIONS?

M.L. O’Connor1,2, Y. Bannon2, E.M. Hudak2, C. Haley3, C. Peronto2, J.D. Edwards2, 1, Psychology, University of Virginia, Charlottesville, Virginia. 2, University of South Florida, Tampa, Florida

Older drivers with mild cognitive impairment (MCI) have been found to perform worse on driving simulator tasks and on-road tests than drivers without MCI (Frittelli et al., 2009; Wadley et al., 2009). Thus, complex driving situations may pose safety concerns for MCI patients. However, it is unclear whether individuals with clinically defined MCI self-regulate their behavior by driving less frequently and avoiding more challenging situations. The current study examined self-reported driving frequency (i.e., days and miles driven per week) and avoidance behaviors among 30 drivers with clinically diagnosed MCI, as well as 53 cognitively normal drivers who resided within the same community. The total sample ranged in age from 60 to 92 years (M = 76.14, SD = 7.64). After controlling for age, gender, and education, MANCOVA results indicated that MCI patients reported driving fewer days per week than normal participants, F(1,61) = 7.37, p < 0.01. Drivers with MCI also more frequently avoided accessing the community, F(9,53) = 4.19, p < 0.05, driving in unfamiliar areas, F(9,53) = 11.14, p < 0.01, and driving on high-traffic roads, F(9,53) = 4.20, p < 0.05. Miles per week and avoidance of bad weather, left-hand turns, and night driving did not significantly differ according to MCI status. Results indicate that drivers with MCI may be aware of decrements in their abilities and regulate their behavior appropriately. However, further research is needed to determine if such self-regulation impacts driving safety.

CAREGIVER PERCEPTIONS OF THE EFFECTS OF COGNITIVE DECLINE ON THE DRIVING ABILITIES OF CARE RECEIVERS

D.P. McCarthy, Occupational Therapy, Florida International University, Miami, Florida

Background: Progressive cognitive decline eventually robs individuals of their safe driving abilities. This not only affects their mobility, but also affects the lives of their family, friends and others. This study examined caregivers’ perceptions of current driving abilities and eventaul driving cessation among drivers experiencing cognitive decline. Methods: Drivers seeking a driving evaluation from a memory disorder clinic were accompanied by family, a friend, or hired help (caregiver). While drivers underwent testing, caregivers completed a questionnaire about their perceptions of the driver, the driver’s abilities, and how the driver’s eventual loss of driving privileges would affect the caregiver. Results: Of the 39 participants who completed the survey, 49% were spouses/partners and 39% identified themselves as relatives. Many drivers (77%) received physician referrals for the driving evaluation. Most (81%) caregivers who expressed concerns had discussed them with the driver. Only 8% of drivers had expressed concerns about their own driving ability. Most (77%) caregivers provided rides for the drivers and 36% reported a disruption in their daily activities. When asked about the effects of drivers’ eventual loss of driving privileges, 73% of caregivers expected an increase in their responsibilities and 56% expected a decrease in their quality of life. Conclusion: The loss of driving privileges is an eventuality for those with progressive cognitive
decline. Drivers’ declining abilities also impact the daily activities and quality of life of their caregivers. Clinicians and others involved with individuals with cognitive decline should be cognizant of these issues and provide supportive services to caregivers.

**THE DRIVINGHEALTH® INVENTORY AS A CLINICAL SCREENING TOOL FOR OLDER DRIVERS – AN ASSESSMENT OF THE FACE VALIDITY AND ACCEPTANCE OF THE DHI IN A CLINICAL SETTING**

M. Crisler1, J.O. Brooks1, S. Healy2, J. Mckee1, J. Crenson Univ; Crenson, South Carolina, 2. Roger C. Peace Rehabilitation Hospital, Greenville, South Carolina

In this study, we examined the acceptability and face validity of the DrivingHealth® Inventory (DHI), a standardized, computer-based older-driver screening tool for clinical applications. 360 volunteers over age 50 (M = 68.7, SD = 9.2) were administered the DHI at a Southeastern US rehabilitation hospital by trained research associates. Volunteers were also administered the Driving Preferences Inventory and other surveys to learn about their health, driving habits, and impressions of the DHI. Volunteers reported strong agreement with statements that suggest they believe the DHI measures abilities important for safe driving and that they would seek or be willing to listen to advice about driving and safe mobility from medical professionals. Correlations observed between DHI results and Driving Preferences Inventory responses suggest that some self-regulation of driving behaviors is already occurring. It was also observed that even though drivers who scored poorly on the DHI were generally positive about its ability to help them understand their ability to drive safely, these drivers were less positive than were drivers who scored well on the DHI. This suggests that early use of such screening measures may encourage acceptance of results as abilities decline later in life; however, further research will be necessary to firmly establish this link and investigate the benefits of using the DHI with diverse clinical populations.

**CUE CARDS: HELP FOR THE STATE HIGHWAY PATROL?**

A. Dickerson1, B. Overton1, 1. Occupational Therapy, East Carolina University, Greenville, North Carolina, 2. NC State Highway Patrol, Raleigh, North Carolina

In recognition of state highway patrol officers being stakeholders in older driver safety, the North Carolina Older Driver Coalition used grant funding from NHSTA and NCST to address educational goals of the highway patrol about older adults. This presentation will describe the process and implementation of the plan, including the development and distribution of cue cards about older drivers with possible cognitive issues. Over 2,000 cue cards were developed and distributed to every North Carolina Highway Patrol officer. An on-line survey was used to collect reactions from the officers over a 6-month period with the intention of improving the cards. Based on the results, cards would be modified and made available to all law enforcement in North Carolina. This presentation will describe the response of the officers. At the 24-Month follow-up, 66 participants (25%) had stopped driving. Baseline perceptions of greater interference with Domestic Arrangements, Life Philosophy/Religion, and Hobbies/Leisure Activities mediated the relations of the other two life goals with cessation. Thus, perceptions that driving cessation will interfere with hobbies and/or leisure activities represent a barrier to changing a potentially high-risk behavior. Interventions that focus on maintaining pursuit of important goals and finding alternative paths for goal pursuit are recommended.

**RISK FACTORS FOR DRIVING CESSATION AMONG OLDER WHITES, BLACKS, AND HISPANICS**

C. Lee, E. Dugan, F.W. Porell, Gerontology, Univ. of Massachusetts Boston, Boston, Massachusetts

The number of older drivers is expected to double in the near future. Information about driving fitness and cessation is needed. This study builds on our previous research exploring racial differences in biopsychosocial risk factors for driving cessation. We now explore driving cessation by investigating the relative contribution of cognitive function measures and indicators of disease severity (such as diabetes, strokes, and arthritis). This study utilized data from the Health and Retirement Study (HRS) (1998-2008 waves). The HRS is a nationally representative longitudinal survey of community dwelling adults in the United States. This study included respondents age 65 and older including Whites (n=34,706), Blacks (n=5,147) and Hispanics (n=3,050). This study performed multivariate logistic regression to estimate the association between risk factors and driving cessation among older adults. The study results presented that demographic factors (age, gender, education, income) and functional limitations were related to driving cessation similarly among those three groups. Also, we found that cognitive impairments had significant impacts on driving cessation (p<0.05). With respect to the severity of chronic conditions, taking insulin for diabetes was associated with driving cessation in White adults (p<0.05). Having recently visited a doctor for a stroke was associated with driving cessation in both Older Whites and Blacks (p<0.05). In combination with our previous research, these findings support racial and ethnic disparities in risk factors for driving cessation. In addition, diagnosed chronic conditions as well as severity of those conditions provide better understanding of racial differences and driving cessation.

**SENIORS AND PHYSICIANS VIEW OF USING DRIVING SIMULATORS IN CLINICAL SETTINGS**

J.O. Brooks1,2, P.J. Venhovens1, S. Healy2, J. Mckee1, 1. Psychology, Clemson Univ, Clemson, South Carolina, 2. Greenville Hospital System University Medical Center, Greenville, South Carolina

Rehabilitation clinics need new tools to help maintain and improve the driving independence of patients of all ages but especially the aging population. The purpose of this research was to gather information from community-dwelling older adults regarding their views of the use of driving simulators in clinical settings. Over 175 adults ranging in age between 50 to 93 years participated. First, participants were given a demonstration of a simulator which included a variety of screenshots from dynamic driving scenarios including straight roads, curvy roads, city streets with heavy traffic, neighborhoods, intersections, roadway goods, but in pursuing their ongoing life goals. In this study we used a health behavior change model to examine the influence of life goals on driving cessation among a group of adults aged 55+, who were having vision problems, and still driving upon entry into a larger longitudinal study. The final baseline sample contained 381 drivers whose ages averaged 75 years. About half the sample were women (52%) and about half were married (48%). We used the Rivermead Life Goals Questionnaire (Wade, 1999) to inquire about the importance of 8 general life goals as well as the degree to which participants perceived driving cessation would interfere with these goals. At the 24-Month follow-up, 66 participants (25%) had stopped driving. Baseline perceptions of greater interference with Domestic Arrangements, Life Philosophy/Religion, and Hobbies/Leisure Activities were related to lower likelihood of driving cessation 24 months later. Interestingly, when all three of these life goals were regressed on driving cessation, Hobbies/Leisure Activities mediated the relations of the other two life goals with cessation. Thus, perceptions that driving cessation will interfere with hobbies and/or leisure activities represent a barrier to changing a potentially high-risk behavior. Interventions that focus on maintaining pursuit of important goals and finding alternative paths for goal pursuit are recommended.
AN EXAMINATION OF MOTORCYCLE CRASHES IN SOUTH CAROLINA

J.O. Brooks1,2, P.J. Venhovens1, V. Hirth1, R. Becco1, R. Boland1, J. Clemson University, Clemson, South Carolina, 2. Greenville Hospital System University Medical Center, Greenville, South Carolina, 3. Palmetto Health, Columbia, South Carolina

It is no longer true that the greatest proportion of motorcycle injuries and fatalities are experienced by the youngest generation of motorcycle riders. As the baby boomer population continues to age, concerns regarding the older vehicle driver population have received significant attention, yet the aging motorcyclist population has not. When examining the number of fatalities in the US between 1997 to 2006, the number of fatalities for each demographic increased but most dramatically for the older population: 50 – 59 year = 307% increase, and >59 years = 280% increase (USDOT, 2007). We examined motorcycle crashes in South Carolina for the years of 2004-2008 for licensed riders in six age groups. A total of 6,711 motorcycle crashes were investigated. The number of crashes for each demographic increased but most dramatically for the older population: <20 years = 35.4% increase, 20 – 29 years = 24.4% increase, 30 – 39 years = 17.7% increase, 40 – 49 years = 55.2% increase, 50 – 59 years = 70.4% increase, and 60+ = 148.8% increase. Failure to yield right of way was the most common among riders age 50 to 59 and over 60 years of age. Failure to yield right of way has also been previously found to be the most common contributing factor among vehicle drivers over the age of 65 in South Carolina. Helmet use, head injuries, fatalities, levels of damage, contributing factors, actions prior to impact, day of the week, and other factors will be discussed.

COMPREHENSIVE DRIVING EVALUATIONS: A RESOURCE IN OLDER DRIVERS’ DRIVING DECISIONS

B. Tracton-Bishop1, L. D’Ambrosio1, B. Kramer2, M. Mohyde1, E. Schold-Davis1, J. Coughlin1, 1. The Hartford Financial Services Group, Inc., Simsbury, Connecticut, 2. MIT AgeLab, Cambridge, Massachusetts, 3. American Occupational Therapy Association, Bethesda, Maryland

While many older drivers drive safely due to a combination of their good judgment, years of experience and self-regulation, some older adults, family members and caregivers struggle with the driving decision. Comprehensive driving evaluations performed by occupational therapists who have earned additional certification in driving can help drivers and families with their decisions around driving through a comprehensive driving evaluation and serve as an impartial evaluator. This qualitative study of occupational therapists who conduct and older drivers who had completed comprehensive driving evaluations found that occupational therapists who engage in these evaluations did not follow a single model, although there were similar elements in the evaluations. Likewise, the results of such evaluations could be more multifaceted than a simple pass or fail response. Occupational therapists stressed that family was important to a successful evaluation process. Older adults underscored the importance of driving to their sense of autonomy and quality of life. Most drivers in the study had evaluations because of a medical event. The paper concludes by considering that if comprehensive driving evaluations are to become a more common element in the older adults’ decisions around driving, then there is a need for future research to connect assessment tests to safe driving behaviors, and to work to raise awareness and underwrite the costs of evaluations for drivers.

NAVIGATING TRAITS: EXPLORING PERSONALITY CONSTRUCTS AND SELF-REGULATORY BEHAVIORS OF OLDER DRIVERS

E. Lea, T. McCallum. Case Western Reserve University, Cleveland, Ohio

To combat declines in functioning, and improve perceived safety, aging drivers often utilize self-regulatory behaviors, such as limiting driving to daylight hours, good weather, familiar roads, and city streets. While many older adults report utilizing these strategies, there is little empirical support for their effectiveness. Further, it is unclear how individual differences, such as personality, may impact older adults’ use of self-regulatory driving behaviors. Therefore, the present study explores the relationships between self-regulatory driving behaviors, demographic factors, perceived health, and personality constructs. A community-based sample of 117 older adult drivers completed self-report measures of driving behavior, health, personality, social desirability, and locus of control. Participants ranged in age from 60 to 97 with a mean age of 73.09 (SD=8.92). The average number of days that participants drove each week ranged from one to seven (M =5.82, SD=1.55). The majority of drivers sampled reported altering driving habits in the last five years to increase safety (62.7%). Older age and greater perceived change in abilities were associated with more frequent self-regulatory driving behaviors. For older drivers, extraversion, emotional stability, and openness were associated with both greater comfort and higher frequencies of driving in challenging situations. External locus of control was associated with greater difficulty adapting driving behaviors, less comfort driving in challenging situations and more frequent avoidance of such scenarios. Given the diverse relationships between individual differences and driving behaviors in older adults, future research should investigate the utility of tailoring driving-related interventions to best suit older adults’ personalities.

UNDERSTANDING OF THE NEEDS OF AGING DRIVERS WHO USE MECHANICAL HAND CONTROLS

J.O. Brooks1,2, P.J. Venhovens1, E. Lowe1, J.P. Bacon1. 1. Psychology, Clemson Univ, Clemson, South Carolina, 2. Greenville Hospital System University Medical Center, Greenville, South Carolina

Mechanical hand controls are adaptive equipment, which allow drivers to operate vehicles when it is not possible to use one’s lower extremities to operate pedals. Diagnoses among the aging population which are associated with the use of hand controls include, but are not limited to, neuropathy, diabetes, degenerative joint disease, knee replacement, lower limb amputation, prosthesis, rheumatoid arthritis, stroke, etc. After completing a review of the current mechanical hand control technologies, it became apparent that there is a lack of research in the US regarding training, safety issues, and further development. Therefore structured interviews were developed for occupational therapists and dealers / installers to gain a further understanding of the needs within the field. Eight occupational therapists trained as driving rehabilitation specialists and ten dealers / installers completed the interviews. The occupational therapists overwhelmingly agree (88%) that training should be required for drivers who need hand controls but also acknowledge (37%) that training may be too expensive for most patients. One reason this percentage may be rather low is because several of the therapists work for VA hospitals where the patients may not have the same financial burden as civilian patients. The majority of the therapists train patients how to use hand controls in parking lots or residential settings. The dealers / installers provided insightful comments on mechanisms to improve safety for both the user of the hand controls and other driv-
TRAINING LAW ENFORCEMENT TO IDENTIFY MEDICAL CONDITIONS IN OLDER ADULTS
L. Hill, J. Rybar, T. Styer, J. Jahns, K. Patrick, R. Coimbra, UCSD, San Diego, California
It is estimated that during the next 19 years, 10,000 ‘baby boomers’ will turn 65 each day; hence, those over 65 are the fastest growing age group. NHTSA estimates that there will be more than 40 million licensed drivers over 65 by 2020. This increase in older drivers renders impairments associated with aging to be an increasingly important public health concern. Older adults often experience a decline in cognition, vision, and motor skills required to complete many of the challenges associated with driving. Law enforcement officers are often the first to encounter an impaired driver, so a timely assessment can be imperative to the driver’s safety. This study reports on training of law enforcement officers (including both highway patrol and local police) in Southern California to identify and manage older adults who are suspected of impairment during traffic contacts. The two hour in-person training increased law enforcements knowledge to: 1) understand how the demographics of the older population and medical conditions can impact driving, 2) recognize and assess for conditions that may require intervention, 3) communicate with at-risk drivers regarding licensing re-examination, and 4) refer to community resources. Officers were provided with reference guides for management and referral, including a cognitive assessment tool to determine the presence of dementia. The training was well received, with high satisfaction scores. Preliminary results indicated that 83% of participants felt confident in their ability to recognize cognitive impairment post training. The presentation will include methods for replication of the training nationwide.

USING A DRIVING SIMULATOR: QUESTIONING TO RECOGNIZE COGNITIVE IMPAIRMENT POST TRAINING. The presentation will discuss the results of a study conducted to determine the presence of dementia. The study’s objective was to investigate why older adults aged 65 years old and above were more implicated in on-road accidents (stereotype threat condition) and half were told that the objective was to understand underlying processes involved in driving. Results showed that negative stereotypes could affect their driving performance. The importance of controlling for self-relevance, number of kilometers driven annually, and education is discussed as well as the implication of these results on driving assessments.

SESSION 1700 (POSTER)

FORM AND FUNCTION OF SOCIAL RELATIONS IN LATER LIFE

THE IMPACT OF STEREOTYPE THREAT ON DRIVING PERFORMANCE OF OLDER ADULTS
M. Joanisse, S. Gagnon, M. Voloaca, J.P. Cheron, School of Psychology, University of Ottawa, Ottawa, Ontario, Canada
ABSTRACT: Understanding how various factors can influence older drivers’ performance and on-road safety is critical to help them maintain their driving privileges, their mobility, and quality of life. The focus of earlier driving research has generally been the identification of the physical, cognitive, and perceptual changes commonly seen in old age, which can mediate or moderate the driving performance. The influence of social variables, such as negative stereotypes, on the performance of older drivers has never been investigated. Given previous research revealing the existence of a predominantly negative view of the older driver and the stereotype threat literature establishing that stereotypes can impact performance, we hypothesized that older drivers’ performance could be altered under a stereotype threat paradigm. Sixty older drivers aged 65 and above completed a simulated driving task. Prior to testing, half of the participants were informed that the objective of the study was to investigate why older adults aged 65 years old and above were more implicated in on-road accidents (stereotype threat condition) and half were told that the objective was to understand underlying processes involved in driving. Results showed that negative stereotypes could affect their driving performance. The importance of controlling for self-relevance, number of kilometers driven annually, and education is discussed as well as the implication of these results on driving assessments.

THE MEDIATING EFFECT OF SOCIAL SUPPORT IN THE RELATIONS BETWEEN SPIRITUALITY AND LIFE SATISFACTION IN MIDDLE AND LATER LIFE: AGE AND GENDER DIFFERENCES
J. Park, School of Social Welfare, University of Albany, Albany, New York
The study aims to examine whether the relationship between spirituality and life satisfaction is mediated by social support regardless of age and gender in middle and later life. Based on the relationship perspective, it was hypothesized that 1) the impact of spirituality on life satisfaction would be mediated by social support in middle and later life; and 2) the mediating effect of social support would be consistent across age and gender. The measure of social support was constructed by the mean across items of each of three subscales of family, friend, and spouse/partner support. Life satisfaction was measured by satisfaction with life at present and rating of life. The measure of spirituality was constructed by the mean across items in each of four domains: private religious practices; religious and spiritual coping; daily spiritual experiences; and mindfulness. The study used data from the Midlife in the United States Survey of 2004 with different age and gender groups: females (N=409, Mean age=51.1, SD=7.045) and males (N=447, Mean age=52.7, SD=6.706) aged 40 to 64; and females (N=128, Mean age=70.8, SD=4.960) and males (N=195, Mean age=71.8, SD=4.729) aged 65 and older. The results of path analysis indicated that social support fully mediated the relationship between spirituality and life satisfaction among males and females aged 40 to 64. Among males aged 65 and older, social support was a full mediator only in the relationship between spirituality and rating of life. In contrast, social support was not a mediator among females aged 65 and older.
TALKING WITH OTHERS ABOUT HEALTH: IMPLICATIONS FOR MANAGING SYMPTOMS

Talking with others about health conditions is one way that social connections can impact well being. This study investigated the influence of social ties on symptom management and help seeking, using urinary symptoms as a case study. Urinary symptoms provide a useful case because they increase in prevalence and severity with age for both men and women, yet many people do not seek formal care for their symptoms. Semi-structured qualitative interviews were conducted with 144 respondents who reported one or more urinary symptoms during a larger representative community study (Boston Area Community Health survey). The qualitative sample included 25 black women, 23 black men, 25 Hispanic women, 22 Hispanic men, 23 white women, and 26 white men. Respondents were asked about whether they talked with family or friends about urinary symptoms and, as appropriate, who they talked with, what was said, or why they had not talked with family or friends. Interviews were transcribed, coded, and analyzed for themes. Talking with others about urinary symptoms was common but had contrasting effects. In some cases, talking with others resulted in gaining a sense of identification with others suffering the same symptoms, receiving practical assistance to ease symptom burden, obtaining suggestions for managing symptoms, and learning about available treatments. In other cases, talking with others served to normalize symptoms so that people saw no need to manage symptoms differently or seek additional help. Results also confirmed prior findings of gender differences in who people talk with about health.

FRIENDSHIP NETWORK STYLES AND THEIR PREDICTORS IN OLD AGE: A LATENT CLASS MODEL
M. Miche1, O. Huxhold2, N. Stevens1, 1. Radboud University Nijmegen, Nijmegen, Netherlands, 2. German Centre of Gerontology, Berlin, Germany

Friendships contribute to well-being in old age beyond family relations. However, studies on later life friendships mostly ignore interindividual differences in friendship patterns that can be found in social reality. The aim of this study, therefore, was to investigate such differences by identifying distinct friendship network styles including their predictors. The study builds on Matthews’ qualitative model of friendship styles. Matthews established three distinct approaches to friendship that differ by number of friends, duration of friendships, and levels of closeness in friendship. We used latent class analysis to retrieve these friendship styles in quantitative data from a sample of adults aged 40 to 85 years (N = 1,876). Data came from the national representative German Aging Survey (DEAS). Our results demonstrated that considerable interindividual differences in the ways in which people organize their friendship relations can be captured by four distinct friendship styles. In accordance with Matthews’ qualitative typology, we identified these as: a discerning style, which focuses on few close relationships, an independent style, which refrains from close engagements, and two acquisitive styles that both acquire new friends across their whole life course but differ in terms of their emotional closeness in their friendship relations. Furthermore, socioeconomic status, gender, health, network-disturbing, and network-sustaining variables predicted friendship network styles. Based on our results, we argue that future studies should consider a more holistic view of friendships in order to better understand associations between friendships and well-being across the lifespan.

AGE HOMOPHILY IN OLDER ADULTS’ SOCIAL NETWORKS
M. Stone, J. Lin, Sociology, Case Western Reserve University, Lakewood, Ohio

The social separation of the young and the old has always been a scholarly and public concern. International research indicates that there are large deficits of young adults in the networks of older people and that few older people have regular contact with younger non-kin adults. Although the structure of core networks in the U.S. has undergone important changes over the past two decades, there is limited research examining older adults’ social networks. The purpose of this paper is to examine older adults’ social networks with a focus on the age composition of their primary social connections, using a nationally representative sample of 3,005 adults aged 57 to 85 years old in the National Social Life Health and Aging Project (NSHAP). Using descriptive techniques, regression models and network analysis, we will address two specific aims. First, we will estimate the extent of age-segregation/age-integration by examining the degree of age homophily in older adults’ network ties. Our second specific aim is to explore factors that influence the social segregation/integration of older adults. For example, scholars have suggested that family is the only institution that provides opportunities for the young and old to interact and as a result, older persons with few kin relationships may be at a higher risk of age-segregation. We will then discuss the implications of age-segregation/age-integration given the changing age and family structure of the U.S. population.

SOCIAL RELATIONSHIPS OF AFRICAN AMERICAN AND HISPANIC OLDER ASSISTED LIVING RESIDENTS: EXPLORING THE ROLE OF RACE/ETHNICITY
N. Park, D. Dobbs, J.V. Carrion, T.L. Young, J. Salmon, University of South Florida, Tampa, Florida

While there is speculation that assisted living (AL) communities are economically and racially segregated, little is known about how social relationships are experienced by racial/ethnic minority residents in assisted living (AL) communities. The purposes of the study were to: (1) describe patterns/processes of social relationships of African American and Hispanic residents in AL settings; (2) examine how residents construct and maintain relationships with other residents and staff. The data were collected using in-depth interviews with 15 African American and 15 Hispanic older adults in eight AL communities in Florida. Salient themes were derived using a grounded theory approach. Interviews included questions dealing with resident to resident relationships and resident to staff relationships. Results: Formation of both resident and staff relationships was described by AL residents as important to their well-being. Between race resident to resident relationships were not common for reasons such as a lack of common values and social interests. Hispanic residents were more likely to be linguistically and socially isolated when they lived in AL communities with few Spanish speaking residents and staff. Both African American and Hispanic residents voiced the lack of meaningful activities, which could promote developing resident to resident and resident to staff relationships. These findings suggest a need for more culturally competent care provision in AL communities that are racially/ethnically diverse.

SOCIAL ISOLATION AND TIME PERSPECTIVE AMONG OLDER ADULTS IN JAPAN
A. Ohashi1, K. Abe2, Y. Arai3, C. Ohl1, K. Mizuno1, 1. Chuubakukin University, Seki, Japan, 2. Kansui University of International Studies, Miki, Japan

Purpose: The purpose of this study was to examine the aspects of social isolation among older adults residing in a rural community in Japan. This study was also to examine differences in time perception depending on the degree of social isolation. Methods: The subjects consisted of 2529 older adults residing in Shirotori Town, Gujo City, Gifu Prefecture. The subjects completed a questionnaire survey regarding the presence of co-residing family members, frequency of communication with family members or friends, and their perception of time relative to the past, present and future. Results: 8.4% of the subjects lived alone and 26.8% lived only with their spouse. Although subjects living alone indicated that their children, relatives or close friends fre-
Longitudinal trajectories of self-rated health after retirement: The protective effects of social support and goal re-engagement

I. Jobin, C. Wrosch, D. Pushkar, S. Torok, Psychology Department, Concordia University, Montreal, Quebec, Canada

Self-rated health is arguably one of the most reliable predictors of mortality in older adulthood (Idler & Benyamini, 1997). Identifying protective factors that maintain self-rated health in the face of increasing rates of chronic illness is a necessary endeavor to understanding successful aging (Cheng, Fung & Chan, 2007). Mechanisms such as social support and goal adjustment capacities may have buffering effects for self-rated health among aging adults (Cheng & Chan, 2006; Wrosch, Miller, Scheier & Brun de Pontet, 2007). This longitudinal study assessed 374 recent retirees every year over a four year period. It was hypothesized that individuals with satisfactory levels of social support and adaptive goal adjustment capacities would have higher levels of self-rated health over a four year period. Furthermore, social support and goal adjustment capacities were expected to interact to predict changes in self-rated health over time. Results indicated that functional disabilities, chronic illness and goal reengagement capacities predicted baseline levels of self-rated health. Longitudinal decreases in self-rated health were found across the entire sample. However, social support satisfaction buffered against decreases in self-rated health over time. Furthermore, social support satisfaction interacted with goal reengagement such that individuals who reengaged in goals and were satisfied with their social support networks were able to maintain their self-rated health over the four years. Results indicate that social support and the ability to reengage in meaningful goals may be protective for older adults’ self-rated health over time. Implications for successful aging will be discussed.

AN EXAMINATION OF SOCIAL SUPPORT SOURCE DIVERSITY AMONG MIDDLE-AGED AND OLDER ADULTS

L.A. Ferrante, K.J. Kimbler, S.A. Lacy, Social & Behavioral Sciences, Florida Gulf Coast University, Fort Myers, Florida

A great deal of research has examined factors related to individuals’ social support. Much of this research has focused on the number of individuals available to provide specific types of support, satisfaction of available support, or total social support network size (e.g., Carney-Crompton & Tab, 2002; Gottlieb & Bergem, 2009, Sarason et al., 1983). The current study focused on the number of relationship types (e.g., spouse, parents, children, siblings, extended family, and friends) that individuals reported as sources of instrumental and emotional social support. Social support was measured with a modified version of the social support questionnaire (Kimbler, Ferrante, & Lacy, 2010) that included 7 items related to instrumental support and 3 items related to emotional support. Participants indicated their level of satisfaction, the individuals who provided each type of support, and the nature of their relationship with those individuals. Results indicate that men and women significantly differ (p < .05) in the number of different types of relationships that are reported as social support sources. Although the types of social support sources were not related to verbal ability or inductive reasoning, there was a significant correlation between the types of social support sources and everyday problem-solving performance (p < .05). Additional analyses examined sex differences in the consistency of social support sources and differences in emotional and instrumental social support sources. The current study suggests that examining the types of social support sources provides important additional information when assessing the complex nature of social support networks.

RELATIONSHIP QUALITY AND HEALTH: AN EXAMINATION OF POSSIBLE BEHAVIORAL AND BIOLOGICAL MECHANISMS

S. Hope, K. Bidtut, Institute for Social Research, University of Michigan, Ann Arbor, Michigan

Positive aspects of relationships are beneficial for health and well-being. Less is known about negative aspects of relationships and the mechanisms by which relationships influence health. This study investigated associations among positive and negative social relationships, self-reported well-being, health behaviors, and bio-measures of health. Participants from the National Social Life, Health, and Aging Project (N = 3005; ages 57 to 85) completed face to face interviews regarding their health and relationships, had their blood pressure tested, and provided blood spots which were analyzed for CRP, EBV, and Hba1c. Participants rated their relationships with spouses, family, and friends with two positive (talk about worries, rely on them for help) and two negative (make too many demands, frequency of criticism) items. Linear regression models revealed that individuals who reported more negative relationships reported fewer health behaviors (e.g., less physical activity, poorer sleep), poorer psychological well-being (e.g., greater depression and anxiety symptoms), and lower self-rated physical health. Individuals with more positive relations reported greater health behaviors (e.g., less physical activity, poorer sleep), greater psychological well-being (e.g., greater depression and anxiety symptoms), and greater self-rated physical health. Surprisingly, there were few associations among relationship quality and bio-measures with the exception of negative friend relationships which was associated with higher blood pressure. Further analyses examine whether associations between relationships and well-being vary by age. In sum, these results shed light on the potential mechanisms accounting for the relationship-health link.

SOCIAL NETWORK ANALYSIS: ASSOCIATION BETWEEN NETWORK CENTRALITY MEASURES AND ACCULTURATION IN KOREAN AMERICAN OLDER ADULTS

S. Rhew1, D.A. Chiriboga2, Jang2, 1. University of South Florida, School of Aging Studies, Tampa, Florida, 2. University of South Florida, Department of Aging and Mental Health Disparities, Tampa, Florida

More acculturated immigrants may be ideal targets in attempts at intervention because they have connections with both the host culture and the social network of fellow immigrants. Their potential to connect with both worlds is utilized in this study. Our goal is to identify characteristics of key players in the social networks of targeted immigrants, Korean American older adults, and examine whether key players are more likely to show higher acculturation than other individuals who have comparable centrality in the network. The sample consisted of 353 Korean American older adults living in central Florida. Summary scores from a 12 item acculturation inventory were computed. Social network analysis was conducted to calculate three types of node-level centrality: degree (persons who are the most visible in the network), betweenness (persons who are literally on the communication paths between two other persons), and closeness centrality (persons who can quickly interact with all others). Fifteen sets of key players identified by social network analysis software can cover 178 people (50.4%) of the network. Non-significant differences were observed in the scores of acculturation for key players and non-key players. Key players showed a more balanced gender distribution (7 males versus 8 females) whereas non-key players who have comparable degree centrality were more...
likely to be male; female was dominant in non-key players who have comparable closeness centrality. Implications for a health service use educator who works with Korean American are discussed.

EXAMINING THE IMPACT OF HUMOR STYLES OF PEOPLE WITH DEMENTIA ON THEIR SOCIAL RELATIONSHIPS
W. Mak, L. Keoh, S. Sorensen, University of Rochester Medical Center, Rochester, California

Older adults often comment that humor is essential for aging well, but in recent years studies have shown that beneficial outcomes related to humor depend on the type of humor used. Specifically four styles have been identified: self-enhancing, affiliative, aggressive, and self-defeating. Self-enhancing humor includes coping humor and affiliative humor focuses on enhancing others’ well-being, both of which are beneficial types of humor. On the other hand, aggressive humor centers on belittling others, and self-defeating humor centers on belittling the self. The role of humor styles and its impact on social relationships has not been studied in people with dementia despite the reported importance of humor and continued social interaction during the progression of dementia. The present study examined how humor styles in people with mild to moderate dementia may be associated with the quality of their social relationships. Correlation and regression analyses were used to assess the association between humor styles and positivity of social relationships, controlling for cognitive status (MMSE). People with an aggressive style of humor were more likely to report worse relationship quality whereas those with a self-enhancing style of humor were more likely to report better relationship quality. Identifying different humor styles in people with dementia may facilitate selection of activities and social partners that would maximize well-being. Results are discussed in the context of informing community-based program development.

SESSION 1705 (POSTER)

HEALTH INTERVENTIONS WITH OLDER ADULTS AND HEALTH WORKERS

ORIENTATION AND MOBILITY TRAINING FOR PARTIALLY-SIGHTED OLDER ADULTS: A REVIEW OF THE LITERATURE
G.I. Kempen, J. Ballemans, G. Zijlstra, School for Public Health and Primary Care, Maastricht University, Maastricht, Netherlands

Objective: This study aimed to provide an overview of the development, content, feasibility, and effectiveness of existing orientation and mobility training programs in the use of the identification cane. Data sources: A systematic bibliographic database search in PubMed, PsychInfo, ERIC, CINAHL and the Cochrane library was performed, in combination with the expert consultation (n=42; orientation and mobility experts), and hand-searching of reference lists. Review methods: Selection criteria included a description of the development, the content, the feasibility, or the effectiveness of orientation and mobility training in the use of the identification cane. Two reviewers independently agreed on eligibility and methodological quality. A narrative/ qualitative data analysis method was applied to extract data from obtained documents. Results: The sensitive database search and hand-searching of reference lists revealed 248 potentially relevant abstracts. None met the eligibility criteria. Expert consultation resulted in the inclusion of six documents. Conclusion: Our review of the literature showed a lack of studies on orientation and mobility training in identification cane use. This finding hampers explicit recommendations regarding the application of the training in practice, but stresses the need for further research, since effective orientation and mobility training in using the identification cane may be essential for independent functioning and participation of partially-sighted older adults.

DEVELOPING A STIGMA QUESTIONNAIRE FOR DIRECT CARE WORKERS IN ASSISTED LIVING
B. Harris-Wallace, J.K. Ecker, J. Schumacher, L. Stapleton, Sociology and Anthropology, University of Maryland Baltimore County, Baltimore, Maryland, 2. University of Maryland Baltimore County, Department of Psychology, Baltimore, Maryland

The purpose of this poster is to document the development of a questionnaire to assess direct care worker stigmatizing attitudes and behaviors toward older adults in assisted living (AL) environments. The initial development of the questionnaire was based on narratives provided by informants from the larger ethnographic parent study titled “Stigma and the Cultural Context of Residential Settings for the Elderly,” which examined the broader sociocultural dynamics and interactions in AL. Using these narrative data and key theoretical underpinnings, domains such as stereotyping, prejudice, social distance and evaluation between workers and residents were determined. Guided by these domains, a questionnaire was developed and evaluated by two direct care worker focus groups. After analyzing the information gleaned from the focus groups, the questionnaire was then revised and piloted among a larger sample of direct care workers. Results from this research may provide insight into the development of an assessment tool to assist AL administrators in determining stigmatizing attitudes prior to hiring new workers and identifying educational and training programs most useful for combating stigmatizing behaviors among current workers in the organization.

EFFECTICITY OF A TRAIN-THE-TRAINER CURRICULUM FOR OCCUPATIONAL THERAPISTS’ MENTAL HEALTH KNOWLEDGE
C. Lysack, C. Leach, P.A. Lichtenberg, Wayne State University, Detroit, Michigan

Introduction: Although occupational therapists (OTs) are trained in mental health assessment and intervention, these skills are under-utilized in clinical practice with older adults. The purpose of this study was to assess the efficacy of a 7-DVD set of depression training materials (Lysack et al, in press) utilizing a randomized control trial design to measure a train-the-trainer curriculum on therapists’ pre and post training knowledge. The DVD topics included Mental Health, Depression, Medications, Caregiving, Falls and Balance, and Driving. Each DVD included video demonstrations of OTs performing patient assessments and interventions. Method: Baseline testing was conducted for all participating OTs (n=70) before any training was conducted to measure pre-training knowledge. The train-the-trainer curriculum consisted of one 2-day intensive training for the 4 OT trainers in the intervention group. The OT trainers then conducted training for their OT staff over a 4 week period. Testing on all OTs was conducted after training was complete for all OTs in the intervention (n=37) and control groups (n=33). A 2X2 Repeated Measures Analysis of Variance showed significant knowledge increases. Results: The intervention group significantly improved their knowledge at post test (from 61 to 78% correct responses) whereas the control group remained at 61% correct at both testing time-points (F=32.25; p<.05) Conclusion: The train-the-trainer model was efficacious in increasing OTs’ mental health knowledge in older adults. Given major shortfalls in the recognition and treatment of late life depression, the study emphasizes the importance of mental health screening in this population.

MOBILE HEALTHCARE: AN INNOVATIVE APPROACH TO ADDRESSING THE HEALTHCARE NEEDS OF RURAL OLDER ADULTS

Twenty-seven percent of persons age 65 and older live in rural areas, and they typically have fewer resources and poorer physical health than urban elders. There is a dire need to improve access to healthcare in
Explicit use of “AD” was associated with enhanced companion but not patient comprehension of the diagnosis. Regression analyses demonstrated that frequency of physician use of “AD,” “dementia,” and “memory problems,” as well as the ratio of “AD” relative to other words, was not associated with patient/companion depression, anxiety, or comprehension. Summary. The term “AD” was used frequently, but not always shared explicitly as the cause of symptoms by physicians delivering a dementia diagnosis. “AD” was used less often by patients and companions, even though they wanted to know when dementia is suspected, and its use was not associated with catastrophic psychological distress.

SESSION 1710 (POSTER)

IMPROVING PROFESSIONAL TRAINING AND PRACTICE

A MULTIPRONGED APPROACH TO IMPROVING GERIATRIC COMPETENCY IN INTERNAL MEDICINE RESIDENTS

T.R. Kostas1, S. Hurwitz2,3, R. Bernacki4,5, 1. Gerontology, Beth Israel Deaconess Medical Center, Boston, Massachusetts, 2. Department of Medicine at Brigham and Women’s Hospital, Boston, Massachusetts, 3. Harvard Medical School, Boston, Massachusetts, 4. Dana Farber Cancer Institute, Boston, Massachusetts, 5. Division of Aging at Brigham and Women’s Hospital, Boston, Massachusetts

Introduction: The demand for geriatric medical care will increase significantly in the coming decades; however, many medicine residents lack confidence in their ability to care for elderly patients. Our objective was to use a multipronged educational intervention to improve residents’ confidence, knowledge, and behavior in caring for elderly patients. Methods: Our intervention involved lectures, a geriatric wiki, and a geriatric pocketcard during the intern geriatric rotation. A survey assessed change in geriatric confidence. A pre- and post-intervention knowledge test assessed change in geriatric knowledge. Chart reviews of 3 elderly patients admitted by each intern before and after the intervention assessed behavioral change. Results: 25 interns underwent the intervention; 22 completed the confidence surveys, and 20 completed the knowledge tests and underwent chart reviews. Over the last year there have been 94 users and 534 hits on the wiki. The intervention significantly improved intern confidence in all areas including knowing medications to avoid in elderly patients, delirium, advanced care planning, managing pain, and functional status assessment (p<0.0001). There was a small but nonsignificant increase in knowledge test scores. As for behavioral change, the increase in documentation of hearing and vision impairments was significantly greater in intervention interns compared with controls (p=0.04). Nonsignificant improvements were observed in documentation of geriatric diagnoses, reduction in prescription of medications to avoid in the elderly, and documentation of fall risk. Conclusion: This multipronged approach to geriatrics education improves residents’ competence in geriatrics by positively impacting their confidence and behavior in caring for the elderly.

IDENTIFYING COMMUNITY-DWELLING FRAIL OLDER PERSONS: EXPERIENCES OF PRACTICE NURSES

J. Bindels1, K. Cox2, O. van Schayck1, G. Widdershoven3, T. Abma1, 1. School for Public Health and Primary Care (CAPHRI), Maastricht University, Maastricht, Netherlands, 2. Fontys University of Applied Sciences, School of Nursing, Eindhoven, Netherlands, 3. Department of Metamedica, VU University Medical Centre, Amsterdam, Netherlands

The number of community-dwelling older persons that are considered as frail is rising. Early problem detection and adequate coaching
for frail older persons is essential to prevent unnecessary loss of function, inefficient use of facilities and decrease in quality of life. Therefore, variations of early detection and treatment aftercare for frail older persons were implemented in three sub-regions in the south of the Netherlands. In all regions practice nurses perform assessments with older persons during home-visits and are considered as case-managers for identified frail older persons. The aim of this study was to compare and map the experiences of the practice nurses. Data were collected over a 6 months period. In-depth interviews were conducted with practice nurses (n=12). Essential topics like selection procedures, approach, assessment, workload and cooperation with other professionals were included. Additionally observations during home-visits took place with a specific focus on the practice nurses and their way of working. The practice nurses faced difficulties with detecting frail older persons: not all frail older persons were detected and many healthy older persons were falsely detected as frail. The home-visits to assess the older persons were experienced as valuable, however they were also considered as time-consuming. Furthermore, practice nurses perceived problems in facilitating care for reluctant frail older persons. Although the practice nurses developed more expertise in the field of detecting and assessing frailty in older persons over time, more support is needed (e.g. from general practitioner or other professionals) to address the bottlenecks they perceive.

ENHANCING HEALTHCARE PROFESSIONALS KNOWLEDGE: HOW AN INTERPROFESSIONAL CONFERENCE INFORMS PRACTICE

C. Ford1, P. Sawyer1, A.G. Rothrock1, E. Kvale1,2, P. Bosworth1, C. Ritchie12, I. Gerontology, Geriatrics & Palliative Care, University of Alabama at Birmingham, Birmingham, Alabama, 2. Birmingham/Atlanta GRECC, Birmingham, Alabama

The University of Alabama at Birmingham’s Geriatric Education Center (UAB GEC) focuses on the training/retraining of healthcare professionals (HP) across the state concentrating on the Care of the Complex Older Adult. To ensure optimal outreach, the UAB GEC offered a statewide 2-day Interprofessional Geriatric Education Conference (iGEC) for the last two years. Originally a partnership with the Alabama Gerontological Society (AGS), the UAB GEC transitioned to a campus-based offering that provides a more cohesive and focused experience for students and practicing HP. The curriculum for the 2011 conference was derived from the needs assessments and previous conference evaluations. This included an assessment completed by attendees from the 2009 AGS Conference (85), the Alabama Department of Public Health (202), the UAB Continuing Medical Education Network’s Community Physicians (33) and evaluations completed by the 2010 iGEC attendees (186). Based on the results, the 2011 conference was expanded to two full days, running four simultaneous tracks: Complex Issues of Aging, Communication Skills, The Active Patient & Caregiver, and Transitions in Care. This presentation will describe the effective transition from a partner-based conference to a solitary-sponsored event, successful strategies to increase attendance, and the benefits of transitioning from a topic-focused curriculum to conference tracks. It will also discuss the challenges of obtaining continuing education credits and steps to ensure compliance with the varying governing board rules. Following this session, attendees will be able to develop and implement a geriatric interprofessional conference for varying levels of learners representing multiple health care disciplines.

GERIATRIC COMPETENCY AND TRAINING: SURVEYING A LOCAL ELDER SERVICES AGENCY

T.L. Aiduk, Bridgewater State University, Bridgewater, Massachusetts

Social Work competency in the field of aging is vital; however, despite increased opportunities to gain the knowledge and skills necessary to work effectively with elders, many currently in the field may not be adequately prepared to help aging clients. The Geriatric Social Work Competency (GSWC) scale was developed to standardize skill development of social work students and has guided the recent development of training resources, curricula, and agency-academia collaboration specific to working with elders. In a unique application of the GSWC scale, this project explored how a local elder services agency fulfills its mission to “support the dignity and independence of elders” in light of workers’ training and geriatric competency. Using a community-based mixed methods approach, data were collected through semi-structured interviews with key staff members (n=20), and administration of the GSWC scale, along with a supplemental survey, to direct care workers (n=50). Findings include managers’ perception of worker competence in aging, workers’ self-assessed geriatric competency, educational and training background of employees and ongoing training opportunities. In spite of above average self-assessed competency and ongoing employee training, direct care workers indicated a strong desire for continued educational opportunities. Workers’ understanding of the importance of geriatric competency was underscored by a response generated list of over 80 aging-related training topics which they believe would increase their ability to better meet the needs of their aging clients. Findings have important implications for the preparation and on-the-job training of geriatric care workers and expanded uses for the GSWC scale.

NURSE AIDES’ PERCEPTIONS OF BARRIERS TO IMPLEMENTING DEMENTIA EDUCATION IN A KOREAN NURSING HOME

E. Kong1, E. Byun2, 1. Kyungwon University, Seongnam, Republic of Korea, 2. University of Pennsylvania, Philadelphia, Pennsylvania

There are rapidly increasing older adults with dementia in Korea. Low quality of dementia care in nursing homes is becoming social issue, which results in increasing dementia-education programs in nursing homes. Korean nurse aides, however, face many problems in implementing dementia education. Purpose: The purpose of this study was to identify and describe the barriers to nurse aides’ implementation of dementia education in a Korean nursing home. Methods: Qualitative descriptive methods were used. A total of 21 informants participated in the interviews three months after they had attended dementia education program. All interviews were one-on-one and face-to-face using semi-structured interview protocols. Qualitative content analysis was used to analyze the data. Results: Six themes were identified: (a) There are gaps between theory and practice; (b) There is complexity of elders’ behaviors; (c) Lack of staff and reward do not motivate us; (d) It requires patience and strong sense of mission; (e) If we regard the elders as my family member…; and (g) We need to learn more. Conclusion: Identifying the barriers to implementing dementia education among nurse aides is important to improve the dementia education program and the quality of dementia care in nursing homes. Health care administrators and researchers need to consider these barriers and develop strategies targeting the barriers.

EVALUATING THE RELIABILITY AND VALIDITY OF THE ROSENBERG SELF-ESTEEM SCALE IN NURSING AIDES

T. McMullen1, B. Resnick21, 1. Doctoral Program in Gerontology, University of Maryland, Baltimore and Baltimore County, Baltimore, Maryland, 2. University of Maryland, School of Nursing, Baltimore, Maryland

Self-esteem develops over the lifespan and involves a process of evaluation and interaction between an individual and the environment. Organizational-based self-esteem is the extent to which individuals view themselves as having significant roles in the workplace. Individuals with a high organizational-based self-esteem excel in their workplace environment and have higher levels of job satisfaction. Understanding self-esteem in the workforce is critically important as it impacts productivity, job satisfaction and success. To this end, measurement of self-esteem has been extensively studied among many work groups including adolescents, minority cohorts, and nursing home residents. It has not been...
considered as much with direct care workers who work in long term care environments (LTC). Utilizing a commonly used measure of self-esteem, the Rosenberg Self-Esteem Scale (RSES), the purpose of this study was to establish the reliability, validity, and dimensionality of this measure with direct care workers in LTC environments. Testing of the RSES was done using baseline data from a randomized controlled trial testing the Res-Care Intervention in nursing homes. Nursing Aides (NAs) (N=523) participated in this study. Testing of the unidimensionality of the measure was done using Rasch analysis and a confirmatory factor analysis. Estimates of internal consistency were performed using Chronbach’s alpha with an alpha coefficient of .70 or greater. And, criterion-related validity was evaluated using multiple regression. Testing of the RSES in NAs yielded a strong reliability and a strong internal consistency with minor inconsistency. Further, the RSES scale yielded two factors of self-esteem: positive and negative self-esteem.

CAREER TRAJECTORIES AND ASPIRATIONS OF ADVANCED GERONTOLOGY DOCTORAL STUDENTS

Until recently, individuals who study aging have been trained in traditional disciplines. Over the last two decades, a growing number of interdisciplinary doctoral programs in gerontology have emerged and are producing a new kind of scholar. At a time when aging research is gaining broader attention and the need for interdisciplinary research is increasing, it is timely for the field of gerontology to examine this new generation of “gerontologists”. In this presentation we report on two cohorts of doctoral students from all gerontology degree granting institutions within the U.S. who have participated in the Gerontology Education Longitudinal Study (GELS). Specifically we examine the career trajectories and aspirations of doctoral students and the kind of research they are producing. Analyses of these longitudinal data reveal the relationships among the early ideals and plans for their careers, their productivity in research, and the relationship of these as they are in the final stages of doctoral training. Preliminary results suggest that the majority of students remain stable in their career aspirations. These aspirations guide their research activities and plans in preparation for the next step in their developmental journey. We discuss the implication of the current economic climate and job availability on the career planning and unfolding trajectories for these scholars.

WHAT LEADERSHIP WANT: STAFF TRAINING WITH ASSISTED LIVING RESIDENTS WITH DEMENTIA

Staff working with individuals that have dementia often have limited training and experience difficulties in managing problem behaviors. Leadership (e.g. executive directors, managers, administrators) frequently encounter challenges in finding trainings that educate their staff on best practices in working with people with dementia. This study asked leadership from assisted living facilities (AL) what they perceived as important outcomes of a training program for direct care staff who work with those with dementia in AL. Five semi-structured focus group interviews with 21 participants; four were male and seventeen were female. The AL sites were diverse in their resident size and payment structures. Private pay for profit (57%), private pay non-profit (29%) and Medicare/Medicaid (14%). Four themes emerged from the data analysis. Theme 1: almost every participant agreed that when considering a training program the length (the shorter the better) was important. Theme 2: knowledge and understanding of skills staff gain and how they applied them in their day-to-day work setting. Theme 3: diversity in culture and communication styles between direct care staff and resident. Theme 4: cost effectiveness. These findings suggest that management are clear and know that they want, meaning short cost effective trainings that provide an applicable skill set in working with residents with dementia and a training that recognizes diversity in culture and communication styles. Additionally, these findings have implications for future staff trainings in assisted living residences to accommodate this growing population.

EDUCATION BACKGROUND AND NEEDS OF SENIOR SERVICE PERSONNEL

D. Martin, The Center for the Study of Aging, McDaniel College, Westminster, Maryland

Directors and administrators of Agencies/Bureaus of Aging, Continuing Care Retirement Communities, Senior Centers, Assisted Living Facilities and non-medical home care agencies acknowledge the need for senior sector employees to be educated in Gerontology, but question whether current employees have the necessary educational background to fully support the needs of the clients and families whom they serve. The purpose of this study was to assess the educational background and present needs of those charged with providing care and assistance to the senior population. Links to an online survey (17 questions) were forwarded to the directors and administrators of seven government agencies and private facilities located throughout central Maryland and south-central Pennsylvania. The recipients were instructed to complete the survey and also to forward the link to their employees via the agency/facility listserv. One-hundred eight survey results were recorded. The data confirmed that administrators and employees in the senior service sector have limited education related to aging and age-related processes. The data further revealed that both the administrators and their personnel desire additional information on topics that varied by position title, but that many were unaware of institutions offering this education. The results highlight the need for institutions offering age-related education to specifically target their marketing efforts to those individuals already employed in the senior service sector.

SESSION 1715 (POSTER)

PHYSICAL AND FINANCIAL ABUSE OF EldERS

ARE GREATER DEPRESSIVE SYMPTOMATOLOGY ASSOCIATED WITH INCREASED RISK FOR ELDER MISTREATMENT IN A US CHINESE POPULATION?

X. Dong1, E. Chang1, E. Wong1, M.A. Simon2, 1. Rush University, Chicago, Illinois, 2. Northwestern University, Chicago, Illinois

Background: Elder mistreatment (EM) is associated with increased morbidity and mortality. The objective of this study is to examine the association between depressive symptoms and EM in a US Chinese population. Methods: A Community-Based Participatory Research approach was implemented to partner with the Chicago Chinatown population. Self-reported EM was assessed using modified VASS instrument. Depressive symptomatology was assessed using the short form Geriatric Depression Scale. Exact logistic regression was used to assess these associations. Results: Of 78 participants, mean age was 74.8 (7.8) years and 52.6% were women. EM was reported in 20.5% of participants. After adjusting for potential confounding factors, higher numbers of depressive symptoms were independently associated with increased risk of EM (Exact-OR, 1.99, 95% CI, 1.23-3.41). Interaction terms analyses suggest that higher educational levels may buffer the risk.
of elder mistreatment associated with depressive symptoms. Conclusion: Greater depressive symptoms are associated with increased risk for elder mistreatment in Chinese older adults. Longitudinal studies are needed to confirm these findings in this US Chinese population.

TEACHING ELDER ABUSE THROUGH CASE-BASED WORKSHOPS
J.M. Halphen, S.L. Pickens, J.A. Larson, S.K. Ostwald, M. Hossain, C. Dyer, 1. Division of Geriatric and Palliative Medicine, University of Texas Health Science Center at Houston, Medical School, Houston, Texas, 2. University of Texas Health Science Center at Houston, School of Nursing, Houston, Texas, 3. University of Texas Health Science Center at Houston, Center for Clinical and Translational Sciences, Houston, Texas

Background: Elder mistreatment impacts morbidity and mortality. Healthcare practitioners have a legal and ethical duty to identify and intervene in suspected cases. Lack of knowledge and perceived barriers to reporting interfere with this duty. Education is a key strategy for implementing change. Method(s): An interactive case-based two-hour workshop was delivered to medical practitioners by a clinician experienced in assessing elder mistreatment. At the workshop, 23 physicians completed pre-tests and 19 completed post-tests of their knowledge. In addition, six months after the intervention, 12 physicians received a follow-up survey by email regarding perceived barriers to reporting elder mistreatment. Results: Physicians (n=23) answered the pre-test knowledge questions correctly 18% of the time. The 19 physicians who completed the knowledge post-test answered the questions correctly 78% of the time, demonstrating a significant increase in knowledge after the workshop (p<.001). In addition, 42% of the physicians receiving the 6 month follow-up survey responded (5 of 12). Their responses demonstrated significant changes in knowledge about what to report (p=0.014), change in their perceptions about the time needed to report (p=0.003), and changes about legal liability concerns (p=0.003). Conclusions: This pilot study demonstrated that a two-hour case-based workshop led by an experienced clinician could increase pre-post knowledge of physicians. In addition, the workshop had long-term positive effects on physician knowledge and attitudes about their elder mistreatment responsibilities. Larger studies are needed to demonstrate that changes in knowledge and attitudes translate into changes in practice behaviors with more reports of elder mistreatment and appropriate interventions.

A DESCRIPTIVE TYPOLOGY OF RESIDENT TO RESIDENT AGGRESSION IN NURSING HOMES

Resident to resident aggression (RRA) in nursing homes is an alarmingly common but understudied phenomenon. This research presents a descriptive typology of the broad range of RRA in an effort to expand current understanding and prevention of aggression in nursing homes. Reports of RRA were systematically collected through interviews with staff and residents, incident reports, and observation by researchers in selected nursing units in five nursing homes in New York City. Aggressive events were reconstructed in narrative form by combining accounts of victims, perpetrators, and bystanders with data from medical charts and direct observation. Qualitative methods were used to create 16 types of events. The descriptive typology of RRA that resulted addresses the complex and varied nature of the phenomenon. Findings from the event reconstructions and typology suggest that widely-accepted definitions of agitation and aggression in a geriatric population do not fully capture the types of conflict and encounters from which nursing home residents report lasting emotional damage. Results are interpreted through behavioral and ecological frameworks, with the broader literature of family violence and relational aggression informing perspectives on victims, perpetrators, and the nature of aggression. Understanding which types of RRA are most frequent and what incidents have in common sets the stage for the important work of education and prevention of this serious threat to quality of life for institutionalized older adults.

THUMBS UP/THUMBS DOWN: READER REACTIONS TO ONLINE NEWS STORIES ABOUT IPV IN LATE LIFE
N. Brossoie, K.A. Roberto, Center for Gerontology, Virginia Tech, Blacksburg, Virginia

Intimate partner violence (IPV) in late life is a hidden public health problem that can result in physical harm, neglect, emotional abuse, and often death of the victim. Using national newspaper reports of IPV experienced by older adults, we identified the types of violence reported and examined how readers responded to the incidents described. For three consecutive months in 2010, we collected and followed online news stories identified through the daily Elder Abuse News Feeds. One-half of the 24 news items about IPV involving older adults included incidents of stabbing, strangulation, torture, and neglect. The remaining stories were reports of murder-suicide. Three themes emerged from a content analysis of readers’ online responses (i.e., written comments, thumbs up/thumbs down, and share) to the news items: overall concern, ageist attitudes, and interpersonal relationships. When readers expressed concern, they focused on the perceived emotional and social impacts of IPV in late life on multiple levels — the individual, family, and society. Comments that included ageist remarks were often mixed with dark humor and represented negative coping strategies used by the writer to make sense of old age and death. Those who focused their comments on relationships focused on the imbalance of power and control in violent relationships. Findings provide insight about societal attitudes towards IPV in late life and can inform the development of strategies to remove stigmas connected to being a victim of IPV and other social barriers that ultimately impact social policy, decision making, and community response strategies.

KEY FACTORS INFLUENCING DECISION MAKING IN RELATION TO ELDER FINANCIAL ABUSE: A CASE SCENARIO STUDY OF CERTAINTY, LIKELIHOOD OF TAKING ACTION, AND ACTION TAKEN
M.L. Gilhooly, M. Davies, P. Harries, K. Gilhooly, D. Cairns, 1. Brunel Institute for Ageing Studies, Brunel University, Uxbridge, United Kingdom, 2. University of Hertfordshire, Hatfield, United Kingdom

Little is known about the factors that influence decision making by health, social care and banking professionals in relation to detecting and preventing elder financial abuse. The research questions for this study were, (1) Which case features are most influential in decision making? (2) Which characteristics of the decision maker are most influential in decision making? Data was collected via the World Wide Web where participants (82 health, 70 social care and 70 banking professionals) were asked to read and rate case scenarios. Data was analyzed quantitatively using two methods: regression techniques to identify the importance of each of the factors in respondents’ decision making and cluster analysis to group participants according to their judgement about the certainty that financial abuse is occurring and likelihood of taking action. Of the many cues (case features) that could be used in making a decision, only a few appear to persuade professionals that financial abuse is taking place. Similarly, only a handful of cues influence decision making in relation to actions taken. The cues that exert the greatest influence are: the mental capacity of the older person; the nature of the finan-
DETECTING ELDER FINANCIAL ABUSE: CUES USED BY HEALTH, SOCIAL CARE AND BANKING PROFESSIONALS IN CLASSIFYING CASES AS TRUE INSTANCES OF FINANCIAL ABUSE

M.L. Gilhooly1, D. Cairns1, M. Davies1, P. Harris1, K. Gilhooly2, A. Gilbert1, D. Stanley1, 1. Brunel Institute for Ageing Studies, Brunel University, Uxbridge, United Kingdom, 2. University of Hertfordshire, Hatfield, United Kingdom, 3. University of Plymouth, Plymouth, United Kingdom, 4. Northumbria University, Newcastle upon Tyne, United Kingdom

The aim of this study was to examine decision-making by health, social care and banking professionals in relation to the detection of elder financial abuse. Three research questions guided this study: 1. What are the cues or patterns that are perceived as triggering suspicions of financial abuse? 2. What kinds of decisions are made? 3. What are the case features that make decisions difficult? Data was collected via in-depth semi-structured interviews (n = 63) using the critical incident technique to focus on each professionals most recent experience of elder financial abuse. Content analysis of the interview transcripts was conducted to consider decision making in the context of such abuse. Results identified critical incidents of financial abuse including stolen possessions, money being taken from bank accounts, and rogue traders. A number of cues were found to raise suspicion of such abuse including: ‘identifier of abuse’, ‘financial problem suspected’, ‘physical and mental capacity’, and ‘living circumstances’ of the older adult. The cues used by health and social care professionals were similar; bankers, being more concerned with safeguarding money, used slightly different cues; who is in charge of the older person’s money was a key cue for those in banking. Decision making was not always straightforward. Study participants reported a number of problems in relation to decision making and knowing the best course of action when elder financial abuse was suspected.

USE OF A SELF-REPORT MEASURE OF FINANCIAL EXPLOITATION IN A COMMUNITY SAMPLE

S. Wood1, P. Liu2, 1. Psychology, Scripps College, Claremont, California, 2. Claremont Graduate University, Claremont, California

The Self-Report Measure of Financial Exploitation of Older Adults (OAFEM) (Conrad et al, 2010) is a 79-item, client self-report measure that has been psychometrically validated. The OAFEM covers 6 conceptual domains of FE: theft and scams, abuse of trust, financial entitlements, coercion, signs of possible abuse, and risk factors. In addition, the article offers guidance on cut-off scales indicative of serious FE. As such, the OAFEM offers a validated tool that should be useful for researchers in the area of FE to use to better describe and characterize FE. In order to ascertain the viability of using the OAFEM in a community sample versus a sample of substantiated cases of financial exploitation, a pilot study was conducted including 136 adults (aged 18 – 93) including both an on-line and community sample examining susceptibility to fraud using the 30-item short form. Results indicated that significant and measurable acts of elder exploitation were present across the lifespan. 2/3 of older adults endorsed at least 1 item on the short form of the OAFEM, with a mean of 1.7 items endorsed. The younger sample was comparable with a mean of 2.0 endorsements. A closer examining of the type of financial exploitation indicated the most common endorsement was entitlement and expectations. This pilot data demonstrates that use of the Conrad et al, (2010) OAFEM is a feasible measure in a community sample and suitable for a dependent measure of susceptibility to elder financial exploitation.

PERCEPTIONS OF ELDER ABUSE AMONG AFRICAN AMERICAN ELDERS AND AFRICAN AMERICAN FAMILY MEMBERS

C.D. Cody-Connor, Winston-Salem State University, Winston-Salem, North Carolina

The purposes of this study were to explore African American elders’ and African American family members’ perceptions of elder abuse and to determine similarities and differences in their perceptions of elder abuse. King’s general systems framework (King, 1981) was used to guide this study. A descriptive correlational mixed method design was used in this study. A sample of 125 African Americans from central North Carolina was surveyed. The total number of caregivers or family members was 72 (57.6%), and the total number of elders was 53 (42.4%). The participants’ written responses to five open-ended questions (Hudson, 1994) produced the qualitative data for this study. The data were analyzed using quantitative and qualitative approaches. Findings indicated that age, gender, role, past experience with abuse, and self-esteem were not related significantly to perceptions of abuse or severity of abuse. Additionally, perceptions of abuse were not related significantly to severity of abuse ratings. However, the coefficients indicated that age was a significant positive predictor of severity ratings. The results suggested that severity ratings increased with increasing age.

THE ECOLOGICAL/CONTEXTUAL PATTERN OF RISK FACTORS FOR RESTRAINT ABUSE OF OLDER ADULTS IN NURSING HOMES: A RANDOM SAMPLE TELEPHONE SURVEY OF ADULTS WITH AN ELDER FAMILY MEMBER IN A NURSING HOME

Few empirical investigations of elder abuse in nursing homes address prevalence and risk factors of restraint abuse. While some restraints (e.g. straps, forced feeding, inappropriate toileting) may be necessary to protect older adults from self inflicted harm or harming others, such restraints become abusive when used punitively or unnecessarily. A random sample of 452 adults with an older adult relative, ≥ 65 years of age, in a nursing home completed a telephone survey regarding elder abuse experienced by that elder family member. Family member respondents reported that 22% of older adult nursing home residents experienced one or more incidents of restraint abuse. SEM estimates of risk factors for restraint abuse addressed: 1) older adult characteristics, such as age, gender, and health status (e.g. ADL’s/IADL’s, diagnosis of dementia); 2) contextual factors, such as the family/older adult relationship (e.g. family member/older adult emotional closeness) and the staff caregiver/older adult relationship, including other types of staff abuse (e.g. physical abuse, emotional abuse). Statistically significant risk factors included: 1) older adult characteristics—age (γ = -0.024; t-value = -3.74; p = 0.000), gender (γ = 0.228; t-value = 1.967; p = 0.49), and ADL’s/IADL’s/Daily Help (γ = -0.218; t-value = -5.415; p = 0.000), 2) contextual factors a)family context—emotional closeness (γ = -0.062; t-value = -4.458; p = 0.000); b) older adult/caretaker relationship—physical abuse (γ = 0.388; t-value = 6.003; p = 0.000), emotional abuse (γ = 1.046; t-value = 2.948; p = 0.003). Findings support an ecological/contextual perspective for identifying risk factors and potential interventions.
SESSION 1720 (POSTER)

ASSESSMENT AND INTERVENTION

COMPARISON OF OBJECTIVE AND SELF-REPORTED METHODS FOR MEASURING PHYSICAL ACTIVITY IN COMMUNITY DWELLING OLDER ADULTS

S. Sahni, S. E. Crouter, R. R. McLean, M. Hannan, Institute for Aging Research, Hebrew SeniorLife, Harvard Medical School, Roslindale, Massachusetts, Dept. of Exercise and Health Sciences, University of Massachusetts, Boston, Massachusetts

Objective: Accurate measurement of physical activity (PA) is often difficult in large studies of elders. This study compared PA measured by accelerometer and two self-reported measures. Methods: From 2009-2010, 26 participants (age range 65-88 yr, 21 women) completed a food frequency questionnaire (FFQ) measuring usual dietary intake over past 6 months and the Physical Activity Scale for Elderly (PASE). Participants also wore an ActiGraph GT1M accelerometer for 7 days. Mean daily energy expenditure (EE) was calculated using: 1) accelerometer counts (METs; EEACC) and 2) FFQ using published equations (EEEFFQ). EEACC was 1.04 ± 0.28 and PASE was 93 ± 49. The (gold standard) EEACC was moderately correlated with EEF (r=0.36, P=0.11) but not correlated with PASE (r=0.05, P=0.82). Persons over age 77 had a stronger correlation between EEACC and PASE (r=0.66, P=0.07) but not with EEF. Conversely for persons <77y EEACC and PASE were not correlated but EEF and EEF showed a strong correlation (r=0.63, P=0.04). Conclusion: There were only moderate correlations between EEACC and EEF and PASE score (range 0-400) adjusting for sex, age and BMI. Correlations were examined for categories of age (≤77 versus >77 yr median age). Results: On average, participants wore the accelerometer for 6 days. Mean EEF was 1.28±0.12 METs, EEACC was 1.04±0.28 and PASE was 93±49. The (gold standard) EEACC was moderately correlated with EEF (r=0.56, P=0.11) but not correlated with PASE (r=0.05, P=0.82). Persons over age 77 had a stronger correlation between EEACC and PASE (r=0.66, P<0.01) but not with EEF. Conversely for persons <77y EEACC and PASE were not correlated but EEF and EEF showed a strong correlation (r=0.63, P<0.01). Conclusion: There were only moderate correlations between measured EEACC and EEF estimated from self-report. It is better to use objective measures of physical activity when possible.

BASE-II-STUDY: COMPARISON OF A SELF ADMINISTERED COGNITIVE TEST WITH THE MMSE TO DETECT DEMENTIA

N. Bucholtz, N. Köster, M. Ibrahim, V. Moskriou, R. Eckardt, E. Steinhausen-Thiessen, H. K. Berthold, Charité University Medicine, Berlin, Germany

Systematic screening for cognitive functions in primary care and non-specialist settings is important for detection of dementia. To minimize operator time, Brown et al. (BMJ 2010) introduced a self-administered cognitive screening test (test your memory, TYM), which was found better at discriminating between patients with and without dementia than the standard Mini Mental Status Examination (MMSE) in a memory clinic setting. The aim of our study was to validate the test in a German language version within the setting of a geriatrics hospital. Geriatric inpatients were assessed in parallel using the TYM and the MMSE. Diagnosis of dementia or MCI was established by clinical neuropsychologists and physicians according to ICD-10. Preliminary results show that 19 of 63 patients had dementia (30%). The TYM and the MMSE total scores were significantly correlated (R²=0.58, p<0.01). The area under the receiver operating characteristic curve for differentiating patients with dementia from patients without cognitive impairment was 0.76 for the TYM and 0.85 for the MMSE. Using a cutoff total score of ≥23/30 for the TYM and ≥24/30 for the MMSE, sensitivity of both tests was 90%, whereas specificity was 50% and 63% for the TYM and MMSE, respectively. Unlike in the study of Brown et al., first results of our study indicate that the TYM is less discriminative than the MMSE test. Practicality (i.e. speed and ease of use, accuracy of self-administration) was not as excellent as expected. Suitability for non-specialist use has to be questioned based on these preliminary results.

CONTEMPORARY METHODS FOR ASSESSING LATE-LIFE FUNCTION USING COMPUTER ADAPTIVE TESTING

C.M. McDonough, I.M. Kopits, P. Ni, F. Tian, A. Jette, Health & Disability Research Institute, Boston University School of Public Health, Boston, Massachusetts, 2. The Dartmouth Institute for Health Policy and Clinical Practice, Dartmouth College, Lebanon, New Hampshire, 3. Geriatrics Section, Department of Medicine, Boston University Medical Center, Boston, Massachusetts

Background/Objectives: Traditional measurement methods present difficult tradeoffs between response burden and both precision and sensitivity to change. This study used Computer Adaptive Test methods (CAT) to build a patient-reported measure of late-life functionality for geriatric research. Design: This was a cross-sectional study. Participants and Setting: We collected data from a convenience sample of 520 community-dwelling older adults. Materials/Methods: We created a bank of 138 functional items using the literature, focus groups, and cognitive testing. Subjects responded to all 138 items that were administered by a trained interviewer. We conducted confirmatory factor analyses (CFA) to assess dimensionality of the item pool and employed Item Response Theory (IRT) methods to calibrate items and to assess data fit with different measurement models. We tested the accuracy of real-data simulated CATs of different lengths compared to the full item bank and estimated the precision of CAT score estimation. Results: CFA results revealed that a bi-factor IRT model of Overall Function fit the data best and we developed separate “self-care” and “mobility” sub-factors within this overall bi-factor model. Fit statistics were CFI=0.93; TLI=0.93; and RMSEA=0.04. The 15-item CAT demonstrated the most accuracy compared with the item bank (r=0.93 or above). RMSE=0.28. Precision was greatest at the middle of the scale than at the extremes. For the 15-item CAT, the standard errors for the Overall Function scores were less than 0.3 across the -2 to 1 logit score range and standard errors for self-care and mobility scores were less than 0.4 across the -2 to 1 logit score range. Conclusions/Significance: The Late-Life Function CAT demonstrated high accuracy and precision and has the potential to advance functional assessment in research with older adults.

CREATING A CONTEMPORARY LATE-LIFE DISABILITY INSTRUMENT USING COMPUTER ADAPTIVE TESTING

C.M. McDonough, I.M. Kopits, P. Ni, F. Tian, A. Jette, Health & Disability Research Institute, Boston University School of Public Health, Boston, Massachusetts, 2. The Dartmouth Institute for Health Policy and Clinical Practice, Dartmouth College, Lebanon, New Hampshire, 3. Geriatrics Section, Department of Medicine, Boston University Medical Center, Boston, Massachusetts

Background/Objectives: Traditional self-report assessment methods pose challenges to balancing response burden and detection of important differences or change. The aim of this study was to build a Computer Adaptive Test (CAT) to measure geriatric disability. Design, Participants and Setting: This was a cross-sectional study of data from a convenience sample of 520 community-dwelling older adults. Materials/Methods: Using an extensive literature review, focus groups and cognitive testing, we built a bank of 54 items, which trained interviewers administered to each subject. Confirmatory factor analyses (CFA) and Item Response Theory (IRT) methods were used to examine item bank dimensionality, calibrate items and assess fit. Real-data simulation was used to test accuracy and precision of 5, 10, and 15 item CATs. Results: CFA revealed that bi-factor multidimensional IRT (MIRT) provided best fit; therefore the Overall Disability Scale was calibrated with separate “relationship” and “doing things” sub-factors. Fit statistics were: CFI=0.94; TLI=0.93; and RMSEA=0.06. The 15-item CAT demonstrated accuracy compared with the item bank (r=0.97; and RMSE=0.23) and better precision in the middle of the scale than at the extremes. Specifically, standard errors for Overall Disability scores for the 15-item CAT were less than 0.3 across -2 to 0 logit score range and less than 0.4 across -2 to 0 logit score range for the subscale scores. Con-
conclusions/Significance: The Late-Life Disability CAT demonstrated high accuracy and precision, indicating promise to improve disability assessment research with older adults.

ASSESSING THE HEALTH OF INDIVIDUALS WITH PARKINSONISM USING THE RESIDENT ASSESSMENT INSTRUMENT-HOME CARE

P. Fletcher1, Q.J. Almeida1, D. Guthrie2, K. Berg3, J. Hirdes1,2, I. Wilfrid Laurier University, Waterloo, Ontario, Canada, 2. University of Waterloo, Waterloo, Ontario, Canada, 3. University of Toronto, Toronto, Ontario, Canada

The dearth of information concerning community-based seniors diagnosed with Parkinsonism hinders the application of evidence-based policy decision-making. In 2001, the Resident Assessment Instrument-Home Care (RAI-HC) was mandated for use in Ontario for all long stay clients accessing home care. As such, this paper will report on the health status, functional status and potential health needs of all community-based individuals with Parkinsonism that accessed home care in Ontario over a 4 year period. In total, 13,021 assessments for Parkinsonism were collected using the RAI-HC between April 2003 and May 2007, representing one of the largest available data sets concerning this population. The RAI-HC, a comprehensive, standardized instrument for evaluating the needs of home care clients, is a screening tool and care planning system that assesses multiple domains for individuals and identifies clients who may be at risk of health-related problems. The primary intent of this poster is to provide descriptive information concerning the health status of these individuals. The health status of the sample was generally compromised (e.g., cognitive impairments, problems with ambulation and instrumental activities of daily living), in addition to being diagnosed with Parkinsonism. Some of the most common clinical areas requiring further assessment or care planning were: cardio respiratory conditions, risk of institutionalization, falls, and medication management. A reliable and valid instrument such as the RAI-HC affords researchers the opportunity to study conditions like Parkinsonism and provides up-to-date health information about individuals accessing home care services.

LATE-ONSET STRESS SYMPATOMATOLOGY: DEVELOPMENT AND VALIDATION OF A SHORT-FORM SCREENING INSTRUMENT

J. Wang1, A. Pless Kaiser2, A.Y. Seligowski1, C. Potter1, A. Spiro1,3, L. King1,2, D. King1,2, C.B. Brady1,2, I. VA Boston Healthcare System, Boston, Massachusetts, 2. Boston University School of Medicine, Boston, Massachusetts, 3. Boston University School of Public Health, Boston, Massachusetts

Late-Onset Stress Symptomatology (LOSS) is a phenomenon among older combat Veterans with no history of chronic stress-related disorders who have begun to think more about their past experiences in the context of normative aging. A potential part of the life review process, LOSS may lead to increased emotional or mental health issues or toward adjustment and well-being. Originally conceptualized based on focus group data with aging Veterans (Davison et al., 2006), a 33-item LOSS scale was developed and validated by King et al. (2007). Our objective was to examine the psychometric properties of an 11-item short form (LOSS-SF) of the LOSS scale developed for broader research application and for clinical use as a screening tool. We examined the concurrent validity of the LOSS-SF versus the full LOSS scale and the LOSS-SF test-retest reliability across two studies of older (Mean age=68 in both) combat Veterans. We also examined the convergent/divergent validity of the LOSS-SF versus the full scale via correlations of each version of the LOSS scale with other measures. The LOSS-SF and full LOSS scale achieved a correlation of .81 and the LOSS-SF’s test-retest reliability was .87 (7- to 14-day interval). Bivariate correlations of age, posttraumatic stress symptomatology, anxiety, and depression with the LOSS-SF were consistent with analogous correlations with the full LOSS scale. Further validation of the LOSS-SF as a clinical screening tool will allow health-care providers to target potential older combat Veterans vulnerable to mental distress.

A MULTI-COMPONENT WEIGHT LOSS INTERVENTION FOR MIDDLE-AGED AND OLDER ADULTS WITH PRE-DIABETES

C.W. Bales, E.O. Granville, S.B. Rose, S.L. Aktan, A. Dathan, L.W. Piner, W.E. Kraus, Medicine, Durham VAMC/Duke Sch of Medicine, Durham, North Carolina

Overweight and obese individuals with risk factors for Type 2 diabetes benefit from modest reductions in body weight (WT); however, the advisability of WT loss in this population is questioned. Thus we examined WT, body composition, and dietary changes in a sub-set (n=10) of subjects (55-70 yrs, mean = 62.4 yrs; BMI=30.1+3.1 kg/m2) participating in an intensive, supervised intervention for reducing diabetes risk (calorie restricted diet to achieve > 7% WT reduction, aerobic physical activity > 30 min on 5 d/wk). Diet intakes were evaluated at baseline (BL) and at the end of the 6 month study (ET); monthly WTs were also recorded. Overall exercise compliance was 87.2%. By study midpoint, subjects had lost clinically important amounts of WT (-4.5 +1.1 kg; 5.3% of BL; P<0.005) and at ET, WT (-6.0 +1.7 kg; 8.1%) was also lower (P<0.006) than at BL. Waist circumference at ET was decreased by 4.2cm and body fat decreased from 41.8% to 35% between BL and ET. Decreases in total fat intake (-12 g/d, P=0.01) and fat exchanges (-1.9/d, P=0.02) were noted, along with meaningful decreases in intakes of kcal (-101/d), alcohol (-2 g/d), and % kcal from fat, and improvements in glycemic index (-2.9) and intakes of fiber (+3.5 g/d), dairy foods, and fruit (+0.43 and +0.44 servings/d, respectively). Thus subjects participating in this intervention improved their body WTs and composition while increasing physical activity and making beneficial changes in several markers of diet quality.

A STUDY ON RELATIONSHIP BETWEEN OCCLUSAL RETENTION WITH NUMBERS OF PRESENT TEETH AND DIAGNOSIS OF DISEASE AMONG THE ELDERLY IN A JAPANESE PREFECTURE

H. Ueda1, M. Kanda2, M. Yoshida2, T. Toyokawa2, 1. Graduate School of Human Sciences, Osaka University, Suita, Osaka, Japan, 2. Hyogo Dental Association, Kobe, Hyogo, Japan

This study examined the relationship between occlusal retention with number of present teeth and diagnosis of disease in the elderly. We obtained the study information from dental and medical receipts under the National Health Insurance scheme. The data covers one-year period from May 2005 to April 2006 and includes a total number of 30,844 elderly residents (13,573 men and 17,271 women) aged 70 and over in Hyogo Prefecture, Japan. The average age of the study sample is 76.2 years old (SD=4.9) for men and 76.5 (SD=5.1) years old for women. Examined diagnoses of disease as dependent variables are cancer, endocrine system, neuro-mental diseases, ontological diseases, circulatory diseases, respiratory diseases, and others. With logistic regression analyses, we found some statistically significant relationships between occlusal retention with number of present teeth and diagnosis of disease such as diabetes, disorder of metabolism, dementia, respiratory diseases, musculoskeletal systems, separately for each sex. Relationships with circulatory diseases were seen for women. On the other hand, we did not observe a relationship with Parkinson’s disease and Alzheimer’s disease. Our research outcomes imply that the occlusal retention with number of present teeth may indicate a relationship with some diseases in old age. It is recommended to further explore those relationships with additional
plausible variables and investigate the mechanism of developing such diseases or reversed oral health outcomes in a longitudinal study in the future.

NURSING CARE AIDE DETERMINATION AND REPORTING OF AGGRESSIVE INCIDENTS IN LONG-TERM CARE
A. Cammer, D.G. Morgan, N.J. Stewart, M. Crossley, University of Saskatchewan, Saskatoon, SK, Saskatchewan, Canada

Through previous research we expanded our understanding of organizational factors that contribute to aggressive behavior within long-term care. We previously reported that while aggressive incidents are a common occurrence in long-term care, most incidents are not reported and formal reporting is not done consistently between facilities nor sometimes within a facility. Without accurate recording of aggressive incidents, the magnitude and nature of this problem cannot be understood. We conducted a subsequent study to explore how nursing care aides understand physical aggression within their worklives, how they describe these incidents, and what criteria they use to determine whether an incident warrants formal documentation and reporting or not. In June 2010, five focus group discussions were held with 44 nursing aides representing twelve of the thirteen health regions of Saskatchewan, Canada. Nursing care aides shared their experiences with aggressive behavior from residents, described the reporting and follow-up processes at various levels of their organizations, and explained the criteria they consider when determining whether an experience of aggression constitutes “an incident”. Aggressive incidents are typically explored from the vantage of isolated incidents or episodes; this project represents an innovation in examining incidents from a broader systemic perspective, and from the perspective of nursing care aides who directly experience the aggression. Analysis yielded four salient categories of consideration in determination of an aggressive incident: cognitive impairment and the ability of the resident to control behavior, power and hierarchical relationships within the long-term care system, infotiy with follow-up processes, and the systemic normalization of aggression.

THE EFFECT OF SLEEP-INDUCING MUSIC ON SLEEP PATTERN IN PERSONS WITH PERCUTANEOUS TRANSLUMINAL CORONARY ANGIOGRAPHY AT CCU
M. Ryu1, J. Park2, H. Park2, 1. Keimyung University Dongsan Hospital, Daegu, Republic of Korea, 2. Keimyung University College of Nursing, Daegu, Republic of Korea

Aims and Objectives The study compared the effect of earplug-delivered sleep-inducing music on sleep in persons with percutaneous transluminal coronary angiography (PTCA) in the cardiac care unit (CCU). Background Diverse types of music have been claimed to improve sleeping elsewhere, but relatively little is known in South Korea. Most studies investigating the effect of sleep-inducing music on sleep have involved persons with insomnia, even though many persons with cardiovascular disease in the intensive care unit suffer from sleeping problems. There is a need to investigate the effect of sleep-inducing music on sleep disorders in persons with PTCA in the CCU. Design An experimental research design was used. Methods Data collection was conducted in the CCU of K University Hospital in D city, from September 3 – October 4, 2010. Fifty eight subjects participated and were randomly assigned to the experimental group (earplug-delivered sleep-inducing music for 52 min beginning at 10:00 pm, while wearing an eyeshield; n=29) and the control group (no music, but earplugs and eyeshield worn; n=29). The quality and quantity of sleep was measured using questionnaires at 7 am the next morning for each group. Results Participants in the experimental group reported sleeping quantity and quality was significantly higher than control group (t=3.181, p=.002; t=5.269, p<.001, respectively). Conclusion Sleep-inducing music significantly improved sleep in patients with PTCA at a CCU. Offering earplugs and playing sleep-inducing music may be a meaningful and easily-enacted nursing intervention to improve sleep for ICU patients.

MODELS OF LOW VISION PRACTICE IN THE UNITED STATES

Clinical low vision care has been in existence in U.S. for 60 years and evolved to provide a range of services in a variety of practice patterns. Low vision clinical care may be provided by an optometrist in a clinical setting such as a hospital, vision rehabilitation organization, or by the Veterans Administration and with diverse multidisciplinary staff involvement. The main objective of this study was to examine the range of low vision practices and settings to determine the current models of low vision service delivery to the growing population of older adults with impaired vision. The study assessed practice patterns and multidisciplinary staff involved in service provision. A total of 55 geographically representative responses to the survey were received. Results indicate that the majority of low vision practices provide care to primarily older adults with half covering all age groups. The majority of respondents have a protocol for low vision exams, but less than half had a documented written protocol. The findings highlight that most clients can be reached through medical referral sources and that those practices with written, documented protocols for the low vision exam also report existing billing and referral practices in place. Results suggest that regardless of size of the practice, provision of low vision care is enhanced through the use of technology. Profiles of best practices across settings will be highlighted along with the diverse patterns of staffing especially the differential use of occupational therapists and vision rehabilitation therapists in certain settings.
VARIATION IN CARE TRANSITIONS AMONG PATIENTS WITH HIP FRACTURES

J. Bynum1, N. Leland2, P.L. Gozalo2, J.M. Teno2, V. Mor2, 1. The Dartmouth Institute for Health Policy and Clinical Practice, Dartmouth Medical School, Lebanon, New Hampshire, 2. Center for Gerontology and Health Care Research, Warren Albert School of Medicine at Brown University, Providence, Rhode Island

Objective: Hip fractures are common, costly, and involve multiple care transitions during recovery. Little is known about the differences across health care markets in the pattern of transitions or the risk for “problem transitions”. The objective of this study is to describe the occurrence of transitions in the first 6 months post-discharge for Medicare beneficiaries who experience their first hip fracture. Study Design: Observational cohort study of variation across 50 US states. Population: All fee-for-service Medicare beneficiaries older than 75 who experienced initial hip fracture between 1999-2007, lived in the United States, and discharged alive (N=1,216,234). Transition rates were adjusted for demographic, comorbid illness, nursing home residence, and index hospitalization characteristics. Principle Findings: Adjusted number of care transitions in the first 6 months post-discharge was 3.75 per person and varied by state (AK 3.23 to AR 4.07). Transitions are movement between health care delivery providers and problem transitions are moving into a higher acuity of care such as hospital readmission. The adjusted average number of problem transitions was 0.95 per person and ranged from 0.72 in Utah to 1.16 in Louisiana. Individuals admitted to an inpatient rehab facility experiencing, on average, more problem transitions (1.16) than individuals admitted to a SNF (0.86 problem transitions). Conclusions: There is significant variation in problem transitions geographically and by first post acute care site. Varying rates of problem transitions suggest that initial site of discharge warrants further investigation of the most efficient way to deliver rehabilitative care for hip fracture patients.

PNEUMONIA AND MORTALITY BEYOND HOSPITAL DISCHARGE IN ELDERLY PATIENTS

R. Rozzini1,2, M. Trabucchi1, 1. Poliambulanza Hospital, Brescia, Italy, 2. CeSOS-Catholic University, Sacro Cuore, Brescia, Italy, 3. Geriatric Research Group, Brescia, Italy

Aim: evaluate the association between pneumonia and three months mortality beyond hospital discharge in elderly patients consecutively admitted to a Geriatric ward (Poliambulanza Hospital, Brescia, Italy) during a 36-months period. Methods: multidimensional evaluation performed after admission includes information on demographics, mental, physical health, and functional abilities using a standard protocol. Pneumonia was diagnosed by clinical signs and chest radiography and treatment done according to the ATS/IDSA guidelines. Results: Among the 3365 elderly patients admitted and 240 patients had Community Acquired-CAP. Severity of somatic, biological, psychic, and functional conditions was higher in patients affected by pneumonia than in those with acute non infectious diseases. In particular, those disabled two weeks before admission were nearly twice in the CAP group. Three-month mortality was significantly higher in pneumonia (19.2%) than in other patients (10.3%). Variables associated with mortality in bivariate analysis were being males, renal failure, stroke and independently being very old (90+), smoking habit, APS-APACHE II subscore (12+), urea/creatinine ratio >60, being disabled two weeks before admission, delirium, dementia, COPD, malnutrition, metastatic cancer, Charlson Index score (5+), and drugs number (7+). Conclusions: hospitalized CAP are associated with many deaths outside the time frame normally considered in this otherwise acute disease. Clinicians must take in consideration the poor outcomes of old pneumonia patients predisposing the most appropriate care, as is due to frail, old patients. Improved understanding of the poor long-term prognosis associated with CAP is needed to modify the dismal outcome of this common disease in elderly patients.

THE MODERATING EFFECT OF DISTRESS ON SELF-EFFICACY AND DIABETES CONTROL IN A SELF-MANAGEMENT RCT

S. Robertson1, A. Bush1, J. Cully1,2, A. Nair1,2, 1. Baylor College of Medicine, Department of Psychiatry & Behavioral Science, Houston, Texas, 2. Baylor College of Medicine, Geriatric Medicine Section, Department of Medicine, Houston, Texas, 3. Michael E. DeBakey Veterans Affairs Medical Center, Health Services Research & Development Center of Excellence, Houston, Texas

Depression and distress are common among individuals with diabetes. While depression is associated with increased risk of adverse outcomes (e.g., stroke, kidney disease), the mechanisms are not well-understood. We previously conducted a randomized clinical trial (RCT) of two primary care group clinics that showed improvements in diabetes control, partially mediated by self-efficacy, among participants randomized to the self-management action planning arm of the intervention. To further understand the findings, we used these data to examine interrelationships among diabetes control, self-efficacy and Depression Anxiety and Stress Scale (DASS) scores. Our sample consisted of 87 participants from the RCT. Participants’ total scores on the DASS were used to measure overall distress. Diabetes self-efficacy was assessed with 8 items assessing confidence in one’s ability to perform specific diabetes self-management tasks, while HbA1c was used as a measure of diabetes control. Controlling for baseline self-efficacy, multiple regression analyses revealed that higher baseline DASS scores were associated with lower 3-month self-efficacy. Additionally, higher DASS scores were associated with greater 3-month HbA1c levels, controlling for baseline HbA1c. After controlling for treatment group in both sets of analyses, the effect of DASS scores on self-efficacy remained significant, however, the association between DASS scores and HbA1c was no longer significant. Importantly, there was a significant interaction between baseline self-efficacy and DASS scores; among participants with higher self-efficacy, those with lower DASS scores had greater HbA1c improvements from baseline to 3-months. These findings suggest that interventions should jointly target self-efficacy and mood difficulties to improve diabetes control.

SELF-PERFORMED ACUPRESSURE FOR PAIN AND SLEEP IN THE AGING POPULATION

M.L. Burns, S. Yoon, Nursing, University of Florida, Gainesville, Florida

Background and Significance: Sleep difficulties and chronic pain are prevalent in older adults. Acupressure may reduce non-malignant pain and sleep difficulties. Self-performed acupressure may be a cost-effective, convenient alternative, and beneficial when it is combined with pharmacological therapies. Purpose: Determine the effectiveness of self-performed acupressure for sleep difficulties and chronic pain. Methods: A convenience sample of 5 men and 12 women, > age 65 (mean age, 73), community dwelling, with self reported chronic pain (neck, shoulder, back, hip, knee) and sleep difficulties > 3/week for >3 months, were assigned to an acupressure (n=7) or a control group (n=6) by geographic location. Subjects in the acupressure group practiced it for 6 weeks after they learned eight acupressure points during a 2 week period. The control group received educational materials. Excluded were those with missing fingers, neuropathies or malignant pain. Results: Sleep difficulty (Pittsburg Sleep Quality Global Sleep) was improved by 23% in acupressure group upon completion of the study, while control group indicated 4% improvement compared to the beginning of the study. Pain experience (0-6 Likert scale) was decreased by 57% in acupressure group compared to pre-intervention, while control group showed increased pain level by 45%. Due to a small sample size, there were no significant differences in sleep difficulty and pain experience between these two groups upon completion of the study. Discussion: Although results were not significant, self-performed acupressure may
be an effective treatment for chronic pain and sleep difficulties. Future work with larger samples is warranted.

CONSIDERING COGNITION WHEN USING BEHAVIORAL ACTIVATION TO TREAT DEPRESSION AND DIABETES IN ADULTS

Type 2 diabetes affects over 26% of older adults in the U.S. An additional 79 million adults and older adults have pre-diabetes, a condition that may develop into Type 2 diabetes if not managed properly (CDC, 2011). Prevalence rates of depression are 20-30% higher in individuals with diabetes compared to those without diabetes (Li et al., 2008). Diabetes and depression are associated with impairments in multiple cognitive domains, including memory (Stewart, & Liolitsa, 1999; Watkins & Teasdale, 2001), attention (Boone et al., 1995; Levens, Muhtadie, & Gotlib, 2009), and decision-making (Boone et al., 1995; Levens, Muhtadie, & Gotlib, 2009; Stewart, & Liolitsa, 1999). Cognitive impairment in those with depression, diabetes, or both can lead to additional challenges in establishing and maintaining healthy self-care behaviors (Eren, Erdi & Sahin, 2008). Unlike some pharmacological treatments for depression, psychotherapeutic interventions can lead to positive diabetes and depression-related outcomes without resulting in further cognitive impairment (Fiske, Wetherell, & Gatz, 2009). Behavioral Activation (BA) is an empirically supported treatment that addresses the links between environment, mood, and behavior and has been effective in reducing depressive symptoms (Dimidjian, Martell, Addis, & Herman-Dunn, 2008). Recent ongoing research reveals promising results when BA is used in a population of low income, middle-aged and older adults with diabetes and depression (Feliciano, Anderson, Steers, & Jay, 2010). Preliminary data on mood, cognition, and diabetes-related outcomes will be presented comparing individuals with comorbid depression and diabetes who were randomly assigned to either BA or a wait-list control group.

USING CBPR TO DEVELOP A QUESTION PROMPT LIST TO IMPROVE CANCER CARE IN OLDER AFRICAN AMERICANS

R. Tkatch, S. Eggly, J. Baker-Calloway, W. Stengle, L. Penner, J.J. Griggs, R. Brown, R. Chapman, L. Karmanos Cancer Institute/Wayne State University School of Medicine, Detroit, Michigan, 2. University of Michigan, Ann Arbor, Michigan, 3. Virginia Commonwealth University, Richmond, Virginia, 4. Henry Ford Hospital, Detroit, Michigan

The use of chemotherapy in the curative setting varies by patient race after controlling for clinical and tumor characteristics. One cause may be that ineffective communication during racially discordant clinical interactions leads patients and oncologists to make inappropriate treatment decisions. The objective of this study was to use a Community Based Participatory Research (CBPR) approach to develop a Question Prompt List (QPL) as an intervention to improve communication between older African-Americans and oncologists as they discuss chemotherapy. We collaborated with experts in health communication, community members, medical oncologists, and current or former chemotherapy patients. We created a large pool of initial questions and formats from various sources. We then held focus groups and individual interviews with community members, oncologists, patients, and families to elicit their perspectives on content, wording, and format. Using an iterative process of eliciting feedback and revising drafts, a final version was created. We noted disagreement between and among oncologists, patients, and community members. Patients and community members wanted many specific questions addressing the diverse needs and concerns of older people with cancer, but some oncologists felt that too many questions would be time-consuming and ineffective. Some questions specifically suggested by community members or patients made oncologists uncomfortable. The CBPR process resulted in a 33-item final version representing multiple perspectives. This tool is currently being tested in a randomized clinical trial with older African American patients to assess its effect on level of patient participation in oncology interactions and on appropriateness of patient and oncologist treatment decisions.

SESSION 1725 (POSTER)

EDUCATION, TECHNOLOGY, AND RESEARCH METHODS

SERVICE LEARNING: PROMOTES OCCUPATIONAL THERAPY GERONTOLOGY EDUCATION AND PRACTICE

B.P. Horowitz, S. Dapice Wong, York College-CUNY, Jamaica, New York, 2. Touro College, Bay Shore, New York

Changing demographics and advances in medicine have increased demand for geriatric rehabilitation practitioners, including occupational therapists. Shortages of health care providers with expertise in geriatrics/gerontology, and limited numbers of students interested in geriatrics/gerontology practice, requires health/ human service education programs to combat ageism and promote practice with older adults. Older adults are increasingly choosing to age-in-place, increasing demand for home health care and community services. The question is: What pedagogies best provide students with knowledge and skills for geriatric/gerontology practice while encouraging interest in gerontology practice? Service learning is recognized as one pedagogy that integrates experiential learning with traditional academic study to advance health science education and civic engagement. This research reports findings from a 3-year intergenerational service learning program (IGSL) involving occupational therapy (OT) faculty, 70 OT students, 12 senior learners, and 225 older adults who participated in fall prevention education sessions. The IGSL program was integrated in 2 occupational therapy courses to advance intergenerational dialogue, knowledge of aging, fall prevention, and encourage future gerontology practice. Senior learners and students participated in classroom activities and jointly provided community fall prevention programs. Evaluation data found the program increased students’ knowledge of aging, interest in geriatric/gerontology practice, and increased skills for community practice. Outcome data following fall prevention sessions found older adults’ increased their awareness of individual fall risks and learned strategies to reduce risks. While this study focused on occupational therapy education, findings are relevant for other health and human service professions.

HERE COME THE BOOMERS: ARE PHYSICIANS PREPARED?

W.P. Moran, P.J. Iverson, General Internal Medicine and Geriatrics, Medical University of South Carolina, Charleston, South Carolina

Many residency curricula are inadequate in equipping doctors with the knowledge and skills needed to properly care for the unique syndromes and concerns of the older adult. This presentation will address these concerns and introduce a new model, Aging Q3: Quality Education, Quality Care, and Quality of Life for the Older Adult, using a rapid cycle process improvement model within the clinical environment. Methods: Aging Q3 was implemented at a major academic health center in the Division of General Internal Medicine and Geriatrics for 30 faculty and almost 100 Internal Medicine residents, and is currently in year 3. This rapid cycle improvement model is based on academic detailing and quality improvement principles to improve geriatric education focused on 16 specific target areas. Steps include faculty development, resident didactic, academic detailing, resident reminders and cues, and skill development at time of outpatient continuity of care training. Data is entered by the resident in the electronic medical record and reports...
are extracted and analyzed from the templates specifically designed for the intervention. Intervention in seven areas has been completed so far including vision, falls, dementia, continuity of care, medication use and safety, and screening and prevention. Results: In the first seven areas, there has been a 78% average faculty attendance at the faculty in-services and 30% average resident attendance at the didactics. An average of 80% of all residents received academic detailing and 73% demonstrated the skill. An average of 82% of the faculty participated in resident academic detailing. Results are measured by attendance reports, participation rates, chart audits, patient survey, and pre/post knowledge tests. Improvement in resident knowledge scores was shown in 66% of the areas. Discussion and Limitations: The Aging Q3 rapid cycle process improvement model has resulted in a high rate of resident participation in hands-on skill training in the outpatient clinic. Future emphasis will need to focus on improvement in evidence based question design to ensure valid knowledge measurement. Conclusion: Experiential and detailing based education on geriatric principles is achievable in a fast-paced resident clinic by creating a learning environment with multiple reminders that lead residents through an improvement in knowledge and skills and a behavior change in practice. Physicians will be better prepared to provide quality care with an increased awareness, confidence, and ability to properly address the unique medical care needs of the rising number of older patients in their care. Sponsor: Donald W. Reynolds Foundation

A PROCESS EVALUATION OF AN AGENCY-WIDE PARKINSON’S DISEASE CARE PROGRAM

This poster summarizes findings of a process evaluation of a care enhancement project for persons with Parkinson’s disease (PD) at a large health and social services agency. The objectives were to develop and implement a model for delivering ongoing, comprehensive training and care guidelines to staff in various long term care settings, including skilled nursing, assisted living, home health care, and adult day services. During the development phase we collaborated with clinicians from the Feinberg School of Medicine at Northwestern University and developed a series of training lectures to be viewed in a self-study mode, along with pre and post quizzes, and a set of discipline-specific care guidelines. During the implementation phase staff members completed training and were provided with care guidelines and additional PD resources. The evaluation results highlight challenges and successes related to: 1) developing training content, format, and learning modes for multiple audiences, 2) selecting appropriate technologies and delivery formats for self-study, 3) developing care guidelines suitable for a variety of disciplines, 4) monitoring completion of the training and use of the care guidelines, 4) assessing trainees’ knowledge gains, satisfaction, and changes in perceptions of care, and 6) identifying factors that contribute to the sustainability of the program in different settings and among different groups of staff. Evaluation findings also have implications for facilitating change in long term care knowledge and practice.

IMPROVING CLINICAL TEACHING IN NURSING HOMES—STRATEGIES AND OUTCOMES
C. Mueller, M. Zaccagnini, M. Goering, K. Talley, D. Winger, Nursing, Univ of MN-School of Nursing, Minneapolis, Minnesota

The majority of nursing faculty are not prepared to do clinical teaching in nursing homes, yet many schools of nursing provide their students with some type of clinical experience in that setting. An undesired, but common outcome, for students who have clinical experiences in nursing homes with faculty who are not familiar with nursing homes or knowledgeable in geriatric nursing, is students having a negative attitude about the nursing home as a practice environment and no desire to consider it as a practice site in their career. A conceptual model of factors that contribute to successful clinical teaching in nursing homes was developed and used to implement a faculty development program that has been provided to over 200 nursing faculty and their nursing home partners in four states. The evaluations from faculty and their nursing home partners participating in the program were extremely positive (high ratings). Pre and post surveys to determine the impact of the program on improving clinical teaching in nursing homes find that most schools of nursing use the nursing home setting for the students’ first clinical experience. Approximately 60% consider the nursing home clinical experience as a way for students to learn about geriatric nursing as a specialty. Although the majority of schools of nursing have a clinical experience for students in a nursing home, more than half are moderately or somewhat satisfied with the experiences the students have in that setting.

TRAINING INITIATIVES IN BEHAVIORAL TREATMENT PLANNING IN LONG-TERM CARE

Older patients with behavioral disturbances and mental health needs constitute a varied population within long-term care facilities, including delirious patients, patients with dementing illnesses, and those with psychiatric disorders. Approximately two-thirds of nursing home residents have dementia, with more than half of these exhibiting behavioral disturbances sometime during the course of their residential care. Despite efforts over the past two decades to train long-term care staff to assess, manage and prevent these behavioral symptoms, there is little evidence that the prevalence of such symptoms has diminished. We conducted a focus group at the Coatesville VA Medical Center to identify barriers to the application of knowledge and skills acquired through prior educational experiences in the care of long-term care residents with dementia and behavioral disturbances. Participants included professionals in staff development, geriatric medicine, nursing, psychology, and recreation therapy. Key findings focused on: 1) lack of skills or experience in the behavioral treatment planning process; 2) inadequate appreciation of the role of care staff across disciplines in the care planning process; and 3) lack of knowledge of systems for documenting and communicating contents of behavioral treatment plans in long-term care. In response to the findings, we pilot-tested a new format and process by conducting six workshop sessions, one for each of the six groups of interprofessional staff representing all three work shifts on two separate nursing home units. The workshop explored potential reasons that the existing plan has not succeeded; and used evidence-based principles to guide the revision of the care plan.

KEEPING GRANNY SAFE THROUGH GRACE? A MULTIFACETED CLINICAL INITIATIVE TO IMPROVE HOUSESTAFF AWARENESS OF DELIRIUM AND ITS RISK FACTORS
D.D. Ołveczky, K. Mukamal, M. Mattison, Internal Medicine, Beth Israel Deaconess Medical Center, Boston, Massachusetts

Many elderly inpatients develop delirium, a preventable, but debilitating condition. Despite this most medical house officers do not recognize its risk factors. We tested whether the Global Risk Assessment and Careplan for Elders (GRACE), a geriatric quality initiative, can improve residents’ awareness of delirium and its risk factors. GRACE is an initiative to optimize care for all hospitalized elders. It implements a bedside care checklist and modifies the hospital’s computerized provider order entry (CPOE) system to prompt providers to remove unnecessary tethers, ambulate elderly inpatients several times daily, and avoid inappropriate medication use. While GRACE was phased in, we administered pre- and post-rotation surveys to residents rotating for four

64th Annual Scientific Meeting 479
A growing number of baccalaureate nursing students have an interest in working with older adults, however most of these students are not choosing to work in nursing homes for their careers. Students feel unprepared for the environment where there is often limited RN and physician support on site, more delegation of work to CNAs and very complex health conditions to manage. The Long Term Care Clinical Scholars Program (LTC-CSP) was created by the University of Wisconsin-Madison and Edgewood College Schools of Nursing to help prepare students interested in working with older adults for careers in nursing homes. This poster describes the development of the summer internship program in collaboration with area nursing homes, the Wisconsin Department of Health Services and several other key stakeholder organizations. Fourteen baccalaureate nursing students applied to the LTC-CSP and seven were selected for internship positions at five nursing homes. Over the internship’s twelve weeks, interns participated in weekly workshops, were matched with two preceptors at their homes, and were hired as Nurse Techs to work at least 24 hours each week. Preceptors were provided with online education, two in-person precepting workshops, and six visits with program staff over the duration of the program. Evaluation of the program focused on intern confidence in skills required for nursing home caregiving, preceptor experiences in coaching and mentoring interns, intern career preferences, and nursing home administrations’ experiences in program participation.

FEASIBILITY OF A WEB-BASED DEMENTIA FEEDING SKILLS TRAINING MODULE FOR NURSING HOME STAFF
Background: For an event that occurs three times daily and offers the most opportunity for socialization, mealtimes warrant careful hand feeding implementation by NH staff. PWD may exhibit aversive feeding behaviors that are misinterpreted. This vital misinterpretation can lead to malnutrition in the PWD and increase the risk of mortality. Objective: The goal of this two-month study was to test clinical feasibility and collect pilot data for an intervention to train nursing home (NH) staff via a web-based dementia feeding skills training module with group coaching. The goal of training was to alleviate mealtimes difficulties in persons with dementia (PWD) who require mealtime assistance. Methods: Two southeastern US nursing homes were randomized by cluster to five weeks on an inpatient medical service. Results: 109 out of 126 eligible housestaff (86%) completed pre-rotation surveys. Seventy-three housestaff (58%) completed post-rotation surveys. The proportion of correct responses to questions on haloperidol dosing and the characteristics of delirium increased from 36% before to 87% after the rotation (p < 0.0001). The proportion of housestaff who reported an improvement in their ability to recall which patients were receiving intravenous fluids increased from 17% to 38% (p = 0.06). Corresponding figures were 21% versus 52% for Foley catheters (p = 0.01), and 28% versus 59% for telemetry (p = 0.01). Similarly the percentage of residents who reported that GRACE improved their awareness of delirium increased from 32% to 80% (p < 0.0001). Conclusion: A quality initiative to improve the care of geriatric inpatients can dramatically improve residents’ knowledge and awareness of delirium and its risk factors.

CHANGE IN ATTITUDES TOWARD AND KNOWLEDGE OF OLDER ADULTS BY PHARMACY STUDENTS OVER THE FIRST TWO YEARS OF THE PROFESSIONAL PROGRAM
C. Sadowski1, L. Strain2, S.H. Simpson3, S. Vannhagen3, 1. Faculty of Pharmacy, University of Alberta, Edmonton, Alberta, Canada, 2. University of Alberta Faculty of Medicine & Dentistry, Edmonton, Alberta, Canada, 3. University of Alberta Faculty of Extension, Edmonton, Alberta, Canada
Background: Students in health professions often have poor attitudes toward and insufficient knowledge of older adults. Objective: The purpose of this project is to determine pharmacy student knowledge of and attitudes toward older adults at various time points in the curriculum. Methods: Pharmacy students at the University of Alberta were recruited to participate in a prospective study regarding their knowledge and attitudes toward older adults. Questions included general demographic, the Palmore Facts on Aging Version 2, and Kogan’s Old People Scale were used. The questionnaires were administered on the first day of orientation to the Faculty (T1), at the end of year 1 after 50 hours of service learning (predominantly long term care) (T2), and part-way through year 2, after the geriatrics module (T3). Only those students who consented to participate were forwarded the online survey. Results: A total of 222 students participated; 67% female, age <20 (32%), age 20-24 (58%). A total of 23% worked in a pharmacy, and 40% had ever lived with an older adult. Mean Palmore scores were 15.3 (SD 2.5) T1, 15.6 (2.7) T2, and 17.8 (2.3) T3, P < 0.001. Kogan scores for negative stems were 63.3 (7.2) T1, 64.8 (5.3) T2, and 64.5 (7.2) T3, p = 0.098. Kogan scores for positive stems were 70.3 (8.4) T1, 70.7 (6.6) T2, and 70.9 (8.5) T3, p = 0.74. Conclusions: The students demonstrated increased knowledge regarding older adults throughout the program. The student attitudes did not change after a service learning experience nor after the geriatrics module.

A PRIMER FOR SYSTEMATIC REVIEWERS AND OTHERS ON THE MEASUREMENT OF HEALTH-RELATED QUALITY OF LIFE IN OLDER ADULTS
Evidence-based guidelines are needed to improve the health of our aging population and inform best practices for clinicians caring for older adults. Systematic reviewers are increasingly focusing on interventions that address the problems of older, multimorbid, functionally impaired populations. Key outcomes for these interventions are function and health-related quality of life (HRQL). The presentation reviews some methods for assessing function and HRQL and provides tools to assess the quality of such evidence. Key measurement properties include responsiveness of the chosen instruments (ability to detect meaningful change) and interpretation of results (is the magnitude of change trivial or important?). Special challenges in older adult populations include...
spare evidence on measurement properties of common HRQL measures; the frequent necessity of using proxy respondents; a paucity of evidence on the magnitude of change that is clinically important; and threats to responsiveness from floor and ceiling effects. HRQL evidence from natural-history cohorts is essential for interpreting results from intervention studies. Implications for systematic reviewers and designers of original studies will be discussed.

THE REASONS OF REFUSING TO TAKE PART IN STUDY IN THE ELDERS OF HIP FRACTURE WITH DIABETES IN TAIWAN

Y. Huang1,2, L. Chen2, S. Tang1, H. Cheng1, Y.L. Shyu2, J. Nursing, Chang-Gung Institute of Technology, Taoyuan, Taiwan, 2. Chang-Gung University, Taoyuan, Taiwan, 3. Ming Chuan University, Taoyuan, Taiwan, 4. Yuanpei University, HsinChu, Taiwan

Clinical and scientific significance. Hip fracture will impair functional activities of elders. Previous researches had shown multidisciplinary interventions benefited the outcomes. In our previous researches which afforded interventions to the elders of hip fracture, the refusal rate was 36.1%; in our present study with the same design but comorbid with diabetes, the refusal rate is significantly higher (47.4%). For ethics, we can’t get details from rejecters; but elders with comorbidities usually have lower functions and worse outcomes than those without, and had better get more interventions. We wonder why they refuse and worry about bias in present study, but little is known about the situation. Research Purpose. The aim is to explore the refusing reasons of rejecters in present study. Data and Methods. Elders above 60 year-old of hip fracture with diabetes were invited to participate in the intervention program at Chang Gung Medical Center in northern Taiwan from 2010 Jan to 2011 Feb. If they refused, researcher explored the reasons after getting oral consent. Transcribed information was analyzed using content analysis technique described by Miles and Huberman. Results. Thirty-seven rejecters were inquired, the main reasons included: (1) they always need care and bother family, so refuse programs lest troubling others, (2) their health are poor and hard to improve, so don’t waste energy. Conclusion. The elders seem unwilling to participate by their weakness and dependence, and avoid bothering others. It may be a research bias that we recruit more healthy and vital cases but lose the feeble ones. Keywords. hip fracture, diabetes, elders, refusal

RECRUITMENT AND RETENTION OF OLDER STROKE PATIENTS: LESSONS LEARNED FROM A FEASIBILITY STUDY

N. Hadidi1, R. Lindquist2, K.C. Buckwalter1, J. Nursing, University of Minnesota, Minneapolis, Minnesota, 2. University of Iowa, Iowa City, Iowa

Patient recruitment and retention has proven to be one of the most challenging aspects of any clinical study or trial. With older participants, the challenge is even more pronounced. It is typically more difficult to recruit this age group, and more common to lose them to illness and death. According to a 2003 report (before HIPAA), 85% of trials did not finish on schedule; 60% to 80% of clinical trials did not meet their chronological endpoints because of challenges in recruitment; and 30% of trial sites failed to recruit even a single participant. We conducted a Feasibility Study of Problem Solving Therapy (PST) to prevent and treat poststroke depression. Twenty-two participants were randomized to a control group receiving one phone call for 10 consecutive weeks. Our experience was a case study demonstrating the importance of establishing a set of strategies to improve participant recruitment and retention in this challenging sample. We found that clear communication regarding randomization, risk/benefits and time commitment was essential in retention. Provider involvement in recruitment was foundational in successful recruitment. Fatigue is a major hindrance in study participation for stroke patients. Thus, being flexible in meeting patients’ needs was essential. Further, involving caregivers in the study was critical to study completion success. We established realistic and rigorous inclusion/exclusion criteria—-but closely monitored potential “lost” participants and appropriately loosened criteria (via IRB) to increase and broaden the capture of subjects who might benefit from PST.

ELECTRONIC MEDICATION ADHERENCE MONITORING HAWTHORNE EFFECT IN OLDER ADULTS

T. Ruppar, 1. Sinclair School of Nursing, University of Missouri, Columbia, Missouri, 2. Katholieke Universiteit Leuven, Leuven, Belgium

Background: Electronic monitoring (EM) of medication adherence is often criticized in that monitor use may impart an unintended intervention effect. In studies of HIV and kidney transplant patients, electronic adherence monitoring showed an intervention effect ranging from 35 to 40 days from initiation. No published studies have evaluated the presence or duration of intervention effect from EM of medication adherence in older adult populations. Methods: A convenience sample of hypertensive older adults (age ≥ 60 years) used EM for six weeks to determine eligibility for an antihypertensive adherence study. The screening data were analyzed by calculating and plotting the percentage of subjects who were adherent on each day of adherence monitoring. Results: Among the 33 participants who completed the monitoring period (median age 74 years), the probability of taking the correct number of daily doses remained stable over six-weeks. At day 1, 90.9% of participants took the correct number of doses, compared with 89.7% at day 42. The probability of taking all daily doses within the correct time interval decreased slightly from day 1 to day 42, from 71.9% to 65.5%, respectively. Additional data is currently being collected to further evaluate these findings. Discussion: The intervention effect of electronic medication adherence monitoring caps seen in previously studied populations was not replicated in this older adult sample. Further study is necessary to determine if this is due to absence of intervention effect from EM use among older adults, or if the intervention effect in older adults is longer than 42 days.

ANSWERING GERONTOLOGICAL RESEARCH QUESTIONS USING LARGE DATA SETS

M. O’Connor, K.H. Bowles, School of Nursing, University of Pennsylvania, Philadelphia, Pennsylvania

A vast amount of quantitative data concerning geriatric Medicare and Medicaid recipients, costs, utilization and providers exists allowing for cross-sectional or longitudinal studies. Centers for Medicare and Medicaid (CMS)-owned data is available to academic, non-profit and government researchers for analysis through the Research Data Assistance Center (ResDAC), the CMS contractor that facilitates data use agreements and purchase. Secondary analysis of CMS-owned large administrative data sets provides the opportunity to generate new knowledge from existing data in a cost-effective and efficient manner but is not without limitations and challenges. In this presentation we explore the three types of CMS data sets (Research Identifiable Files, Limited Data Sets, and Non-Identifiable Files) as well as provide an overview of the individual data sets available. The data sets available include eligibility and demographic information, claims files for the multiple provider types receiving reimbursement from CMS, assessment and survey data, and prescription drug costs. Varying files are available on a claim and beneficiary level while others are summary level files. Information on how to obtain permission to use them, the strengths and limitations of employing nationally represented data, and suggestions regarding how to prepare the data sets for analysis are presented. This presentation includes an exemplar describing the matching of beneficiaries, and the merging and analysis of multiple CMS-owned data sets.
The Wii balance board could be used to assess elderly risk of falling, concordance, resulted in a weighted kappa statistic of 0.79 (p=0.03). Researchers who made the short performance scale and a set of tests with the Wii balance board. The elderly population is growing due to a global demographic transition. The appearance of diseases in this age group has some peculiarities, and many of them were minted in entities known as geriatric syndromes. These include falls, which are of particular interest due to their health and social consequences: fractures, immobility, dependence and early institutionalization among others. In addition, falls are markers of overall health in elderly. The aim of this study was to determine the effectiveness of the Wii ™ balance board in the evaluation of the balance of a group of ambulatory elderly in Mexico City. We assessed 20 patients (40 intervention and 72 control) at 4 rural senior centers in West Central Ohio. Intervention participants were instructed to use a telehealth kiosk at least once per week while visiting the center. If the initial BP was elevated, participants were instructed to rest for 15 minutes, take a second measurement and answer an on-screen questionnaire. BP data were streamed from the kiosk to a central server that was accessed remotely by study nurses who monitored patients according to protocols provided by participants’ physicians. Participants were interviewed in-person at baseline and followed for 10 months. Their mean age was 74.1 years, 74% were female, and 84% reported having used an automatic blood pressure cuff in the past. Baseline systolic BPs were 131±21 and 138±21 mmHg in the intervention and control groups, respectively. Weekly use of the technology increased over the first 5 months of the study, reaching 80% in month 5, but then declined, falling to a low of 47% in month 10. Weekly use of the technology was 69% over the entire study period. Overall compliance with taking a second BP measurement among persons with an initially high reading was 61%, and compliance with use of the pop-up questionnaire was 13%. End of study systolic BPs were 126±20 and 132+/21 mmHg in the intervention and control groups, respectively. Although senior center personnel and clients embraced the idea of using this venue for telehealth-mediated chronic disease management, practical issues—most notably the need for reliable internet service—presented substantial operational challenges in the rural areas in which this project was conducted. This pilot study suggests that senior centers have the potential to act as hubs for community-based chronic disease management using telehealth technology, and that hypertensive seniors will use of the technology in this setting if it is available.

THE WII BALANCE BOARD AS AN EFFECTIVE INSTRUMENT TO ASSESS BALANCE OR STABILITY IN THE ELDERLY

The elderly population is growing due to a global demographic transition. The appearance of diseases in this age group has some peculiarities, and many of them were minted in entities known as geriatric syndromes. These include falls, which are of particular interest due to their health and social consequences: fractures, immobility, dependence and early institutionalization among others. In addition, falls are markers of overall health in elderly. The aim of this study was to determine the effectiveness of the Wii ™ balance board in the evaluation of the balance of a group of ambulatory elderly in Mexico City. We assessed 20 elderly (age range 60-98), and used standard tests (timed up and go and the short performance scale) and a set of tests with the Wii balance board. The board was connected via Bluetooth to a computer with a freeware, which allowed the analysis of the frequencies. We divided the subjects in three: stable, intermediate and unstable. Researchers who made the tests with the balance board were blinded to the clinimetric results. The concordance, resulted in a weighted kappa statistic of 0.79 (p=0.03). The Wii balance board could be used to assess elderly risk of falling, this study showed that it could discriminate between three different groups (compared with usual clinimetric tools). Also, we found an increased use of energy in those classified as unstable. Further work is needed to assess the Wii effectiveness in predicting falls, but certainly it appears a easy-to-use tool with promising results.

THE GLOBAL RISK ASSESSMENT AND CAREPLAN FOR ELDERLY (GRACE): AN INNOVATION TO STANDARDIZE AND IMPROVE CARE OF HOSPITALIZED ELDERLY

A. Botts, J. Moran, C. Kristeller, R.N., D. Olveczky, M. Mattison, G. Investigators, Medicine, Harvard Medical School - Beth Israel Deaconess Medical Center, Boston, Massachusetts

Background: Delirium and functional decline are common complications associated with the hospitalization of elders. GRACE is a novel, interdisciplinary initiative to standardize the care of older, hospitalized patients and thus limit delirium and prevent functional decline. Methods: GRACE uses a bedside checklist and modifications to the computerized provider order entry (CPOE) system to provide a standard geriatric care plan for all patients 80 years and older. The checklist includes delirium assessment and detection by a daily screen for inattention, as well as delirium prevention strategies, specifically a mobility protocol, promotion of sleep hygiene and a daily tether check. Modifications to the CPOE system include decision support to encourage appropriate ordering of antipsychotic and analgesic medications; an alert system for a subset of Beers medications; and default best-practice guidelines for daily activities (mobility, sleep, vital sign monitoring). Evaluation: Outcomes from May 1-November 30, 2010 include the number of orders for antipsychotic medication and the activation of the rapid response team (“triggers”) for change in mental status. Among patients 80 and over, the mean percentage given antipsychotics was (mean ±SD) 10.7±2.0 in 2009 and 9.3±1.3 in 2010 (p<0.05). The mean number of “triggers”, including altered mental status, was 4.4±4.0 per 1000 discharges in 2009 and 11.8±4.5 in 2010 (p<0.01). Compliance with completion of the bedside checklist averaged 34%. Conclusions: A multi-disciplinary team approach to standardizing best practices for older adults can improve recognition of altered mental status by bedside staff and shows a trend for reducing overall use of antipsychotic medication.

DEVELOPMENT OF A COMPUTER ADAPTIVE INTERACTIVE VOICE RESPONSE FUNCTIONAL MONITORING SYSTEM

N. Latham1, A. Jette1, R. Friedman2, 1. Boston University School of Public Health, Boston, Massachusetts, 2. Boston Medical Center, Boston, Massachusetts

BACKGROUND: Computer adaptive tests (CAT) such as the Late Life Function and Disability Instrument CAT (LLFDI-CAT) provide accurate assessments of function with few items. Interactive voice response (IVR) is a time- and cost-efficient way to obtain information. To date, these two technologies have not been combined. AIM: The aim of this project was to develop an IVR version of the LLFDI-CAT. METH-OIDS: A dialogue of the IVR version of the LLFDI-CAT was developed and evaluated in five cognitive testing sessions to ensure that the content could be understood by older adults when delivered over the telephone. The IVR system was built and the LLFDI-CAT program was embedded in the system. In house simulations and debugging of the IVR program took place, followed by pilot testing in six community dwelling older adults with functional limitations who provided informed consent over the telephone. Participants provided quantitative and qualitative evaluations of the system with a research assistant at the end of the call. RESULTS: The system performed well in all six calls. One minor technical problem was identified and easily corrected. Participants were able to complete all items on the functional test. They did not require any outside assistance and reported high satisfaction and low levels of difficulty with the IVR CAT. DISCUSSION: This system shows promise...
as an efficient way to monitor function in older people. Work is now underway to compare the performance of the IVR system to direct telephone administration of the LLFDI-CAT in 50 older people.

SESSION 1730 (POSTER)

EPIDEMIOLOGY

PHYSICAL PERFORMANCE ASSOCIATIONS WITH INCIDENT ADL/IADL LIMITATIONS AND MORTALITY AMONG OLDER WOMEN

J. Lyons, J. Keysor, T. Heeren, L. Fredman, Epidemiology, Boston University, Boston, Massachusetts

Individual and summary measures of physical performance and muscle strength are predictive of functional status and health outcomes in various populations, though few studies have been performed on older women over a long follow-up period. We evaluated associations between quartiles of individual performance tasks (chair stand speed, usual walking pace, grip strength) and a 12-point summary performance scale based on these three measures and modeled after the Short Physical Performance Battery, with development of incident limitations in basic and instrumental Activities of Daily Living (ADL/IADLs) and mortality over 7 years. The sample included 491 females from the Caregiver Study of Osteoporotic Fractures. At baseline, participants were aged 70-93 years (mean = 80.5), reported no limitations in ADL/IADLs, and had physical performance measures. In unadjusted Cox Proportional Hazards analyses, participants with lower summary performance scores (i.e., poorer functioning) had a significantly increased risk of incident limitations (Hazard Ratio, HR: 1.35, 95% Confidence Interval, CI: 1.18-1.54) as well as mortality (HR: 1.33, CI: 1.01-1.72). When adjusted for age, depressive symptoms, and medical conditions, these associations remained (incident limitations HR:1.25, CI: 1.09-1.45; mortality HR: 1.20, CI: 0.92-1.59). While usual pace and grip strength were associated with these outcomes, the summary performance score was a stronger predictor than any individual performance task. In summary, these results in a sample of high-functioning, older women suggest that the relationship between summary physical performance measures and incident disability that has been observed in younger populations also applies to older populations.

DIABETES AND COGNITIVE DECLINE IN OLDER PATIENTS

F. Limongi, S. Maggi, M. Noale, G. Romanato, G. Crepaldi, CNR, Institute of Neuroscience, Padova, Padova, Italy

Analyses were based on the Italian Longitudinal Study on Aging, a community-based cohort study including 5,632 individuals aged 65-84 years with two follow-ups (1996;2000). The cognitive assessment included the Mini Mental State Examination, the Prose memory Test and the Attention Matrix Test. The mean scores on the 3 tests, at baseline and follow-ups, and mean changes between baseline and follow-ups, were compared between diabetics and non-diabetics according to the Generalized Linear Models. Logistic regression models were defined to study the influence of diabetes and of glycated hemoglobin on cognitive decline on the 3 tests at follow-ups, adjusting for baseline scores and other variables. At baseline, diabetic women had significantly worse scores on all cognitive tests compared to non-diabetic women, but did not show worsening over time, whereas men with diabetes did not show worse scores on cognitive tests at baseline compared to nondiabetic males; however, diabetes in men was associated with a risk of cognitive decline over time, particularly in attention. A poor glycaemic control was associated with poorer performance on Prose memory tests at follow-up in both sexes. The impact of diabetes on cognitive status might differ in older men and women, probably because of a survival effect, with a higher mortality at a younger age among diabetic men. The association between a poor glycaemic control and the risk of cognitive decline is extremely important, since impairment in even a single domain may favor progressive decline in cognitive capacities. A routine assessment of diabetes complications should include cognitive evaluation.

OSTEOARTHRITIS AND DIABETES IN ELDERLY POPULATION

P. Siviero1,2, S. Zambon1,2, S. Zanoni1,2, G. Crepaldi1, J. CNR, Institute of Neuroscience, Padova, Padova, Italy, 2. Department of Medical and Surgical Sciences, University of Padova, Padova, Italy

The aim of this study was to explore the relationships between osteoarthritis (OA), diabetes and other potential risk factors in an Italian aged population. 1,572 participants of the Progetto Veneto Anziani observational cohort study, aged 65 and older, with hand, knee and hip X-rays were analyzed. Hand radiographs were scored for the presence of OA in the distal and proximal interphalangeal joints (IP) and in the first carpometacarpal joint using a standard atlas; for knee and hip the Kellgren-Lawrence grading scale was used. Only for IP and hip OA there was a significant association with diabetes. 49.7% of subjects with diabetes presented IP OA vs 32.1% of subjects without; 28.8% of subjects with diabetes presented hip OA vs 19.7% of subjects without. Multivariate regression analysis identified as significant risk factors for IP OA age, sex, BMI and diabetes. Subjects with IP OA were women of 72 years and older. A non diabetic subject with BMI ≥27.3 kg/m2 was almost 2 times more likely to have an IP OA compared to a diabetic subject with BMI ≤27.3 kg/m2. A diabetic subject with BMI ≥27.3 kg/m2 was estimated to be 0.27 times as likely to have an IP OA compared to a diabetic subject with BMI ≥27.3 kg/m2. A diabetic subject with BMI ≤27.3 kg/m2 was 6 times more likely to have an IP OA than a non diabetic subject with similar BMI. Significant risk factors for hip OA were male sex, age; physical activity and alcohol use were protective factors.

TRAJECTORIES OF MUSCULOSKELETAL PAIN AMONG OLDER ADULTS IN THE CARDIOVASCULAR HEALTH STUDY

Objectives: To characterize the trajectories of musculoskeletal pain among a community sample of older adults over a five-year period, and to identify factors associated with remission of pain. Design and Setting: Retrospective analysis of data from six annual examinations of a community-based cohort study in four American counties, part of the Cardiovascular Health Study. Participants: 5093 men and women aged 66 years or older. Measurements: Pain was assessed each year by a single question about the presence of pain in any bones or joints during the last year. If affirmative, participants were queried about pain in seven locations (hands, shoulders, neck, back, hips, knees, hips). Results: At the first measurement point, 41% of subjects reported experiencing musculoskeletal pain. The median number of pain locations was three. Women were more likely to report pain than men, as were those with poor self-rated health, greater depressive symptoms, more medications, and obesity. 24% of the subjects who reported pain at one year did not report it the following year. 54% of those who had any pain at the first measurement had at least one year observed without pain. Factors associated with remission of any pain included increased age, male sex, better self-rated health, not being obese, taking fewer medications, and having fewer depressive symptoms. Conclusion: Musculoskeletal pain in older adults follows a dynamic trajectory, occurring commonly but remitting frequently. Pain does not seem to be an inevitable consequence of getting older, nor a fixed or progressive symptom.
FRAILTY AND FALLS, FRACTURE, AND DISABILITY: A MULTIPLE COUNTRY STUDY

S.E. Tom1, 2, A. Wyman, A.Z. LaCroix1. 1. Department of Preventive Medicine and Community Health, University of Texas Medical Branch, Galveston, Texas, 2. Group Health Research Institute, Seattle, Washington. 3. Center for Outcomes Research, University of Massachusetts Medical School, Worcester, Massachusetts, 4. Fred Hutchinson Cancer Research Center, Seattle, Washington

Background: We used a sample of women aged 55 years and over from Australia, Europe, and North America to test the hypothesis that women with increasing evidence of frailty would have greater risk of falls, fractures, and disability, compared to women who were not frail, across age. Methods: Components of frailty (slowness/weakness, poor endurance/exhaustion, physical activity, and unintentional weight loss) at baseline and report of falls, fracture, and disability at one year of follow-up were available for 48,636 women. Results: Among those aged <75 years, U.S. women were more likely to be prefrail and frail than women from Australia, Canada, and Europe. The distribution of frailty was similar by region for women aged ≥75 years. Increased evidence of frailty was related to increased risk for each outcome for women aged <75 years, but risk patterns were less consistent for women aged ≥75 years. For example among women aged <65 years, frail women (OR: 1.52; 95% CI: 1.36, 1.69) and prefrail women (OR: 1.09; 95% CI: 1.01, 1.18) had a greater risk of falling than nonfrail women, with attenuated risks for women aged 65 – 74 years. However, in the age group ≥75 years, only frail women had increased risk for falls (OR: 1.11; 95% CI: 0.99, 1.24). Results did not vary by geographic region. Conclusions: Increased evidence of frailty is associated with increased risk for falls, fracture, and disability among women aged ≥55 years in ten countries. Associations were less consistent among oldest women.

ACCURACY OF SELF-REPORT OF PHYSICIAN DIAGNOSIS FOR ASCERTAINING CHRONIC OBSTRUCTIVE PULMONARY DISEASE IN CLINICAL RESEARCH STUDIES OF OLDER ADULTS

S.S. Chang1, C.A. Fragozo1, S. Chen1, G. McAway1, T.M. Gill1, 2. Geriatrics/Internal Medicine, Yale School of Medicine, New Haven, Connecticut, 2. Yale School of Public Health, New Haven, Connecticut

Background: Accuracy in ascertaining chronic obstructive pulmonary disease (COPD) in older adults is essential to establishing validity in clinical research and informing the translation of significant findings into clinical practice. Self-report of physician diagnosis is often used to identify COPD in research studies. However, the accuracy of this measure for ascertaining COPD in older adults remains unclear. Methods: Baseline data were from the Cardiovascular Health Study, a prospective cohort of community-dwelling adults aged ≥65 (N=3248). Self-report of physician-diagnosed COPD was obtained by questionnaire. Spirometric criteria for airflow limitation, the physiologic hallmark of COPD, served as the reference to establish COPD, using the Lung Research Society of America criteria. The Lambda-Mu-Sigma method, an approach which accounts for age-related changes in lung function. Participants with asthma and a spirometric restrictive-pattern were excluded. Accuracy of self-report in identifying COPD was determined by calculating the sensitivity, specificity, predictive values, and likelihood ratios (LRs). Results: The prevalence of COPD ascertained by self-report was 7.3% (N=237) and by spirometry was 15.3% (N=496). Self-report of physician-diagnosed COPD was associated with a sensitivity of 21.2% (95%CI, 17.7-25.0%), specificity of 95.2% (95%CI, 94.3-96.0%), positive predictive value of 44.3% (95%CI, 37.9-50.9%), and negative predictive value of 87% (95%CI, 85.8-88.2%). The likelihood that self-report accurately identified COPD status was fair-to-good if positive (LR+, 4.4; 95%CI, 3.5-5.6) and poor if negative (LR− , 0.83; 95%CI, 0.79-0.87). Conclusions: Self-report of physician diagnosis fails to capture COPD adequately in older adults, which could lead to inaccurate inferences of research findings. To enhance accuracy, COPD ascertainment should be guided by spirometric criteria.

MIDLIFE JOB STRAIN AS A DETERMINANT OF MORTALITY – A 28-YEAR PROSPECTIVE FOLLOW-UP

Objectives: The aim was to investigate the association of psychological job strain in midlife with total mortality and mortality after the age of 65 years. Methods In 1981, psychological job strain was assessed for 5733 people aged 44 to 58 years. Psychological job strain was categorized as: low demands, low control (passive job); low demands, high control (low strain); high demands low control (high strain) and high demands, high control (active job). Death dates were followed up for 28 years from the Finnish National Population Register. Results 1838 (32.1%) participants died, and of them 1408 died aged 65 years or over. Compared to the men with low job strain, men in passive jobs (Relative Risk, RR, 1.41, 95% CI 1.20-1.66), men in jobs with high job strain (RR 1.39, 95% CI 1.19-1.63) and men in active jobs (RR 1.28, 95% CI 1.07-1.52) had higher age-adjusted risk of death. Adjusting for socioeconomic, lifestyle and chronic diseases attenuated the risks but did not completely explain the higher mortality risk of men with passive jobs (RR 1.20, 95% CI 1.01-1.43). Limiting analyses to deaths that took place after age 65 showed an increased adjusted mortality risk among those with high job strain (RR 1.24, 95% CI 1.00-1.52) but not among those with passive or active jobs compared to those with low job strain. No associations were observed among women. Conclusion Psychological work strain in midlife influences early deaths differently from deaths after the age of 65 years and over.

SABE STUDY: HEALTH, WELLNESS AND AGING IN COLIMA, MEXICO

Introduction: PAHO promotes the SABE Study (1997) in Latin America in order to understand the nature and magnitude of health and social care problems of elderly, and make public policy to produce acceptable levels of welfare. It has been recently conducted in the State of Colima. Methods: Cross-sectional, multi-stage, random, and proportional study, participants n=1,222 community-dwelling elders 60 and older. Using SABE-survey data were collected: socio-demographic characteristics, economic status, employment and housing, chronic diseases, nutritional status, oral health, access to health services and medication use, anthropometric measurements, functionality, blood pressure, as well as glucose, cholesterol and triglycerides measurements. Data were captured simultaneously by using minicomputers. Analysis was performed on SPSS program. Results: Mean age was 72.16±8.52, 62% women, 16.3% illiterate. Living alone 15.2%, satisfied with their family 94.9%. Most (94.3%) have been married in his life, currently only 61.1%. Religion is important for 85.2%, most of the catholic (92.5%). Cognitive impairment was found in 17.5%. The perception of health was good to excellent in 32.7% and poor in 15.1%. The most frequent diseases were: hypertension 49.2%, diabetes mellitus 28.3%, and arthritsis 17.2%. It was found urinary incontinence in 20.6% and fecal 5.6%. During the last year 35.2% has suffered falls. 57.3% have lost half of their teeth, 56.3% use full or partial denture, only 4.9% keeps your teeth intact. Conclusion: The results show social and health implications as well as the need of better health services for aging. They pose several challenges at governmental, social, community and family level.
INFLAMMATION AND COGNITIVE TEST PERFORMANCE IN THE BEAVER DAM OFFSPRING STUDY

M.A. Wichmann1, K.J. Cruickshanks1, B.E. Klein1, R. Klein1, M.E. Fischer1, J.S. Pankow2, C.R. Schubert3, J. University of Wisconsin School of Medicine and Public Health, Madison, Wisconsin, 2. University of Minnesota, Minneapolis, Minnesota

Our goal was to determine if markers of inflammation and endothelial dysfunction were cross-sectionally associated with cognitive test performance in a middle-aged cohort. Beaver Dam Offspring Study participants (n=3285) with data on either serum interleukin-6 (IL-6) or intracellular adhesion molecule (ICAM-1), and at least one cognitive test, Trail Making Test A (TMTA), Trail Making Test B (TMTB) or Grooved Pegboard test (GPB), were included (n=2700, mean age = 49 years). Associations were analyzed using linear regression. Adjusted for age, sex, and education, neither IL-6 nor ICAM-1 was associated with TMTA. Those with higher levels of IL-6 took longer to complete the other cognitive tests (3rd vs. 1st tertile difference, TMTB: 3.5s, p=0.02; GPB: 4.4s, p<0.001). Similarly, those in ICAM-1 tertile 3 took longer (vs. t1, TMTB: 3.7s, p=0.01; GPB: 2.7s, p=0.007). The associations were attenuated and no longer statistically significant in models adjusting for additional potential confounders (for IL-6 - TMTB: sedentary lifestyle, diabetes; for ICAM-1 - TMTB: sedentary lifestyle, diabetes, alcohol use in past year; for IL-6 - GPB: waist circumference, diabetes, arthritis; for ICAM-1 - GPB: waist circumference, diabetes, and alcohol intake level). In this middle-aged cohort, inflammatory and endothelial dysfunction markers were associated with cognitive test performance in models adjusted for socio-demographic factors. Further adjustment for potential confounding factors diminished the associations to a non-significant level, but it is unclear whether some factors may also be in the causal pathway. Longitudinal studies are needed to investigate these relationships.

IN THE BEAVER DAM OFFSPRING STUDY

INFLAMMATION AND COGNITIVE TEST PERFORMANCE

should be evaluated in longitudinal studies.

by less recommended cardiovascular drug therapy than nonagenarians and octogenarians. Whether this reflects an age or cohort effect should be evaluated in longitudinal studies.

FINANCIAL STRAIN IS ASSOCIATED WITH INCREASED OXIDATIVE STRESS: THE WOMEN’S HEALTH AND AGING STUDIES

P.Palta1, S.L. Szamoner2, R. Sembra1, R. Thorpe1, R. Varadhan1, L.P. Fried4, I. Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland, 2. Johns Hopkins University School of Nursing, Baltimore, Maryland, 3. Johns Hopkins University School of Medicine, Baltimore, Maryland, 4. Columbia University Mailman School of Public Health, New York, New York

Elevated oxidative stress levels may be one underlying biological mechanism that contributes to poor health outcomes, including atherosclerosis and diabetes. Financial strain in adulthood is consistently associated with poor health. High oxidative stress and financial strain are each predictors of morbidity and mortality, but little research has investigated their relationship. This study investigated whether financial strain was associated with elevated oxidative stress levels. A cross-sectional analysis was conducted on 728 community-dwelling older women from the Women’s Health and Aging Studies I and II at the baseline visit. Linear regression was performed to quantify the relationship between financial strain and oxidative stress. Financial strain was measured as three-level ordinal response to: “At the end of the month, do you have more than enough money left over, just enough, or not enough?” Oxidative stress was measured using protein carbonyl concentrations obtained from serum samples. Those who reported high financial strain exhibited 14.6% higher protein carbonyl concentrations compared to individuals who reported low financial strain (p = 0.002). Findings show that high financial strain among community-dwelling older women may be associated with increased oxidative stress, suggesting that oxidative stress could mediate the associations between financial strain and poor health outcomes. These results are of critical importance because individuals from lower SES backgrounds consistently exhibit poorer health outcomes.

THE EFFECT OF CHRONIC DISEASES ON SURVIVAL AFTER LIFE EXPECTANCY

D. Rizzuto1, A. Marengoni1,2, R. Bellocco3,4, C. Qu1, L. Fratiglioni1,4, 1. Karolinska Institutet, Aging Research Center, Department of Neurobiology, Health Care Sciences and Society, Stockholm, Sweden, 2. University of Brescia, Department of Medical and Surgery Sciences, Brescia, Italy, 3. University of Milano-Bicocca, Department of Statistics, Milan, Italy, 4. Stockholm Gerontology Research Center, Stockholm, Sweden, 5. Karolinska Institutet, Department of Medical Epidemiology and Biostatistics, Stockholm, Sweden

Aims: To determine the impact of chronic diseases on survival and mortality in community-dwelling older persons. Methods: 1099 subjects aged 78 years and older enrolled in the Kungsholmen Project, Sweden, were evaluated. The impact of most common chronic diseases, grouped to ICD-9, on survival was evaluated using two measures: years lived after disease diagnosis (YLD) and potential years of life lost due to the disease (PYLL). The impact of chronic morbidity on all-cause mortality was estimated during both a short period (less than 2 years of follow-up) and a long period (between 2 and 6 years of follow-up). Data were analyzed using Cox and Laplace regression models stratified by age groups (78-87 and 88+ years). Results: Short-term mortality was mostly affected by malignancy, CVD and urological disorders, whereas in the long-term, neuropsychiatric disorders emerged as relevant as CVD and malignancy. Chronic diseases were differently related to YLD and PYLL, but in general in both the youngest and oldest age group most of the chronic disorders were associated with a long survival after diagnosis, with the exception of cancer and renal failure where the years lost due to these diseases exceeded the years lived with the disease Cancer and urological disorders were the most malignant with approximately 4 PYLL, followed by mental, respiratory, and blood disease with 2.5 PYLL in the youngest-age group. After age 88, the effect of all chronic

64th Annual Scientific Meeting 485

Downloaded from https://academic.oup.com/gerontologist/article-abstract/51/suppl_2/1/646194 on 30 April 2018
conditions on life expectancy was weak, except for malignancy, urological, and digestive diseases. Conclusions: In spite of the lethality of some disorders such as malignancy and renal failure, most chronic diseases lead to long survival after diagnosis even after age 75, which stresses the relevance of further investigation concerning the individual life quality and related health care needs.

**ASSOCIATION OF ESTIMATED GLOMERULAR FILTRATION RATE WITH COGNITIVE PERFORMANCE AND GAIT SPEED IN OLDER ADULTS**

W. Akhtar1,2, J. Guralnik1, K. Patel1, J. Laboratory of Epidemiology, Demography and Biometry, National Institute on Aging, National Institutes of Health, Bethesda, Maryland, 2. Department of Epidemiology, University of Florida, Gainesville, Florida

Background: Chronic kidney disease (CKD) increases with advancing age and is associated with increased risk for cardiovascular disease and mortality in older adults. However, the functional consequences of CKD are not well characterized. The purpose of this study is to assess the association of renal function with cognitive performance and gait speed in adults aged 60 and over. Methods: Data on 2,986 participants of the 1999-2002 National Health and Nutrition Examination Survey were analyzed. Estimated glomerular filtration rate (eGFR) was calculated using the CKD Epidemiology Collaboration equation. Cognitive performance was assessed with the Digit Symbol Substitution Test (DSST), while usual gait speed was assessed over a 20 foot distance. Multiple linear regression models were used to assess the association of CKD with gait speed and cognitive function. Results: Reduced eGFR was associated with decreased performance on the DSST (p for trend across eGFR categories= 0.017), independent of several potential confounders, including diabetes, hypertension, and cardiovascular diseases. Reduced eGFR was also associated with decreased gait speed adjusting for demographic factors (p=0.003). This effect was attenuated after further adjusting for DSST (p=0.048) and was eliminated when adjusting for diabetes and hypertension (p=0.349). Conclusions: In this nationally representative sample of older adults, reduced renal function was associated with decreased cognitive performance, which likely reflects a common pathogenesis. However, renal function was not independently associated with gait speed. Chronic kidney disease might lie in the causal pathway from diabetes and hypertension to decreased physical performance, but further research, particularly longitudinal studies, is needed.

**MULTIDIMENSIONAL HEALTH TRANSITIONS IN AGING PROCESS**

W. Chang1, S. Wu1, F. Lu1,2. 1. Institute of Health Policy and Management, National Taiwan University, Taipei City, Taiwan, 2. Department of Geriatrics and Gerontology, National Taiwan University Hospital, Taipei City, Taiwan

Background: Previous studies have provided considerable knowledge about health transition among older adults, but mostly focused on a single dimension. This study aimed to investigate the characteristics of multi-dimension and heterogeneity of health changes in aging process by applying latent transition analysis (LTA). Methods: Data analyzed was from a national-wide, representative Taiwanese sample of 2,756 people aged 50 years or older in 1996 who were surveyed in 1996, 1999, 2003, and 2007. We used LTA to identify health status subgroups and probabilities of membership and transitions. Three indicators, including comorbidity, frailty, and ADLs-disability, were used to measure the latent health status. Sex, age in 1996, education, social engagement, and fall experience were covariates predicting health status transition. Results: We identified five types of health status among the middle- and old-aged Taiwanese, including Healthy, Comorbid, Prefrail, Comorbid-prefrail, and Comorbid-frail-disable, with baseline membership probabilities of 32.88%, 22.89%, 26.39%, 16.23%, and 1.61%, respectively. After adjusting for the other covariates, compared to staying in the same status between two time-points, being male, higher education, and social engagement were associated with lower probabilities of deteriorating transitions, i.e. from Healthy to Comorbid or Prefrail, or from Comorbid-prefrail to Comorbid-prefrail-disable, and higher probabilities of improving transition, i.e. from Comorbid-prefrail to Comorbid. Having fall experience was associated with higher risk of deterioration. Conclusions: By applying LTA, we manifested the heterogeneity and qualitative health transitions with multi-dimension in aging process, and found some covariates relating to transitions. The findings could help to achieve the goal of healthy aging.

**IMPACT OF SELF-RATED HEALTH ON ALL-CAUSE MORTALITY AND MEDICAL AND CARE COSTS IN OLDER JAPANESE**

H. Yoshida, Y. Fujiiwara, M. Nishi, T. Fukaya, H. Murayama, M. Kim, S. Shinkai, Tokyo Metropolitan Institute of Gerontology, Tokyo, Japan

This study examined the impact of self-rated health (SRH), which was categorized as very good, good, fair, and poor, on all-cause mortality and medical and long-term care expenditures in older Japanese. The subjects were those aged ≥70 years (n=1,039) who responded to the baseline survey conducted in 2001 in Kusatsu, Gunna, Japan. We followed-up 916 individuals (88.2%) for 4 years. 137 subjects (15.0%) died during the 4-year follow-up period. Among 872 subjects except for those who moved, 210 subjects (24.1%) with fair/poor SRH were divided into a poor SRH group, while 662 subjects (75.9%) with very good/good SRH were divided into a good SRH group. We compared period to the death, accumulated medical and long-term care expenditures between the two groups during the 4-year follow-up period. Cox proportional hazard model was used to examine the association between baseline SRH and all-cause mortality after adjustment for age, gender, and generic mobility scale. The relative hazard ratio (HR) of all-cause mortality was higher for those in the poor group than in the good group (HR=1.69, 95% CI: 1.14-2.51, P=0.009). The mean expenditures per capita for the accumulated medical and long-term care during 4-year follow-up period were 3.4 million yen and 1.1 million yen, respectively in the poor group, while those in the good group were 1.7 million yen and 4.5 hundred thousand yen, respectively. SRH in older Japanese was not only a significant predictor for adverse health outcomes, but it had a strong impact on the future medical and long-term care expenditures.

**TRANSFER OUT OF REGION PRIOR TO DEATH IN RURAL AREAS**

P. St. John1,2, V. Menec2, S. Nowicki2. 1. Section of Geriatric Medicine, University of Manitoba, Winnipeg, Manitoba, Canada, 2. Centre on Aging, University of Manitoba, Winnipeg, Manitoba, Canada

Objective: To determine factors which predict hospitalization in a different region from residence, prior to death. Setting: Rural regions of the Canadian province of Manitoba. Methods: Administrative data for community-dwelling residents of rural regions over the age of 65 who died between April 2003 and April 2006 were used. The outcomes were hospitalization outside the region of residence or hospitalization in the 180 days preceding death. Predictor variables were age, gender, marital status, income, region of residence, cause of death, hospital beds/1000 population of the region, physicians/1000 population of the region, and having had surgery. Results: There were 5550 persons who died, of those 79.0% were hospitalized during their last 180 days of life. For those hospitalized during their last 180 days of life, 79.8% were hospitalized in their region of residence. There were 3263 people who died in hospital (i.e. hospitalized on their day of death), and of those 79.2% died in their region of residence. After adjusting for other factors, the odds of hospitalization increased with increasing bed ratios (Adjusted Odds Ratio (AOR) 1.29 [1.11,1.49]). However, the odds of being hospitalized out-of-region decreased with increasing bed ratios (AOR 0.79 [0.67,0.93]). Increasing physician ratios were not associated with hospitalization, but the odds of being hospitalized out-or-
region decreased with increasing physician ratios (AOR 0.12[0.05,0.29]). Conclusions: Rural older adults who died were more likely to be hospitalized in their own region if they resided in a region with more hospital beds and more physicians in their region.

THE OUTCOME AT DISCHARGE IS RELATED TO THE CLINICAL AND FUNCTIONAL CHARACTERISTICS AT ADMISSION IN A POPULATION OF ORTHOPEDIC PATIENTS

P. Mazzola¹, G. Belledi¹, M. Corsi¹, P. Baccella¹, G. Castoldi¹, G. Zatì¹, G. Ammon¹. 1. University of Milano-Bicocca, Geriatric Clinic, Monza, Italy, 2. Geriatric Research Group, Brescia, Italy, 3. University of Milano-Bicocca, Orthopedic Clinic, Monza, Italy

Background and aim: in the last years orthogeriatric management has become a consolidated approach for the hip fracture care in the elderly. The aim of our study is to evaluate the outcomes at discharge in a population of older patients admitted to the Orthogeriatric Section (OGS) of the Geriatric Clinic at San Gerardo University Hospital – Monza, with a diagnosis of proximal femur fracture (PFF). Materials and methods: patients consecutively discharged from the OGS in the period March 2007-December 2010 with PFF have been considered. Baseline characteristics, time of management, occurrence of complications, and outcome at discharge (return to living home, transfer to rehabilitation facilities, institutionalization, death) have been registered. Statistical analysis has been performed with PASW Statistics 18. Results: patients have been divided in two groups according to the outcome at discharge: those transferred to rehabilitation facilities (group 1), and those returned home because not eligible for rehabilitation, discharged to nursing home, or deceased (group 2). Patients in the group 2 were significantly older, more frequently dependent in function and demented before PFF, had more postoperative complications and a longer length of stay than their counterpart. The persistence of delirium was associated with poor outcomes (i.e. the longer the duration the poorer the outcome). Conclusion: the outcome at discharge is affected by both patient’s baseline characteristics (in particular functional dependence and pre-existing diagnosis of dementia) and time of management (in particular the time from admission to operation). Furthermore, delirium incidence and its persistence were associated to the worst outcome.

THE ASSOCIATION BETWEEN HEALTHY EATING INDEX-2005 SCORES AND DISABILITY AMONG OLDER AMERICANS

B. Xu¹, D.K. Houston², J.L. Locher³, D. Buys¹, C. Zizza¹. 1. Auburn University, Auburn, Alabama, 2. Wake Forest University School of Medicine, Winston-Salem, North Carolina, 3. University of Alabama at Birmingham, Birmingham, Alabama

Nutritional status is vital to older adults’ physical health and may prevent the onset of disability. The purpose of this study was to examine the association between overall dietary quality and self-reported disability among a nationally representative sample of Americans aged 60 and older. Cross-sectional data obtained from the 1999-2004 National Health and Nutrition Examination Survey (NHANES) were used. Overall dietary quality was assessed using the United States Department of Agriculture’s (USDA) Healthy Eating Index-2005 (HEI-2005). Self-reported measures of disability included activities of daily living (ADLs), instrumental activities of daily living (IADLs), leisure and social activities (LSAs), lower extremity mobility (LEM), and general physical activities (GPAs). Multiple logistic models were used to examine the association between HEI-2005 scores and self-reported measures of disability. Older adults with higher HEI-2005 scores were less likely to experience LEM (p for trend < 0.001) and GPAs (p for trend < 0.001) disability. Compared to older adults whose HEI-2005 scores were in the lowest quartile, the likelihood of both LEM and GPA disability were significantly lower in individuals whose scores were in quartiles two, three, and four. Compared to those who had HEI-2005 scores in the lowest quartile, the odds of IADLs disability were significantly lower in older adults whose scores were in quartile two and three. Older adults who do not adhere to the 2005 Dietary Guidelines for Americans report disability more frequently than those who do adhere to the guidelines.

SESSION 1735 (POSTER)

NEUROSCIENCE, PHYSIOLOGY, IMMUNOLOGY

AGE-ASSOCIATED CHANGES IN THE EFFECTS OF DUAL TASKING ON THE BILATERAL COORDINATION OF GAIT

M. Plotnik¹,², A. Jacobs¹, M. Brozgol¹, N. Giladi¹,², J. Hausdorff¹,²,³, 1. Tel Aviv Sourasky Medical Center, Tel Aviv, Israel, 2. Tel Aviv University, Tel Aviv, Israel, 3. Harvard Medical School, Boston, Massachusetts

Background: While basic gait features generally remain intact with normal aging, bilateral coordination of gait (BCG) is reduced. Aims: To compare the effect of dual tasking (DT) on BCG in elderly and young subjects. Methods: 17 healthy elderly subjects (64.1 ± 2.5 y) and 14 healthy young adults (25.9 ± 2.5 y) wore force-sensitive insoles that measured the timing of each gait cycle during 2 min of usual and DT walking (serial 3s and 7s for the elderly and young, respectively). The stride duration of one foot, i.e., the gait cycle, was defined as 360°. The relative timing of contra-lateral heel-strikes defined the phase, φ (ideally, φ=180°). The sum of the coefficient of variation of φ and the mean absolute difference between φ and 180° defined the phase coordination index (PCI), representing variability and inaccuracy, respectively, in phase generation. Results: During usual-walking, mean PCI values (±SEM) were significantly higher (less coordination; p < 0.01) among the elderly (4.1 ± 1.0°), compared to the young subjects (3.2 ± 0.5°), but gait speed only tended to be slower (1.3±0.1 m/s and 1.4±0.1 m/s, respectively, 0.05 < p < 0.1). DT decreased gait speed in the young adults (p=0.007), but PCI was not affected by DT (p=0.524). Both parameters were compromised in the elderly during DT (p<0.01). Conclusions: DT compromised BCG only in the elderly subjects, even though they performed a relatively easier DT. Age-associated decline in attention and DT abilities apparently produces unstable supra-spinal control of the spinal neural mechanisms that mediate left-right stepping phasing.

MEMORY IMPROVEMENTS RESULTING FROM A SPATIAL MEMORY INTERVENTION PROGRAM IN HEALTHY ELDERLY

V. Bohbot¹, N. Anderson¹, R. Sham¹, K. Konishi¹, L. Dahmane¹, V. Kurdi¹, L. Bherer², 1. Douglas Mental Health University Institute, Department of Psychiatry, McGill University, Verdun, Quebec, Canada, 2. CRUUGM, Department of Psychology, University of Montreal, Montreal, Quebec, Canada

Cognitive deficits, including episodic and spatial memory dysfunction, have been observed in normal aging. These memory deficits in normal aging have been associated with decreased function of the hippocampus (HPC). Hence, one objective of the current research was to find intervention methods that will strengthen memory that is dependent on the HPC. Previous research in our laboratory demonstrated that healthy participants spontaneously use different strategies when navigating in a virtual environment. Magnetic Resonance Imaging studies showed that spatial memory strategies are specifically associated with increased activity and grey matter of the HPC. People using stimulus-response strategies, however, show increased activity and grey matter in the caudate nucleus. Consequently, we spent the last five years developing and validating a spatial memory intervention program (SMIP) that aims to stimulate the HPC with the extensive use of spatial memory strategies, taking particular attention to minimize the use of stimulus-response strategies. Twenty-eight healthy older adults (mean age = 65.44 ± 4.41) participated in this experiment and eleven (mean age = 65.7 ± 4.31) underwent the SMIP. Comparison of results from a battery of transfer tests, including virtual navigation tests balanced for version
DECREASES IN SPATIAL STRATEGIES ACROSS THE LIFE SPAN IN A VIRTUAL NAVIGATION TASK

V. Bobhol1, S. McKenzie1, R. Schachar2, M. Boivin1, P. Robaey1. 1. Douglas Mental Health University Institute, Department of Psychiatry, McGill University, Montreal, Quebec, Canada, 2. Hospital for Sick Children, Toronto, Ontario, Canada, 3. Dept. of Psychology, Laval University, Quebec, Quebec, Canada, 4. Department of Psychiatry, Ste-Justine Research Center, Montreal, Quebec, Canada

Anatomy of the human brain changes across the entire life span. Throughout childhood, there are changes in both function and size of numerous brain structures. During normal aging, decreases in memory and executive function are observed. Using a virtual maze (VM), we investigated navigational strategies in different age populations ranging from eight-year-old children to 80-year-old healthy older adults. One hundred and eighty-eight children (mean age: 8.0), 175 young adults (mean age: 25.1) and 112 older adults (mean age: 66.4) participated in this study. During navigation, spatial learners spontaneously use environmental landmarks in contrast to response learners who use a pattern or series of movements from certain stimuli. We found that 80.3% of children spontaneously used spatial memory strategies as opposed to response strategies. In young adults, a sharp decrease in the use of spatial strategies was observed, as 47.4% used spatial strategies in contrast to response strategies. Finally, older adults exhibited an even more pronounced decrease in spatial strategies (39.3%), and the remaining used response strategies. The chi-squared analysis yielded a significant difference in the use of spatial strategies across all age groups (χ2 = 64.49, p < 0.0001). Our results show that while the majority of children use spatial strategies, the proportion of people using spatial strategies continually decreases with age until senescence. These results have important implications for understanding factors involved in healthy and successful aging.

THE APOE ε4 GENOTYPE ACCELERATES TERMINAL DECLINE IN COGNITION IN THE OLDEST-OLD

M.A. Praetorius, V. Thorvaldsdon, L.B. Hassing, B. Johanssion, Department of psychology, University of Gothenburg, Gothenburg, Sweden

Several studies have been published recent years which states that differences in individual cognitive change in old age is associated with impending death. The relationship between individual cognitive change in old age and survival is however still unclear. Several issues need to be clarified. In the present study we investigated if the association between individual cognitive change and survival is mediated by differences in gene characteristics such as APOE genotype. Participants were 498 individuals aged 80+ from the longitudinal Swedish OCTO-Twin study, tested at five measurement occasions. Inter-individual differences in intra-individual change were analysed using multilevel modelling (MLM) which provides both overall growth estimates for the entire sample as well as individual and within-pair variation in growth. The results showed that APOE was significantly related to differential patterns of terminal decline in all tests measuring long-term memory (semantic and episodic memory). There were non significant similar trends in almost all other tests. APOE ε4 genotype carriers had a steeper survival related decline than the other genotype carriers. The results indicate that APOE is not just the most important biological marker for developing Alzheimer’s disease. It plays, in a for dementia controlled sample, a significant role for survival related differences in cognitive change.

SPATIAL MEMORY INTERVENTION PROGRAM IMPROVES MEMORY IN PATIENTS WITH MILD COGNITIVE IMPAIRMENT

R. Shami1, V. Nair2, H. Chertkow3, S. Gauthier1, V. Kuri1, L. Bherer2, V. Bobhol1, 1. Douglas Mental Health University Institute, Department of Psychiatry, McGill University, Montreal, Quebec, Canada, 2. CRUIGM, Department of Psychology, University of Montreal, Montreal, Quebec, Canada, 3. Jewish General Hospital, Department of Neurology and Neurosurgery, McGill University, Montreal, Quebec, Canada

Atrophy of the hippocampus (HPC) has been observed in patients with Mild Cognitive Impairment (MCI) and has been shown to be a predictor of conversion to Alzheimer’s disease (AD). Hence, it is important to find methods that can delay the onset of dementia among people who are at a high risk of developing AD. Previous research in our laboratory has shown that healthy participants spontaneously use different strategies when navigating in a virtual environment. More specifically, the use of spatial memory strategies has been found to be associated with increased activity and grey matter in the caudate nucleus. Since AD affects the function and volume of the HPC, we developed a computerized spatial memory intervention program (SMIP) to specifically stimulate this region. Participants with MCI (N = 3, mean age = 71 ± 0.60), before intervention, showed severe spatial memory impairments on transfer tests which include several virtual navigation tasks. After the SMIP, significant spatial memory improvements were observed in these individuals. Subjective reports furthermore indicated a renewed sense of hope as participants witnessed their improvement on the spatial memory tests. Though these results are preliminary, they are promising and suggest the effectiveness of SMIP at reducing symptoms associated with MCI.

A SPATIAL MEMORY INTERVENTION PROGRAM INCREASES GREY MATTER IN THE HIPPOCAMPUSS AND NEOCORTEX

K. Konishi1, V. Kuri1, L. Dahmani1, R. Shami1, N. Anderson1, L. Bherer2, V. Bobhol1, 1. Douglas Mental Health University Institute, Department of Psychiatry, McGill University, Montreal, Quebec, Canada, 2. CRUIGM, Department of Psychology, University of Montreal, Montreal, Quebec, Canada

Atrophy in the hippocampus has been associated with normal aging and is responsible for many cognitive deficits such as memory impairments. It is therefore of great interest to prevent degeneration of the hippocampus and to increase hippocampal grey matter in the aging population. Previous research in our laboratory demonstrated that healthy participants spontaneously use different strategies when navigating in a virtual environment. The use of spatial memory strategies, which involve building relationships between landmarks, has been shown to be associated with increased activity and grey matter in the hippocampus. In contrast, individuals who use stimulus-response strategies, which involve following a pattern or a series of movements to certain stimuli, show increased activity and grey matter in the caudate nucleus. Consequently, over a period of five years, a spatial memory intervention program (SMIP) that aims to stimulate the hippocampus was developed and validated. This program maximizes the use of spatial memory strategies and minimizes the use of stimulus-response strategies. Structural Magnetic Resonance Imaging on seven healthy older adult participants (mean age = 66.86 ± 4.3) administered before and after the SMIP showed grey matter increases in a number of regions of the brain including the hippocampus (t = 1.64; x = -29.0, y = -21.8, z = -19.9) and neocortex. These results suggest that spatial memory intervention can lead to
increases in grey matter in a network of regions known to be involved in Alzheimer’s disease.

**INCREASED ACTIVITY IN THE HIPPOCAMPUS AFTER A SPATIAL MEMORY INTERVENTION PROGRAM**
L. Dahanani, K. Konishi, V. Kurdi, R. Sham, N. Anderson, L. Bherer, V. Bohbot, Douglas Mental Health University Institute, Department of Psychiatry, McGill University, Montreal, Quebec, Canada

Cognitive deficits that arise during the normal aging process are associated with deterioration of the hippocampus and a decline in hippocampal activity. It is therefore of interest to develop interventions for the aging population that will restore function and increase grey matter in the hippocampus. Previous studies in our laboratory have uncovered how people use different strategies to navigate virtual worlds. Individuals who rely on spatial memory strategies, which involve the formation of cognitive or “mental” maps of an environment, show greater activity and grey matter in the hippocampus. Conversely, individuals who rely on stimulus-response strategies, which involve the construction of a pattern of movements around a given stimulus, exhibit increased activity and grey matter in the caudate nucleus. Over the last five years, we have created and validated a spatial memory intervention program (SMIP) which promotes the use of spatial memory to stimulate the hippocampus while specifically discouraging the use of stimulus-response strategies. Nine participants (mean age = 65.89 ± 4.7) underwent functional Magnetic Resonance Imaging before and after the SMIP. Results showed a significant increase in activity of the hippocampus (t = 3.47, p < 0.005, uncorrected) while participants were engaged in a virtual navigation task. Furthermore, increased activity in the hippocampus from pre- to post-SMIP correlated with the spatial memory improvement that was specific to each participant (t = 3.24, p < 0.01, uncorrected). These results show that spatial memory intervention can have a significant impact on restoring the lost function of the hippocampus associated with normal aging.

**FMRI ACTIVITY IN THE HIPPOCAMPUS OF OLDER ADULTS CORRELATES WITH SPATIAL STRATEGY USE DURING VIRTUAL NAVIGATION TASK**
K. Konishi, S. Roy, N. Etchamendy, N. Rajah, V. Bohbot, Douglas Mental Health University Institute, McGill University, Montreal, Quebec, Canada

Navigation in a virtual maze relies on spatial or response strategies. Spatial strategies involve using environmental landmarks while response strategies involve forming a pattern or series of movements from certain stimuli. Using functional Magnetic Resonance Imaging (fMRI), we have previously shown that younger adults who use spatial memory strategies have increased activity in the hippocampus, whereas response strategies are associated with activity in the caudate nucleus. This study was undertaken to examine the effects of aging on navigational strategies and brain function. Healthy participants (N=53) were tested on a virtual maze task in a 1.5 T fMRI scanner; 23 young adults (mean age: 24.2) and 30 older adults (mean age: 64.7). Young adults who were previously shown to favor the spontaneous use of spatial strategies, had fMRI activity in the hippocampus. On the other hand, older adults who were previously shown to predominantly use response strategies, had caudate nucleus activity. Interestingly, the older participants who used a spatial strategy to learn the task, similar to young adults, also had activity in the hippocampus. These findings suggest that the aging process involves a shift from hippocampal-dependent spatial strategies towards caudate nucleus-dependent response strategies. This reduced use of hippocampal-dependent spatial strategies may lead to hippocampal atrophy, which is a risk factor for cognitive deficits in normal aging and Alzheimer’s disease. Conversely, increased use of spatial strategies may be associated with a healthy hippocampus and successful aging.

**GREY MATTER IN THE HIPPOCAMPUS CORRELATES WITH SPATIAL STRATEGIES IN OLDER ADULTS ENGAGED IN VIRTUAL NAVIGATION**
R. Sham, K. Konishi, V. Bohbot, Douglas Mental Health University Institute, McGill University, Montreal, Quebec, Canada

Healthy young adults spontaneously use different strategies when navigating in a virtual maze. Spatial strategies involve using environmental landmarks while response strategies involve forming a pattern or series of movements from certain stimuli. Functional Magnetic Resonance Imaging (fMRI) and structural Magnetic Resonance Imaging (sMRI) studies previously confirmed that people who use spatial memory strategies show increased hippocampal activity and grey matter, whereas response strategies are associated with increased caudate nucleus activity and grey matter. A growing number of studies report that cognitive decline with normal aging is associated with a decrease in hippocampal volume. Consequently, we asked whether spatial strategies in aging are associated with greater grey matter volume in the hippocampus, as found in our previous study with young healthy participants. Thirty-one healthy adults (mean age: 64.5) were tested on a virtual navigation task. Using Voxel Based Morphometry, we regressed MRIs against performance on the navigation task and found a significant correlation in the right hippocampus (t = 3.55, x = 37.0, y = -30.8, z = -11.4, p < 0.05). Reports in the literature indicate that significant reduction in the volume of the hippocampus is associated with cognitive deficits in normal aging. Furthermore, a decrease in hippocampal volume is a risk factor for dementia. Our results show that older participants who use spatial strategies when navigating have greater amounts of grey matter in the hippocampus. This suggests that using spatial memory in our everyday lives may increase hippocampal grey matter and healthy and successful aging.

**SPATIAL STRATEGIES IN HEALTHY AGING ARE ASSOCIATED WITH LOWER RISKS OF DEMENTIA ASSESSED WITH THE MOCA**
F. Dossa, S. McKenzie, N. Etchamendy, V. Bohbot, Douglas Mental Health University Institute, McGill University, Montreal, Quebec, Canada

Navigation in a virtual maze relies on using either a spatial or response strategy. Spatial strategies involve using environmental landmarks while response strategies involve forming a pattern or series of movements from certain stimuli. Previous research has revealed a link between the use of spatial strategies and increased hippocampal function and grey matter, the latter of which reduces risks of developing dementia. This study investigated navigational strategies in older adults and whether spatial strategies are associated with better overall cognition as measured with the Montreal Cognitive Assessment (MoCA), a standard neuropsychological test sensitive to dementia. Forty-five healthy young adults (mean age: 24.9) and 112 older adults (mean age: 66.4) were administered two virtual maze tasks that assess navigational strategies. A higher proportion of older adults used a response strategy relative to young adults. Similarly, older adults had impaired performance compared to young adults. A correlation analysis in older adults showed a negative correlation between age and strategy, suggesting that as people age, they are more likely to use a response strategy. Importantly, performance also correlated with MoCA scores (r = -0.214), indicating that older adults engaging spatial strategies have better overall cognition. These results provide evidence that as people age, they are more likely to use response strategies and that these response strategies are associated with poorer MoCA scores and higher risks of dementia. This study indicates that individuals who are able to maintain spatial strategies have better overall cognition.
ASSOCIATION BETWEEN MICROBIAL TRANSLLOCATION AND ADIPOSITY IN HEALTHY ELDERLY ADULTS
J.R. Stohle, B. Nicklas, S.B. Kritchevsky, D.W. Kitzman, X. Leng, K. High, Wake Forest University Baptist Medical Center, Winston-Salem, North Carolina

Background: Microbial translocation (MT), systemic exposure of microbes/microbial products without overt bacteremia, may be pronounced with age. MT is indicated by blood levels of microbial products (lipopolysaccharide, LPS) and responsive host proteins (soluble CD14, sCD14; LPS binding protein, LBP). MT induces inflammation, however links between MT and age-related changes in inflammation, adiposity, and physical function is unexplored. Design: We assessed gender-adjusted cross-sectional relationships between two biomarkers of MT (sCD14, LBP) and adiposity, physical function (short physical performance battery, SPPB) and common biomarkers of inflammation (CRP, IL6, TNFα, TNFα receptor I[TNFαR1]) in 61 older (60-89 yrs) healthy men and women (no evidence of acute or chronic illness). Pearson correlation coefficients are presented. Results: SPPB scores were inversely correlated with both LBP (-0.42; p=0.002) and sCD14 (-0.33, p=0.01) indicating lower physical function is associated with higher MT. In addition, sCD14 (0.350, p=0.009) and LBP (0.246, p=0.07) correlated positively with percent body fat measured by DEXA. The MT markers correlated (0.27, p=0.05) indicating they may be responsive to similar initiators. sCD14 correlated with three inflammatory MT markers correlated (0.27, p=0.05) indicating they may be responsive to similar initiators. sCD14 correlated with three inflammatory markers: TNFα (p=0.09) and TNFαR1 (p≤0.08), and IL-6 (p=0.08) and TNFαR1 (p≤0.08), and IL-6 (p=0.08) and IL1β (p=0.09), and CRP (p=0.007) indicating MT is related to chronic inflammation. LBP showed the strongest association with age (p=0.13) among the markers in this older (>60yrs) age group. Conclusion: MT markers correlate with important phenotypes associated with aging (physical function, percent body fat, and inflammation). These data provide evidence supporting a mechanistic link between MT, adiposity, and age-related loss of function.

THE ROLE OF MEMORY T-CELL SUBSET SECRETED CYTOKINES ON INFLUENZA CYTOTOXIC CD8+ T CELLS

The age-related decline in cytolytic activity has been mainly described in CD8+ T cells, with relative sparing of CD4+ T cells. We show that effector memory (CD45RA-CCR7-) and efferctor (CD45RA+CCR7-) CD8+ T-cell subsets in older compared to young adult PBMC responding to influenza A/H3N2 challenge have limited cytolytic activity against influenza-infected autologous targets. We also identified CD45RA+CCR7-CD127+CD25+GranzB+Perfor+ virus-specific T-cell subset in CD8+ T cells which plays a critical cytolytic role in the response to influenza virus post-vaccination. Furthermore, we show there is a decline in IL-2 secretion but enhanced IL-6 levels in influenza-stimulated PBMCs in vaccinated healthy older compared to vaccinated young adults. Further, recombinant IL-2 and IL-6 can help naïve CD8+ T cells differentiate into effector memory and effector T cell phenotypes. We successfully used effector memory IL-2- and IL-6-producing T cells to enhance the proliferation and cytotoxicity of the CD8+CD45RA+CCR7- effector T-cell subset in healthy older adults post-vaccination.

MRSA SCREENING ON ADMISSION IN A GERMAN GERIATRIC CLINIC
K. Hager, M. Parsel, V. Grosse, M. Brecht, Clinic for Medical Rehabilitation and Geriatrics, Hanover, Germany

Background: Patients with a colonization or even an infection with methicillin resistant staphylococcus aureus (MRSA) are found more often in a geriatric population and hence in geriatric units. Colonization with MRSA may lead to severe infections or even bacteremias. Objective: To better protect those not yet colonized as well as those already carrying MRSA a screening was done on admission to a German geriatric clinic. Patients and Methods: From January to June 2008 from all patients admitted to the clinic a swab from mouth and nose was taken. In the further course of treatment another microbiological culture was done only in case of an infection. Results: 33 of 771 patients had a MRSA detected either on admission or in the course of the treatment. 4.3% of patients had a MRSA detected in the first 48 hours, so that it was assumed that they imported the bacterium into the clinic. In 91% this was not known or was not communicated. 27% of the patients with a MRSA were detected after 48 hours, so that in about a quarter the germ was probably acquired within the clinic. 76% were just colonized, in 24% an infection was present. A decolonization was possible in 76% of the patients. Several indicators for the MRSA load were calculated. Conclusion: The rate of MRSA-positive patients in our hospital corresponded to data from other countries. Compared to German hospitals the geriatric unit had to deal with a 7.4 fold higher percentage of imported MRSA. Despite this high percentage, the amount of nosocomial MRSA-days was lower than expected. Because the patients of the clinic were most often transferred from other clinics, the data about the MRSA load corresponded better to German rehabilitation clinics. Due to the special situation of geriatric patients a reduction of the MRSA load will only be possible by means of a national or at least regional effort.

ASSOCIATION BETWEEN ALA16V BAL SUPEROXIDE DISMUTASE GENE POLYMORPHISM AND HYPERCHOLESTEROLEMIA IN A BRAZILIAN ELDERLY POPULATION
I.B. da Cruz, M.R. Manica-Cattani, R.N. Moresco, M.M. Duarte, Health Center, Universidade Federal de Santa Maria, Santa Maria, Brazil

Evidences suggest that aging is associated to oxidative stress processes that could to increase the susceptibility to several chronic degenerative diseases as hypercholesterolemia (HC). HC induces endothelial dysfunction due to excessive production of reactive oxygen species, as superoxide ion. Since the dismutation of superoxide is catalyzed by superoxide dismutase enzymes (SOD), we postulated that efficiency of mitochondrial MnSOD could influence the elderly susceptibility to HC morbidity. To test this hypothesis we performed a case control study to compare the genotype and allele frequencies of Ala16Val-MnSOD polymorphism. The study included 915 subjects, 407 hypercholesterolemic (cholesterol levels ranging from 250 to 529 mg/dL, mean age= 67.6±6.8 years) and 508 healthy control subjects (67.3±7.2 years). Additionally, we tested the possible interaction between the polymorphism and hypercholesterolemia on levels of plasma lipid and inflammatory biomarkers using 100 hypercholesterolemic subjects who were recently diagnosed and not yet treated. We found a positive association between Ala16Val MnSOD genotypes and HC since lower AA frequency occurred in HC group. The odds ratio risk to V allele carriers present HC was 1.931 (95% CI: 1.349-2.734). The total cholesterol, LDL-chol, hs-CRP, OxLDL and OxLDL autoantibodies levels were higher in HC subjects as well as V allele carriers. The gene and HC interaction analysis showed that AA-hypercholesterolemic subjects have HDL-chol levels similar to control group. The results suggest that the lowest HDL-chol levels present in VV and AV carriers could to contribute in the metabolic pathways triggering a lipid imbalance.

AGING OF LOWER EXTREMITY COMPARTMENTS AND ASSOCIATIONS WITH PHYSICAL FUNCTION IN OLDER ADULTS

This study investigated lower-extremity tissue composition in young and older adults and the relative importance of individual tissue compartments to the physical function of older adults. A total of 43 older...
EXPLORATORY STUDY OF THE RISKS AND BENEFITS OF ONLINE RELATIONSHIP SEEKING

C. VandeWeerd, J. Corvin, M. Coulter, E.A. Perkins, R. Telford, University of South Florida, Tampa, Florida

In addition to browsing the internet, an increasing number of older women have begun to use the internet to seek dating relationships, yet little is known about the benefits, risks or adverse outcomes this kind of relationship seeking poses. To better understand the benefits, risks and adverse outcomes associated with online dating, this study collected pilot data from a stratified random sample of 45 women (15 Caucasian, African American and Hispanic), over the age of 50, who self-identified as “seeking relationships” on MySpace.com or Latino MySpace.
and who were living within a 25 mile radius of Tampa Bay, Florida. Participants were contacted for study participation via the secure email feature of their publically available MySpace account and were asked to complete an online qualtrics survey which contained both fixed choice questions around issues such as the frequency, duration, and purpose of their social network/dating site behaviors; as well open ended questions about the type of information they shared with potential suitors, screening of potential mates, and positive or negative experiences outcomes that have arisen from the online dating process. Quantitative data were analyzed via SPSS and qualitative data were imported into Atlas TI and analyzed using content analysis. Results indicated that adverse events such as intimate partner violence and financial abuses are being experienced by older women who seek relationships online and that many women do not feel safe, even though they continue to use these services. Implications will be discussed in terms of policy, practice and future research.

IMPROVING OUTCOMES FOR VICTIMS OF FINANCIAL EXPLOITATION: THE EFFECT OF AN ELDER ABUSE FORENSIC CENTER

A.E. Navarro1, K. Wilber1, D.C. Homeier1,2, J. University of Southern California, Davis School of Gerontology, Los Angeles, California, 2. University of Southern California, Keck School of Medicine, Los Angeles, California

Elder financial exploitation is defined as the taking or misappropriation of an older person’s property, possessions, or financial assets. As society identifies victims, arriving at a remedy can be time-consuming and complex, requiring cooperation from a diverse array of institutions. This National Institute of Justice study focuses on outcomes from a specific type of multidisciplinary team (MDT)—the elder abuse forensic center (the Center)—comprised of a diverse collaborative of problem-solving professionals, meeting weekly to focus on complex elder abuse cases, using enhanced forensic resources with the ultimate goal of protecting older adults. Propensity score matching was used to compare the value added from the Center to “usual care.” Each older victim of financial abuse reviewed at the Center (n=241) between January 2007 and December 2009 was matched from an unduplicated Adult Protective Service (APS) pool of clients (n=33,650) served during the same period. The sample consists of community-dwelling adults, aged 65 years and older, residing in Los Angeles County, California (n=482). Covariates include socio-demographic characteristics, additional types of abuse, and referral sources. Outcomes from APS, Office of the Public Guardian, and the District Attorney’s Office were merged and include professional assessments, initiation of conservatorship and/or criminal prosecution, successful results of legal proceedings, and decreased time to resolution. Preliminary evidence suggests combined expertise of health, social service, and justice professionals improves efficient resolution of financial exploitation cases, having implications for both policy and practice related to the national replication of elder abuse forensic centers designed to protect older adults.

BREAKING BARRIERS: USING PROMOTORES TO IDENTIFY ELDER ABUSE IN AN URBAN LATINO COMMUNITY

M. Riparetti-Brown, Z.D. Gassoumis, K. Wilber, Davis School of Gerontology, University of Southern California, Los Angeles, California

Latino immigrants are an understudied population in the field of elder abuse due in part to cultural and language barriers that impede research access. To overcome these barriers, this study recruited and trained Promotores—local Latino residents who serve as community advocates—to gain entry into a low-income, Spanish-speaking immigrant population (age 65 and older) residing in Los Angeles (N=198). Promotores conducted door-to-door interviews to assess the frequency of caregiver neglect, physical assault, psychological aggression, sexual abuse, and financial exploitation using a multi-domain abuse instrument. The majority of the sample, 63.8%, emigrated from Mexico at an average age of forty-one. Fifty-six percent of the sample is female. Psychological aggression was reported by 24.8% of respondents, 10.7% reported physical abuse, 9.0% indicated sexual abuse, and 16.7% reported financial exploitation. Neglect was reported by nearly 12% of the participants. Overall, 45% of older Latinos indicated experiencing some form of abuse in the past year, a proportion that far exceeds previous findings in nationally representative studies on elder abuse. Regression analysis indicated that cognitive and functional impairment and a history of prior abuse are major risk factors for elder mistreatment in this community. This is the first study to use Promotores to capture the prevalence and risk factors of domestic elder abuse in a previously unexplored population of undereducated, low-income Latino immigrants. Future research should determine whether these high rates of abuse are representative of the broader immigrant population and conceptualize how elder mistreatment is defined, recognized, and resolved in disadvantaged ethnic communities.

ENTERING THE ABYSS: DESIGNED NEGLECT OF ALZHEIMER’S DISEASE (AD) HOME CARE PATIENTS AND CAREGIVERS

W.D. Cabin, Stockton College, Glen Rock, New Jersey

The Medicare home health benefit limits care to AD patients and their caregivers. A two year mixed methods study documented the limitations, their impact on patient and caregiver care, their impact on nurse and social worker coping strategies, and the failure to use evidence-based practice (EBP) to determine coverage. The study includes a New York City metro area-based convenience sample of 72 home care nurses and social workers interviews and a national survey of over 2,000 home care nurses and social workers. Among the major findings are: regulatory constraints and organizational culture limit nurse and social worker willingness to meet known patient and caregiver needs; limitations increase nurse and social worker burnout; nurses and social workers are generally unaware of EBP interventions for the AD population, controlling for age, ethnicity, gender, education level, and years in home care practice; and home care nurses and social workers prefer the palliative care model for treating the home care AD population, despite its lack of coverage. Practice and policy implications are discussed.

SCREENING AND REPORTING ELDER MISTREATMENT: AN EXPLORATION OF KENTUCKY-BASED PHYSICIANS’ BEHAVIOR AND PRACTICE

A.E. Sokan, Graduate Center for Gerontology, University of KY, Lexington, Kentucky

Elder mistreatment (EM) increases risk of premature death and institutionalization for victims; raises economic, healthcare, and social costs for society; and may expose physicians to risk of malpractice suits for non-detection and poor quality care. Physicians are in an advantageous position to screen for and report EM because they come into contact with older adults seeking health care. Studies indicate that physicians do not routinely screen and are less likely than other healthcare professionals to report EM, often despite mandatory reporting laws, although they are most likely to encounter it. Reasons for apparent physicians’ reluctance to screen and report EM include lack of time, appropriate training, reimbursement, and confidence in ability to detect EM. Employing in-depth qualitative interviews with 22 Kentucky-based physicians, this study identifies barriers to physician screening and reporting of EM and explains physician behavior and practice. Findings indicate: the importance of physician values and experience, the role of personal definitions of EM, the relationship between confidence/competence and reporting, differences in attitudes between referral and non-referral-based practices, and differences between rural and urban practitioners. Furthermore, participants indicated that the environment in
CIVIC ENGAGEMENT AND SUCCESSFUL AGING

DEVELOPING OLDER ADULT CIVIC ENGAGEMENT INITIATIVES IN URBAN COMMUNITY-BASED SETTINGS: TESTING A PILOT PROJECT
A. Cohen-Callow, A. Jones, School of Social Work, University of Maryland Baltimore, Baltimore, Maryland

This study utilized quantitative and qualitative methods to examine the development of volunteer activities for older adults in local community agencies. A nationally funded civic engagement pilot project employed community asset mapping in collaboration with each agency and its native contingent of older adult volunteers. Data collected during the first year of project implementation included older adult volunteer engagement, organizational capacity to engage volunteers, and volunteer management best practices. Additionally, interviews with agency staff added contextual background information. A comparison was made between the level of success implementing the volunteer initiative and: 1) agencies' responsiveness to the prioritized through asset mapping, and 2) agencies' organizational capacity to engage older adults in volunteer activities. In terms of #1, volunteers age 50+ (n = 260) did not see themselves as effective change agents, however community asset mapping identified such volunteers as a key resource. Agencies (n = 6) indicated that community priorities identified during the asset mapping process were addressed only when they were aligned with pre-existing agency defined needs. Conversely, agencies continued to pursue agency defined needs even when asset mapping indicated that they were not community priorities. In terms of #2, agency informants (n = 7) indicated that they felt they had limited capacity to engage volunteers without additional resources. Staff wanted more training, technical assistance, and support to assist in recruitment and management of older adult volunteers. Implication of findings for improving volunteer management of older adults will be discussed.

INTERGENERATIONAL ACTIVITIES AND WELL-BEING OF THE ELDERLY: IMPLICATIONS FOR COMMUNITY PRACTICE
L. Liu1, Y. Qui2, 1. Department of Social Work, Tunghai University, Taichung City, Taiwan, 2. ESmE Creative Studio, Taichung City, Taiwan

In modern society extended families are no longer the norm. It is not uncommon that older adults do not live together with their young family members in communities. The significantly increased older population living along in communities have raised some fundamental issues, such as community revitalization, family relationships, and generation stereotypes. Intergenerational programs served by community organizations give us the opportunity to bring old and young generations back together. In addition, it allows us to create a strong sense of community as a whole and to empower residents engaging in community revitalization. Using qualitative analysis, this study presents how a community grassroots group in mid-Taiwan collaborated with local businesses as well as district schools to develop an intergenerational service program as "Humanities Tea Ceremony." The paper shows how the service program has improved connections between generations and changed the stereotypes of young generations toward old population in communities. In addition, it made community residents began to care about senior citizens and developed the social support network for the elderly in their neighborhoods. Moreover, there has been a revival of interest in Teasim in communities. When tea is more than a drink, Tea Ceremony is often associated with arts, culture, and philosophy. In Chinese culture it presents as a sign of respect, a way of family gathering, a form of apology and deep thanks, as well as a symbol of value. The implications of this intergenerational program on services for the elderly and community cohesion are discussed in this study.

VOLUNTEER TRANSITIONS AMONG OLDER ADULTS: THE EFFECTS OF HUMAN, SOCIAL, AND CULTURAL CAPITAL IN LATER LIFE
E. Gonzales1, T. McNamara2, 1. George Warren Brown School of Social Work, Washington University in St. Louis, St. Louis, Missouri, 2. Sloan Center on Aging & Work at Boston College, Boston, Massachusetts

OBJECTIVES. We aim to understand how human, social, and cultural capitals are associated with the volunteer process: engagement (starting), intensity (number of hours), and cessation (stopping), among older adults. METHODS. Data from the 2000 through 2008 Health and Retirement Study and the 2001 through 2009 Consumption and Activity Mail Survey provides a sample of 4,526 respondents. Random-effects pooled time series analyses incorporate not only the presence of various types of capital, but also the quality of that capital. RESULTS. Human capital (education/health/assets) and cultural capital (religiosity) were positively associated with increased volunteer involvement and negatively associated with cessation. Effects of social capital (relationships in the family, employment status, and the community) depended on the quality of the relationships, not necessarily on their presence alone. For instance, providing 10+ hours/month of care to parent resulted in reduced volunteering intensity (b = -3.39, p<.05) and affected the probability that a person would have volunteered over the last month (probability = .07, p<.05). Full-time employees unable to reduce the hours on the job, volunteered on average 2.12 (p<.001) hours fewer per month than their not employed counterparts. DISCUSSION. Results suggest that bolstering older adults’ capitals, particularly among lower socioeconomic status groups, can increase volunteer engagement and intensity, and reduce cessation. Additionally, a variety of organizational policies including respite programs for caregivers and flexible work arrangements might indirectly affect participation rates and commitment. More research is necessary to identify how to recruit and retain individuals in social networks where volunteer participatory rates are low.

VOLUNTEER PERSPECTIVES TO THE TEAM APPROACH OF MEETING NEEDS IN TERMINALLY-ILL COMMUNITY-BASED AGING INDIVIDUALS: A QUALITATIVE ANALYSIS
C. Azuero1,2, G. Harris1,2, E. Kvale3,4, C. Ritchie3,4, B.R. Williams1,2, R.S. Allen1, 1. Center for Mental Health and Aging, Tuscaloosa, Alabama, 2. Psychology, University of Alabama, Tuscaloosa, Alabama, 3. Department of Veterans Affairs, Birmingham/Atlanta Geriatric Research, Education, and Clinical Center (GRECC), Birmingham, Alabama, 4. University of Alabama at Birmingham Department of Medicine-Division of Geriatrics, Gerontology and Palliative Medicine, Birmingham, Alabama

Purpose: This presentation describes the experiences of volunteers with the UAB Support Team Network (STN) involved in meeting the needs of community-dwelling individuals with chronic life-limiting illnesses. The UAB STN was developed in early 1990, growing out of a movement to care for acutely ill HIV/AIDS patients dying in the community. As HIV/AIDS became chronic, this caring model expanded to community-based aging individuals living with an assortment of conditions. Methods: Using a semi-structured qualitative interview guide, we interviewed 10 individuals with volunteer experience within this model. Emerging themes were identified and coded using a phenomenological approach within a grounded theory framework. Results: Participants were white (100%), female (90%) age 40–62, 70% were affiliated with support teams organized by religious/spiritual organizations. Analysis of the interview data revealed an interaction among four ecological levels: Individual, Team, Organizational, and Socio-cultural environment. On the individual level, volunteers derived meaning from their...
VOLUNTEERISM AMONG OLDER ADULT IMMIGRANTS IN THE UNITED STATES

H. Jang, Washington University in St. Louis, St. Louis, Missouri

Abstract PURPOSE: Although the number of foreign-born older adult immigrants is rapidly increasing in the United States, studying volunteering for this demographic is a neglected topic. This study aimed to examine how human, social and cultural capitals, along with other economic resources, are associated with volunteering among older adult immigrants. DESIGN AND METHODS: Data were drawn from the 2009 Volunteering Supplement. Current Population Survey, with a sample of 4,536 who were 50 years of age and older; there were 587 volunteers. One logistic and two multinomial regressions were completed: (1) identified factors associated with volunteering, (2) included volunteer activities, and (3) types of organizations. RESULTS: Human capital (education), social capital (participation of public affairs and neighborhood) and cultural capital (donation) were positively associated with volunteering. High intensity volunteers were more involved with teaching/religion, religious activity, and medical/professional services. Medium and high intensity volunteers were strongly involved in religious organizations. Asian older adults had lower volunteer rates, but those that did volunteer did so at high levels of intensity in religious organizations. Interestingly, older adults who had income less than $30,000 and lived in non-metropolitan areas showed high volunteering intensity. IMPLICATION: Findings suggest that religious organizations play a pivotal role in strengthening older adult immigrants’ volunteering. Connection between ethnic religious organizations and communities such as schools, hospitals, and professional institutions will enhance engagement of volunteering. Institutional program development may enhance volunteer opportunities for those who had low income and lived in non-metropolitan areas.

VOLUNTEERING AND EGO INTEGRITY OF OLDER ADULTS: LEVELS AND PERCEIVED BENEFIT OF VOLUNTEERING

This study examines the association between the level and benefit of volunteering and the ego integrity of adults aged 60 and over in Korea. With proportional quota sampling, we collected data from 460 older volunteers in 2009. The level of volunteering is measured by duration and monthly mean hours of volunteer activities. Perceived benefit of volunteering is measured by 11 items developed by Morrow-Howell, Kinney, & Mann (1999). The ego integrity is measured by 31 items representing six domains of current life satisfaction, wisdom, attitude to life, acceptance of the past, acceptance of aging and death (Kim, 1988). Hierarchical regression analysis results show that those with no work, having higher monthly income, living in urban areas, with better self-rated health, with no need for IADL support are more likely to report higher levels of ego integrity (R2=.175). In a next step, older adults who volunteer for longer time, who engage in more hours of volunteering, and perceive greater benefits of volunteering report higher levels of ego integrity (R2=.278). In a final step, perceived social support mediates the effect of longer duration on ego integrity (R2=.415) whereas monthly mean hours and perceived benefit of volunteering have directly positive associations on ego integrity. The findings shed lights on volunteer activities as an important, but not necessarily causal, pathway to ego integrity in later life. Future research is necessary for longitudinal analysis to test a causal relationship between productive engagement and ego integrity of older adults.

NEW REALITIES: ENGAGING COMMUNITIES TO ENHANCE DIGNITY AND INDEPENDENCE

K. Black1, D. Dobbs1, S. Gregory1, T. Dutton1, 1. College of Arts and Sciences, University of South Florida Sarasota - Manatee, Sarasota, Florida, 2. University of South Florida, Tampa, Florida, 3. SCOPE, Sarasota, Florida

There is increasing interest in developing innovative ways to enhance the ways in which people age in their community -in their homes and their neighborhoods. There is also emergent interest in promoting meaningful aging - within the context of daily life and interactions. Combined, these two foci implore us to ask: To what extent can a community be mobilized to enhance dignity and independence among its oldest residents? The Aging with Dignity and Independence Initiative is a community-based project in Southwest Florida. The project combined both qualitative and community-based participatory research to better understand and engage the community to enhance the aging experience. This presentation reports on the findings from a unique aspect of the project that utilized an Appreciative Inquiry approach in which persons of all ages throughout the community were invited to share their story of a positive interaction with an older adult. A total of 217 stories were collected both in person, via community forums, and electronically, via online participation. Content analysis was conducted yielding a total of five primary themes (1) Promoting Socialization; (2) Importance of aging in place; (3) Provisions from A to Z; (4) More than first impressions; and (5) Secrets of positive interactions. The novel methods and creative approaches about how the data was shared to mobilize and engage the community are also presented.

THE EFFECT OF VOLUNTEERING AND OTHER SOCIAL ACTIVITIES ON LIFE SATISFACTION IN LATER LIFE

Y. Shih, Gerontology Department, University of Massachusetts Boston, Boston, Massachusetts

Volunteering, as one of many social activities, has been recognized for its health benefits among older adults. However, research solely focusing on volunteer work ignores that older volunteer may engage in other social activities. Little is known about how volunteering is related to other social activities, and how the combinations of volunteering and other social activities are associated with older adults’ well-being. In response, the current study examines these two types of social activities on older adults’ life satisfaction. Data come from the 2008 Health and Retirement Study Leave-Behind Questionnaire. Overwhelmingly, older volunteers are involved in one or more other social activities. In a nationally representative sample of 6,640 older Americans, about 30% of them report participation in volunteer work in the previous month, and 80% of them report participation in other social activities at the same time. Multivariate logistic regression analysis is used to estimate whether the benefits of volunteering vary with levels of participation in other social activities, controlling for personal characteristics such as employment, marital status, functional limitations, and psychosocial measures. Findings suggest that both volunteering and other social activities independently increase the chance of reporting higher life satisfaction, and that older volunteers with other social activity involvement are more likely to have higher life satisfaction than those who only participate social activities. The results show a fuller picture of older adults’ everyday lives, and suggest that modeling concurrent activities is important for a better understanding of well-being among older adults.
WHO ARE THE FAMILY CAREGIVERS? A COMPARATIVE STUDY BETWEEN THE U.S. AND KOREA ON PARENTAL CAREGIVING

Y. Lee, F. Tang, University of Pittsburgh, Pittsburgh, Pennsylvania

Considering the population aging, the demand for informal care will increase exponentially in the next few decades both in the U.S. and Korea. Though there are some similarities regarding how elder parents are cared between countries, there are also differences. We used two nationally representative datasets: Health and Retirement Study (HRS) in the U.S. and Korea Longitudinal Study of Aging (KLSoA) of 2008. This study examined the characteristics and differences of family caregivers in two countries. Commonly, the primary caregivers for elderly parents were female in the U.S. and Korea. While adult children in both countries provided most of family caregiving, spousal caregivers were 6% in the U.S. and 29.7% in Korea, respectively. Among child caregivers, adult children consisted of 50%, and children-in-law took 11% in the U.S., whereas in Korea, the eldest son and daughter-in-law took most of caregiving responsibility (31.8%), followed by daughter and son-in-law (15.3%). Caregiving by son in Korea was actually done by their wife. Our results indicated that parental care in Korea is provided from adult children who living together with their elderly parents, whereas American elders live alone but are still cared by their children. Also, cultural expectations with regard to parental caregiving tend to fall on the female, especially daughters in the U.S. and daughters-in-law in Korea. Findings imply underdevelopment of formal caregiving system in Korea because of cultural values on family responsibility and informal care as a substitute for formal care system in the U.S.

RECRUITING FAMILY CAREGIVERS IN RURAL AMERICA: CHALLENGES AND LESSONS LEARNED

M. Luptak1, B.L. Hicken2, C. Daniel1, R. Hilt1, R. Zheng3, M. Grant2, C. Moreno2, R. Rupper1, 1. University of Utah College of Social Work, Salt Lake City, Utah, 2. VA Office for Rural Health - Western Region, Salt Lake City, Utah, 3. VA Salt Lake City Healthcare System Geriatric Research Education and Clinical Center, Salt Lake City, Utah, 4. University of Utah Department of Educational Psychology, Salt Lake City, Utah

Supporting Caregivers of Rural Veterans Electronically (SCORE) is a randomized controlled pilot study examining in-home delivery of support and education to caregivers of rural veterans with dementia. Outcome variables included caregiver burden, caregiver efficacy and care receiver health care utilization data. Internet-naıve participants were assigned to a group which employed a simple in-home information collecting device or a group which received telephone support. Internet-savvy participants were assigned to an internet user group or a group which received telephone support. This presentation describes the recruitment process, challenges inherent in this process, and lessons learned. After querying electronic medical records to identify veterans who were diagnosed with dementia-related disorders or prescribed anti-dementia medications, we sent an informational letter and followed up with a phone call. Of 561 caregivers contacted, 277 were ineligible, 209 declined, and 75 enrolled. Participation barriers included: 1) caregiver awareness of the veteran’s dementia but limited awareness of the caregiver role (43%), 2) caregiver recognition of dementia and the caregiver role, but no time to participate (19%), and 3) caregiver minimization of progressive symptoms (7%). To optimize recruitment and enhance caregiver participation, we adopted a multi-faceted approach. For example, we contacted caregivers at a time convenient for them; provided contact information for multiple staff; reviewed the consent form in person before/after veterans’ scheduled VA appointments to minimize travel barriers; and employed licensed clinical social workers who were able to respond to multiple caregiver concerns and offer support when reviewing the consent form. Further strategies will also be discussed.

HOW DO FAMILY MEMBERS EXPERIENCE CARING FOR OLDER ADULTS WITH DEPRESSION?

M. Henry1, M. Luptak1, C.E. Duffy1, S.M. Metzner1, 1. University of Utah, Salt Lake City, Utah, 2. Resources for Human Development, Assertive Community Treatment, New Orleans, Louisiana

Involvement of family members of older relatives with depression and how involvement affects well being is poorly understood. This study explored the experiences of family members of older community-dwelling individuals with a diagnosis of major depression. Twenty older adults meeting study criteria were recruited; they identified family members involved in their care who were then invited to participate. Thirty-eight family members completed face-to-face interviews which included questions from six subscales of the Family Experiences Interview Schedule (FEIS). Statistical evaluation of responses to the FEIS was used to describe the experiences of caregivers. Most caregivers reported positive elements of the relationship: the older adult was important in the respondent’s life (97.4%), the respondent was proud of the older adult (81.6%), and the older adult made the respondent happy (78.9%). Yet a large majority also worried about the older adult’s physical health (97.3%), social life (81.1%), and safety (77.8%), and a minority reported disappointment (23.7%), irritation (36.8%), anger (15.8%), and embarrassment (26.3%). An analysis using Pearson’s correlation coefficient suggested relationships between various characteristics of the caregiver and reports of caregiving benefits and burdens. For example, married participants were less likely than unmarried participants to report benefits related to financial support from the older adult (r = -.412, p = .01) or companionship (r = -.391, p = .02). Findings support the need for evidence-based strategies to improve and support the health and well being of older adults with depression and the family members who care for them.

DEPRESSION IN SPOUSAL ELDER CAREGIVERS IN HONG KONG

E. Chow, Applied Social Studies, City University of Hong Kong, Kowloon, Hong Kong

Care for the elder has become a major social issue as the ageing population in Hong Kong raises rapidly in the recent years. Spouses commonly serve as the primary caregivers of older adults as their children are faced with conflicting demands of employment as well as housing and living conditions. To enhance understanding on the psychological wellbeing and needs of spousal elder caregivers, the present study aims to examine caregiver burden, depression, self-esteem, purpose in life, proactive coping, and social support. 131 elderly caregivers aged 65 and above were recruited from 13 caregiver resource centers in Hong Kong. Frequency results revealed that 13% of the caregivers were suffering from depression. Stepwise hierarchical multiple regression analysis revealed that purpose in life, caregiver burden, and self-esteem can significantly explain 57.2% of the variance in depression. The actual demands required in caregiving, social support, and proactive coping did not predict depression. The findings suggest that the perceived experience of caregiving is more important in explaining depression in spousal elder caregivers than the situational factors. Findings are discussed in relation to needs of spousal caregivers followed by implications for development of policy making, professional practice and support programs.

A GENDERED EXPERIENCE OF CARING IN LATER LIFE: EVIDENCE FROM THE ENGLISH LONGITUDINAL STUDY OF AGING

A. Vlachantoni, Centre for Research on Ageing, University of Southampton, Southampton, United Kingdom

The 2001 Census in the United Kingdom for the first time included a question on the provision of unpaid care to family members, friends,
neighbours or others, because of ill-health/a disability, or problems related to old age, within or outside the household. However, much less is known about the provision of care more broadly, for example towards one’s spouse or grandchild. We also know little about the provision of care in the latter part of the life course, particularly among those aged 50 and over. This poster presents the results of a project analysing the demographic characteristics, caring patterns, socio-economic characteristics and health patterns of carers aged 50 and over in England. It employs bivariate and multivariate analysis of data from Wave 3 (2006) of the English Longitudinal Study of Ageing (ELSA) to illustrate three key results. Firstly, the extent and nature of care provision changes at different points of the life course, for example caring for one’s spouse/partner is more prevalent in older ages compared to younger ages. Secondly, in addition to changing across different age groups, care provision is a profoundly gendered experience, for example women are more likely to look after children or grandchildren, while men are more likely to look after their spouse/partner. Finally, ‘round-the-clock’ carers, who constitute one-fifth of all carers aged 50 and over, report a better health status and are more likely to be employed than certain groups of less intense carers.

FAMILY CAREGIVING TO OLDER, MINORITY CANCER SURVIVORS LIVING IN THE COMMUNITY: PERSPECTIVES FROM A RANDOMIZED CONTROL TRIAL OF CAREGIVER PROBLEM-SOLVING SKILLS TRAINING

Background: Cancer is among the most prevalent chronic health disorder that can lead to impaired functioning and mortality in the elderly. Recognition of the centrality of families’ role in patients’ treatment and recovery is widespread. Less attention, however, has been focused on developing programs and interventions that include or target the families’ role during the cancer survivorship period, a period when patients are coping with the consequences of cancer and its treatment. Methods: Funding from NCI, Office of Cancer Survivorship supported delivery of a brief problem-solving skills training program for familial caregivers to lower income older (60+) post-treatment cancer survivors. Familial caregivers accrued through Community/Migrant Health Centers (C/MHCs). Results: Program satisfaction high, caregivers recognizing utility of training. Shared session materials with survivor, relatives/friends, suggesting caregivers could be the point of engagement for multilevel outreach support. Requested more sessions on additional topics, supporting need for education and training on specific survivorship care issues. Requested help accessing community resources, suggesting a need to implement family-focused community case management. Felt more confident about addressing situations emerging during survivorship period and more likely to apply a problem-solving approach in case situations. Conclusions: Caregiver education and training programs should target caregiver informational and training needs during the survivorship period given families’ direct involvement in health care decision-making, health advocacy and care provision. Low-cost, brief, evidence-based programs that can be implemented in community settings and effective in maximizing families’ care giving abilities and skills and provide them with the skills and resources are needed.

THE PREDICTORS OF ACCESS TO CARE, PREVENTIVE SERVICES USE, AND LIFESTYLE BEHAVIORS AMONG CALIFORNIA CAREGIVERS: FINDINGS FROM THE 2009 CALIFORNIA HEALTH INTERVIEW SURVEY
C. Mendez-Luck, G. Hoffman, UCLA School of Public Health, Los Angeles, California

Approximately one in every four California adults cares for a family member or friend with a long-term illness or disability, at an annual estimated value of $48 billion. The health risks associated with caregiving have been well documented; however, the findings are mixed about the relationship between caregiving, care-seeking and lifestyle behaviors. Using data from the 2009 California Health Interview Survey, this study will examine these relationships through separate multivariate regressions, with barriers to health care services, non-utilization of preventive services, and health behaviors (e.g., smoking, physical inactivity, alcohol use) as our main outcome variables. Our main predictor variables will include caregiving characteristics (e.g., length of caregiving, time spent weekly caregiving, number of persons being cared for, living arrangements, caregiver-care recipient relationship). Control variables will include sociodemographics (e.g., age, race/ethnicity, gender, rural-urban status, income) and health characteristics (e.g., diagnosed chronic conditions, self-rated health, disability). Our analyses will be guided by the Andersen Model, developed to study the determinants of health services use, and currently the most widely-used model of access to care. The study results will add to the scholarship in this area by 1) elucidating the factors of the caregiving situation that contribute to caregivers’ poor access, low service use, and health risk behaviors, and 2) identifying the caregivers at elevated risk for poor health outcomes.

CHANGES IN ROLE CHARACTERISTICS: A 10-YEAR FOLLOW-UP OF WORKING, SANDWICHED-GENERATION COUPLES
M.B. Neal1, L.B. Hammer1, A.M. Pines2, T. Bodner1, 1. Institute on Aging, Portland State University, Portland, Oregon, 2. Ben Gurion University, Beer-Sheva, Israel

This study examined changes in marital, child-care, parent-care and work role occupation over a 10-year period and how these changes affect work-family fit, health, well-being and work outcomes among a sample of dual-earner, sandwiched-generation couples (i.e., couples who were caring for children and aging parents and who were engaged in paid work). The original data were from a national study funded by the Alfred P. Sloan Foundation which examined general effects of being “sandwiched” on work and well-being (Neal & Hammer, 2007). At the time of the first wave of the survey, all couples (N=309) held all four roles. Ten years later, with the help of a grant from the U.S. Israel Bina
tional Science Foundation, a follow-up survey was administered by mail to these couples. Of the original 309 couples, both members of 101 couples could be located and agreed to participate in the 10-year follow-up survey, and one member each of another 33 couples agreed to participate. Only 18 of the 101 couples, and 7 of the 33 individuals still held all four roles. To determine the effects of these role changes on work-family fit, well-being and work, hierarchical regression analyses were conducted separately for men and women, including the objective role loss indicators and the Wave 1 dependent variable as predictors. The results and their implications for organizations, policy makers, and sandwiched couples and individuals themselves will be discussed.

CHARACTERISTICS OF PARENTAL CAREGIVERS IN THE HEALTH AND RETIREMENT STUDY, 1992-2008
3.C. Greenfield, Washington Univ. in St. Louis, Saint Louis, Missouri

Informal care is the backbone of the U.S. long-term care system, and caregiving prevalence is expected to rise dramatically as baby boomers age. Parental caregivers are of particular interest because caregiving may strain their health and finances, thereby undermining their own preparation for retirement and long-term care needs. Understanding trends in parental caregiving is essential to ensure that policies and programs are responsive to caregiver needs. Using nine waves of data from the Health and Retirement Study (HRS) – specifically, 51-61 year-old respondents from 1992-2008 – an exploratory analysis of parental caregivers’ socio-demographic characteristics was conducted to describe these caregivers and to compare the age, gender, race, education, self-
rated health, income and assets of parental caregivers and their non-
caregiving peers at each wave. For example, in 1992, there were 113
respondents (14%) who reported providing care for a parent or parent-
in-law; these caregivers were 85% (n=85) White, almost 100% female
(n=112), and had a median income of $44,500 ($67,778 in 2008 dol-
lars). By 2008, caregiving prevalence among this age group had
increased to 42% (n=583), while only 68% (n=394) were women, 83%
(n=486) were White, and the median income had decreased to $52,800.
Differences between caregivers and non-caregivers were detected in all
waves; for instance, caregivers were more likely to be women and White
in all waves, but gender and racial disparities decreased over time.
Median income also decreased over time. Findings suggest that preva-
ence of caregiving is increasing, and that changes in gender and racial
disparities are emerging as well.

CAREGIVING DECISION-MAKING AMONG ELDERLY
CHINESE IN SHANGHAI: FINDINGS FROM
QUANTITATIVE AND QUALITATIVE DATA
L. Chen1, M. Ye2, 1. Social Welfare, University of California, Los
Angeles, Los Angeles, California, 2. Bowling Green State University,
Bowling Green, Ohio
The purpose of this study is to describe the nature of caregiving deci-
sion-making, especially institutionalization, among Chinese elders in
Shanghai from both quantitative and qualitative data analysis. This study
also explores the transforming concept of filial piety during the care-
giving decision-making process from Chinese elders’ perspectives. A
theoretical framework of modified Andersen Behavioral Model helps
to conceptualize this study. The dataset is 2005 Shanghai Elder Citizen
Longitudinal Tracking Study, which used stratified sampling and sur-
veyed 1,327 community-dwelling elders about caregiving decision-mak-
ing and quality of life. The study uses age, gender, marital status, edu-
cational level and satisfaction of intergenerational relationships as
predisposing factors, monthly income as an enabling factor, monthly
medical cost and self-care capability as need factors and institutional
decision-making as a dependent variable. Logistic regressions revealed
that elders who had higher education, higher monthly income, but with
lower satisfaction on intergenerational relationships and lower capa-
bility of taking care of themselves were more likely to accept institu-
tional caregiving. Interviews with 11 elderly residents in a nursing home
in Shanghai investigated their perspectives on institutionalization and
their relationships with adult children during the decision-making
process. Results from interviews echoed survey results. Elderly resi-
dents reported that self-care capability, monthly medical cost, and inter-
generational relationship have direct implications on their considera-
tion of institutionalization. Combining results from the survey and
interviews, this study finds that filial piety, under the influences of eco-
nomic reform in urban China, although has been culturally and socially
reconstructed, it still has strong impacts on caregiving decision-making
of Chinese elders.

CAREGIVERS OF VETERANS WITH DEMENTIA:
ACCESSING SERVICES
C.M. Daniel1, B.L. Hicken1, M. Grant1, M. Luptak2, R. Hill2, R. Rupper12, 1.
GRECC, VA Salt Lake City HCS, Salt Lake City, Utah, 2. University of
Utah, Salt Lake City, Utah
Background: Caregivers of persons with dementia face significant
challenges in accessing support from local, state, and VA resources, and
typically rely on informal sources of support, such as family, neighbors,
and fellow church members. The present study aims to utilize health
care access models (Aday 1974) to improve resource use among this
population. Methods: Caregivers (N=75) of patients with dementia par-
ticipated in a tele-caregiver support program. The program provided:
1) educational information disseminated using the Internet or a home
telehealth device; and, 2) brief intervention and psychosocial support
via a remote licensed clinical social worker. Educational curriculum
addressed topics related to skill training, mood management, and
resource access for the caregiver. The remote care manager documented
support needs and strategies to address those needs. Both qualitative
and quantitative analyses were used to examine the data. Results: Par-
ticipation in the program improved knowledge of and access to VA and
community resources. For example, care managers provided most (55%)
caregivers with information about local, state, and federal resources,
including those provided through VA. Community referrals to mental
health services and local aging resources were also common (23%).
Finally, end of life care planning was also needed. Care managers
addressed Advance Directives for both the caregiver and care recipient
(16%). Conclusions: Telehealth support programs not only provide infor-
mation about resources, but they also help connect caregivers with VA
and community resources. Establishing strong VA-community part-
nerships and educating caregivers about VA and community resources
enhances access to much-needed services for this population.

INTERACTION BETWEEN OLDER CAREGIVERS AND
OTHER HELPERS
S.H. Sigurdardottir12, M. Ernsth Bravell1, 1. University of Iceland,
Reykjavik, Iceland, 2. Institute of Gerontology, Jönköping University,
Jönköping, Sweden
Objectives of the study: The aim of the study is to describe older
informal caregivers and how they interact with the formal care system
and other informal caregivers when providing care. Method: In the study
Icelandic older people (ICEOLD), data was collected using a national
sample of persons aged 65 and over living in their own homes in ICE
land. A telephone interview was conducted with 782 individuals, 441
women and 341 men, 65-98 years of age. The response rate was 66%.
The participants were asked about living standards, help received and
whether they provided help to someone living in their own household
or somewhere else. The study is based on descriptive analysis. Results:
About one fifth (21%) of the total sample of respondents helped or
provided care for another person (n=157). The results demonstrate that
older caregivers living with someone are more often informal caregivers
than those living alone. Emotional support is the most frequent help
given. The older caregiver is often alone in his/her role as a caregiver,
but when care becomes too burdensome, the formal care system pro-
vides help in tandem with the older caregiver. More than half of the
informal caregivers need help themselves with ADL tasks. Conclu-
sion:The results from this study show that older caregivers in Iceland
are an important resource in providing care. Light must be shed on older
informal caregivers and further research is needed to assess how municip-
alities can support them in their roles as caregivers.

SESSION 1755 (POSTER)
HEALTHCARE DISPARITIES

HEALTH CARE DISPARITIES: HOME HEALTH AGENCY &
SYSTEM BARRIERS TO HEALTHY AGING
J.K. Davitt, R. Frasso, J. Bourjolly, School of Social Policy & Practice,
University of Pennsylvania, Philadelphia, Pennsylvania
Home health care plays a pivotal role in the health status of older
adults. However, recent studies indicate disparate outcomes for minor-
ity recipients of home healthcare. This work explores home health
agency staff perspectives on the agency and system factors which con-
tribute to disparate outcomes for minority home care recipients. Qual-
itative, focus group interviews were conducted with both professional
and paraprofessional home healthcare staff from a variety of agencies
in a tri-state metropolitan area. Staff reported the following agency and
system factors that contribute to disparities in home health care out-
comes: agency policies and procedures related to cost control, cover-
age issues and staffing assignments; and system factors including health
care access, costs, insurance issues, and the culture of healthcare. We

64th Annual Scientific Meeting 497
discuss the interrelationships between factors identified by agency staff and access/quality, suggesting a mediating path to enhancing patient health status. We relate these results to both theoretical frameworks and existing empirical understanding of this complex problem to inform the development of a more equitable system of home health care delivery. Best practice recommendations will be discussed. Ultimately, the goal of this research is to alleviate disparities and improve health outcomes for all patients thus enhancing late life health.

IS LANGUAGE PREFERENCE RELATED TO CARE RECEIVED AND QUALITY OF LIFE OF NEW HOME CARE ENROLLEES?

Purpose. To determine whether the preference for speaking Spanish among elders newly enrolled in a long-term care (LTC) program is related to receipt of formal and informal care and self-reported quality of life (QoL). Methods. The analysis is part of the Health Related Quality of Life: Elders in Long-term Care (PI: Naylor NIA/NINR R01 AG025524) study. We focused on baseline data of elders enrolled in a home-based LTC program (n=124). Simple differences in means and proportions were compared and multivariate models estimated to determine whether language preference is related to care received and self-reported QoL. Results. There were 76 Spanish-speaking and 48 English-speaking participants. Mean age was similar but health status and living arrangements were not: Spanish speakers reported worse overall health status (p=0.065) and were less likely to be living alone (36% vs. 67% of others; p<0.001). Simple comparisons showed statistically significant differences between the two groups in primary caregiver (p=0.011) and whether the caregiver provided personal care (60% Spanish vs. 39% English; p=0.036) with worse QoL reported by Spanish speakers (p=0.042). In preliminary multivariate models, differences in care received and QoL substantially diminish after adjusting for health status and other patient characteristics. Conclusions. Spanish- and English-speaking participants had significantly different health status and access/quality, suggesting a mediating path to enhancing patient health status. Implications. Understanding of similarity and difference of health status among different groups Asian American older adults can help health professionals provide best services to these populations.

HEALTH DISPARITIES OF OLDER ASIAN AMERICANS: A COMPARATIVE STUDY OF CHINESE, FILIPINO, ASIAN INDIAN, AND OTHER ASIAN/PACIFIC ISLANDER
J. Tan, Bridgewater State University, Bridgewater, Massachusetts

Purpose of the study. This study examined the health disparities US Chinese, Filipino, Asian Indian, other Asian/Pacific Islander (API), and non-Hispanic white older adults by using nationally representative data. Design and Methods. Aggregated data file from the National Health Interview Survey from 2000 to 2008 was analyzed. Sample included 282 Chinese, 271 Filipino, 93 Asian Indian, 580 “other API”, and 63270 non-Hispanic white older adults aged 65 and older. Bivariate and multivariate analyses were used to examine the relationship between Asian ethnicities and health status. Results. The descriptive statistics show that there are significantly differences of health status and activity limitations among different groups of Asian older adults. Compared to non-Hispanic whites, Asian Indian older adults had better self-reported health; while Chinese, Filipino and other API older adults had poorer self-reported health (F=5.02, p<0.001). In terms of activity limitations, all Asian older adults groups had fewer limitations than non-Hispanic whites (χ2=30.34, p<0.001). Age, marital status, education, live arrangement, citizenship and health insurance status are all significant factors related to health status. Implications. Understanding of similarity and difference of health status among different groups Asian American older adults can help health professionals provide best services to these populations.

MEDICARE PART D AND ITS IMPACT ON RACIAL/ETHNIC DISPARITIES IN ACCESS TO PRESCRIPTION MEDICATIONS
E. Mahmoudi, G.A. Jensen, Wayne State University-Institute of Gerontology, Detroit, Michigan

Objectives. This study evaluates the impact of Medicare Part D on racial/ethnic disparities in access to prescription medications. This paper seeks to answer four questions: (1) Has Medicare Part D increased access to prescription drugs within different racial/ethnic groups, and if so, by how much? (2) Has Medicare Part D reduced racial/ethnic disparities in access to prescription drugs? (3) Has Medicare Part D reduced disparities in out-of-pocket and total spending on prescription drugs, and in out-of-pocket and total healthcare spending? And (4) Do the answers to these questions vary when different definitions for a “disparity” are used, and if so, how? Data. Medical Expenditure Panel Survey (MEPS) data covering 2003 through 2008 will be used for the analysis. Six measures of access will be examined: whether an individual has prescription drug insurance, the number of prescriptions actually filled during the year, annual out-of-pocket and total spending on prescription medications, and annual out-of-pocket and total healthcare spending. The “treatment group” will consist of MEPS respondents ages 65-70, and the “comparison group” will consist of MEPS respondents ages 59-64. Methods. A “pre-post-with-comparison-group” quasi-experimental design will be implemented using the framework of multivariate regression analysis. Specifically, a regression-based difference-in-differences (DD) estimator will be adopted to quantify Medicare Part D’s effects on each of the six outcome measures. Three alternative definitions for a “disparity” between a minority group and Whites will be explored, specifically, the AHRQ definition, the IOM definition, and a third one, called the “Residual Direct Effect” definition in the literature.

IMPROVING ORAL HEALTH AMONG VULNERABLE LOW INCOME SENIOR HOUSING RESIDENTS IN CENTRAL CONNECTICUT

Oral health is critical to healthy aging. It impacts appearance, self worth, nutritional status, and chronic disease progression. This current study identifies significant disparities in oral health among low income, primarily minority community dwelling adults residing in senior housing in Central Connecticut. We propose that reducing disparities necessitates addressing gaps in existing infrastructure. Methods include: developing long term relationships with in senior housing in the region; building a transformative Academic Health Center/community partnership, the Oral Health Research Strategic Alliance (OHRSA), linking UCONN School of Dental Medicine, the Institute for Community Research and the North Central Area Agency on Aging with other local organizations/institutions to support oral health programs; supporting local data collection on oral health and service barriers among vulnerable older/disabled adults; building and disseminating curricula to support community-based partnership research and developing a 10-year strategic research agenda. We have made entry into eight senior residencies in the targeted region and solicited resident interest in oral health and oral health research; organized the OHRSA, which has met twice and has identified at least three future areas of research; critically reviewed undergraduate curricula in geriatric oral health for dental students in the US; submitted a collaborative SDM/ICR planning grant to develop a building-level and individual-level intervention to improve
or oral health self-management of senior housing residents. We conclude that we can build an oral health research alliance, integrate oral health and prevention into senior buildings, and develop collaborative research efforts to improve oral health self-management in the region.

DIVISION AMONG DIVISIONS: THE AARP AND DIFFERENT DISCOURSES ON DIABETES AMONG ANGLOS AND HISPANICS

K. Moody¹, M. Rivera-Hernandez², 1. The University of Iowa, Iowa City, Iowa, 2. Miami University, Oxford, Ohio

In 2010, there were about 25.8 million people aged 20 years and older affected with diabetes (CDC, 2010). About 11.8% of Hispanics had been diagnosed with diabetes, but, the risk of developing diabetes is 66% higher for Hispanics. Hence, Hispanics are at higher risk to develop diabetes compared to non-Hispanic whites and Asian Americans (CDC, 2011). The lack of representation of Hispanics within printed publications seems to dispute that statistical evidence, and suggests a lack of presence or importance within national debates on obesity and diabetes. Our study looks at how Hispanics are represented within health campaigns and magazine advertisements, particularly in health magazines such as AARP Magazine. We looked at specific news stories on diabetes on the AARP Magazine website in both English and Spanish, checking to see if there was any difference in terms of content and message. By performing a content analysis of twelve months of publication (January 2010 – December 2010), our studies will see if there is a difference in terms of discussion of diabetes between health magazines published in the United States versus those published for Hispanic audiences. By examining the content that is archived online, we hope to show a) what differences exist in communication between different audiences, and b) how the discourse about diabetes grows and evolves over time. The end result is a greater understanding of what universal qualities exist in terms of diabetes discourse, as well as important racial and community differences among health professionals and publications aimed at older individuals.

THE ROLE OF SOCIOECONOMIC STATUS IN PREDICTING CHRONIC HEALTH CONDITIONS IN OLDER ADULTS WITH POOR VISION AT MIDLIFE

A. Chun¹, B. Steinman², 1. GERONTOLOGY, USC, Los Angeles, California, 2. Brown University, Providence, Rhode Island

There is growing interest in the association between socioeconomic status (SES) early in life, and health outcomes in later life. Indicators of low SES, including low income, employment status, and educational attainment are statistical predictors of many health problems experienced by older people. Because of institutional and social barriers including discrimination, racial minority groups are often among those most at risk for low SES, and to experience health disparities associated with social disadvantages. In many regards, people who age with severe vision impairments and/or other disabilities may be similar to racial minority groups in that they are likely to experience many of the same barriers leading to low SES. The purpose of this study was to compare SES characteristics of middle-aged adults with poor vision and good vision, and to examine the degree to which low SES among persons with vision impairment at midlife functions as a predictor of age-related chronic conditions in older persons. We analyzed six consecutive waves (1998 thru 2008) of the Health and Retirement Study using Cox Regression to determine risk of acquiring each of seven chronic conditions. Controlling for demographic variables and SES covariates, we assessed the effects of two levels of self-reported vision (poor and good). Results suggest that for middle-aged persons with poor vision, some SES variables are associated with lung problems, psychiatric disorders, and arthritis in old age. Consequently, middle aged persons with severe vision impairments may benefit from public support services and behavioral interventions that address modifiable indicators of low SES.

SESSION 1760 (POSTER)

HOME AND COMMUNITY BASED SERVICES

CONSUMER VOICES IN SETTING STANDARDS FOR OPTIONS COUNSELORS

D. White¹, P. Cardel², S. Elliot¹, A.F. Tressider¹, S. Jackson², D. Truxillo¹, 1. Portland State University, Portland, Oregon, 2. Seniors & People with Disabilities, Salem, Oregon

Options counseling is an emerging profession in the aging network. Options counselors (OC) provide information and decision support to consumers and their families. Consumers include those over 18 years of age with a disability and/or long-term services and supports needs. Person-centered planning and support is central to the role, with an emphasis on consumer values and preferences. The Administration on Aging is supporting the development of professional OC standards. This poster presents the processes used in Oregon, starting with a systematic job analysis with OCs, their supervisors, and national experts on options counseling. The result was a comprehensive list of task statements and job requirements which were then prioritized by OCs and OC experts. Consumer data also contributed to the development of standards. Fifty consumers or family members were interviewed to determine their perceptions of options counseling and the extent to which the OC delivered person-centered services and supports. Preliminary results indicated congruence between key aspects of the job (e.g., listening to concerns, providing appropriate information, demonstrating knowledge of services and resources, and not pushing for a particular decision) and the experiences the consumers and families valued most. These interviews also highlighted how gaps in the service system (e.g., transfers from one setting to another; affordable home care) can limit the effectiveness of OCs. Knowledge gained from this project can inform OC practices in other states, person-centered practices, and provide evidence about what matters to older persons and their families as they look for guidance with long-term care decisions.

MULTI-STATE SURVEY OF SUPPORT BROKER/PLANNERS IN PARTICIPANT-DIRECTED SERVICES PROGRAMS

H. Jeon¹, K.J. Mahoney¹, D.M. Loughlin¹, L. Simon-Rusinowitz¹, M. Sciegaj¹, S. Crisp¹, 1. Boston College, Newton, Massachusetts, 2. University of Maryland, College Park, Maryland, 3. Pennsylvania State University, University Park, Pennsylvania

Participant-directed long-term services programs successfully serve older adults and people with disabilities by providing choice and control over the services they receive. One component of these programs has been the significant contribution made by support brokers (also called support planners, counselors or consultants) who assist participants to develop the care plans they need. Although many aspects of the effectiveness of participant-directed programs have been reported, there is still much to learn about time management and the job-specific training and funding needs of support brokers. We conducted a multi-state survey of support brokers to learn about their roles. We included specific items about support brokers’ professional backgrounds, usual tasks, as well as the availability of training and their preparedness to perform such tasks. We followed up with phone interviews to obtain a better understanding of the survey findings. This presentation reviews the preliminary findings and presents suggestions for future training topics.

ELDERS’ EXPECTATIONS OF COMMUNITY SERVICES IN CHINA

J. Liu, The School of Social Work, Iowa City, Iowa

In China, the older population is growing rapidly. According to Chinese culture, families are expected to take care of their elders. However, the family capacity to support elders is shrinking, because the One-Child Policy reduced the number of potential family caregivers. Therefore, it is necessary to develop community services to satisfy elders’ physical,
psychological and social needs. The purpose of this study is to explore whether Chinese elders expect to receive community services and what factors influence their expectations. Following the ecological perspective, this study hypothesizes that elders’ well being and environmental conditions are related to their expectations of community services. This study uses a nationally representative dataset from the Chinese Longitudinal Healthy Longevity Survey to analyze Chinese elders’ expectations of eight types of community services and the factors that influenced their expectations. The results of expectation frequencies and logistic regressions indicate that Chinese elders expect their communities to provide services for them and these expectations are strongly related to their psychological and social well being, and the availability of family support and rural registration. The findings of this study imply: to support the increased elder population, the government should emphasize developing community services concerned with their psychological and social well needs; to further explore elders’ expectations of community services, researchers should collect more comprehensive data about Chinese elders’ well being and their environmental changes; to provide effective services, administrators of community service programs should assess individual well being and environmental conditions of their targeted elder populations.

CHARACTERISTICS OF OLDER ADULTS WHO SEEK HOME AND COMMUNITY BASED SERVICES THROUGH AN AREA AGENCY ON AGING IN THE UNITED STATES
F. Wilby, C. Chambless, College of Social Work, University of Utah, Salt Lake City, Utah

The United States and other nations around the world are on the cusp of a demographic transition that will result in a dramatic increase in the number of older adults. Associated with the graying of the world, experts identify the need for programs that manage chronic disease and enable older adults to remain in their homes for as long as possible. This study was conducted to identify the characteristics of 260 adults, 65 and over, who applied for services through an Area Agency on Aging in a western state in the United States, and determine the conditions that resulted in referral to the state-funded Home and Community Based Alternatives Program (Alternatives) or the Medicaid Aging Waiver program. Logistic regression was used to examine the characteristics that determined referral to the two programs. Although most of the sample lived at or near poverty levels, results suggest that higher monthly income and savings and living alone predict referral to the Alternatives program, whereas greater need for assistance with bathing and performing heavy housework are the primary determinants of referral to the Medicaid Waiver program.

AN ANALYSIS OF CURRENT AND PROJECTED RURAL OLDER ADULT LEGAL SERVICE NEEDS
L.W. Kaye1, J. Crittenden1, M.A. Adle2, D.C. Wihry1, J.L. Martin2, J. Center on Aging, University of Maine, Bangor, Maine, 2. Maine Legal Services for the Elderly, Augusta, Maine

A comparative legal needs assessment of rural-based older adults was conducted by analyzing research conducted in six states and service data from Maine. Findings indicate that up to half of all older adults will need legal assistance in the next 5-10 years, and this will be even higher among low income elderly where from 45% to 86% experienced legal problems in the prior three years. Help with health insurance was the greatest need across all states with 25% of intervention directed toward such issues. In Maine, help with financial issues was the second-most frequently provided service, compared to fourth nationally. More than half of those cases involved collections and 10% were for help with debt relief/bankruptcy. These cases have been increasing in Maine due to the economic downturn. About 25%-45% of older adults across states need help with estate planning. More than 15% of cases addressed in Maine involved housing issues including foreclosures. Housing issues may also be increasing for older adults compared to just three years earlier. In Maine and nationally, elders are not seeking help when facing abuse/exploitation. Less than 2.5% of older adults report abuse to authorities, but 6%-12% self-identify as being abused. While Maine’s elders, like those in other resource poor states, rely upon the legal assistance provided by Legal Services for the Elderly, data confirm such services are not sufficient to meet the growing need. Without free legal assistance, people who can’t afford a lawyer are most likely to ‘do nothing’ about their legal problems.

HOME- AND COMMUNITY-BASED SERVICE USE OF AFRICAN AMERICAN ELDERS LIVING IN INNER-CITY NEIGHBORHOODS
A.J. Lehning, M. Kim, R. Dunkle, School of Social Work, University of Michigan, Ann Arbor, Michigan

Historically, although African Americans are at an increased risk for chronic illnesses and functional limitations in later life, they have used nursing homes significantly less than Whites. Over the past decade, however, rates of nursing home use by Whites declined while those of African Americans increased. With research suggesting that nursing home use is linked to less use of HCBS, it is important to better understand the factors influencing HCBS use among African Americans. This study examined the association between predisposing characteristics, enabling resources, and need using Andersen’s Behavioral Model of Health Services and Access to Care and HCBS use in a representative sample of 517 African American elders age 60 and older living in inner-city Detroit. Results indicate that the role of predisposing, enabling, and need factors depends on the type of service used (i.e., in-home care, functional care, household services, and out-of-home care). For example, in terms of need factors, the number of health conditions was associated with an increased odds of using in-home (e.g., home health care) and functional care (e.g., home-delivered meals, homemaker assistance) services and decreased odds of household (e.g., home repair, legal assistance) services.

SESSION 1765 (POSTER)

HOUSING POLICY AND SAFETY ISSUES

CONSTRUCTING FIRE SHELTERS IN RESIDENTIAL BUILDINGS FOR ELDERLY AND DISABLED
B. Chang, C. Chou, S. Lin, Chinese Culture University, Taipei, Taiwan

Among all types of fires in the past decade, building fires, especially residential fires, occurred most frequently based on data from the Fire Agency in Taiwan. Today, the older population in Taiwan has reached 2.6 million, which is about 10.7% of the total population. Among these older individuals, 41,185 older individuals live in nursing or long-term care facilities, and 181,000 older individuals are cared for by foreign nursing aides at home. Due to the fact that physical limitations may cause strains on elderly and disabled to escape from fires successfully, it has drawn our attention to constructing fire shelters in residential buildings. First, we selected bathrooms from residential units as our study object based on the concept of “relative shelter,” including the frequency of fires, types of construction, risk factors, economic benefits, and residents’ physical and mental status. We conducted pre- and post-tests on air-tightness in 8 residential bathrooms by sealing sinks, air vents, and bathtubs. The results showed that fire shelters should: 1) be constructed by fire-proof materials, 2) allow escape individuals to breathe, and 2) have at least 50Pa pressurization to prevent the invasion of smoke and toxic gas. Air-supply equipment should be also installed to provide fresh air at least 12.8 m3 per minute and to be paralleled with emergency power. Under these conditions, these bathrooms will be able to resist fire, resist high temperature, and maintain air-tightness, and may serve as fire shelters for elderly or disabled in residential buildings or nursing facilities.
**HOUSING ACCESSIBILITY OF THE ELDERS IN SHANGHAI**

L. Chen, Population Research Institute, East China Normal University, Shanghai, China

Family planning policy has been implemented in China for over three decades. Now the first cohort of one-child parents have overwhelmingly become elders. The aging of one-child parents will be a unique feature of the situation of aging in urban China. Meanwhile, China has been witnessing dramatically rising housing price in urban areas in the past ten years. Housing becomes one of the most-heated topics in China. However, attentions have been paid mostly to the young generation, less is related to the elders. This paper investigates the housing condition of one-child elders. Shanghai was selected to conduct a survey of 976 one-child elders in 2010. The research finds that housing problems parallel with medical-treatment-caused poverty and constitute one of the two paramount categories of problems among the one-child elders. The low accessibility featuring multiple-storey housing without lift is the most worried problem of elders in terms of housing, which will impede their independence of daily living and social participation in the future. However, housing transformation encounters collective action problem and policy restrictions in the context of condominium-dominated housing structure in urban China.

**SOCIAL INTERACTION AND SOCIAL ACTIVITY AMONG RESIDENTS IN AFFORDABLE ASSISTED LIVING**

While aging research has consistently noted the importance of social involvement and social support in the lives of older adults, there have been very few studies exploring social interaction in assisted living (AL). The present study explored how residents in an affordable AL facility perceived their involvements with residents, staff, and family. Qualitative interviews were conducted with a purposive sample of 20 AL residents. All participants had resided in the facility between 6 months and 2 years. The sample consisted of almost equal numbers of African American (N = 8) and White (N = 11) elders, ranging in age from 65 to 93 years of age. Based on qualitative analysis of the data, four themes emerged capturing residents’ social involvement and feelings about social interactions. The themes reflected generally low expectations for social involvement with other residents. The major theme - “We all get along” - reflected casual, non-intimate social interactions with other residents. Interactions with fellow residents were clearly not viewed as friendships. Maintaining social distance appeared to as a strategy for avoiding conflicts and adapting to communal living. The remaining themes reflected limited expectations and desire for social activity. While most elders did not participate in formal activities, they acknowledged that there is “lots to do, if you want to.” However, low expectations for social involvement were related to general satisfaction. Finally, a sense of impermanence limited a desire to be involved with other residents. Findings provide important insight into how low-income elders in affordable ALFs view social involvements.

**PROXIMITY OF ASSISTED LIVING FACILITIES ACCEPTING MEDICAID WAIVER TO FLORIDA NURSING HOMES AND THE RELATIONSHIP TO LOW-CARE RESIDENTS**

Florida’s Medicaid Assisted Living for the Elderly (ALE) Waiver Program was designed to provide less costly personal care and supervision services in assisted living facilities (ALFs) for eligible individuals who would otherwise need nursing home (NH) care. The purpose of this study was to determine if access to Medicaid-funded care provided in ALFs is related to the prevalence of low-care residents in Florida NHs. Because county measures do not account for differences in local market characteristics, each NH was assigned a 15-mile radius used to identify the NH market. Using ArcGIS, we calculated the number of ALFs accepting ALE waivers located within each NH market. Data come from the Minimum Data Set, Online Survey Certification and Reporting Dataset, Area Resource File, and data derived from geospatial analysis for 662 Florida NHs in 2007. Hierarchical linear models were used to estimate the relationship between the number of ALFs accepting ALE waivers in a NH market and the proportion of low-care NH residents. The average Florida NH had 8.0% (SD=6.1% range 0-38.5%) of residents identified as low-care and the model adjusting for facility and market characteristics indicated that for every additional 10 ALFs that accept Medicaid waivers in a NH market, there was a .08% decrease in low-care NH resident prevalence (est= -0.008, SE=0.02, p=0.005). Results suggest that the number of ALFs accepting ALE waivers were associated with the prevalence of low-care residents in Florida NHs. Medicaid HCBS waiver services provided in an ALF may have served as a substitute for individuals with low-care needs.

**HOW USEFUL ARE CALIFORNIA'S RCFE PUBLIC RECORDS FOR CONSUMERS CHOOSING AN ASSISTED LIVING FACILITY?**

C.M. Murphy,1,2 C.L. Selder, M. Garret, 1. San Diego State University, San Diego, California, 2. Consumer Advocates for RCFE Reform, San Diego, California

Purpose: This study describes enforcement practices and patterns by the licensing and regulatory agency (Community Care Licensing Division (CCLD), Department of Social Services (DSS) for California’s Residential Care Facility for the Elderly (RCFE)) an understudied component of long-term care. Method: This ten-year retrospective descriptive study reviewed 348 public files of licensed RCFEs in California. Files obtained through California Public Records Act requests were reviewed; data corresponding to defined parameters regarding enforcement variables (citations by type and by inspector) were collected. Data was analyzed in aggregate, by facility size (i.e. bed capacity), state inspector - Licensing Program Analysts (LPA), and other parameters. Findings: Findings revealed variations and irregular enforcement patterns by LPA, irregularities in assessment and collection of civil penalties, and identified the Top Ten cited regulations by facility size. Also, a widespread pattern of missing and incomplete data in the facilities’ public record was shown. Implications: Because of variations and irregular enforcement patterns, and irregularities in assessment and collection of civil penalties, among other findings, the public record offers the consumer incomplete and inaccurate information to base her selection of an assisted living facility. Findings further imply that regulations lack the precision necessary for meaningful enforcement. Systemic patterns of missing and incomplete data contribute to information asymmetry by preventing the consumer from accessing a complete public record on individual RCFE performance.

**SESSION 1770 (POSTER)**

**LONG TERM CARE WORKFORCE**

**NURSING ASSISTANTS’ JOB SATISFACTION AND INTENT TO LEAVE IN NURSING HOME: A MULTILEVEL ANALYSIS**

J. Choi1, M. Johantgen1, 1. University of Kansas School of Nursing, Kansas City, Kansas. 2. University of Maryland School of Nursing, Baltimore, Maryland

Purpose: There has been little methodologically strong research to try and understand the complex factors influencing the job satisfaction and intent to leave of nursing assistants, essential care providers in nursing homes. The study examined the influence of relevant work-related and personal factors on Certified Nursing Assistants’ (CNAs) job satisfaction and intent to leave while accounting for the nested nature of
SATISFACTION IN NURSING HOMES: A MULTILEVEL ANALYSIS OF HEALTHCARE WORKER CANDIDATES FROM INDONESIA AND THE PHILIPPINES BASED ON ECONOMIC PARTNERSHIP AGREEMENT (EPA)

N. Tsukada, Nihon University Graduate School of Business, Tokyo, Japan

It has been about two years and half since Japan started hiring foreign nursing care worker candidates based on Economic Partnership Agreement (EPA) in August 2008. As of January 2011, a total of 612 nursing care worker candidates from Indonesia and the Philippines were working in Japan. The major purposes of this study are to find out how senior personnel of nursing homes, which have hired foreign nursing care worker candidates, would perceive their experiences and to find out if there were any differences between candidates from the two countries. The extensive-interview data, obtained from senior personnel of these nursing homes (N=46:20 hiring Indonesian candidates and 26, the Philippines candidates) between August 2010 and February 2011, were qualitatively analyzed. Preliminary analyses reveal that all participants of this study cited that foreign nursing care worker candidates work very hard with smiles and sincere attitudes towards residents. The biggest concern of the participants pertained to the National Care Worker License Examination scheduled in January 2012, for which the candidates will have only one chance, and if they fail to pass it, they will be sent back to their home countries. Although no differences were found in the working attitudes between the two groups of candidates, the dropout rates differed significantly (Indonesia, 1.62% and the Philippines, 5.34%). The major explanations of the difference would be cultures and conditions of the countries, in which candidates from the Philippines would be able to obtain employment as nursing care workers in other countries much easier than the Indonesians.

LOVING THE JOB BUT STILL CHOOSING TO LEAVE: UNDERSTANDING TERMINATIONS AMONG HOME CARE WORKERS
S.S. Butler1, M. Brennan2, S. Wardamasky1, 1. University of Maine, Orono, Maine, 2. AIDS Community Research Initiative of American, New York City, New York

The number of people projected to need personal assistance services is expected to double in the first half of this century. Although family caregivers provide much of this care, there is an increasing need for paid personal care workers, particularly for people living alone and with high levels of need. Personal care is one of the fastest growing occupations in the country, but with the high turnover rate among workers, there remains a critical "care gap". This paper reports on a mixed-method longitudinal study investigating turnover among home care aides in a northern New England state. The longitudinal design of this inquiry improves upon previous cross-sectional studies which have relied on "intent to leave" as a proxy for actual job termination. A sample of personal care workers was sent to 444 registered nurses, auxiliary nurses and unskilled nursing assistants. Structured interviews were administered to 40 ward managers and 13 directors and 900 hours of field observations were conducted in 40 nursing home wards throughout Norway. Results: We found a significant relationship between job satisfaction and task-oriented and relationship-oriented leadership styles, with a stronger effect for task orientation. The effect of the two leadership styles varied significantly across wards. Furthermore, staff stability had both a significant positive direct effect and a moderating effect on job satisfaction, whereas the two other ward-level predictors yielded no significant contributions. Conclusion: The relatively stronger effect of task-oriented leadership on job satisfaction, particularly in wards with low staff stability, is in contrast to most previous studies and suggests that there may be specific conditions in nursing homes that favour the use of this leadership style. The varying effect of both leadership styles indicates that staff in different nursing home wards could benefit from the use of different leadership styles.
personal care workers (n=261) from 11 home care agencies serving all regions of the state were followed for 18 months over which time 90 (34.5%) terminated their employment. Binary logistic regression (x2 9 = 31.715, p<.01) indicates factors at Time 1 predicting turnover 18 months later include younger age, lack of health insurance, lower mental health, and, surprisingly, stronger feelings of personal accomplishment regarding the work. Analysis of qualitative data from telephone interviews with these terminated workers reinforces the finding that workers quit the work while continuing to enjoy it. More than half (53.4%) reported more positive aspects to the job (e.g., helping elders is rewarding) than negative aspects (e.g., wages are too low). Implications related to increasing retention of these valuable workers will be explored.

WHAT MAKES THEM STAY? FACTORS PREDICTING LONG JOB TENURE AMONG HOME CARE WORKERS

High turnover rates among direct care workers are costly both to employers and society. When a worker leaves an organization, there are replacement costs related to recruitment and training. For society, there may be a reduction in care or no care at all for older adults. This paper reports on a mixed-method longitudinal study investigating factors related to retention among home care aides in a rural state. Home care workers (n=261) from both nonprofit agencies and for-profit companies (n=11) serving all regions of the state were followed for 18 months, completing two mail surveys and a telephone interview regarding employment experiences. The length of employment among the study participants, which included 90 terminations during the data collection period, ranged from less than three months to over 13 years, with a median tenure of just under three years. One quarter of the study participants had worked for their home care agency for at least five years and 6% had held their job for 10 years or more. A regression model (R2=.363) indicates older age, living rurally, higher wages, and higher sense of autonomy predicted longer job tenure. Surprisingly, lower physical function and lower sense of personal accomplishment also predicted longer tenure which may be a function of greater age. Themes from the telephone interviews demonstrate differences between long-tenure workers (e.g., enjoys flexible schedule) versus those who terminate in less than a year (e.g., inconsistent hours are problematic). Implications will be discussed regarding increasing retention of this critical component of long-term care.

COMPASSION FATIGUE: IMPACTS FOR PROFESSIONALS WORKING WITH OLDER ADULTS

Compasion Fatigue (CF) is becoming recognized in helping professions as a silent disease which is beginning to impact people in the helping professions who are increasingly stressed, and impacted by trauma for prolonged periods of time. Professionals working with older adults are a group of silent victims, whose vulnerability is often unnoticed and underestimated. Thus, unrecognized CF for professionals can lead to a lack of ability to detect signs of mental distress for older adult consumers. This presentation will describe some of the signs and symptoms of CF, differentiate CF from ‘burnout’ and present some findings on the incidence and prevalence for professionals working with older adults. Data examining three subscales, compassion fatigue, compassion satisfaction and burnout (Stamm, 2003) were used to identify the level of CF experienced by helping professionals working with older adults in rural settings in the Midwest (n=212). Findings suggest that the longer a person has been in their specific helping role, the more likely they are to be suffering from burnout and compassion fatigue, and the more likely they are to suffer from dissatisfaction with their role.

Training and education do not seem to serve as a mediating factor, however, marital status does serve as a protective factor. Solutions will be addressed at the conclusion of the paper.

HHR BEST PRACTICES FOR HEALTH CARE WORKER RETENTION IN RURAL ORGANIZATIONS
D. Spokus, E. Yoder, Health Policy and Administration, Penn State, University Park, Pennsylvania

Numerous studies have documented the current and projected short-age in the health care work force (Harmuth & Dyson, 2005; HANYSâ€™ Workforce Survey, 2008; BLS 2007; ADGAP, 2007). The projected population that has traditionally worked in the health care field is projected to only increase slightly which will not be enough to satisfy the growing need for health care workers, especially considering the persistent challenges related to recruitment, development and retention of health care workers. The current study examined from a human resource perspective the issues related to development and retention of older (55 or older) health care workers. This paper reports on a mixed-method longitudinal study investigating factors related to recruitment, development and retention of older health care workers. Two areas were examined: (1) associations between organizational factors and social support factors with retention/turnover intentions of older health care workers and (2) human resource best practices employed by organizations in addressing recruitment, development and retention of older health care workers. Study participants (n=148) from three rural health care organizations were included in the study. Logistic regression results indicated indicators of quality of work life were an important indicator to retention/intention to leave. Also found to be significantly associated with retention/intention to leave were indicators of corporate/organizational fit and indicators of role/job ambiguity. The results provide baseline information for personnel in HRD divisions of health care organizations to develop best practices for the recruitment, development and retention of older health care providers in rural areas.

WORK-RELATED INJURIES AMONG NURSING HOME CERTIFIED NURSING ASSISTANTS
N. Bryant, Center for Applied Research, LeadingAge, Washington, District of Columbia

This is a nationally representative data on work-related injuries among certified nursing assistants (CNAs) in nursing homes as well as demographic characteristics and perceptions of CNAs associated with having a work-related injury in the last year. Data are from the 2004 National Nursing Assistant Survey (NNAS). The findings are based on data from 2,881 respondents, representing approximately 676,300 CNAs nationwide. In 2004, 58% of CNAs were injured over the course of one year. The types of injuries included scratches, open wounds, cuts; back injuries; black eyes; pulled muscles/other strains; and human bites. The majority of injuries occurred because of aggression by residents and by lifting, bathing, and handling residents. Over the course of one year, CNAs had an average of 4.5 injuries, were unable to work an average of 3 days because of the injury, and 16% were assigned other duties or jobs because of the injury. Adjusted logistic models showed that a significant association persisted between reported work-related injury over the course of a year and CNAs’ perception of needing other equipment to make the job safer, being a female, being White (relative to Black), job dissatisfaction, and CNAs’ perception that turnover interferes with their ability to do the job. The model predicts odds of a work-related injury over the past year as .681. The data show some characteristics of CNAs and their perceptions that might help to identify those at higher risk for a work-related injury.

WHAT ARE THE PREDICTORS AND OUTCOMES OF MAINTAINING CNA STAFFING LEVELS VOLUNTARILY?
K.M. Smith, K.S. Thomas, K. Hyer, H. Meng, University of South Florida, Tampa, Florida

The primary objective of this study is to examine provider response to relaxed minimum staffing levels and its effect on patient outcomes.
Prior to July 2008, the Florida mandated minimum staffing levels for certified nursing assistants (CNA) were 2.9 hours per resident day (HPRD) with a daily minimum of 2.7. Due to reimbursement cuts in July 2008, sanctions for violations of these mandated minimum levels were relaxed for facilities staffing above 2.6 HPRD for a 12-month period. Staffing levels have been shown to have a direct relationship with quality of care. This study uses the structure, process and outcome model (SPO) to examine the effect of maintaining higher levels of staffing (structural component) on restraint use (process component) and quality measures (outcome components). Data from quarterly Florida staffing reports and the Online Survey Certification and Reporting database were used to examine CNA staffing levels of free-standing nursing homes during 2008-2009. Results indicated that relaxed requirements precipitated an immediate drop of CNA staff in 61% of Florida’s nursing homes. Nursing homes maintaining higher staffing levels were more likely to be non-profit, $\chi^2(1)=14.25, p<.05$ and have lower Medicaid ratios ($t=3.48, p<.001$). Outcomes included pressure sores, four point activities of daily living decline, and incontinence. These findings reinforce the importance of adequate state reimbursement for Medicaid residents to assure that all residents receive adequate care and quality of care is not determined by reimbursement. Future research should explore how quality outcomes vary given different staffing, process of care and reimbursement levels.

SESSION 1775 (POSTER)

SOCIAL SUPPORT

SOCIAL SUPPORTS AS PREDISPOSING FACTORS IN RURAL AND NON-RURAL NURSING HOME ADMISSIONS

A.L. Cohen, J. Bulanda, Sociology and Gerontology, Miami University, Oxford, Ohio

In this study, we use nine years of longitudinal data to examine the role of social supports as predisposing factors for nursing home admissions in individuals living in both rural and non-rural communities. Data from the 1998 through 2006 waves of the Health and Retirement Study are used to examine rural-nonrural differences in odds of being admitted to a nursing home for thirty days or more over a two-year time period. Results show that rural elders have higher odds of nursing home admission than do non-rural elders. Controlling for health factors reveals that rural elders’ higher risk of nursing home admission is due to the fact that they are in poorer health, on average, than their non-rural counterparts. A number of social support factors are significant predictors of nursing home entry, including marital status, proximity of children, and frequency of visits with neighbors.

COMPARING THE EFFECTIVENESS OF SOCIAL SUPPORT FROM DIFFERENT SOURCES IN DEPENDENT ELDERLY

S. Chao\(^1\), P. Lu\(^1\), J. Tzu Chi University, Hualien City, Taiwan, 2. National Chengchi University, Taipei City, Taiwan

Background: Taiwan is facing a growing aging population and increasing needs in long-term care. Previous research indicated functional disability was a significant risk factor for the increase of depressive symptoms. Social support may moderate the linkage between functional status and depression. This longitudinal study explored the buffering effects on depression of instrumental and emotional support from different sources against the impact of increasing functional disability. Methods: Random effects modeling was utilized with data from a nationwide longitudinal study in Taiwan. There were a total of 6,722 observations from 2,856 elder study subjects over a 10-year period. Findings: 1. Sons were the most common providers of instrumental assistance, followed by spouses and daughters-in-law. However, Chinese elders turned primarily to their spouses for emotional support, followed by sons and daughters. 2. Instrumental support from sons and daughters-in-law as well as emotional support from spouses and sons yielded greater effects on depression than other sources. 3. Receiving instrumental support from family members and formal organizations appeared to moderate the linkage between increasing functional disability and depression. Conclusions and Implications: The results here support the importance of encouraging a partnership between natural helpers and health care professionals. Improved integration between formal and informal networks may more effectively meet the needs of the frail elderly and their families. This study also calls for more attention to cultural competence issues in health care policy and service delivery.

AN EVALUATION OF AN ELDER COHOUSING COMMUNITY

A.P. Glass, University of Georgia Institute of Gerontology, Athens, Georgia

To determine if this intentional community succeeds in meeting expectations and maintaining or improving quality of life for residents, this research is an evaluation of one of the first elder cohousing communities in the U.S. The researcher has gathered data annually for five years, using a mixed-methods approach of surveys and in-depth interviews. Baseline data were collected from a total of 43 residents over this period. All respondents were white, the majority (79%) were female, and the average age was 74 (range = 65 to 88). Respondents reported common chronic health problems, but were generally independent in functioning. There was no significant difference in physical or mental health across time. Sense of community and mutual support were the primary reasons respondents gave for moving. When asked how living here compared to expectations, 22 of 32 (69%) said it was either “very close” or “exceeded” expectations. On a 2010 “overall satisfaction” measure, 29 (91%) respondents were “somewhat” (n = 9, 28%) or “very satisfied” (n = 20, 63%). Mutual support is occurring. There was high satisfaction across all 30 quality of life aspects. The “total” satisfaction score based on summing these aspects was highly correlated with the “Brief Sense of Community” scale (p = 0.000). Almost all (97%) would recommend elder cohousing to others their age. More than two-thirds of the charter residents (n = 28, 71%) remain involved in the community. Lessons learned are shared. Findings suggest that while there are challenges, self-managed elder cohousing is a viable option.

SOCIAL CAPITAL AND FEELINGS OF UNSAFETY IN LATER LIFE

L. De Donder, N. De Witte, S. Dury, T. Buffel, D. Verté, Vrije Universiteit Brussel, Brussels, Belgium

This contribution explores the relation between social capital, defined in terms of social ties, place attachment and civic participation, and feelings of unsafety in later life. The data for the present research are derived from the Belgian Ageing Studies, a project which uses structured questionnaires to collect information about various aspects of quality of life of older adults at the level of municipalities. Using data from 26,766 older adults, the results of the multiple regression analysis reveal a lack of opportunities for political participation as the most important factor in understanding feelings of unsafety. In addition, several features of place attachment proved to be associated with feelings of unsafety such as neighborhood satisfaction and neighborhood involvement. The quantity of social ties and potential social support are less important when other aspects of social capital are taken into account. Based on these results, a number of policy recommendations to tackle feelings of unsafety amongst older people will be critically discussed. The argument is developed that enhancing opportunities to give older people a voice in the process of political decision-making are important actions in reducing feelings of unsafety in later life.
DIFFERENCES IN PREFERENCES FOR PET DOGS VERSUS HUMAN COMPANIONSHIP AND DEPRESSION IN CAUCASIAN AND LATINO ELDERS

H. Miltiades, J. Shearer, California State University, Fresno, Fresno, California

This research study compared preferences for pet dogs versus human companionship among 115 Caucasian and 47 Hispanic older adults. Depression was then regressed on pet preference and social and demographic characteristics. Results: The respondents were on average, 67 years old, mostly female (60%), married (73%), and over half (55%) had a high school education. Analysis revealed that 45% of Caucasian elders preferred their pet dog to family and friends, whereas only 14% of Hispanics preferred their pet to family and friends, chi2 = 11.07, p = .01. Regression analysis revealed that inability to pay bills, Caucasian ethnicity, and ability to adequately care for the dog was associated with a higher likelihood of preferring the pet to family and friends. Depression was predicted by social network, gender, ability to care for the dog and pet preference. An interaction term revealed that Caucasian elders who preferred their pet had higher levels of depression than Hispanic elders who preferred their pet. Conclusion: This research indicates that there may be cultural differences in how older adults form pet attachments. Furthermore, some Caucasian and Hispanic elders prefer dog to human companionship and this may result in depression. Further research is needed to explore how pet preference develops.

GENDERED RELATIONSHIPS BETWEEN SOCIAL CAPITAL AND HEALTH AMONG OLDER ADULTS IN CHINA

Q. Xu, J. Norstrand, Social Work, Boston College, Newton, Massachusetts

Goal: Goal of study was to examine how social capital (SC) relates to health among older Chinese, particularly from a gender perspective. Method: Sample (N=1,854) of older Chinese (60 years and over) demographic variables only. Model 2, SC dimensions were added. Results: Significant differences were found on some dimensions of SC by gender. Regressions indicated different associations between dimensions of SC with health outcomes by gender. Implications: Accounting for gender may be important when developing interventions to maximize SC in communities of China.

SOCIAL ISOLATION, LONELINESS AND HEALTH AMONG OLDER ADULTS

C. Coyle, Univ. of Massachusetts Boston, Boston, Massachusetts

As the percentage of older adults increases over the next few decades, particularly those that live alone, social isolation and loneliness are likely to increase. Previous research has identified social isolation as well as feelings of loneliness as risk factors for adverse health outcomes, particularly among older adults. However, these two constructs are rarely studied together as two unique constructs, making it unclear whether subjective feelings of loneliness or objective measures of social isolation are more detrimental to the health of older adults. The primary objective of this study is to examine the independent relationships between social isolation and feelings of loneliness and health outcomes. Using data from two waves of the Leave Behind Questionnaire from the Health and Retirement Study (2006 and 2008), (n=14,732) several indicators were combined to form a scale of social isolation, and the Hughes 3-Item Loneliness scale was used to measure feelings of loneliness. Logistic regression analysis results show that both feelings of loneliness and social isolation have independent relationships with several binary health outcome measures (self-reported fair/poor health and multiple chronic conditions) after controlling for a wide range of demographic variables. Continued research on separating these two constructs could provide valuable information on how to combat the deleterious impacts of isolation and loneliness on health in later life.
rapamycin extends lifespan despite impairing insulin action. Our data further reveal that mTORC2 disruption is an important mediator of rapamycin’s effects in vivo.

POST-DEVELOPMENTAL, LIVER-SPECIFIC KNOCKDOWN OF IGF-1 IN MICE: A NOVEL MODEL OF VASCULAR AGING

L. Bailey-Downs1, M. Mitschelen1, D. Sosnowska1, P. Toth2, A. Kolier2, W. Sonntag2, Z. Ungvari1, A. Csiszar1, I. Reynolds Oklahoma Center on Aging, Department of Geriatric Medicine, University of Oklahoma Health Sciences Center, Oklahoma City, Oklahoma, 2. Department of Physiology, New York Medical College, Valhalla, New York

Age-related dysregulation of Nrf2-dependent antioxidant pathways impairs cellular redox homeostasis, exaggerating age-related oxidative stress and increasing sensitivity of aged vessels to oxidative stress-induced cellular injury. Circulating levels of IGF-1 substantially decline with age, which significantly increase the risk for cardiovascular diseases in humans. To determine whether adult-onset IGF-1 deficiency results in vascular Nrf2 dysfunction, we utilized a novel mouse model with a liver-specific adenoviral knockdown of the IGF-1 gene using Cre-lox technology (Igf1f/f +MUP-iCre-AAV8), which manifests a significant post-developmental decrease (~50%) in circulating IGF-1 levels. In the aorta of IGF-1 deficient mice there was a trend for decreased expression of Nrf2 and Nrf2 targets genes (GCLC, NQO1 and HMOX1). In cultured aorta segments of Igf1f/f +MUP-iCre-AAV8 mice treated with oxidative stressors (high glucose, oxLDL and H2O2) induction of Nrf2-driven genes was significantly attenuated as compared to control vessels, which was associated with an exacerbation of endothelial dysfunction, increased ROS levels and apoptosis, mimicking the aging phenotype. Thus, IGF-1 deficiency is associated with vascular Nrf2 dysfunction, which likely promotes adverse vascular phenotypic alterations in pathophysiologic conditions associated with increased ROS production (i.e. diabetes mellitus) and results in accelerated vascular impairments in aging.

OXIDATIVE STRESS RESISTANCE IN A NOVEL ANIMAL MODEL OF AGING WITHOUT SENECEENCE

S. Milton, M. Reiterer, L. Bruce, H. Prentice, Biological Sciences, Florida Atlantic University, Boca Raton, Florida

Oxidation of the amino acid methionine (Met) to methionine sulfoxide (Met(o)) by reactive oxygen species (ROS) causes loss of biological activity and age-related diseases. The antioxidant system of the methionine sulfoxide reductases (MsrA, MsrB) catalyzes the reaction Met(o) -> Met, thus preventing and repairing oxidative damage to proteins to restore biological function, as well as scavenge ROS. MsrA and MsrB provide potential therapeutic targets for age-related pathologies; Msr overexpression is known to increase lifespan in some animal models. The long-lived turtle Trachemys scripta provides a unique model to investigate ROS handling, as it survives both extended anoxia and reoxygenation without neuronal deficit, and suppresses oxidative damage. The turtle thus provides an exciting new animal model in which to examine the relationship between ROS and aging. Msr levels and ROS production and damage were examined in anoxia (4h) and upon reoxygenation in the turtle. ROS levels increase 2-fold upon reoxygenation following anoxia, but without protein carbonyl increase. We hypothesize that high Msr levels may ameliorate oxidative stress and age-related senescence. Anoxic MsrA mRNA and protein levels increased 9- and 7-fold, respectively, with mRNA but not protein levels falling upon reoxygenation. MsrB transcription increased 2- and 3-fold during anoxia and reoxygenation, respectively, with protein increases of 8- and 15-fold. Msr upregulation is vital for cell survival, as MsrA knockdown with siRNA more than doubled cell death in neuronal cultures. This is the first report in any system of the regulation of Msr transcription and protein levels by oxygen supply.

ESSENTIAL GENES AND STEM CELL QUALITY MODULATE SURVIVAL AND EXCEPTIONAL LONGEVITY IN C. ELEGANS

S. Curran, Davis School of Gerontology, University of Southern California, Los Angeles, California

Aging is a universal and inevitable process driven by diverse molecular pathways. Recent work suggests that the genes that most potently influence the rate of aging in C. elegans are those that are essential for growth and development. More than 90% of these genes have conserved developmental roles from yeast to man and together may represent an evolutionarily conserved program to modulate lifespan. Many of these genes function independently from the canonical longevity-modulating pathways including insulin/IGF-I signaling, dietary restriction, mitochondrial respiration and reproduction. Inactivation of one group of longevity modulators results in somatic cells with germ cell-like characteristics, increased tolerance of genotoxic stress and increased lifespan. We have developed a new model to explain the exceptional longevity phenotype of some C. elegans essential gene mutants. We identified the misexpression of germ cell specific factors in the somatic cells of the insulin-like signaling mutants, in animals RNAi depleted for the cytosolic chaperonin complex, and in animals with diminished protein synthesis. An important question is how this pathway is triggered in C. elegans and why some cells are more responsive than others. As a first step, we have examined the key transcriptional regulators of many longevity-promoting pathways and found that the misexpression phenotype requires at least two transcription factors; the worm ortholog of FoxO/DAF-16 and Nrf2/SKN-1. Both of these transcription factors receive inputs from multiple signaling pathways including insulin signaling, JNK and the p38 MAPK pathways, but the specific signal that initiates the misexpression of germine specific genes in somatic tissues remains a mystery. Importantly, both of these transcription factors potentiate the longevity phenotype identified from post-developmental inactivation of many essential genes.

AGE-RELATED SARCOPENIA AND BONE LOSS

CONFIRMATION OF MOUSE MODEL OF SARCOPENIA BY GENOME WIDE EXPRESSION STUDY IN HUMANS

D. Melzer1, L. Harries1, L. Pilling1, S. Bandinelli1, J.M. Guralnik2, A. Singleton1, D. Hernandez1, L. Ferrucci1, 1. Epidemiology and Public Health, University of Exeter, Exeter, United Kingdom, 2. National Institute on Aging, Baltimore, Maryland, 3. Azienda Sanitaria di Firenze, Florence, Italy

Introduction A ‘knockout’ mouse study suggested a key role for CCAAT / enhancer-binding protein β (C/EBP-β) in muscle fibre regeneration and sarcopenia like changes. We aimed to identify in vivo leukocyte gene expression associated with muscle strength in the human adult population. Methods We undertook a genome wide expression microarray screen, using immediately stabilized blood RNA samples from INCHIANTI study participants (ages 30-104 yrs). The Short Physical Performance Battery score (SPPB) tested walk speed, chair stand and balance. Logged expression intensities were regressed with muscle strength using models adjusted for multiple confounders. Key results were validated with TaqMan Low Density Arrays. Results C/EBP-β expression was associated with handgrip strength (coeff = 0.20560, p=1.03*10^-6, genome-wide data False Discovery Rate q-value=0.014): this association was independent of physical activity levels. Estimated mean handgrip strength in 70 yr old men in the lowest C/EBP-β expression tertile was 35.2 kg compared to 41.2 in the top tertile. TGF-β3 (p=3.4*10^-5, q=0.12) and CEBP-α expression (p=9.67E-5, q=0.18) showed near study-wide positive associations, but there was no association with C/EBP-α expression. C/EBP-β expression was associated with hip, knee, ankle and shoulder strength and the SPPB performance.
LOSARTAN RESTORES SKELETAL MUSCLE REMODELING AND PROTECTS AGAINST DISUSE ATROPHY IN SARCOPENIA
T.N. Burks1, E. Andres-Mateos2, R. Marx3, J.D. Walston1, C.W. Ward1, R.D. Cohn1, 1. Institute of Genetic Medicine, Johns Hopkins University School of Medicine, Baltimore, Maryland, 2. University of Maryland School of Nursing, Baltimore, Maryland, 3. Division of Geriatric Medicine and Gerontology, Johns Hopkins University School of Medicine, Baltimore, Maryland

Sarcopenia, the physiological process of aging characterized by a critical loss of muscle mass and function, significantly contributes to morbidity and mortality in older adults. Additionally, it increases the incidence of pathologic fractures causing prolonged periods of hospitalization and rehabilitation. The molecular mechanisms underlying sarcopenia are poorly understood, but recent evidence suggests that increased TGF-β signaling contributes to impaired satellite cell function and muscle repair in aged skeletal muscle. We therefore evaluated whether antagonism of TGF-β signaling via losartan has a beneficial impact on the muscle remodeling process of sarcopenic mice. We demonstrate that mice treated with losartan develop significantly less fibrosis and exhibit improved in vivo muscle function after cardiototoxic-in-induced injury. Interestingly, we find that losartan not only blunts the canonical TGF-β signaling cascade, but also modulates the non-canonical TGF-β mitogen-activated protein kinase pathway. We next assessed whether losartan was able to combat disuse atrophy in aged mice that were subjected to limb immobilization. We show that immobilized mice treated with losartan are protected against the loss of muscle mass. Remarkably, this protective mechanism is not mediated by TGF-β signaling, but is due to an increase of the IGF-1/Akt/mTOR pathway. Thus, blockade of the AT1 receptor using losartan proves to have clinical benefits to combat injury-related muscle remodeling and to protect against disuse atrophy in sarcopenia by mediating various critical pathways important for skeletal muscle homeostasis.

AGE RELATED BONE LOSS IS PARTIALLY DUE TO ALTERATION IN OSTEOCLAST DIFFERENTIATION POTENTIAL IN MICE
S. Lee, S. Mun, P. Hernandez, G.A. Kuchel, Center on Aging, University of Connecticut Health Center, Farmington, Connecticut

Background: Human aging is often complicated by bone loss, which leads to osteoporosis and its associated increase in bone fragility and fracture risk. Osteoclasts remove old matrix while osteoblasts form new bone and aging is believed to affect both systems. Methods and Results: To determine if mice lose trabecular and cortical bone with age, we examined 6 and 22 month old male C57BL/6 mice. In aged mice, femoral bone mass by microCT was decreased (72%; p<0.01) compared to younger mice. We also examined OCL numbers forming in bone marrow cultures. Bone marrow cells from aged mice showed a significant increase in TRAP(+) OCL numbers when treated with RANKL and M-CSF. OCLs from aged mice were also larger. Flow cytometry analysis demonstrated no significant difference in osteoclast precursor numbers. Subsequently, we examined inflammatory cytokines in the serum and found significant increases in the levels of IL-1α, MCP-1 and MIP-1α in aged mice. Lastly, mRNA expression analysis demonstrated a significant increase in the RANKL/OPG ratio in calvaria and femurs from aged mice. Conclusions: These results indicate that bone marrow osteoclast precursors from aged mice have greater potential to differentiate into OCL. These more active and larger osteoclasts and increases in RANKL/OPG ratio may contribute to the development of age related bone loss and fracture risk through enhanced bone breakdown. This work was supported by NIH/NIAMS Grant R01AR055143.

AMINO ACIDS FOLLOWING AEROBIC EXERCISE ENHANCE MUSCLE PROTEIN SYNTHESIS & mTORC1 SIGNALS IN ELDERS
M.M. Markofski1, K.L. Timmerman1,2, C.S. Fry2, J.M. Dickinson1, D.K. Walker1, B.B. Rasmussen1,2, E. Volpi1,2, J. Sealy Center on Aging, University of Texas Medical Branch, Galveston, Texas, 2. Division of Rehabilitation Sciences, University of Texas Medical Branch, Galveston, Texas

Even in older adults that appear healthy, sarcopenia is a serious concern. Aerobic exercise and essential amino acid supplementation have been suggested as possible treatments for sarcopenia. The purpose of this preliminary study was to investigate the acute effects of aerobic exercise and essential amino acid supplementation on muscle protein metabolism in older adults, specifically fractional synthetic rate (FSR) and mammalian target of rapamycin complex 1 (mTORC1) signaling. Methods: To date, eighteen sedentary (4050±1241 steps/day) but otherwise healthy older adults (68-81 years) completed the acute phase of the study. Baseline postabsorptive muscle samples were collected, and subjects were randomized to either rest in bed (REST) or 45 minutes of treadmill walking at ~70% of resting HR reserve (EX). Immediately following the REST or EX period, subjects consumed either a leucine-enriched essential amino acid (EAA) or placebo (PLA) beverage (double-blind). Muscle biopsies were collected one and three hours post-beverage. FSR and mTORC1 signaling were measured with stable isotope techniques and immunoblotting procedures, respectively. Preliminary results: FSR and mTOR phosphorylation were elevated above baseline by 40% and 30%, respectively, in the EAA+EX group. Conclusion: Aerobic exercise in combination with essential amino acid supplementation may be beneficial for the treatment of sarcopenia. Completion of the study will increase power and provide information on the mechanism by which EAA+EX enhance muscle anabolism in older adults. Funded by NIH/NIA grant #R01AG030070

SESSION 1790 (PAPER)

AGING IN A CHANGING WORLD: THE MIGRATORY ‘LENS’
S. Torres, Dept. of Sociology, Uppsala University, Uppsala, Sweden

Globalization is challenging social gerontologists’ notions of who older migrants are and how to cater to their needs. This presentation aims to show that there are specific risks for social exclusion associated with the migratory life-course even if mechanisms of social exclusion are bound to work differently depending on the when, why and where surrounding the migratory life-course. The manner in which social exclusion is experienced by older migrants will depend, however, not only on the type of migration they have engaged in (e.g. international labor migrants, family-reunion migrants, amenity-seeking migrants and refugee) but also on the social positions (class, ethnicity and gender to name a few) from which they depart. The presentation will show the differences in conceptualizations of social exclusion that are characteristic of both, gerontological research and research in migration/ethnicity-related issues, since these streams of research depart from different approaches to social exclusion. As such they put forth different solutions to the problem of social exclusion and have different conceptualizations of what social integration is. The presentation will address these differences as well as the implications they have for gerontological research, policy and practice.
THE UK HOUSEHOLD LONGITUDINAL STUDY (UNDERSTANDING SOCIETY) – A RESOURCE FOR COMPARATIVE RESEARCH
S.L. McFall, Inst. for Social and Economic Research, University of Essex, Colchester, United Kingdom

Gerontologists are familiar with cross-national comparisons using the Health and Retirement Survey and the English Longitudinal Study of Ageing. The new UK Household Longitudinal Study, Understanding Society is another interesting data source for comparative research on the life course. The initial release of data from the first half of wave 1 was in December 2010 and had 9,718 persons aged 50 or older and 4,385 persons aged 65 or more. The full wave 1 data released in Winter 2011 will have at least double the number of older persons. The study has a stratified and clustered equal probability sample of addresses in the UK, with an over-sample of five ethnic minorities. This paper summarizes health and family data frequently used by social gerontologists. Several varieties of health data are collected in main or self-completed surveys, annually or in rotating modules. Nurse collection of objective biomarkers was introduced for adults in Wave 2. They include anthropometrics, blood pressure, lung function, and the collection of whole blood for DNA and analytes. Data linkage will be used to examine health care use, diagnoses, and mortality. With respect to family, there is extensive information about household composition/relationships. Adults report on family background when young, family networks, care giving, and quality of relationships with spouse or partner. Wave 2 has information about division of labour and social support. Understanding Society can be used to examine health and social variation and permits examination of older persons in the context of family, community and society.

WHO STAYS AND WHO LEAVES? AN EMPIRICAL EXAMINATION OF THE DEMOGRAPHIC CHARACTERISTICS OF MEXICAN ELDERLY RETURN MIGRANTS
A. Vega, University of California, Berkeley, Berkeley, California

With the number of foreign-born elderly in the United States growing rapidly, return migration to the country of origin among this population will become increasingly important in coming years. Perhaps no other group highlights this issue more so than Mexican elderly in the U.S. The number and characteristics of Mexican immigrants who return migrate in old age not only affects social service consumption in the U.S. but also our understanding of foreign-born elderly well-being. Estimates of the prevalence of Social Security use, employment status, and educational level among foreign-born elderly will be biased if a non-representative group of immigrants return to their home country during old age. This study compares the socio-demographic characteristics of Mexican immigrants who remain in the U.S. upon reaching retirement age and those who return migrate during this time. Moreover, because of the complexity of studying migrant activity, this study conducts this comparison using multiple data sources as an added robustness check. The results of this study reveal that elderly Mexican return migrants are more likely to be male, have higher levels of schooling, are more likely to be married, and are less likely to receive any form of retirement income than their U.S.-residing counterparts. These findings highlight the importance of considering elderly return migration in assessments of how well foreign-born elderly fare in the U.S.

GRANDPARENTS’ GENDER AND GRANDPARENTS’ SEXUAL ORIENTATION: OVERLOOKED ISSUES THAT INFLUENCE GRANDPARENTING
N. Orel1, C.A. Fruhauf2, 1. Gerontology, Bowling Green State University, Bowling Green, Ohio, 2. Colorado State University, Fort Collins, Colorado

Although researchers have empirically examined the grandparent-grandchild relationship for over fifty years, there has been a lack of attention given to understanding the diversity and contextual variation within this intergenerational relationship when grandparents self-identify as Lesbian, Gay, Bisexual, or Transgender (LGBT). This presentation will provide the results of a comprehensive overview and critique of the available research and literature on LGBT grandparents using a life course perspective. The life course perspective is an extremely useful theoretical and organizational structure that can be applied to the role of LGBT grandparenting and the relationship between grandparents and grandchildren. From this theoretical orientation, two overlooked issues that influence grandparenting (i.e., grandparents’ gender and grandparents’ sexual orientation) will be explored. The authors will specifically discuss two overarching themes that are evident in the available research on LGBT grandparenting: 1) Mediating role of parents in the grandparent-grandchild relationship, and 2) Managing disclosure of sexual orientation and gender identity. Recommendations for programs, policy, and practice that recognize LGBT grandparents and their grandchildren will be provided.

SESSION 1795 (PAPER)

CORRELATES OF VOLUNTEERING IN LATER LIFE

LEAVING HOME: HOW OLDER ADULTS PREPARE FOR INTENSIVE VOLUNTEERING
C. Check1, K. Piercy2, S. Grainger1, 1. Human Development and Family Studies, Penn State, Mont Alto, PA, Pennsylvania, 2. Utah State University, Logan, Utah. 3. Independent Researcher, Bristol, United Kingdom

Many people reaching retirement choose volunteering as a way of finding personal meaning (Haber, 2009). One type of service that older adults increasingly choose is intensive volunteering, which is volunteering done a 24-hour basis away from home. Because of the multiple demands of family, employment, and health that are present from middle age onward, potential volunteers often find that they need to plan ahead in order to serve intensively. This study used semi-structured interviews to explore planning and decision-making processes for 19 men and 19 women over 50 years old. The Mormon, Mennonite, and Lutheran participants who gave intensive humanitarian or disaster relief service averaged 56.24 years old (SD = 6.22), were mostly married (86.8%), and served an average of 81.95 weeks (SD = 61.2). Using McCracken’s five step method for qualitative data analysis, our results suggested that there were five stages related to preparation and performance of intensive service: pondering, anticipating, mobilizing, serving, and evaluating for possible re-enlistment. During this process, study participants made decisions about the feasibility of intensive service and engaged in preparatory behaviors that included downsizing homes, dealing with health issues, and making arrangements for stability during their absence (insurance coverage, house-sitting, payment of bills, and care of family members left behind). Increased knowledge of planning and decision-making processes for intensive service can aid sponsoring organizations in recruiting and supporting older volunteers. References Haber, D. (2009) Gerontology: Adding an empowerment paradigm. Journal of Applied Gerontology, 28, 283-297

VOLUNTEERING AMONG OLDER AMERICANS: UNEXPECTED DIFFERENCES BETWEEN THOSE UNDER 75 AND THOSE 75+
B. McIntosh1, N. Danigelis2, 1. School of Business Administration, University of Vermont, Burlington, Vermont, 2. Sociology Department, University of Vermont, Burlington, Vermont

Recent evidence appears to indicate that, among those 65 and older, volunteering rates tend to be lower for those aged 75+ (Independent Sector, 2000; Prisuta, 2003; Zedlewski and Schaner, 2005). Some reasons offered for this difference include better health, more education, and higher incomes in the age group between 65 and 74 (Morrow-How-
ARE OLDER ADULTS’ PERCEPTIONS OF GENERATIVITY GROUNDED IN REALITY?
T. Gruenewald, Medicine/Geriatrics, University of California, Los Angeles, Los Angeles, California

A growing body of research suggests that older adults’ perceptions that they make important contributions to others are linked to better psychological and physical well-being in later life. However, relatively little is known about the behavioral correlates of such generativity perceptions, including whether older adults who feel more generative also more frequently engage in activity that benefits others. This hypothesis was examined in the current study using data on perceptions of generativity and frequency of engagement in generative activities (volunteer, informal caregiving, social support provision) in older adults (age 55+; N = 2,499) collected during two waves of survey data collection in the national Study of Midlife in the U.S. (MIDUS). Results indicate that older adults with greater feelings of generativity reported greater engagement in volunteer, caregiving, and support provision activity (all p’s < .05 for linear trends of time spent in generative activity by quartiles of generativity). Activity differences were sizable, for example those with high as compared to low perceived generativity, volunteered and provided instrumental and emotional support for 14, 5, and 23 more hours per month (on average), respectively, and provided twice as much informal caregiving (20.6% vs. 10.2%). Similar findings emerged from analyses of daily reports of time spent in these activities during 8-day diary substudies. Results indicate that not only may perceptions of generativity be linked to older adults own well-being, but such perceptions are also grounded in actual generative activity which may benefit others in older adults’ social environments.

MOTIVATION FOR THE CONTINUATION OF WORK: THE CASE OF SENIOR EXPERTS IN GERMANY
A.M. Woehrmann, L.M. Maxin, J. Deller, SMARD, Leuphana University Luenberg, Luenberg, Germany

Many people aged 65 plus remain in good mental and physical health and devote their time to various post-retirement activities. This quantitative study explores the motivation of German retirees working on a voluntary basis with Senior Expert Service (N=661). Personal characteristics (motivational dispositions, such as achievement, generativity) and their relationship to situational job characteristics (e.g., feedback, possibilities to pass on knowledge) are examined. Results show that meeting Senior Workers’ motivation structure in situational job characteristics enhances job satisfaction. Knowledge about motivational patterns of active retirees can help better to understand the individual requirements to realize post-retirement work in a variety of settings. This would help enhance the satisfaction and well-being of a group feeling healthy and motivated to contribute. This talk will give participants a deeper understanding based on empirical data of the motivational pattern, beyond financial need, of German Senior Experts. After attending this presentation, participants will be able to define basic job characteristics, which enhance work motivation in retirement. The specific conditions that organizations have to provide to meet the demands of Silver Workers if they want to profit from their experience are discussed.

SESSION 1800 (PAPER)

INFORMAL CAREGIVING: FACTORS ASSOCIATED WITH CAREGIVER WELL-BEING

FACTORS INFLUENCING QUALITY OF LIFE FOR CAREGIVERS OF PERSONS WITH DEMENTIA
W.D. Duggleby¹, J. Swindle², S. Peacock¹, 1. Nursing, University of Alberta, Edmonton, Alberta, Canada, 2. University of Alberta, Edmonton, Alberta, Canada

Purpose: Hope is a critical psychological resource for family caregivers’ of persons with Alzheimer’s Disease. It is defined as transitional dynamic possibilities within uncertainty. The purpose of this cross-sectional correlation design was to examine the relationships among demographic variables, hope and quality of life in family caregivers of persons with dementia. Methods: The Alzheimer Society of Alberta/NWT and Calgary distributed 170 surveys to family caregivers of persons with dementia. Surveys included a demographic form, questionnaires on hope [Herth Hope Index (HHI)] and quality of life [World Health Organization Quality of Life –BREF (WHOQOL-BREF)]. Results: Seventy-Nine surveys were completed and returned. The majority of family caregivers were older ( Mean age 67.2, SD 10.7), female (85%) and married (88.6%). The majority of carees were older (Mean age 78.1, SD 8.7) males (59.5%). Variables that significantly correlated with quality of life were entered into a linear regression model. Health status of the caregivers compared to one year ago, length of time caregiving, hope scores (HHI) (positively correlated) and the number of services used (negatively correlated) accounted for 64.9% variance in overall quality of life scores (df=4, F= 12.7, p=.000). Tolerance levels were within acceptable limits. Conclusions: The findings suggest that hope, caregivers’ health status, length of time caregiving and the number of services used have a significant influence on quality of life of family caregivers of persons with dementia. As family caregivers provide 80-90% of the care of persons with chronic disease, health care providers should consider the importance of these factors in supporting family caregivers.

THE IMPACT OF FAMILY AND NON-FAMILY ROLES ON CAREGIVER HEALTH OVER TIME
A.E. Matzek, University of Minnesota, St. Paul, Minnesota

Using stress process and life course theory, this research investigated pathways of adult child caregivers’ family (caregiving, marital, parenting) and non-family (employment) roles and their relation to caregiver psychological and physical health over time. Eight waves of data (1992-2006) from the Health and Retirement Study were analyzed for 1,300 adult child caregivers. Latent class analysis provided strong substantive and statistical evidence for a 4-class model of caregivers’ role pathways. The four pathways of adult child caregivers were (a) Married, Working Caregivers (22.5%), (b) Married, Retired Caregivers with Co-Residing Child (12.5%), (c) Married, Retired Caregivers (30.5%), and (d) Not Married, Retired Caregivers (34.6%). According to regression analyses, Married, Working Caregivers, who were more likely to be male, White, and younger than most other pathways, had more optimal psychological and subjective physical health, but were more likely to have high blood pressure compared to other pathways. Results suggest that
(a) adult child caregivers have distinct family and non-family role pathways, (b) caregivers’ gender, race/ethnicity, and age predict pathway membership, and (c) caregivers’ role pathways are related to their psychological and physical health over time. Findings suggest that future research should explore how adult child caregivers’ role pathways structurally differ for male versus female and younger versus older caregivers in order to further explain the heterogeneity of adult child caregivers’ role pathways. Practitioners can utilize findings to create resources (i.e., educational materials, support groups, policies) for caregivers that are specific to caregivers’ diverse family and non-family role pathways and health outcomes.

CARE-RECIPIENT RESISTANCE: WHAT MATTERS TO FAMILY CAREGIVER EMOTIONAL AND PHYSICAL WELL-BEING – FREQUENCY VS. UNPREDICTABILITY?

Y. Shirai, S.S. Koerner, University of Arizona, Tucson, Arizona

We know from existing research that care-recipient resistive behavior during necessary care provision (CR-resistance) can be very challenging for family caregivers (CGs). However, based on results from these conventional cross-sectional studies, we are not certain about whether it is the frequency and/or the unpredictable nature of CR-resistance that most influences CG emotional and physical well-being. In order to document and capture details of CG experiences of CR-resistance, the present study applied a mixed-methods design that combined an 8-day quantitative survey (n = 63) and a follow-up semi-structured interview (n = 19). The daily surveys captured the average frequency (mean-level) as well as the unpredictable nature (daily fluctuation) of CR-resistance; whereas the in-depth qualitative interviews obtained a nuanced, emic view of CR-resistance. Hierarchical Linear Modeling analyses of the survey data revealed that neither the frequency nor the daily fluctuation (unpredictable occurrence) of CR-resistance by themselves appeared to have a significant impact on CG emotional or physical health. However, the combination of having a relatively high frequency of CR-resistance along with relatively high daily fluctuation had a significant, unfavorable impact on CG physical health (b = .34, p < .01). Furthermore, qualitative thematic analyses of the interview data provided supportive, insightful evidence that CGs who experienced a relatively high frequency of CR-resistance (which often required constant emotional and physical attention without a break), were particularly vulnerable to the unpredictable nature of CR-resistance—daily fluctuation. Implications for enhancing family CG support and professional CG training will be discussed.

DOES BECOMING A SPOUSAL CAREGIVER INCREASE DEPRESSION?

R. Dunkle1, S. Feld2, A.J. Lehning1, H. Shen2, H. Kim1, S. Park1, M. Kim1, 1. School of Social Work, University of Michigan, Ann Arbor, Michigan, 2. Hunter College, New York, New York

Nearly one-quarter of those providing informal care to older adults are spouses. Previous research has found that a significant proportion of spousal caregivers have symptoms of depression. Furthermore, higher levels of caregiver depression can increase the likelihood of care recipient’s institutionalization. Little is known, however, about how a change in spousal caregiver status impacts a change in depressive symptoms. Using data from 12,067 respondents from the 2000–2006 waves of the Health and Retirement Study, this study explored the relationship between changes in spousal caregiver status for Activities of Daily Living and depressive symptoms. Scores on the 8-item Center for Epidemiologic Studies Depression scale (CES-D) were compared between four groups: those who became a spousal caregiver, those who remained a spousal caregiver, those who stopped being a spousal caregiver, and those who remained a non-caregiver. Multilevel models included factors from the stress process model developed by Pearlin and colleagues, including the background and context of the stress process, primary stressors, secondary stressors, and mediating conditions. Preliminary results indicate that compared to remaining a non-caregiver, becoming a spousal caregiver is associated with an increase in depressive symptoms. Remaining a caregiver or stopping caregiving activities did not have a significant relationship with change in CESD score. Findings suggest that interventions designed to ameliorate depressive symptoms of caregiving spouses should focus on the beginning of the caregiving career.

SESSION 1805 (PAPER)

LIFE COURSE TRAJECTORIES

REACHING ADVANCED OLD AGE: ARE THERE ANY EFFECTS ON AFFECT?

O.K. Schilling, H. Wahl. Department of Psychological Ageing Research, University of Heidelberg, Heidelberg, Germany

Up to now, the scarce body of longitudinal oldest-old studies revealed only few empirical knowledge about the development of affect when people exceed their cohort’s life expectancy. In the current study, we analyzed intra-individual medium- and long-term changes in measures of positive affect (PA), negative affect (NA), and depressive symptoms in a sample of very old, in order to further the empirical findings on affective dynamics in very old age. By use of data from the German LateLine study (N=115, born 1911-1921, measured 2009 and 2010), which followed up survivors from the ENABLE-AGE project (measured 2002 and 2003), we analyzed changes across medium- (1 year) and long-term (6 years) intervals by means of Structural Equation Modeling. Basically, the results show substantial long-term worsening on average in all measures, as well as large inter-individual variability in such changes. However, in-depth analyses reveal notable differences in change characteristics between the measures analyzed, suggesting that PA decline results from loss of functional competencies, impeding positive everyday experiences. In contrast, increases of NA in very old age may mirror basic processes of psychological or biological degradation, unfolding in the terminal phase of the human lifespan. In sum, the findings underscore that reaching advanced old age crucially affects the affective system, in terms of a destabilization of affect under end of the life conditions, which marks a crucial aspect of psychological terminality.

SOCIAL INTERACTION AND LONGEVITY AMONG A RURAL JAPANESE COMMUNITY: TWENTY YEARS OF STUDY

T. Anme1, M. McCall1, J. Tsukuba University, Tsukuba, Japan, 2. Psychology, Saint Mary’s College of California, Moraga, California

The relationship between social activity and longevity has been found in the United States and several European countries. In Japan, Sugisawa and colleagues (1994) suggested that by examining this relationship in multiple diverse sociocultural contexts the robustness of findings can be increased. They found in a 3-year longitudinal study of Japanese elders that social participation was directly and inversely related to mortality. However, very few studies have been done on the same community over a span of 20 years, as this presentation does. The study of elders in a rural village of Japan began in 1991 and data have been collected regularly over the last two decades. In addition to multiple times of measurement, this study also includes a wide range of activities that people report as important to maintain a sense of social connection and integration, ranging from watching television to reading local newspapers. Results demonstrate that some factors that are important for social interaction over 5 or 7 years are somewhat different from those that are related to longevity over longer periods of time – 11 years. In addition, age differences reveal the changes in the types of social activities that are related to longevity, leading to questions about the meaning of various activities to elders as they grow older and lose some capabilities. We pose questions for...
consideration of how and what we measure as indicators of what constitutes social interaction, social integration and meaningful pursuits in later life.

A YEAR IN THEIR LIVES: TRAJECTORIES OF WELL-BEING AMONG PATIENTS DIAGNOSED WITH ADVANCED STAGE CANCER
G. Kypriotakis1,2, J. Rose1, K.F. Bowman1, 1. Case Western Reserve University, Cleveland, Ohio, 2. Louis Stokes VA Medical Center, Cleveland, Ohio

Patients diagnosed with advanced stage cancer face complex and unique challenges that threaten their physical, psychosocial and spiritual well-being. Despite recent interventions to improve well-being, little is known about how advanced stage cancer patients adapt to their diagnosis. In this study we analyzed longitudinal data on patients with advanced stage cancer in order to describe multiple dimensions of their experience. The goals of this study are to: 1. identify trajectories and model the patterns of change of different domains of well-being. 2. capture variation in well-being outcomes attributed to modifiers such as demographics and utilization. 3. examine the interplay of different domains of well-being over time. Five hundred seventy six patients at baseline are analyzed who have data until death or for up to one year. Longitudinal variables are analyzed using generalized latent growth models. The results from these analyses suggest that patients’ well-being is compromised in the first 3-6 months after diagnosis followed by an improvement in the psychosocial domains but not in the physical. Treatment types at baseline (~8 weeks from diagnosis) have differential effects on the initial level and rate of change among the different domains of well-being. Finally, changes in social support and in spirituality are not related to physical or to mood changes throughout the illness experience. On the contrary, changes in the psychological domains of are closely related to changes in the physical well-being. Results can be used to identify times of increased need where interventions may be more needed.

TRAJECTORIES OF SOCIAL ROLE OCCUPANCY, STRESS, AND SATISFACTION AND THEIR ASSOCIATIONS WITH DEPRESSIVE SYMPTOMS ACROSS THE LIFE COURSE
J. Sauter, Duke University Medical Center, Durham, North Carolina

This study examines how disaggregated trajectories of multiple social role occupancy, measured by level and dynamics of spouse, parent, and worker roles, are associated with concurrent disaggregated trajectories of depressive symptoms. Role strain, role enhancement, role context, stress process, and life course theories frame hypotheses examining both within-person changes over age and between-person predictors of health status. Data are from adults age 25-85 in the Americans’ Changing Lives Study, a nationally representative accelerated cohort panel study of U.S. adults interviewed in 1986, 1989, 1994, and 2001/2. I use latent trajectory analysis to estimate disaggregated trajectories of role occupancy, role strain, role satisfaction and depressive symptoms across the adult life course. I then use multinomial and logistic regression analyses to examine associations between role trajectories and depressive symptom trajectories. I find that (1) there is significant heterogeneity in trajectories of role occupancy and characteristics across the adult life course; (2) higher levels of social role occupancy are associated with better depressive symptom outcomes; (3) lower levels of role strain and higher levels of role satisfaction are associated with better depressive symptom outcomes, and (4); the association between role occupancy and health is robust to the inclusion of role characteristics. Thus, I find support for the role enhancement hypothesis in that higher levels of role occupancy are associated with better mental health outcomes irrespective of reward and strain associated with those roles.

AGE TRENDS IN SENSE OF COHERENCE OVER THE SECOND HALF OF LIFE
J. Heap1, M. Silverstein1, C. Lennartsson1, M. Thorslund1, 1. Aging Research Center, Karolinska Institutet / Stockholm University, Stockholm, Sweden, 2. University of Southern California, Los Angeles, California

Sense of coherence (SOC) — the belief that one’s life is comprehensible, manageable, and meaningful — has been shown to be an important internal resource that moderates negative health outcomes induced by stress. Although SOC is moderately stable over time, with a tendency to grow stronger with age, little research has examined change in SOC into advanced old age, across successive birth cohorts, and in relation to time-varying social and physical conditions related to aging. This study addresses these issues using data from a sample of 1,841 individuals aged 56 and older who participated in up to five waves of a nationally representative survey conducted in Sweden between 1991 and 2010. Sample replenishment allowed the investigation of cohort differences as well as aging effects. Latent growth curve modeling revealed a non-linear pattern with SOC increasing up until age 70, after which it began to decline. SOC was stronger in later birth cohorts and among men, the more highly educated, and those who worked in non-manual occupations. Poor self-rated health and psychological distress weakened SOC while being married and having more social contact with family and friends strengthened it. The non-linear age effect remained with covariates controlled, suggesting that SOC is as much structured by life stage as it is by the resources and deficits associated with aging. Growth and later decline in SOC are discussed in the context of developmental theory and the adaptive capacity of the oldest-old to handle stress and maintain well-being.

SESSION 1810 (PAPER)
PERSONAL AND SOCIAL ADAPTION IN WIDOWHOOD

WIDOWHOOD, LIVING ARRANGEMENTS, SOCIAL SUPPORT, AND DEPRESSIVE SYMPTOMS AMONG OLDER ADULTS IN MEXICO
M. Monsrud, R. Wong, University of Texas Medical Branch, Galveston, Texas

In developing countries with low institutional support, such as Mexico, the wellbeing of older adults can be contingent on their living arrangements and the availability of social support. Drawing on data from two waves of the Mexican Health and Aging Study (2001-2003), we investigate gender differences in the effects of intergenerational coresidence, geographic proximity of kin and friends, and support from children and friends on depressive symptoms among recently and continuously widowed Mexicans, in comparison with their married counterparts (N = 8,708; aged 50 and over). The results of negative binomial regressions demonstrate several gender similarities and differences. Compared to the married older adults, recently widowed ones had more depressive symptoms, regardless of gender. In contrast, among continuously widowed adults, only men reported more depressive symptoms. Irrespective of marital status, for both men and women, greater emotional support from children was associated with fewer depressive symptoms, whereas greater instrumental support from children was linked to more depressive symptoms. Furthermore, for men, coresidence with adult sons and financial support from children was related to more depressive symptoms, while coresidence with siblings, the presence of relatives in the neighborhood, and emotional and instrumental support from friends were predictive of fewer depressive symptoms. For continuously widowed women, coresidence with adult daughters led to fewer depressive symptoms, whereas coresidence with parents had the opposite effect. Continuously widowed men, however, reported fewer depressive symptoms when they had relatives in the neighborhood.
For recently widowed women, coresidence with adult sons was associated with fewer depressive symptoms.

WIDOWHOOD AND HEALTH TRAJECTORIES: RACE/GENDER INTERSECTION
D. Unberson1, I. Sasson1, P.A. Thomas1, H. Liu2, M. Thomeer1, I. University of Texas at Austin, Austin, Texas, 2. Michigan State University, Lansing, Michigan

National data reveal a troubling trend: the health gap between the married and widowed has grown steadily over the past 30 years, especially for women. The health gap is also striking for African Americans. Except for the widowed, all other African American marital status groups exhibited improved health over the past three decades. Given the poorer health of African Americans compared to whites, the greater prevalence of widowhood among women and African Americans, and the adverse effects of widowhood on health, it is surprising that so few studies have considered how the effects of widowhood vary across race/gender groups. We analyze national longitudinal data from the Health and Retirement Survey to consider how widowhood influences multiple health outcomes among mid to late life adults. Results suggest that vulnerabilities vary by race and gender. African American women are particularly vulnerable because they enter widowhood in very poor health and, although they are more likely than other groups to be overweight prior to widowhood, they experience much greater weight loss than other groups following widowhood. Compared to other widowed groups, African American men exhibit greater decline in self-rated health over time. White men and African American women seem to be more vulnerable than white women and African American men to psychological distress following widowhood. These findings suggest that key areas of vulnerability to widowhood differ by race, gender, and the type of health outcome considered. Intervention and policy strategies should address group differences in vulnerability to promote health for diverse widowed populations.

DAILY STRESSORS AND WELL-BEING IN WIDOWED AND MARRIED OLDER ADULTS
E.A. Hahn1, K.E. Cichy2, D. Almeida3, 1. School of Aging Studies, University of South Florida, Tampa, Florida, 2. Kent State University, Kent, Ohio, 3. Pennsylvania State University, State College, Pennsylvania

Despite the fact that widowhood may result in potentially stressful changes to daily routines, research has yet to examine how daily stressors contribute to well-being in widowed versus married older adults (OA). This study examined how daily stressor reactivity varies for widowed versus married OAs. Participants included 100 widow(er)s and 342 married adults over age 65 from the National Study of Daily Experiences (NSDE), a daily diary study from the second wave of the Midlife in the United States (MIDUS II). Daily stressors were measured using the Daily Inventory of Stressful Events (DISE); well-being was assessed with the Positive and Negative Affect Scale (PANAS). Married OAs had more days when they experienced daily stressors compared to widow(er)s (p<.0001). Controlling for age, gender, education, and marital status, multi-level models revealed that married and widowed OAs reported stressor-related increases in negative affect (p=.05). At the within-person level, results revealed that married OAs were more reactive to interpersonal stressors, whereas at the between-person level widow(er)s who reported avoiding more arguments with family members reported greater negative affect. Both groups were emotionally reactive to home- or work-related stressors (p<.0001). Results suggest that while married OAs may be more emotionally reactive to some types of daily stressors, widowed adults are not immune to the negative effects of other daily stressful events as evidenced by similarity in reactivity to home or work-related stressors among married and widowed OAs.

DYNAMIC TRAJECTORIES OF SOCIAL SUPPORT, AGE, AND CAREGIVER DURATION ON DEPRESSION DURING BEREAVEMENT
N.E. Pisce1, B.G. Knight1, S. Nolen-Hoeksema2, 1. Davis School of Gerontology, University of Southern California, Los Angeles, California, 2. Yale University, New Haven, Connecticut

This study examined longitudinal data from 155 bereaved adults. We formulated a latent growth curve model hypothesizing that increases in the amount of social support received by bereaved individuals caused a decrease in depression, independent of caregiving duration. Participants were from the Stanford Bereavement Project, a longitudinal prospective study that included 5 waves of data from 1989 to 1992. Subjects were assessed before the death of their loved one and then at 1, 6, 13, and 18 months post-loss. We found considerable individual variability and change in both depression and the amount of social support in univariate latent growth curve analyses. A multivariate latent growth curve analysis revealed caregiving duration had no effect on either initial social support or change in depression. However, age had a positive effect on the intercept and negative effect on slope in depression. The mechanism for increases in depression is a decrease in the amount of social support received.

SESSION 1815 (SYMPOSIUM)

COMMUNITY, CONNECTIVITY, MOBILITY AND LATER LIFE
Chair: I.R. Jones, Social Sciences, Bangor University, Bangor, Gwynedd, United Kingdom
Discussant: C. Phillipson, Keele, Keele, Keele, United Kingdom

In recent decades, just as community and communities have been subject to economic and social disruption, so later life has experienced rationalized disconnections from previous stable and institutionalised life courses. Just as community has been associated with a crisis of meaning and a nostalgic longing for an earlier age so later life is seen to be subject to the contingencies and vicissitudes of social change. This symposium is based on work undertaken under the UK Arts and Humanities Research Council (AHRC) ‘Connected Communities Research Reviews’. The symposium will provide an overview of the findings from the research reviews and papers addressing specific and related research questions. The first paper ‘Social Networks and Well-being in Later Life’ will focus on the relationship between social connectivity, attachment to place/belonging and levels of well-being in later life. The second paper ‘Ageing, mobilities and place attachments: changing conceptions of community in later life’ examines how people in later life make a variety of adjustments to changed circumstances and considers the implications for the ways in which individuals use and relate to space and place. The third paper ‘Connectivities in the Third Age: from fixity to fluidity?’ examines how developments in technology, travel and tourism have eroded the centrality of place and looks at how new connectivities in later life provides an important vector of understanding the development of the Third Age.

SOCIAL NETWORKS AND WELL-BEING IN LATER LIFE
I.R. Jones, Social Sciences, Bangor University, Bangor, Gwynedd, United Kingdom

There are important gaps in our knowledge of the link between social networks and well being in later life. Recent social changes have had important consequences for levels of connectivity, social networks and social support in later life. Social networks have been found to be protective for dementia while social isolation and poor social relations appear to be harmful to health and are associated with cognitive decline. Recent research however, suggests important inter-generational aspects to lack of connectivity in old age. The networks that older people have tend to be deficient in younger adults while participation in organizations that include people of diverse ages increases the likelihood of older...
people interacting with younger non-kin. This paper reviews the evidence for the importance of connectivity in maintaining well-being in later life and examines theoretical approaches to connectivity and well-being in the context of migration, ageing in place and retirement to place.

**AGEING, MOBILITIES AND PLACE ATTACHMENTS: CHANGING CONCEPTIONS OF COMMUNITY IN LATER LIFE**

G. Day, Social Sciences, Bangor University, Bangor, United Kingdom

People in later life make a variety of adjustments to changed circumstances. These include ‘downsizing’, retirement migration, new patterns of travel to maintain (or sometimes escape from) family and social networks, and the take up of new technological fixes to manage distance and space. These adaptations have implications for the ways in which individuals use and relate to space and place, freeing some to express their preferences through an elective attachment to place, while others remain restricted by or embedded in prior commitments. Through a comparative review of international literature, this paper will examine evidence for variations in such practices, and consider how they relate to traditional and more recent conceptions of ‘community’. It will also explore how these relationships are likely to change, in the light of the shocks associated with the current recession, which has disrupted many of the plans and expectations which previously underpinned such mobility practices.

**CONNECTIVITIES IN THE THIRD AGE: FROM FIXITY TO FLUIDITY?**

C.J. Gilleard, P. Higgs, Research Strategy, UCL, London, United Kingdom

The context of later life is changing and one element in that change is the nature and form of community. Conventional approaches toward the idea of community in old age were based around attachment to place and the day to day presence of the community of propinquity. Later life was thought to be rooted in the spatial location of neighbourhood. Within this paradigm, movement represented risk – the risk of dissolving the safety, solidarity and social networks of the local community. Developments in technology, travel and tourism are eroded the centrality of place and have potentially replaced the risks of mobility with the opportunities provided by alternative lifestyle choices in the shape of post-safety, solidarity and social networks of the local community. Examination of these new connectivities in later life provides an important vector of understanding the development of the Third Age.

**SESSION 1820 (SYMPOSIUM)**

**CONDUCTING RESEARCH WITH INDIVIDUALS WITH DEMENTIA**

Chair: K. Judge, Psychology, Cleveland State University, Cleveland, Ohio
Co-Chair: S. Yarry, VA Palo Alto Health Care System, Palo Alto, California
Discussant: K. Judge, Psychology, Cleveland State University, Cleveland, Ohio

Due to the cognitive difficulties experienced by individuals with dementia (IWDs), few studies have focused on IWDs as active participants in the research process or included IWDs in the implementation of intervention protocols. An emerging area of research is how to best design data collection and psychosocial intervention protocols to include IWDs. The following symposium will examine and discuss key issues related to conducting research with IWDs. The first paper reports on thematically analyzed qualitative data from 115 IWDs about their concerns and fears associated with memory loss and how this information can be utilized when working with IWDs. The second paper discusses key elements of survey construction (i.e., types of responses used, how questions are asked) that facilitate or impede IWDs’ ability to complete self-report questionnaires. The third paper presents self-report quantitative data from IWDs (n=115) on their perspectives on key psychosocial measures, including symptoms of depression and anxiety, dyadic relationship strain, feelings of embarrassment and isolation, and difficulty and distress when completing instrumental and personal activities of daily living. The fourth paper presents a Strength-Based Approach for developing and implementing interventions for IWDs that utilizes a cognitive rehabilitation framework for understanding how cognitive processes are spared or compromised due to memory loss. Discussion will focus on 1) the benefits of including IWDs in the research and intervention process; 2) how to facilitate IWDs’ active participation in research and intervention protocols; 3) methods for developing effective intervention protocols for IWDs; and 4) future directions in conducting research with IWDs.

**PSYCHOSOCIAL CONSTRUCTS FROM THE PERSPECTIVE OF AN INDIVIDUAL WITH DEMENTIA**

N.T. Dawson1,2, S. Powers3, M. Wilson2, 1. University of Akron, Akron, Ohio, 2. Cleveland State University, Cleveland, Ohio

Little is known about the illness experience from the perspective of individuals with dementia (IWDs), as most research has focused on IWDs’ psychosocial issues from the viewpoint of the caregiver. Using the Stress Process Model for Individuals with Dementia (SPM for IWDs), the following paper will present self-report data from IWDs (n=115) about their illness experience, including primary objective and subjective stressors (i.e., cognitive and functional symptoms of dementia; perceived difficulty and distress associated with cognitive and functional symptoms); secondary role and intrapsychic strains (i.e., dyadic relationship strain, feelings of embarrassment and isolation, self-efficacy) and psychological well-being outcomes (i.e., quality of life, symptoms of depression and anxiety). Discussion will focus on IWDs’ profiles across these domains of the SPM for IWDs along with using this information to identify areas amenable to interventions through specific internal and external mediators that serve to buffer the effects of the stress process for IWDs.

**A STRENGTH-BASED COGNITIVE REHABILITATION APPROACH FOR INDIVIDUALS WITH DEMENTIA**

S. Yarry1, N.T. Dawson2, K. Judge2, 1. VA Palo Alto Health Care System, Palo Alto, California, 2. Cleveland State University, Cleveland, Ohio

Much attention in research and practice has been given to cognitive deficits as a result of dementia. A substantially smaller amount of attention has been given to remaining cognitive strengths, an equally important aspect of daily life among individuals with dementia. In an attempt to move away from this deficit-focused approach, we have previously...
proposed a shift in philosophy to a strength-based approach that focuses on remaining skills as opposed to declines and losses (Judge, Yarry, & Orsulic-Jeras, 2009; Orsulic-Jeras, Britton, & Shepherd, 2003; Yarry, Judge, & Orsulic-Jeras, 2010). This presentation will outline fundamental components of the strength-based approach model for designing cognitive rehabilitation tasks for individuals with dementia. Four essential components of the approach include education, strengths assessment, active participation, and flexibility. A strength-based approach is particularly well-suited for treating individuals with cognitive impairment and this will be shown through the demonstration of key cognitive rehabilitation techniques.

INCLUDING INDIVIDUALS WITH DEMENTIA IN THE RESEARCH PROCESS: UNDERSTANDING THE IMPACT OF SCALES AND RESPONSE CATEGORIES USED IN SURVEYS
M. Wilson, S. Yarry, N.T. Dawson, Psychology, Cleveland State University, Cleveland, Ohio. 2. University of Michigan, Ann Arbor, Michigan

Recently, researchers have implemented strategies to reduce barriers to participation in surveys associated with cognitive limitations. However, empirical information is lacking. The current study presents data from structured interviews with memory impaired elderly (n=125). Survey questions asked for either objective or subjective information, which was indicated using full range or simplified response choices. Response choice sets were either unidirectional ratings of frequency/amount (e.g., not at all, a little, a fair amount, or a great deal) or bidirectional ratings (e.g., strongly agree, agree, disagree, or strongly disagree). Results showed that greater cognitive impairment was associated with use of more simplified response categories, especially when answering questions with bi-directional response choices. Subjective or objective question content did not influence participants’ ability to use the full response set. These results highlight the need to consider individual cognitive abilities when constructing response choices to survey questions for older adults with memory impairment.

SESSION 1825 (SYMPOSIUM)

CONTEXTUAL EFFECTS ON INDIVIDUAL DEVELOPMENT ACROSS ADULTHOOD AND OLD AGE
Chair: D. Gerstorf, Department of Human Development and Family Studies, Pennsylvania State University, University Park, Pennsylvania
Co-Chair: N. Ram, Department of Human Development and Family Studies, Pennsylvania State University, University Park, Pennsylvania
Discussant: T. Glass, Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland

Lifespan and gerontological research has long acknowledged the contextual embeddedness of individual development. This symposium brings together four papers that highlight how contextual factors at various different levels of analysis shape individual development in different phases of adult development. Wilson-Genderson and Pruchno use census-tract data throughout New Jersey to demonstrate intrinsic linkages between social advantage and health behaviors. Piazza and colleagues use data from the MIDUS to investigate how perceptions of neighborhood characteristics are related to 10-year change trajectories in well-being and control beliefs and how this differs between adults in midlife and old age. Williams and colleagues use data from the MIDUS and NSDE studies to link contextual factors to individual health outcomes and daily stress processes. Utilizing both objective census tract data and subjective perceptions of neighborhoods, the authors show that relying exclusively on objective characteristics may underestimate the health and stress implications of living environments. Gerstorf and Ram combine individual- and county-level data from the German SocioEconomic Panel to examine how physical, service, and social aspects of the environment shape late-life changes in well-being. The discussion by Glass integrates the four papers, highlights their theoretical and methodological contributions, and considers challenges and opportunities of research linking socio-structural characteristics and individual-level outcomes.

SOCIAL ADVANTAGE AND HEALTH BEHAVIORS OF OLDER ADULTS: MODELING INDIVIDUAL AND NEIGHBORHOOD EFFECTS
M. Wilson-Genderson, R.A. Pruchno, New Jersey Institute for Successful Aging, University of Medicine & Dentistry School of Osteopathic Medicine, Stratford, New Jersey

Neighborhood characteristics are associated with the health behaviors of older adults, yet confounding between individual-level attributes and neighborhood-level characteristics has limited understanding of their influence. We tested hypotheses about the relationship between neighborhood-level advantage and adherence to guidelines regarding alcohol consumption, exercise, smoking, and diet. Data derived from a random-digit-dial sample of 5,688 community-dwelling adults aged 50-74 residing in 1,644 census tracts throughout New Jersey. We utilized multilevel structural equation models (ML-SEM) to permit the inclusion of a latent construct representing neighborhood advantage (high household income, % with professional occupation, % college degree), thus adequately accounting for structural relationships as well as geographical clustering. Analyses indicated that neighborhood advantage has significant effects on multiple health behaviors that are independent of individual-level attributes. Findings suggest the importance that neighborhood plays vis-à-vis the health behaviors of older adults.

PERCEPTIONS OF NEIGHBORHOOD QUALITY AND CHANGES IN PSYCHOLOGICAL WELL-BEING OVER TIME

The current study examined how perceptions of neighborhood quality influenced trajectories of psychological well-being across a 10-year period. Participants (n = 3,897) from the Midlife Development in the United States (MIDUS) Survey were interviewed between 1994-1995 and again between 2004-2005. These interviews, participants rated the safety of their neighborhoods and the helpfulness and trustworthiness of their neighbors (Keyes, 1998). They also completed questionnaires assessing their psychological well-being (Ryff, 1998) and sense of control (Lachman & Weaver, 1998). Higher levels of perceived neighborhood quality were associated with greater well-being and sense of control, and with positive changes in these variables over time (p’s < .01). Results suggest that the well-documented association between socioeconomic status and well-being may be partially explained by how people perceive the quality of their neighborhoods.

NEIGHBORHOOD SOCIOECONOMICS, PERCEPTIONS, AND HEALTH: CONTEXTUAL HEALTH EFFECTS AMONG OLDER ADULTS
J. Williams, S.T. Charles, D. Almeida, Psychology and Social Behavior, University of California, Irvine, Costa Mesa, California. 2. Penn State University, University Park, Pennsylvania

A growing body of evidence suggests that social and physical neighborhood characteristics influence residents’ health and well-being. The current study used the MIDUS and NSDE datasets to assess relationships between census tract SES and a range of health outcomes and daily stress processes. Median neighborhood income was negatively associated with BMI and chronic conditions, and positively associated with self-rated physical and mental health in this adult sample, even after controlling for individual SES and other sociodemographic variables. Although this objective measure of neighborhood SES did not predict...
daily stress processes, subjective assessments were significant predictors. Maintaining positive perceptions about one’s neighborhood buffered the adverse effects of daily stressors on self-reported negative affect and physical symptoms. Focusing exclusively on objective neighborhood SES may thus mislead contextual studies examining daily stress processes. Results from this study indicate the importance of both objective and subjective neighborhood factors for well-being and physical health outcomes.

WHERE PEOPLE LIVE AND DIE MAKES A DIFFERENCE: INDIVIDUAL AND CONTEXTUAL EFFECTS ON WELL-BEING PROGRESSION AT THE END OF LIFE
D. Gerstorf, N. Ram, Department of Human Development and Family Studies, Pennsylvania State University, University Park, Pennsylvania

Lifespan psychological research has long been interested in the contextual embeddedness of individual development. Contextual factors can be expected to support or constrain processes of adaptation and regulation, particularly when individual resources are scarce. We use longitudinal data from more than 3,000 deceased participants of the national German Socioeconomic Panel to illustrate how late-life well-being can be better understood by modeling associations between change and measures of both individual and contextual characteristics. First, we show that sizeable portions of between-person differences in both level and decline of well-being reflect regional differences (e.g., individuals nested within counties nested within East vs. West-Germany). Second, we demonstrate that regional differences often amplify the disparities in late-life change attributed to individual factors. Third, we investigate the shared and unique contributions of individual perceptions of the service, physical, and social characteristics of their living contexts to late-life developmental trajectories of well-being.

SESSION 1830 (SYMPOSIUM)

EARLY LIFE FACTORS AND LATE LIFE OUTCOMES: ANALYSIS OF DATA FROM THE SURVEY OF HEALTH, AGING AND RETIREMENT IN EUROPE
Chair: H. Litwin, Hebrew University, Jerusalem, Israel
Discussant: A. Boersch-Supan, Mannheim Institute for the Economics of Aging, Mannheim, Germany

Modeled after the Health and Retirement Survey, the Survey of Health, Ageing and Retirement in Europe (SHARE) is one of the key longitudinal aging surveys in the world today. The third wave of the survey introduced retrospective life histories among some 30,000 respondents aged 50 and older (SHARELIFE). This symposium will utilize the unique capacity of SHARE to examine the late-life consequences of a varied range of factors in early life. The paper by Youssim and Litwin examines the association between capitals inherited from the family of origin and the scope of productive involvement among people aged 50 and older in Israel. The work by Garrouste and Pacagnella estimates structural relationships among childhood SES, education, and income at the first and last job in selected SHARE countries. Sirven and Or investigate the influence of early-life circumstances on variations in health care utilization habits of different cohorts in 13 European countries. Dijkstra et al. consider the variation in late-life loneliness across Europe, with special attention given to the effects of early-life events (marital and parenthood history). Finally, Brandt et al. investigate the role of childhood conditions and societal context in older Europeans’ propensity to age successfully, constructing an analytic model based upon Rowe and Kahn’s conceptualization. Axel Boersch-Supan, the founding coordinator of SHARE, will discuss the papers and their implications for public policy in aging societies.

RECEIPT OF FAMILIAL CAPITALS AND PRODUCTIVE INVOLVEMENT AMONG PEOPLE AGED 50 AND OLDER IN ISRAEL
I. Youssim, H. Litwin, Hebrew University, Jerusalem, Israel

Aim: This study addresses the question whether capitals inherited from family of origin influence the scope of productive involvement among people aged 50 and older in Israel. Method: To examine the hypothesis, we used Israeli data from the first wave of Survey of Health, Aging and Retirement in Europe (SHARE). Number of productive activities a person is involved in was regressed on three blocks of variables: human capital (e.g., education), social capital (e.g., number of children) and capital originating in family (e.g., parental occupational status). We also controlled for demographic background. Results: After controlling for a wide range of variables, receipt of better resources from family — in terms of housing, financial support or expecting inheritance of wealth — is positively correlated with being highly productive. Discussion: The findings support the hypothesis that familial social characteristics should be taken into account to explain productive involvement among older people.

EARLY-LIFE CIRCUMSTANCES AND LATE-LIFE INCOMES
C.L. Garrouste, O. Pacagnella, 1. Department of Statistical Sciences, University of Padua, Padova, Italy, 2. European Commission - Joint Research Centre (EC - JRC), Ispra (Varese), Italy

Aim: This paper aims at evaluating and comparing across selected European countries the influence of early-life circumstances on incomes in later life. Method: Using life-history data from SHARELIFE, country-specific structural relationships among childhood SES, education attainments and incomes at the first and the last job are investigated through the estimation of recursive models, controlling for individual, labour market conditions and contextual covariates. Results: Poorer socioeconomic conditions during childhood are associated with higher differentials in years of full-time education and higher income inequalities. Early-life circumstances affect directly the entry wage and indirectly further wages. The extent of these results however varies across countries. Discussion: Findings suggest that education policies may play a role in explaining the observed differences across countries. The introduction of support systems fostering access to education of students from disadvantaged households can weaken their financial dependence from parents and loosen the persistence in socio-economic conditions across generations.

EARLY-LIFE CIRCUMSTANCES AND REGULAR HEALTH CARE UTILIZATION IN EUROPE
N. Sirven, Z. Or, IRDES, Paris, France

Aim: To investigate the influence of early-life circumstances on variations in healthcare utilization habits of different cohorts in 13 European countries. Method: Using life-history data from SHARELIFE and multilevel logistic models over countries and cohorts, we tested whether a measure of health status at age 10 and an index of childhood comfort at age 10 are associated with five variables of regular and preventive care utilization. Results: Individuals with higher levels of childhood health and childhood socio-economic status have a higher propensity to make regular use of blood pressure tests, blood tests, vision tests, gynecological visits, and mammograms throughout their life. Discussion: These results suggest that there is significant room for public health policies for reducing disparities in regular use of health services over the life-cycle. Health promotion at early ages can play an essential role for assuring equal and timely treatment of diseases within and across countries.
CROSS-NATIONAL DIFFERENCES IN OLDER ADULT LONELINESS
P.A. Dykstra1, T. Fokkema2, J. Gierveld2, 1. EUR, Rotterdam, Netherlands, 2. NIDI, The Hague, Netherlands

Aim: To examine the variation in late-life loneliness across Europe and its determinants. Method: Using data from SHARE-wave2 and (multilevel) logistic models, three types of explanations for country differences were tested: differences in population composition, cross-national variations in the “loneliness-threshold” (perceived social contacts needed to avoid loneliness), and the role of certain country specificities. With regard to the first explanation type, special attention was given to the effects of early-life events (marital and parenthood history), collected in the SHARELIFE project. Results: Despite more favourable social conditions, older adults in the “familialistic” southern European countries were generally more lonely than their peers in the “individualistic” northern European countries. Moreover, the prevalence of late-life loneliness in Eastern Europe was found to be relatively high and largely attributable to economic deprivation and poor health. Discussion: The findings stress the importance of different, country-tailored approaches to prevent or combat loneliness among older adults.

TRACING THE ORIGINS OF SUCCESSFUL AGING: THE ROLE OF CHILDHOOD CONDITIONS AND SOCIETAL CONTEXT
M. Brandt1, C. Deindl2, K. Hank2, 1. MEA SHARE University of Mannheim, Mannheim, Germany, 2. Research Institute for Sociology, University of Cologne, Cologne, Germany

Aim: To investigate the role of childhood conditions and societal context in older Europeans’ propensity to age successfully. Method: Successful aging was assessed following Rowe and Kahn’s initial conceptualization, using baseline interviews from the first two waves of the Survey of Health, Ageing and Retirement in Europe (SHARE), which we merged with participants’ retrospective life-histories, collected in 2008-09 as part of the SHARELIFE project. We estimated (multilevel) logistic models including demographics, childhood conditions, later life risk factors and country characteristics. Results: Better housing conditions, math and reading skills, as well as self-reported health during childhood were associated with successful aging. Moreover, higher levels of public social expenditures and lower levels of income inequality were positively associated with aging well. Discussion: Unfavorable childhood conditions exhibit a harmful influence on individuals’ chances to age well. Policy interventions should thus aim at improving the conditions for successful aging throughout the entire life-course.

SESSION 1835 (SYMPOSIUM)

EMOTION REGULATION PROCESSES IN DAILY LIFE ACROSS THE LIFESPAN: WHAT CAN WE LEARN FROM TIME- AND EXPERIENCE-SAMPLING APPROACHES?
Chair: S. Scott, Gerogia Tech, Atlanta, Georgia
Co-Chair: C.A. Hopmann, University of British Columbia, Vancouver, British Columbia, Canada
Discussant: D. Isaacowitz, Brandeis University, Waltham, Massachusetts

A key ingredient of emotion-regulation is responding to shifting situational demands to maintain emotional experiences in a contextually appropriate and manageable range. Time-sampling studies can capture the respective dynamic processes in an ecologically valid setting. This symposium examines emotion regulation processes across the adult lifespan as they occur in individuals’ own environments using time-sampling methods. Wruetz et al. find that age differences in affective and physiological responses to negative events depend on event complexity, suggesting that complex as opposed to circumscribed events demand more resources for successful emotion regulation. Slade and colleagues examine the link between goal-regulation and emotional experiences, differentiating between anger and sadness. Specifically, anger was related to persistence in goal pursuits, whereas sadness was associated with thinking about alternative goals. Scott and colleagues examined negative emotion prevention strategies as an important mediator of age differences in positive and negative affect. Findings suggest that negative emotion prevention strategies mediate age-positive affect associations but not age-negative affect associations. Slawinska et al. report differential associations of positive and negative mood with reports of subjective health and health constraints. Negative emotional states strongly predict subsequent momentary reports of worse subjective health and health constraints; whereas positive emotional states show little relationship with subsequent momentary reports of subjective health and health constraints. Together, the studies highlight the role of events, goals, strategies, and health in emotion regulation in day-to-day life. Laura Carstensen’s discussion focuses on the potential and the challenges of time-sampling studies of emotion regulation.

ON THE ADAPTIVE ROLE OF NEGATIVE EMOTIONS: POTENTIAL BENEFITS OF ANGER AND SADNESS FOR GOAL REGULATION
L. Slade1, C.A. Hopmann1, F. Blanchard-Fields2, 1. University of British Columbia, Vancouver, British Columbia, Canada, 2. Georgia Institute of Technology, Atlanta, Georgia

While feeling good is desirable, sometimes we feel blue. Importantly, negative emotional experiences may be adaptive because they contribute to goal regulation (Wrosch & Miller, 2009). We use 10 day time-sampling information from 185 participants aged 20-81 years to investigate negative emotion-goal regulation linkages in a daily-life context. Preliminary analyses suggest that individuals differentiate between anger and sadness and that these two negative emotions serve different functions. Specifically, anger is negatively associated with goal disengagement, suggesting that individuals are more persistent in pursuit of their goals when reporting elevated anger. Sadness, in contrast, is positively associated with thinking about alternative goals and seems to give rise to thoughts about different behavioural options and goal pursuits. Follow up analyses address age-group and goal type differences in relation to negative emotion-goal associations and subsequent well-being. Participants will learn of the functionality of specific negative emotions and their potential influences throughout the lifespan.

NEGATIVE EMOTION PREVENTION STRATEGY USE AS AN EXPLANATION OF AGE DIFFERENCES IN EMOTIONAL EXPERIENCE
S. Scott1, C.A. Hopmann1, F. Blanchard-Fields1, 1. Gerogia Tech, Atlanta, Georgia, 2. University of British Columbia, Vancouver, British Columbia, Canada

Research on age differences in emotional experiences suggest that emotional experiences become more positive across the adult lifespan. However, the mechanisms underlying these differences in emotional experience are not as well understood. In this study, we used data from a 10 day time-sampling study of adults aged 18-70 years old. Participants completed PDA surveys 5 times each day about their current mood and strategies used to prevent the experience of negative emotions. Using mediational models, we found that although the use of negative emotion strategies does not appear to explain age differences in negative affect, the use of these strategies may be one of the ways in which older adults boost their positive affect compared to young and middle-aged. Results contribute to the literature on whether older adults seek to maximize positive experiences or minimize negative ones in order to maintain higher levels of emotional functioning.
AFFECTIVE AND CARDIOVASCULAR RESPONSES TO DAILY HASSLES: COMPLEXITY OF EVENT MATTERS FOR AGE EFFECTS
C. Wirzus, V. Müller, G.G. Wagner, U. Lindenberger, M. Riediger, I. Max Planck Institute of Human Development, Berlin, Germany, 2. German Institute for Economic Research, Berlin, Germany

Two studies investigated the hypothesis that age differences in affective responding to unpleasant events are particularly evident in complex, highly resource-demanding situations that overtax older adults’ capacities. In Study 1, we used a mobile phone-based experience-sampling technology in 378 participants ranging in age from 14 to 86 years. Over three weeks, participants reported, on average 54 times, their momentary negative affect and occurrences of unpleasant events. In Study 2, a subsample of 92 participants were an ambulatory psychophysiological monitoring system for 24 hours in addition to the experience-sampling procedure while pursuing their daily routines. Result showed more pronounced psychological and cardiovascular responding with higher age when dealing with complex unpleasant events, but less pronounced cardiovascular responding when dealing with circumscribed unpleasant events. We conclude that taking the nature of affective events into account helps clarifying the currently inconclusive literature on adult age differences in affective responding.

MOMENTARY AND DAILY RELATIONSHIPS BETWEEN SUBJECTIVE HEALTH AND AFFECT
M. Sliwinski, D. Almeida, L. Martire, J. Mogle, E. Munoz, S. Wilson, Pennsylvania State University, University Park, Pennsylvania

Decades of research have linked emotional dispositions and states to numerous disease and health outcomes. Other lines of research have shown that health conditions constrain emotional well-being, particularly in older adults. The present study used ecological assessments to examine the temporal associations between subjective health reports and mood across momentary and daily timescales in a sample of adults, ages 20 to 80 years. Our preliminary results reveal differential associations of positive and negative mood with subjective health and health constraints in daily activities. Negative emotional states strongly predict subsequent momentary reports of worse subjective health and health constraints; whereas positive emotional states show a weak or no relationship with subsequent momentary reports of subjective health and health constraints, respectively. Prior reports of subjective health and functional constraints predict subsequently lower levels of positive but not negative affect. We discuss the implications of these disassociations between positive and negative mood with momentary health reports for developmental health and aging.

SESSION 1840 (SYMPOSIUM)

LIFESTYLE EFFECTS ON HEALTH AND LIFESPAN: EPIDEMIOLOGICAL EVIDENCE
Chair: L.C. Barry, Internal Medicine, Yale University School of Medicine, New Haven, Connecticut
Co-Chair: D.K. Miller, Indiana University, Indianapolis, Indiana
Discussant: C. Mendes De Leon, University of Michigan, Ann Arbor; Michigan

Evaluating the effect of modifiable lifestyle factors on health outcomes in older persons is essential to developing interventions to promote independent living and reduce mortality risk. Using longitudinal epidemiologic studies, we can determine the association between lifestyle-related factors and subsequent functional status and mortality. Furthermore, repeated assessments, which are characteristic of longitudinal studies, provide a unique opportunity to evaluate the association between lifestyle factors and changes in and trajectories of health outcomes. Dr. Shaw will discuss the use of two longitudinal studies of Swedes to evaluate the association between lifestyle factors in mid-life (e.g., smoking, drinking, diet) and their effect on mortality and health outcomes in old age. Dr. Koster will present data from the National Health and Nutrition Examination Survey describing the association between objectively measured sedentariness and mortality in older persons. Dr. Byers will then describe how repeated assessments of depressive symptoms collected in the Study of Osteoporotic Fractures were used to determine depressive symptom trajectories and how lifestyle factors are associated with these trajectories. Using data from the Taiwan Longitudinal Study on Aging, Dr. Chiu will describe lifestyle factors as mediators and moderators of the relationship between diabetes and change in cognitive function. In the final presentation, Dr. Shea will describe how findings from lifestyle intervention trials were used to evaluate the effect of intentional weight loss on mortality in older persons. The discussion will focus on the value of evaluating the relationship between lifestyle factors and health outcomes and future research directions.

HEALTH BEHAVIOR PROFILES DURING MIDLIFE AS PREDICTORS OF MORTALITY AND MORBIDITY IN LATER LIFE

Background: We examined whether midlife health behavior profiles (“lifestyles”), including smoking, diet, alcohol use and physical activity, are associated with health and mortality in the ensuing decades. Methods: Data came from a national sample of Swedish adults (n=3,022), interviewed in 1968 (at ages 33-63), 1981, 1991, and 2002. Twelve lifestyle groups, identified in 1968, were used to predict mortality, health trajectories between midlife and late life, and health outcomes in old age. Results: Only the lifestyles involving smoking were associated with increased mortality risk, but risk was significantly lower for lifestyles that combined smoking with other healthy behaviors. Among survivors, some of the same lifestyles that mitigated mortality risk were associated with increased health problems throughout midlife and into old age. Conclusions: Examining the joint effects of multiple risk behaviors at midlife reveals that some lifestyles are associated with shortened lives, and others with expanded morbidity during later life.

ASSOCIATION OF SEDENTARY BEHAVIOR WITH MORTALITY INDEPENDENT OF PHYSICAL ACTIVITY
A. Koster, P. Caserotti, K. Patel, D.R. Van Domelen, T. Harris, 1. National Institute on Aging, Bethesda, Maryland, 2. Maastricht University, Maastricht, Netherlands

Physical inactivity is a well-known risk factor for mortality. It is, however, unclear whether the increased mortality risk is due to lack of exercise or a more sedentary lifestyle. This study examined the association between objectively measured sedentary time and all-cause mortality. Data on 1906 men and women, aged ≥50 years from the 2003-2004 National Health and Nutrition Examination Survey were analyzed. Sedentary time was assessed using an ActiGraph accelerometer and defined as <100 counts/minute. Over on average 2.8 years of follow-up, 145 people died. Participants in the highest quartile of percent sedentary time had a 5.9 times greater risk of death compared to those in the lowest quartile (95%CI:2.33-15.00) independent of physical activity, demographics, morbidity and physical function. These results suggest that sedentariness is a risk factor for mortality independent of physical activity. Further investigation, including studies with longer follow-up, is needed on the health consequences of sedentary behavior.
CHARACTERIZATION OF LONG-TERM DEPRESSIVE TRAJECTORIES AMONG ELDERLY WOMEN

Little is known about the long-term course of depression in older adults, especially factors that influence depression trajectories into oldest-old years. Using a sample of 7,240 older women (mean age 72.8 ± 4.7) from the Study of Osteoporotic Fractures, we describe the natural course of depressive symptoms among elderly women followed for nearly 20 years and determined key characteristics associated with these trajectories. Four trajectories were identified (minimal, persistently low, increasing, and persistently high). The prevalence of physical and cognitive impairment increased from respondents with minimal to high symptoms (16 to 75% and 6 to 11%, respectively; p < 0.001 for trend). Women with the highest versus lowest depression trajectory over time smoked more (17 vs 4%), reported poor health (48 vs 3%), and exercised less (1046 ± 1330 vs 2053 ± 1765 kcal/wk) (p < 0.001 for trend). We will present further results and discuss implications for clinical care.

HEALTHY LIFESTYLE AND PSYCHOLOGICAL WELL-BEING BUFFER DIABETES-RELATED COGNITIVE DECLINE: FINDINGS FROM THE TAIWAN LONGITUDINAL STUDY ON AGING
C. Chiu, L.A. Wray, Pennsylvania State University, University Park, Pennsylvania

Diabetes is associated with increased dementia risk and lower levels of cognitive function. Few studies have evaluated the association between diabetes and change in cognitive function over time and how lifestyle and psychological well-being may impact that relationship in older Taiwanese. This study drew data from 4,658 adults aged 51 and older from the 1996-2003 Taiwan Longitudinal Study on Aging and employed cohort sequential multilevel modeling to explore sociodemographic, comorbidity, lifestyle, and psychosocial factors as mediators and moderators of the association between diabetes and cognitive function. Our results show that adults living with diabetes in Taiwan have lower levels of cognitive function and faster rates of deterioration in this outcome. Lower levels of cognitive function in adults with diabetes may be explained by gender, educational, and racial/ethnic differences. However, steeper cognitive decline related to diabetes may be buffered by increased leisure time activities, more protective diet behaviors, and fewer depressive symptoms.

THE EFFECT OF INTENTIONAL WEIGHT LOSS ON TOTAL MORTALITY IN OLDER ADULTS: A POOLED ANALYSIS OF TWO RANDOMIZED-CONTROLLED TRIALS
K. Shea1, D.K. Houston1, B. Nicklas1, M.E. Miller1, S.P. Messier1, M.A. Espeland1, S.B. Kritchevsky1, 1. Internal Medicine/Gerontology, Wake Forest University, Winston-Salem, North Carolina, 2. Wake Forest University-Public Health Sciences, Winston Salem, North Dakota

Although weight loss can improve physical function and age-related morbidity in overweight/obese adults, there is reluctance to recommend weight-loss to older adults because some observational studies have associated it with higher mortality. Differentiating intentional from unintentional weight loss is difficult to do in observational studies. We examined the effect of an 18-month behavior-based weight loss intervention on total mortality using pooled data from two randomized-controlled trials comprised of 901 older adults (mean(SD) age=67(5) years, BMI=32(3) kg/m2). At the end of the trials weight losses (mean(SD)) were 4.6(5.8)kg and 1.0(4.2)kg in the weight loss and non-weight loss groups, respectively. Eight years after enrollment, the mortality rate was 38% lower among those randomized to weight loss [n=452; 63 vs. 81 deaths, HR(95%CI)=0.62(0.40-0.98), adjusted for age, gender, race, history of CVD, and trial]. Randomization to behavioral interventions for weight loss does not increase total mortality risk in older overweight/obese adults.

SESSION 1845 (SYMPOSIUM)

CONDUCTING MIXED METHODS RESEARCH ON LIFE COURSE TRAUMA AND STRESS WITH ETHNICALLY DIVERSE OLDER ADULT PRISONERS
Chair: T.M. Maschi, Fordham University, New York, New York

This mixed methods study explored older prisoners (aged 55+) cumulative trauma and stress, coping resources, and physical-mental well-being. It used a correlational mixed methods design and a sample of older prisoners (N=320) housed in the NJ Department of Corrections in 2010. Quantitative and qualitative data was gathered using an anonymous mailed questionnaire consisting of closed and open ended questions. Qualitative data was analyzed using Tuttty and colleagues (1996) qualitative data analysis scheme. Older prisoners reported prison stress related to oppressive/abusive environment, unfair treatment from staff and younger prisoners, family separation, and situations of uncertainty, such as fear of death and reentry. Older prisoner reported coping resources that involved spiritual practices, physical exercise, reading, and the arts. Methodological challenges overcome include using mixed methods to understand sensitive topics, such as trauma, maximizing response rate using mail methods, reaching Spanish-speakers, and qualitative data management for large samples.

QUALITATIVE RESEARCH ON RISK AND RESILIENCE WITH OLDER LATINA WOMEN DIAGNOSED WITH CANCER
I.V. Carrion, Social Work, University of South Florida, Tampa, Florida

Disparities in end of life health decision-making are important health care concerns particularly among older Latinos diagnosed with cancer who experience social inequalities, including discrimination, cultural and language barriers (Kramer, & Auer, 2005) due to limited English language proficiency. This research explored the obstacles to accessing knowledge and information regarding treatment options, advanced care planning and decision making when confronted with an end stage cancer diagnosis. The qualitative design facilitated the understanding of the social and cultural contexts of participants. Forty-five females were recruited to participate in the semi-structured interviews, 15 from each group of Colombian, Mexican and Puerto Rican women. Participants were recruited from community based organizations, clinics, and churches. Late diagnosis, personal losses, physical debilitation, communication barriers and caregiver stress directly impact Latinos with cancer. Methodological challenges that were effectively confronted included recruiting Latina participants with cancer, transportation constraints, immigration issues, and language barriers.

EXPLORING “HOME” AT AN ASSISTED LIVING FACILITY WITH PHOTOVoice: LOOKING THROUGH RESIDENTS’ LENSES
T. Levinson1, V. Robinson-Dooley2, 1. School of Social Work, Georgia State University, Atlanta, Georgia, 2. Kennesaw State University, Kennesaw, Georgia

This study explored descriptions of “home” among 10 African American older adults at an assisted living facility. In this qualitative design, we recruited and engaged residents in PhotoVoice, a participatory research method (Valera, Gallin, Schuk, & Davis, 2009; Wang, 1999) that allows individuals to critically evaluate shared concerns through
the use of photography and focus groups. The process of transitioning to a new residential context can be difficult. Therefore, this methodology helped “give voice” to residents who are often in the position of having decisions about their home environments decided by relatives or facility administrators. After data collection, analysis included constant comparative and content analysis techniques. Findings include key photographic images that depict “home” inside the assisted living facility, suggested strategies for improving resident transitions to an assisted living hotel. Additionally, in this symposium, solutions for implementing Photovoice methodology with aging adults in a residential care environment will be discussed.

THE LIVED EXPERIENCES OF OLDER LESBIAN ADULTS WITH ALCOHOLISM
N. Rowan, Kent School of Social Work, University of Louisville, Louisville, Kentucky

Little is known about the health and mental health challenges and strengths of older lesbian adults in recovery from alcoholism. This presentation will discuss issues with accessing this often hidden and under-studied population. The Seidman (2006) approach of a three part semi-structured interview was utilized in a sample of 20 participants for a total of 60 interviews. In accordance with guidelines on phenomenological research, it is vital for immersion in the data to become more fully aware of the experiences of the respondent (Padgett, 2008; Patton, 2002; Wertz, 2005) and repeatedly listen to the transcripts and read and reread the transcripts numerous times (Seidman, 2006; Wertz, 2005). A case study will be described to illuminate the lived experience with emphasis on resiliency and quality of life.

SESSION 1850 (SYMPOSIUM)

PERSONALITY TRAITS AND PROCESSES: ASSOCIATIONS WITH LIFESTYLES, HEALTH, AND MORTALITY
Chair: G.W. Edmonds, Oregon Research Institute, Eugene, Oregon
Discussant: M. Lachman, Brandeis University, Waltham, Massachusetts

Personal traits are established predictors of health and longevity. Personality is also related to a host of lifestyle factors that affect health. These include both modifiable lifestyle factors such as health behaviors, and social environmental factors. The variety of ways that personality can influence both lifestyles and health outcomes suggest many different processes that have yet to be illustrated and have potential value for public health. The four talks in this symposium each provide different perspectives on the larger picture of how personality is related to lifestyle factors essential to health. We present research employing diverse samples, varying time spans, and a variety of outcomes. Turiano, Hill, Roberts, Spiro, & Mroczek present longitudinal data spanning 18 years where they employ a novel method in order to explain the association between conscientiousness and mortality via tobacco consumption. Lodi-Smith & Roberts report on how self-concept clarity, an important component of personality organization, varies across the lifespan and is associated with lifestyle factors. King, Dmitrieva, & Almeida describe patterns in health behaviors measured at the daily level, and relate these to personality. Edmonds, Roberts, & Hampson present a novel way of modeling the healthy lifestyle, and demonstrate the degree to which the healthy lifestyle mediates the personality and health relationship. The discussant, Margie Lachman, integrates these results and suggests how personality can be further incorporated into models that include lifestyle factors, health, and mortality.

THE HEALTHY LIFESTYLE AS A MEDIATOR OF THE PERSONALITY HEALTH ASSOCIATION
G.W. Edmonds1,2, S.E. Hampson1, B.W. Roberts3, 1. Oregon Research Institute, Eugene, Oregon, 2. The University of Illinois at Urbana-Champaign, Champaign, Illinois

Components of the Healthy Lifestyle (HLS) are often invoked as ad hoc explanations for inconsistent effects in health research. Modifiable HLS components are also advocated as a panacea for the most common threats to public health. Biases resulting from the HLS are theorized to result from covariance among its parts. This covariance has not yet been formally modeled. Furthermore, no mechanism has been proposed to explain this covariance among these factors. Using data from the Hawaii Longitudinal Study, we constructed a latent HLS variable. We evaluated the degree to which the shared variance of HLS components is accounted for by personality traits. We then tested the HLS as a mediator of the personality health relationship. The HLS fits well as a latent variable, partially accounted for by personality traits, and partially mediates the effects of personality traits on health. In all cases personality traits have direct effects on health independent of the HLS. Modeling the HLS as a latent variable provides a novel way to evaluate its potential effects both as a source of bias, and as a public health intervention. Additionally, these results suggest that personality traits have predictive validity with respect to health exceeding that provided by commonly used lifestyle predictors. Implications for health and epidemiological research will be discussed.

SELF-CONCEPT CLARITY ACROSS THE LIFESPAN
J. Lodi-Smith1, B.W. Roberts2, 1. Canisius College, Buffalo, New York, 2. University of Illinois, Urbana-Champaign, Champaign, Illinois

Self-concept clarity captures individual differences in the coherence, consistency, and confidence of cognitive evaluations of identity. The current research examines self-concept clarity in two large samples of adults ages 18 to 94. First, we show that self-concept clarity has a curvilinear relationship with age. Next, we address how socioeconomic and lifestyle factors moderate and mediate this curvilinear relationship such that controlling for these factors helps account for lower levels of self-concept clarity in older adulthood. Finally, we present preliminary data on the longitudinal trajectory of self-concept clarity in these two samples and potential socioeconomic, lifestyle, and trait mechanisms for individual differences in self-concept clarity change. We discuss the implication of these findings for modern conceptualizations of psychological health in older adulthood, positing that self-concept clarity is an important component of psychological health across the life-span that is maintained through many of the same pathways as physical health.

SMOKING MEDIATES THE ASSOCIATION BETWEEN CONSCIENTIOUSNESS AND MORTALITY
N.A. Turiano1,2, P.L. Hill1, B.W. Roberts1,2, A. Spiro1, D. Mroczek1,2, 1. Human Development & Family Studies, Purdue University, West Lafayette, Indiana, 2. Center on Aging and the Life Course, West Lafayette, Indiana, 3. University of Illinois at Urbana-Champaign, Champaign, Illinois, 4. VA Boston Healthcare System, Boston, Massachusetts, 5. Boston University, Boston, Massachusetts

The current investigation examined whether tobacco use mediated the relationship between conscientiousness and mortality. We utilized data from the Veterans Affairs Normative Aging Study. In 1990-91, 1349 men completed the Goldberg (1992) adjectival markers of the Big Five and as of 2008, 547 (41%) had died. We employed proportional hazards modeling through an SEM framework to examine whether smoking mediated the relationship between conscientiousness and 18-year all-cause mortality. Higher levels of conscientiousness significantly predicted longevity (lower mortality risk) and smoking fully attenuated this effect. This study showed that, at least in this sample of older men, conscientiousness affected mortality through the mediator of tobacco use. More generally, we demonstrate the effectiveness of using an SEM
NEUROTICISM AND DAILY HEALTH BEHAVIORS
H. King, N. Dmitrieva, D. Almeida, Human Development and Family Studies, The Pennsylvania State University, University Park, Pennsylvania

Health behaviors play an important role in clarifying the neuroticism-health link, and there is growing interest in examining how personality is manifested in everyday behaviors. Linear and logistic regression models were used to investigate associations between neuroticism and several daily health behaviors (i.e., sleep duration, smoking, alcohol use, physical activity) among 2,022 participants (mean age = 56, range = 33-84; 57% female) of the second wave of the National Study of Daily Experiences (part of MIDUS). Respondents completed 8 consecutive daily telephone interviews. Analyses indicated that higher neuroticism was associated with shorter sleep length and greater within-person day-to-day fluctuations in sleep duration. In addition, higher neuroticism was associated with consuming more alcoholic beverages (among drinkers), but not time spent on physical activity. Participants higher in neuroticism were also more likely to smoke. The contribution of the results to the study of neuroticism and daily health will be explored and discussed.

SESSION 1855 (SYMPOSIUM)

RESULTS FROM THE INTERNATIONAL TRANSGENDER METLIFE INTERNATIONAL SURVEY ON END OF LIFE PREPARATION IN TRANS-IDENTIFIED POPULATIONS
Chair: T.M. Witten, Virginia Commonwealth University, Richmond, Virginia

While the LGBT population is gaining a place at the gerontological and geriatric research tables, typically research in this area focuses on capturing the GLBT population as a whole rather than focusing on one sub-population. This can lead to survey questions that do not capture the required particulars for a given sub-component of the GLBT population. In order to address this challenge, Witten altered the former MetLife GLBT survey questionnaire to focus solely upon transgender-identified populations and released this version as an online survey. As of this writing, there are currently n = 1,068 respondents to the survey (currently 18 countries), which contains both qualitative and quantitative questions. In this symposium Witten will introduce the audience to the basics of the Trans-MetLife survey including the basic demographics and some of the responses to end of life questions. McFadden will present an analysis of the qualitative responses to some of the written end of life comments. De Vries will offer a comparison of some of the Trans-MetLife responses with the prior MetLife responses as well as the MetLife control population.

DEMOGRAPHIC AND QUANTITATIVE END OF LIFE RESULTS FROM THE INTERNATIONAL TRANS-METLIFE SURVEY
T.M. Witten, Center for the Study of Biological Complexity, Virginia Commonwealth University, Richmond, Virginia

The International Trans-MetLife survey instrument attempts to capture information on the late life needs and challenges of the transgender-identified population. In order to address this challenge, we altered the former MetLife Phase 2 GLBT survey questionnaire to focus solely upon transgender-identified populations and released this version as an online survey. As of this writing, there are currently n = 1,068 respondents to the survey (currently 18 countries from ages 18 to over 70), which contains both qualitative and quantitative questions. In this presentation we briefly review the presenter’s previous survey work (TLARS) leading to the new Trans-MetLife survey. We then present the basic structure of the Trans-MetLife survey and review the demographic results of the respondents. Finally, we examine some of the challenges the trans-respondents face as identified through their responses to some of the questions in the survey.

END OF LIFE PREPARATIONS AMONG LGBT BOOMERS
B. de Vries, San Francisco State University, San Francisco, California

There is growing interest in the experience of both the “boomer” and LGBT populations; this presentation looks at their intersection through a focus on end of life preparations drawing from the MetLife nationally representative samples of 1201 LGBT persons ages 45 to 64 and a comparably aged sample of 1206 from the general population, as well as a previous sample of 1000 LGBT persons ages of 40 and 61. Analyses reveal that less than half of LGBT boomers had prepared a will or other end-of-life document; most respondents feared being unable to care for themselves. Almost half (45%) of the LGBT sample want hospice care at home, compared to 35% of the comparison sample. LGBT Boomers are far less likely to want to spend their last days at home without hospice care: 24% versus 37%. These results may be interpreted through the lens of minority stress and fear of discrimination.

“HAPPY JUST TO BE MYSELF”: TRANSGENDER/INTERSEX PERSONS REFLECT ON AGING
S. McFadden, S. Frankowski, S. Hahn, Psychology, University of Wisconsin Oshkosh, Oshkosh, Wisconsin

This paper reports on 141 participants age 61 and older in an online survey. They mostly noted their sexual orientation as heterosexual (n = 35), lesbian (n = 26), and bisexual (n = 23), and described themselves to others as transgender (n = 42), transsexual (n = 29), and heterosexual (n = 21). NVIVO 8 software along with Interpretive Phenomenological Analysis were employed to analyze responses to questions about fears and concerns about aging, needing and giving care, as well as how being GLBTIQ-identified prepared participants for aging, factors contributing to successful aging, and wisdom they wish to pass on to others. Fears and concerns centered on interactions with judgmental healthcare providers and finding an accepting long-term care residences; 40 persons claimed to have no fears about aging. Successful aging was described in terms of self-acceptance, exercise, financial well-being, positive attitudes, religious and spiritual beliefs, and doing good for others.

SESSION 1860 (SYMPOSIUM)

THE ADAPTIVE VALUE OF REMINISCENCE IN LATER LIFE
Chair: P. Cappeliez, Psychology, University of Ottawa, Ottawa, Ontario, Canada
Discussant: T.W. Pierce, Radford University, Radford, Virginia

Older adults face several challenges associated with aging, like cognitive decline, deteriorated physical health, and loss of psychological and social resources, situations which can lead to psychological distress. Empirical research has now established that certain forms of reminiscing can help to ward off psychological distress and enhance psychological well-being while others can accelerate the spiral of mental suffering. Still our understanding of how these particular reminiscences are linked with these outcomes is very limited. The first part of the symposium attempts to shed light on this issue, targeting on coping and psychological resources. The first communication examines the activation of assimilative and accommodative coping as key processes explaining how reminiscence relates with psychological well-being in a large of older adults. The second presentation
investigates to which extent psychological resources (sense of mastery and life meaning) mediate the relation between reminiscence and psychological distress, in the case of older adults reporting moderate depressive symptomatology. Although there is now substantial evidence for the efficacy of reminiscence interventions as a treatment of depression in later life, little is known about the modalities of intervention delivery that are best suited for older adults with different needs. The third and last presentation of the symposium describes and discusses two randomized controlled trials of a life-review therapy, the first in a group format and the second as a guided self-help intervention. The symposium concludes with a discussion about the work in progress in research on the functions of reminiscence and on reminiscence interventions.

COPING MEDIATES THE RELATIONSHIPS BETWEEN REMINISCENCE AND PSYCHOLOGICAL WELL-BEING AMONG OLDER ADULTS

P. Cappeliez, A. Robitaille, Psychology, University of Ottawa, Ottawa, Ontario, Canada

Cross-sectional and longitudinal studies have demonstrated an association between various functions of reminiscence and well-being in later adulthood. This study investigates to what extent the links between reminiscence (self-positive and self-negative functions) and psychological well-being (depressive symptoms, anxiety level, life satisfaction) are mediated by assimilative and accommodative coping. This mediational model was tested using structural equation modeling. The results support the hypothesis that coping completely mediates the links between reminiscence and psychological well-being. Specifically, self-positive reminiscences are related to improved psychological well-being via assimilative and accommodative coping, while, in contrast, self-negative reminiscences are associated to reduced psychological well-being through their negative relationships with both coping modes. These findings suggest that reminiscence contributes to psychological well-being in part because it promotes assimilative and accommodative coping, which are protective mechanisms through which the self system constructs continuity and meaning over the life course.

MEANING IN LIFE AND MASTERY MEDIATE THE RELATIONSHIP OF NEGATIVE REMINISCENCE WITH PSYCHOLOGICAL DISTRESS AMONG DEPRESSED OLDER ADULTS

J. Korte, P. Cappeliez, E.T. Bohlmeijer, G. Westerhof, 1. University of Twente, Enschede, Overijssel, Netherlands, 2. University of Ottawa, Ottawa, Ontario, Canada

To understand the adaptive value of reminiscence, a mediational structural equation model of reminiscence was tested in a sample of older adults with mild to moderate depressive symptoms. It was investigated if psychological resources (mastery, presence of meaning in life and search for meaning in life) mediated the relation between reminiscence (self-positive: identity and problem solving, and self-negative reminiscence: bitterness revival and boredom reduction) and psychological distress (depression and anxiety). Results showed that psychological resources fully mediated the relation between self-negative reminiscence and psychological distress. Specifically, self-negative reminiscencing was related to decreased psychological distress through meaning in life and sense of mastery. This study contributes to current knowledge on the relation between reminiscence and mental health. It helps to understand better how reminiscence is related to psychological distress, especially in depressed older adults. Furthermore, the findings suggest the usefulness of focusing on strengthening psychological resources in therapeutic reminiscence-based strategies.

THE EFFECTIVENESS OF A GROUP AND A SELF-HELP LIFE-REVIEW THERAPY INTERVENTION FOR OLDER ADULTS WITH MODERATE DEPRESSIVE SYMPTOMATOLOGY

Although there is substantial evidence for the efficacy of life-review as an early treatment of depression in later life, the effectiveness in its natural setting has not been studied and most trials evaluated group interventions. Therefore, this presentation focuses on two large randomized controlled trials; one that evaluated a group life-review therapy intervention in its natural setting (n=202) and one that evaluated life-review therapy as a guided self-help intervention (n=174). The group intervention was compared with care-as-usual, whereas the guided self-help intervention was compared with care-as-usual and a minimal intervention (expressive writing). Results of the first trial showed that, although the group intervention primarily alleviates depressive symptoms, it is also effective in reducing anxiety symptoms and strengthening positive mental health. Besides, moderator analyses showed that the intervention is broadly applicable. Results of the second trial will demonstrate if life-review therapy can also be successfully implemented as a guided self-help intervention.

WORKING MEMORY CAPACITY AND OVERGENERAL AUTOBIOGRAPHICAL MEMORY IN YOUNG AND OLDER ADULTS

L. Ros Segura, J.M. Latorre, J.P. Serrano, 1. Psychology, School of Medicine, Albacete, Albacete, Spain, 2. Facultad de Medicina, Albacete, Albacete, Spain

ABSTRACT The objectives of this study are to compare the Autobiographical Memory Test (AMT) performance of two healthy samples of younger and older adults and to analyse the relationship between overgeneral memory (OGM) and working memory executive processes (WMEP) using a structural equation modelling with latent variables. The AMT and sustained attention, short-term memory and working memory tasks were administered to a group of young adults (N = 50) and a group of older adults (N = 46). On the AMT, the older adults recalled a greater number of categorical memories (p = .000) and fewer specific memories (p = .000) than the young adults, confirming that OGM occurs in the normal population and increases with age. WMEP was measured by reading span and a working memory with sustained attention load task. Structural equation modelling reflects that WMEP shows a strong relationship with OGM: lower scores on WMEP reflect an OGM phenomenon characterized by higher categorical and lower specific memories. Keywords: Autobiographical memory; Overgenerality; Aging; Executive processes; Working memory.

SESSION 1865 (SYMPOSIUM)

THE IMPACT OF ENVIRONMENTAL CHANGE ON THE LIFESTYLE AND LIFESPAN OF OLDER ADULTS: AN INTERDISCIPLINARY PERSPECTIVE

Chair: C.A. Mingo, Institute on Aging, University of North Carolina - Chapel Hill, Chapel Hill, North Carolina

When taking an ecological approach to aging, it is imperative to explore the impact of environmental change (i.e., natural, physical, built, social) on the lifestyles and lifespan of a rapidly aging population. Recent scholarship as well as the Environmental Protection Agency (EPA) Aging
initiative has started to emphasize the impact, both negative and positive, of environmental change in the health and quality of life in an aging population. Older adults are often considered to be vulnerable due to the increased risk of chronic conditions, low income, functional impairment, and social isolation. However, little is known about the vulnerability risk of environmental change on the aging population. Utilizing an interdisciplinary perspective, emerging scholars, representing various sections within GSA (e.g., Health Sciences), will present research examining the relationship between environments and aging. Topics to be highlighted include the relationship between neighborhood characteristics and health, the impact of hurricanes on both evacuated and non-evacuated nursing home residents, how environmental and behavioral factors affect genetics, the impact of environmental change on the role of health care providers, and the life course, home, and the negotiation of environmental change. The discussion centers on the importance of public health, policy, and future research implications so that fewer older adults find themselves at risk for poor health outcomes. This symposium is the Presidential Symposium sponsored by the Emerging Scholars and Professional Organization.

THE IMPACT OF HURRICANE GUSTAV AND NURSING HOMES’ DECISIONS TO EVACUATE ON THE MOST VULNERABLE NURSING HOME RESIDENTS

K.S. Thomas, University of South Florida, Tampa, Florida

Evacuation can have detrimental effects to morbidity and mortality rates for NH residents. Merging MDS and Medicare data, we describe and compare outcomes for the most functionally impaired residents in NHs exposed to Hurricane Gustav in 2008 compared to similar residents residing at the same facilities during non-exposure years (2006-2007). We compare outcomes of residents that evacuated versus those that sheltered in place. The 30 and 90 day mortality and hospitalization rates of the most functionally impaired residents residing in exposed NHs were considerably higher than residents residing at the same facilities over the same period of time during non-exposure years. Among survivors, there was a significant increase (63%) in functional decline. There was also a notable increase in morbidity and mortality for those residents who evacuated compared to those that sheltered in place. These findings call for further examination of evacuating the frailest residents and appropriateness of evacuation.

NEIGHBORHOOD EXPOSURES, WALKING SPEED, AND WALKING AMONG OLDER ADULTS: THE CARDIOVASCULAR HEALTH STUDY

To investigate effects of neighborhood on walking speed (seconds to walk 15 feet) and amount of walking (number of city blocks walked in the prior week), we construct race-stratified linear regression and negative binomial regression models using data from the Cardiovascular Health Study, a longitudinal population-based cohort study of older adults (≥65 years). Neighborhood exposures were measured by neighborhood socioeconomic status (NSES), street connectivity, and block length. Residing in the lowest NSES quartile compared to the highest NSES quartile was associated with slower walking speed for African Americans (n=856) and less amount of walking for whites (n=4050). NSES was not associated with walking speed for whites and amount of walking for African Americans. Street connectivity and block length were not associated with walking speed and amount of walking. Further study is needed to understand mechanisms through which neighborhood influence walking speed and amount of walking among older adults.

NEIGHBORHOOD BUILT ENVIRONMENT AND LOWER EXTREMITY FUNCTION AMONG OLDER WOMEN

C.L. Nagel, Y.L. Michael, J. Newsom, 1. Oregon Health & Science University, School of Nursing, Portland, Oregon, 2. Drexel University, School of Public Health, Philadelphia, Pennsylvania, 3. Portland State University, School of Community Health, Portland, Oregon

Among older adults, declines in lower extremity function are associated with increased risk of subsequent disability, institutionalization, and death. Understanding the modifiable determinants of lower extremity function is a critical step in promoting healthy aging in the community. While the individual-level determinants of lower extremity functional decline have been well identified in previous studies, little is known about the neighborhood-level factors associated with lower extremity function. We conducted a retrospective longitudinal study of the relationship between objective measures of neighborhood built environment and trajectory of gait speed over a sixteen-year period among a sample of 2010 community-dwelling older women enrolled in the Study for Osteoporotic Fractures during the time period 1986-20002. Though longitudinal analyses are currently in progress, cross-sectional analyses of baseline data support an independent association between neighborhood built environment and lower extremity function. Results from the completed longitudinal analyses will be presented during this symposium.

HEALTH AND LIFESTYLE FACTORS MODERATE GENETIC INFLUENCES UNDERLYING COGNITIVE AND PHYSICAL FUNCTION

There is growing recognition that environmental and behavioral factors can affect gene action and gene expression. Twin studies can identify factors that might modify the importance of genetic factors. This presentation reviews recent studies from the Vietnam-Era Twin Study of Aging that have examined how health and lifestyle factors modify the heritability (i.e., the proportion of variance explained by genes) of aging phenotypes in men. For example, we found lower heritability in unmedicated hypertensives, as compared to non-hypertensives and medicated hypertensives, for certain aspects of cognitive function. This decrease in heritability was driven by a decrease in genetic variance. In a separate study, decreased heritability in pulmonary function resulted from heavier smoking. However, this effect was driven by an increase in environmental variance among smokers, rather than a change in genetic variance. These studies highlight that differences in heritabilities of aging phenotypes can arise via both genetic and environmental mechanisms.

INFLUENCE OF THE ENVIRONMENT ON THE ROLE OF HEALTH PRACTITIONERS IN DISASTERS

Research suggests that recent disasters are a result of environmental change and may have a profound effect on older adults. If disasters continue to increase in severity and scope, the aging population may be significantly affected. This presentation addresses how disasters can affect older adults and how health practitioners of older adults can play...
an important role if they are required to respond to older adults during disasters. Using data collected through a literature review, key expert interviews and a case study review, resources, tools, and best practices that provide emergency management information for practitioners were identified. Overall findings suggest that a significant amount of information is available for facility practitioners; however, further work needs to be done to increase the limited amount of resources for community practitioners. In order for older adults to remain living independently in the community, access to health services is imperative, especially during natural disasters.

LIFE COURSE, HOME, AND THE (RE)NEGOTIATION OF ENVIRONMENTAL CHANGE
A.S. McIlwain, Graduate Center for Gerontology, University of Kentucky, Lexington, Kentucky

The process of developing a sense of home involves the (re)negotiation of a series of environmental changes, both physical and sociopolitical. This presentation offers a critical examination of the process, using a life course perspective and the case of older Irish immigrants. Changes resulting from major disruptions in residential history, such as transnational migration as a young adult, are shown to influence the ways in which these older immigrants develop, maintain, and communicate their conceptions of home over the life course and across generations. Study participants were recruited from the greater Boston metro area. Most emigrated from economically depressed rural areas in the West of Ireland to Boston in the late 1940s and 1950s, a period in Ireland’s history marked by mass emigration and population decline. Data were collected from deep narrative interviews and analyzed using a grounded theory approach. Findings have implications for home and mobility scholarship.

SESSION 1870 (SYMPOSIUM)

THE POSITIVE AND NEGATIVE SIDE OF SOCIAL RELATIONSHIPS: INFLUENCES ON WELL-BEING
Chair: G. Luong, University of California, Irvine, Irvine, California
Co-Chair: S.T. Charles, University of California, Irvine, Irvine, California

Discussant: K.S. Birditt, University of Michigan, Ann Arbor, Michigan

Social relationships have been linked to health and well-being in both positive and negative ways. This symposium presents research examining how emotional perceptions and experiences are embedded in various social contexts, from interactions with close family ties and strangers to appraisals about broader social networks and social isolation. The first two presentations cover the influences of social interactions on emotional experiences. The opening presentation reviews research on dynamic family interactions and the transfer of emotional experiences between parents and their adolescent children. These findings suggest that parents’ emotional experiences may have an important influence on their child’s emotion regulatory efforts and vice versa. The second presentation will focus on age differences in affective reactivity in response to negative social interactions with a stranger. These age differences are partially explained by age differences in goals to maintain social harmony and change the partner’s behaviors. The last two presentations will review research on perceptions of the broader social network and of social embeddedness in the community and their associations with well-being. The third presentation covers research on the quality of social networks and their association with feelings and acts of forgiveness in their relationships. The final presentation focuses on the effects of loneliness on age differences in cardiovascular reactivity to a social stressor. Loneliness exacerbates age differences in stress reactivity and recovery. Altogether, these findings suggest that various social contexts have important implications on emotional experiences and well-being across the adult lifespan.

THE ROLE OF GOALS: AGE DIFFERENCES IN AFFECTIVE REACTIVITY TO NEGATIVE SOCIAL INTERACTIONS
G. Luong, S.T. Charles, University of California, Irvine, Irvine, California

According to socioemotional selectivity theory, older adults are motivated to regulate their emotions by maintaining harmony with their social partners. Past studies have confounded the length of time that older adults have known their partners and the avoidance of conflict. For example, older adults may avoid conflict because they have known their partners longer. To control for this possibility, the current study had participants interact with a confederate, who they believed was another research participant matched on age-group, gender, and cultural group (European American or Chinese American). Confederates were scripted to be uncooperative and direct with the participants. Older adults reported less negative affective reactivity in response to the interaction than younger adults. These findings were partially explained by age differences in goals to maintain social harmony with the confederate. Older adults were also less likely to try to change the confederate’s behaviors, which was associated with greater affective reactivity.

LONELINESS ACCENTUATES AGE DIFFERENCES IN CARDIOVASCULAR RESPONSES TO SOCIAL EVALUATIVE THREAT
C.A. Riffin1, A.D. Ong1, J. Rothstein2, B. Uchino3, 1. Cornell University, Ithaca, New York, 2. University of Utah, Salt Lake City, Utah, 3. Yale University School of Medicine, New Haven, Connecticut

The effects of aging and loneliness on cardiovascular responses to the Trier Social Stress Test (TSST) were examined in 91 young (18-30 years) and 91 older (65-80 years) normotensive adults. Piecewise linear growth curve analysis was used to model group differences in resting, reactivity, and recovery levels of systolic blood pressure (SBP) and diastolic blood pressure (DBP). Replicating and extending prior research, analyses revealed age-related increases in resting SBP and DBP. Adjusting for demographics and health covariates, interactions were found for SBP in which loneliness differences in stress reactivity and recovery were greater in older than in younger adults. Findings provide further evidence that loneliness interacts with age to augment cardiovascular risk to social evaluative threat.

SOCIAL RELATIONS AND FORGIVENESS
T.C. Antonucci1, K. Ajrouch2,1, K.S. Birditt1, 1. Institute for Social Research, University of Michigan, Ann Arbor, Michigan, 2. Eastern Michigan University, Ypsilanti, Michigan

This study examines social relations and forgiveness. We examine the factors that predict forgiveness with a particular focus on social relations. Two hundred eleven telephone interviews have thus far been conducted with respondents from the Detroit metropolitan area. People were asked to identify their close personal relationships; i.e. who they felt close to and about the quality of their relationships. They were also asked a series of questions about forgiveness. Preliminary analysis indicates that network size was not related to feelings about forgiveness but positive quality social relations was associated with more forgiving (r = .37; p<.001). These preliminary data suggest that quality of social relations influence feelings of forgiveness. Additional analyses will further explore these associations and how they vary for three racial/ethnic groups.

This study examines social relations and forgiveness. We examine the factors that predict forgiveness with a particular focus on social relations. Two hundred eleven telephone interviews have thus far been conducted with respondents from the Detroit metropolitan area. People were...
asked to identify their close personal relationships; i.e. who they felt close to and about the quality of their relationships. They were also asked a series of questions about forgiveness. Preliminary analysis indicated that network size was not related to feelings about forgiveness but that positive quality social relations was associated with more forgiving (r = .37; p < .001) and negative quality relationships with the expressed need for more forgiveness needed in the world (r = .17, p < .05). These preliminary data suggest that quality of social relations influence feelings of forgiveness. Additional analyses will further explore these associations and how they vary for three racial/ethnic groups.

**COREGULATION OF DAILY AFFECT IN PARENTS AND ADOLESCENTS WITH TYPE 1 DIABETES**

C.A. Berg1, D.J. Wiebe1, P.S. King1, J. Butner1, J. Butler1, J. Psychology, University of Utah, Salt Lake City, Utah, 2. University of Texas Southwestern Medical Center, Dallas, Texas

Families are regulating systems (Repetti et al., 2009), whereby the daily emotional experience of one member of the family is affected by another family member. We examined the co-regulation of daily negative (NA) and positive affect (PA) between mothers and fathers and their adolescent, who was dealing with type 1 diabetes. Two-hundred and seven adolescents (10.5 to 14.5 years old) with diabetes and their mothers and fathers and 162 fathers completed a diary for 14 days. Results indicated significant negative affect covariation between mothers and adolescents (b = .17, p < .01) and fathers (b = .07, p < .01) and adolescents, such that on days when adolescents experienced greater NA, mothers and fathers also experienced greater NA. Significant PA covariation was only found between mothers and their adolescents (b = .07, p < .01). Results are discussed within the literature on coregulation among families of healthy adolescents (Repetti et al., 2009) and moderators of these effects are explored.

**SESSION 1875 (PAPER)**

**PHYSICAL FUNCTION**

**FUNCTIONALITY IN THE ELDERLY REDUCES THE FEAR OF FALLING AND ITS HARMFUL CONSEQUENCES**

M. Machado, F. Carnide, V. Moniz-Pereira, H. André, F. Ramalho, A. Veloso, Biomechanics and Functional Morphology Laboratory, Faculty of Human Kinetics, Technical University of Lisbon, Cruz Quebrada, Portugal

PURPOSE: Fear of falling (FoF) is a common and potentially disabling problem among elderly. The purpose of this study was to determine FoF and its impact on the impediment of performing the activities of daily living (ADLs). METHODS: A cross-sectional study was designed to determine the effect of FoF and its consequences regarding perception of health (PH), falls prevalence (FP), physical activity (PA) and functional fitness (FF) among 211 Portuguese older adults (72,6±6,6 yrs; 74,9% women). FoF, PH, PA and FP were assessed by questionnaires. FF was evaluated by field tests. Mann-Whitney and Chi-Square test were used to identify differences among PH, PA, FF, and FP according to FoF and how it affects the ADLs. Logistic regression analyses (forward conditional) was performed. RESULTS: FoF was reported by 52,1% while associated activity impediment was observed only in 23,1%. Gender, PH, visual and hear health perception (VHP, HHP), chronic diseases, FP, medications and walking time are associated with both variables. For the outcome FoF, women, medications and VHP are risk factors, while balance score is a protective one. For the impediment outcome, medications and HHP also appears as risk factors, and balance score assumes again a protective role. CONCLUSION: Functionality seems to protect the elderly from FoF and its harmful impact in ADLs. Preventive efforts to engage older persons in an active lifestyle, especially by increasing walking and achieve good balance could have a positive effect on autonomy of the elderly and in quality of life in later years.

**DO SEX, RACE AND PHYSICAL ACTIVITY MODIFY THE RELATIONSHIP BETWEEN OBESITY AND PHYSICAL FUNCTION IN OLDER ADULTS?**

A. Fowler-Brown1, E. Marcantonio1, C. Wee1, E. Newton2, L. Lipsitz1,2, S.G. Leveille1,2, J. Medicine, Beth Israel Deaconess Medical Center, Boston, Massachusetts, 2. Hebrew SeniorLife, Boston, Massachusetts, 3. University of Massachusetts, Boston, Massachusetts

With the rising burden of obesity in the aging population, differences based on sex, race and physical activity could distinguish groups most at risk for obesity-related disability in old age. In the population-based MOBILIZE Boston study, 744 adults aged ≥70 years attended baseline assessments to measure height and weight, SF-12 Physical Component Subscale (PCS), ADL disability and the Short Physical Performance Battery score (SPPB). Physical activity was assessed using the Physical Activity Scale for the Elderly (PASE). All measures were repeated at the 18-month assessment. We performed multivariable GEE modeling adding interaction terms to models to determine whether sex, race or physical activity modified the obesity-disability relationship. Both men and women with NHLBI class 2/3 obesity had lower SPPB scores compared with their non-obese counterparts (sex/obesity interaction p-value, 0.63). However, obesity was associated with PCS and ADL disability only in women (sex/obesity interaction p-values, 0.094 and 0.014, respectively). There were no racial differences in the relationship between obesity and any disability outcomes. Although obese persons who were physically active had better function than their sedentary counterparts, the relationship between obesity and ADL disability was strongest in physically active persons (PASE/obesity interaction p-value, 0.003). The inverse association between obesity and SPPB was similar across PASE levels. Older women were more susceptible to obesity-related disability than older men. Physical activity did not mitigate the detrimental impact of obesity on disability, suggesting that exercise interventions may need to include weight loss strategies to effectively reduce risk for disability in obese older adults.

**BIRTH WEIGHT AS A DETERMINANT OF PHYSICAL FUNCTIONING IN OLDER AGE: FINDINGS FROM THE HELSINKI BIRTH COHORT STUDY**

M. von Bonsdorff1, T. Rantanen1, J. Eriksson2,3,4, J. Health Sciences, Gerontology Research Centre, University of Jyväskylä, University of Jyväskylä, Finland, 2. University of Helsinki, Helsinki, Finland, 3. National Institute for Health and Welfare, Helsinki, Finland, 4. Vasa Central Hospital, Vasa, Finland

Objective. We investigated the association between birth weight and physical functioning in 57- to 70-year-old persons. Methods. The longitudinal data include 2003 participants (46.3% men) who belong to the Helsinki Birth Cohort Study born between 1934 and 1944 and who participated in a clinical study at the mean age of 61 years. Physical functioning was assessed with 10 items from the Short Form-36 questionnaire. The summary scores were dichotomized into lowest tertile vs. the two highest tertiles. Birth weight and weight at 1 year were retrieved from the hospital birth records and child welfare clinic records. Results. Among men, compared to those who weighed 3.0-3.5 kilograms (kg) at birth, the age-adjusted risk for low physical functioning in older age was 3.01 (95% CI 1.48-6.12) times higher among those weighing less than 2.5 kg. 1.79 (95% CI 1.22-2.97) for those weighing 2.5-3.0 kg and 1.90 (95% CI 1.13-3.82) for those weighing over 4 kg at birth. Adjustment for later life height, weight, occupation, smoking, physical activity and alcohol use increased the risk of lower physical functioning for those with low birth weight but attenuated the risk for those weighing more than 4 kg compared to those weighing 3.0-3.5 kg at birth. Among women, low birth weight did not correlate with physical functioning at 524 The Gerontological Society of America
the mean age of 61 years. Conclusions. Physical functioning seems to be programmed during prenatal life. Low and high birth weight increase the risk of lower physical functioning in old age but the underlying mechanisms might differ.

DETERMINANTS OF SIT TO STAND PERFORMANCE IN OLDER PERSONS

N. Deshpande1, F. Zang1, E. Metter2, J.M. Guralnik3, L. Ferrucci1. 1. School of Rehabilitation Therapy, Queen’s University, Kingston, Ontario, Canada; 2. National Institute on Aging, Baltimore, Maryland; 3. National Institute on Aging, Bethesda, Maryland

Inability to rise quickly from a sitting position is associated with institutionalization and an increased risk of falling in community living older persons. We examined the sensorimotor and psychosocial determinants of sit-to-stand (STS) performance in older persons. 1,004 community-living elderly (age 73.8±7.0, 556 females) participated. They were asked to stand up from a sitting position 5 times as quickly as possible (5STS), without using hand support. Participants’ Cumulative Somatosensory Impairment Index (CSII), Visual acuity and contrast sensitivity, quadriceps strength, lower limb coordination (heel-shin test), cognition, depressive symptoms, personal mastery, social support, years of education and demographics (age, sex, BMI) were recorded. Fifty-seven participants could not stand up without hand support. For those who completed 5STS (n=927), multiple linear regression revealed that, in the order of weighting, lower limb coordination, quadriceps strength, personal mastery and BMI were significant independent predictors of time for 5STS. The odds ratios from binary logistic regression showed that lower limb coordination measured using the clinical heel-shin test is a much stronger determinant of the time required for 5STS. Poor lower limb somatosensory function, and not lower limb strength, is the strongest predictor of the inability to stand up without hand support. BMI and personal mastery are possibly, strong modulators of STS performance. Further studies should investigate causal relationships.

PHYSICAL PERFORMANCE AND CARDIOVASCULAR DEATH IN A GENERAL POPULATION OF OLDER JAPANESE

S. Shinkai1, Y. Fujiwara2, H. Yoshida1, M. Nishi1, H. Murayama1, Y. Taniguchi1, H. Yoshida1, T. Suzuki2, 1. Tokyo Metropolitan Institute of Gerontology, Tokyo, Japan; 2. National Center for Geriatrics and Gerontology, Ohbune, Japan

Physical performance, especially walking speed, is a good predictor of total mortality in the elderly. However, little is known about the relationship between physical performance and causes of death. 1,048 initially non-disabled older adults aged 65-89 who lived in two communities in Japan undertook three performance tests (usual walking speed, grip strength and one-leg standing with eyes open). They were followed for 8 years. Mortality was categorized into three major causes of death (cancer, cardiovascular disease and others). The Cox proportional hazard model was applied for determining independent associations between respective physical performance and cause of death, controlling for demographics, conventional mortality risk factors (medical history, alcohol drinking and smoking status, BMI, Hb, Alb, HbAlc, total and HDL-cholesterol, systolic BP), and renal function (proteinuria, eGFR, cystatin C) and inflammation measures (WBC, CRP, TNF-α, IL-6). During a median follow-up of 7.7±5.9 years, 83 cardiovascular and 73 other causes mortality occurred. All three performances were strongly associated with cardiovascular mortality and other causes mortality. As compared with individuals having the lowest tertile of usual walking speed, grip strength or one-leg standing, those having the lowest tertile of respective performance showed adjusted hazard ratios of 1.46-5.82) for cardiovascular mortality, respectively. Physical performance is a strong predictor for cardiovascular death in a general population of older Japanese, independent of conventional mortality risks, renal function and inflammation measures. The investigation of potential mechanisms is warranted for future study.

SESSION 1880 (PAPER)

TECHNOLOGY AND HEALTH

ENHANCING GERIATRIC FALL RISK ASSESSMENT WITH WEARABLE MOTION SENSOR DATA

M. Marschollek1, M.D. Schulze1, M. Gietzelt2, K. Wolf2, G. Nemitz3, H. Meyer zu Schwabedissen1, 1. Peter L. Reichertz Institute for Medical Informatics, Hannover Medical School, Hannover, Germany; 2. University of Braunschweig - Institute of Technology, Braunschweig, Germany; 3. Braunschweig Medical Center, Braunschweig, Germany

Falls and their consequences constitute a significant factor in morbidity and mortality. Accurate fall risk assessments play a significant role in targeting preventive measures in order to reduce the number of falls. The aim of our research work is to examine whether self-reported activity and objective motion data obtained with a wearable triaxial accelerometer during a Timed Up&Go test (TUG) and a 10m walk can enhance the predictive accuracy of conventional fall risk assessment. A sample of 46 geriatric inpatients was followed up for one year after performing the above-mentioned tests and undergoing conventional geriatric assessment using the STRATIFY score, Barthel index and TUG. Based on these data and employing a ten-times tenfold cross-validation procedure, predictive accuracy was computed for two classification tree models, one based on conventional tests alone and one using additional motion parameters derived from sensor data and the overall activity level. The results show that the model based on all data performs better than the one based on conventional assessments: sensitivity 87%/83%, specificity 95%/79%, PPV 78%/79%, NPV 96%/85%, Cohen’s kappa 0.74/0.59. While the generalizability of our results is limited due to the small sample size, we may conclude that triaxial acceleration data and self-reported activity can be used to enhance the predictive accuracy of conventional fall risk assessment data.

REMOTELY DETECTED ACTIVITY CHANGES IN OLDER ADULTS DURING A NOROVIRUS EPIDEMIC

J. Kaye1,2, N.C. Mattek1,2, I. Campbell1,2, S. Maxwell1,2, T. Hayes1,2, D. Austin1,2, W. Hart1,2, M. Pavel1,2, 1. Oregon Health & Science University, Portland, Oregon; 2. Oregon Center for Aging & Technology, Portland, Oregon

To identify how pervasive computing environments may detect changes in activity patterns due to acute illnesses. The Intelligent Systems for Assessing Aging Changes (ISAAC) study is a longitudinal community cohort study that has deployed an unobtrusive home-based remote health and activity assessment platform in the homes of 225 older adults in Portland, OR. In March 2010 residents of an ISAAC participating retirement community were quarantined for a norovirus outbreak. This circumstance provided a naturally occurring opportunity to prospectively determine individual differences in patterns of activity during the viral outbreak. We compared within-subject computer usage (mean time on computer/day and # of days on computer), time out of the house and room-to-room transitions for a pre-quarantine period of 18 days to the 18-day period during quarantine for 40 participants. Subjects were mean age 84 years; 75% women. Five of the 40 reported being ill with the virus. We detected within-subject changes in all four activity measures using unobtrusive in-home activity monitoring. Subjects spent more time on the computer/day during the quarantine as compared to prior (p<0.001). Subjects spent more time at home during the quarantine and the median number of room-to-room transitions was higher except in those who became ill. Using this community epidemic...
as a case study, we were able to detect significant within-subject differences in several measures of in-home activity using this assessment platform. Refinement of prediction algorithms may allow for early detection or close surveillance of illness or epidemics at the small community level using this approach.

**USING GPS TO ENHANCE OUR UNDERSTANDING OF MOBILITY IN OLDER ADULTS**

D.E. Rosenberg, B. Belza, University of Washington, Seattle, Washington

**Purpose:** 1) describe the use and acceptance of the Global Positioning System (GPS) in a study of built environment impacts on aging adults’ mobility; and 2) describe opportunities for applying GPS methodology to other aging populations. Methods: We used a mixed methods approach. Participants over 50 years old with mobility disabilities (i.e. use an assistive device to ambulate) carried GPS (Q-Starz BT-Q1000XT) devices for 2 week days and 1 weekend day. The maps generated from the GPS devices were used to prompt recall during home-based in-depth interviews about destinations, transportation modes, and built environment barriers and facilitators. Data from the GPS will be uploaded to the Physical Activity Location Measurement System (PALMS) in order to derive quantitative data. Results: To date, 24 older adults with mobility disabilities have been recruited; 8 have worn GPS devices in their neighborhood and been interviewed. All participants have found the GPS units acceptable to use. No technical problems have been reported. The generated maps are successfully being used to better understand mobility patterns in this population. One theme from the interviews is the importance of access to transportation to obtain services and participate in community activities. By July 2011 we will have enrolled 40 participants and have data uploaded to the PALMS. Conclusions: The GPS has the potential to expand our understanding of mobility patterns, choices, frequency, barriers and facilitators of mobility in aging populations including those with mobility disabilities.

**FIELD MEASUREMENTS OF CIRCADIAN LIGHT EXPOSURES, ACTIVITY LEVELS, MELATONIN CONCENTRATIONS, AND DEGREES OF CIRCADIAN ENTRAINMENT IN OLDER ADULTS**

M. Figueiro1, P. Higgins2, T.R. Homick3, M.S. Rea4, 1. Lighting Research Center, RPI, Troy, New York. 2. Case Western Reserve University, Cleveland, Ohio

Aims: Failure to entrain to a regular 24-hour cycle of light and dark may contribute to poor sleep efficiency and consolidation in older adults. Circadian-effective light and circadian entrainment have not been widely measured in the field, so clinicians may have limited confidence in prescribing light treatments to improve sleep quality. The goal of this study was to measure circadian light, activity and circadian entrainment in older adults. Methods: 18 healthy adults 65 and older with no reported sleep problems wore 4 calibrated light and activity measurement devices, one located near the plane of the cornea to measure light entering the eye (the Daysimeter) and three others (Dimesimeters) worn as a pin, a pendant, an attachment to spectacles, or a wrist-watch. Saliva samples were collected every 4 hrs for melatonin assays. Analyses: The Daysimeter and Dimesimeter measured the patterns of circadian light exposure and activity, which together with melatonin levels, provided a measure of circadian entrainment using phasor analysis. Results: In sharp contrast to persons with Alzheimer’s disease, this population received sufficient, regular circadian light exposures to maintain good circadian entrainment as shown by the phasor analysis. Despite differences in the amount of activity and circadian light exposure, all devices provided similar phasor magnitudes and angles. Conclusions: The field-deployable devices and methods used here can be used to quantify circadian entrainment. The next step will be to determine if field-measured circadian disruption is related to sleep disturbances in older adults. Support: U01DA023822, R01AG034157.

**FEASIBILITY OF INTEGRATING THE USE OF REGIONAL HEALTH INFORMATION ORGANIZATION FOR A VA-BASED CARE TRANSITION INTERVENTION**

W.W. Hung1,2, B. Morano1,2, K. Boockvar1,2, 1. Health Services Research and Development Research Enhancement Award Program and the Geriatrics Research, Education, and Clinical Center, James J. Peters Veterans Affairs Medical Center, Bronx, New York, 2. Department of Geriatrics and Palliative Medicine, Mount Sinai School of Medicine, New York, New York

Older veterans often use both VA and non-VA care, which may lead to care fragmentation and increase risk for adverse outcomes, particularly during hospitalizations. Regional Health Information Organizations (RHIO), which are regional electronic medical record systems, have the potential to bridge information gap between health systems. Objectives: This is a pilot study to determine the feasibility and effectiveness of using RHIO to support a care transition intervention (CTI) for older veterans discharged from non-VA hospitals. Methods: Patients aged 65 and over who utilized both VA and non-VA health systems in the previous 2 years were enrolled. Bronx RHIO alerted the VA care teams when patients were admitted to non-VA hospitals; CTIs, which contained components of patient education and empowerment, were delivered after discharge. Goals of CTIs were to reduce rehospitalizations and improve satisfaction during transitions. Process outcomes of RHIO utilization, including accuracy of notification and retrieval of clinical information, were measured. Results: 60 male patients, with mean age of 80.3 (SD 7.1), 47% white, 80% with ≥3 chronic diseases, were tracked on RHIO for a mean duration of 167 days (SD 81 days). Patients had a total of 25 hospitalizations (0.9 events per patient-year), 14 (56%) were non-VA events (0.5 per patient-year); 7 CTIs were delivered. RHIO delivered timely notification of all non-VA events, except one delay due to mismatch on birth-date. Conclusion: Early experience suggests that RHIO can provide real-time notification to VA providers of non-VA hospitalizations, and can be used to improve care transitions across health systems.

**SESSION 1890 (SYMPOSIUM)**

**IN-DEPTH INVESTIGATION OF HEALTHY AND UNHEALTHY LIFESTYLES AND DETERMINANTS IN OLDER ADULTS**

Chair: M. Visser, Health Sciences, VU University Amsterdam, Amsterdam, Netherlands, VU Medical Center, Amsterdam, Netherlands

Discussant: S.B. Kritchevsky, Wake Forest School of Medicine, Winston-Salem, North Carolina

A healthy lifestyle includes a diet rich in fruits and vegetables, moderate – and only moderate- alcohol consumption, regular exercise and no smoking, and contributes to good health and functioning in old age. Unfortunately, many older people do not adhere to these criteria. In this symposium we zero in on the prevalence, trajectories and determinants of lifestyle behavior. Empirical data from the Longitudinal Aging Study Amsterdam will be presented. This study has established a follow-up of over 16 years, with broad information about lifestyles and social, emotional, cognitive and physical determinants of lifestyle behavior. After a short introduction by the chair, C. Dijkstra will focus on the adherence to the fruit, vegetable and fish consumption guidelines. Which older persons do adhere to these guidelines and what are the characteristics of persons who overestimate their intake? The second presentation by M. Huisman will discuss smoking behavior in older persons and how this changes over time (within persons). Characteristics of smokers will be presented as well as information about the intention to quit. In a third presentation H. Comijs will focus on alcohol consumption, the prevalence and determinants of excessive drinking and its change over time. The final presentation by M. Visser will discuss sedentary and physical activities of older persons and their interplay. The deter-
minants of sedentary behavior will also be discussed. The symposium will provide attendants with an excellent overview of lifestyle behavior of older persons, how lifestyle changes over time and the major determinants of unhealthy lifestyles.

DETERMINANTS OF SEDENTARY AND PHYSICAL ACTIVITY IN OLDER PERSONS

M. Visser, 1. Health Sciences, VU University Amsterdam, Amsterdam, Netherlands, 2. VU Medical Center, Amsterdam, Netherlands

Our aim was to investigate the association between self-reported sedentary and physical activity in older persons and their determinants. We included 1421 persons aged 60-100 y, participants of the 2008/09 wave of the Longitudinal Aging Study Amsterdam. Sedentary (SA) and physical activity (PA) were measured using validated questionnaires. Mean SA time was 10.8 (SD 5.6) and PA time 2.4 (1.6) h/d. SA was not correlated with PA (Spearman’s rho -0.01, p=0.78). Obesity and older age were associated with more SA and less PA. Higher education, male gender and underweight were associated with less SA and PA. Current smoking and excessive alcohol use were associated with more SA only, while mobility limitations and poor mobility performance were associated with less PA. An unhealthy lifestyle correlated more strongly with SA than PA. Poor functional status negatively affected PA only. These results support that high SA and low PA are two different concepts.

ADHERENCE TO DIETARY GUIDELINES AND MISPERCEPTION IN DUTCH OLDER ADULTS

S. Dijkstra, M. Visser, VU University, Amsterdam, Netherlands

This study investigated the adherence to the dietary guidelines for fruit, vegetables and fish and the degree of misperception in older Dutch adults. Cross-sectional data of the Longitudinal Aging Study Amsterdam of 1058 older adults (65-80 year, independently living, good cognitive function) are presented. Dietary intake was assessed by a food frequency questionnaire in 2007. Guidelines for fruit, vegetable and fish were met by respectively 82.5%, 65.1% and 31.7% of the older adults and less often in men and lower educated older adults. Misperception (=overestimation) was most common with regards to the vegetable guideline (24.1%) and occurred more frequently in men and the lower educated. This study indicates that adherence to the dietary guidelines can be improved and misperception is present among older Dutch adults. Attention towards education level and gender in nutrition promotion programs for older adults may potentially increase their effectiveness.

LONG-TERM PATTERNS AND DETERMINANTS OF SMOKING BEHAVIOUR IN DUTCH OLDER ADULTS

M. Huisman, M. Visser, D.J. Deeg, VU University Medical Center, Amsterdam, Netherlands, 2. VU University, Amsterdam, Netherlands

Background. Current older adults in the Netherlands and many western countries have been highly exposed to lifetimes of smoking behaviour. Do these older adults still quit smoking once they reach old age? What are their attitudes with regards to smoking? And what are the determinants of their smoking behaviour? Methods. We investigated these questions in data from the Longitudinal Aging Study Amsterdam (LASA), a longitudinal study of Dutch men and women aged 55-84 years in 1992. A follow-up on smoking behaviour was obtained of 16 years. Results. More than half of older men and women aged 75+ years in 2008 had quit smoking at some point during 16 years of follow-up. Unfavourable smoking behaviour was associated with psychological disadvantage (more depressive symptoms, more loneliness) and having no partner. Conclusion. Older adults still often succeed at quitting smoking. There may be a disadvantaged group of smokers needing more help with quitting.

ALCOHOL USE IN OLDER PERSONS

H.C. Comisj1, D.J. Deeg1, 1. Psychiatry, GGZinGeest/VUMC, Amsterdam, Netherlands, 2. VU University Medical Center, Amsterdam, Netherlands

The aim of the present study was to investigate the prevalence and changes in alcohol use among older persons within a time frame of 12 years. Data was used from the Longitudinal Aging Study Amsterdam, an ongoing population-based prospective cohort study among persons initially aged 55 to 85 in the Netherlands. Mild alcohol use was defined as 1-2 glasses per day for women and 2-3 glasses per day for men. The results showed that about 72% of the elderly were mild alcohol users, whereas 13.4% were severe drinkers. Severe alcohol use was more common among the younger age group (< 75 yrs) and among women (22.2%). With increasing age and increasing mental and physical health problems, alcohol use decreases or is completely stopped. The results showed an increase in mild and severe alcohol use over a period of twelve years. This increase seems to be related to social behavior.

SESSION 1895 (SYMPOSIUM)

LOW VISION REHABILITATION FOR OLDER ADULTS: REVIEW AND RECOMMENDATION

Chair: S. Berger, Occupational Therapy, Boston University, Boston, Massachusetts

There are 2.4 million Americans suffering from low vision. Age-related vision loss is the main cause of low vision which has a profound impact on older adults’ lifestyle and quality of life. To help researchers and health care professionals face the challenge of vision loss in older adults, this symposium will present the results of four systematic reviews of the literature that examine effects of various rehabilitation interventions. The systematic reviews focus on four areas critical to daily performance and participation of older adults with low vision: 1) reading ability, 2) activities of daily living and instrumental activities of daily living, 3) social and leisure participation and 4) driving and community mobility. This symposium is a partnership between the American Occupational Therapy Association and three academic institutes. Specific findings from each review project will be presented along with implications for practice, education and research.

EVIDENCE REVIEW OF THE EFFECT OF LOW VISION REHABILITATION ON IMPROVING INDEPENDENCE IN DAILY ACTIVITIES FOR OLDER ADULTS

C. Liu, M. Brost, V. Horton, K. Mears, S. Kenyon, Indiana University at Indianapolis, Indianapolis, Indiana

Age-related vision loss is associated with limitations in daily activities and high rates of depression. The condition is irreversible so that rehabilitation often focuses on using remained vision and learning compensation strategies to increase independence. The purpose of this review is to examine effects of low vision rehabilitation on daily activities in order to provide impetus for translating research findings into practice, and to draw implications for future studies and education. Studies were searched and screened from multiple electronic databases. Studies published between 1990 to 2010 and rated at the evidence level III or above were included. The review yielded 18 trials (Level I evidence = 9, Level II evidence = 5, level III evidence = 4). A strong effect was found in studies that applied: a multi-component education program, a multi-disciplinary team service, or multiple intervention sessions.

LEISURE AND SOCIAL PARTICIPATION: INTERVENTIONS FOR OLDER ADULTS WITH VISUAL IMPAIRMENT

J. Kaldenberg1, S. Berger2, K. Scheier2, J. McAteer2, 1. New England Eye Institute, Boston, Massachusetts, 2. Boston University, Boston, Massachusetts

Leisure and social participation is not just fun and games it is essential for health and well-being. A limitation in participation can lead to
social isolation and loneliness, depression, and decreased life satisfaction. This presentation will present results from a systematic review of the literature related to interventions that address leisure and social participation for older adults living with vision loss. Results show providing interventions aimed at improving lighting, problem-solving strategies, and a combination of low vision services is helpful in maintaining leisure and social participation. In addition, more research is needed to develop specific leisure and social participation outcome measures as well as increased research focusing on leisure and social participation outcomes which have clear definitions. As our population ages we will need geriatric practitioners who understand the unique needs of older adults living with vision loss and its impact on leisure and social participation.

**IMPROVING THE READING ABILITY OF OLDER ADULTS WITH LOW VISION: A SYSTEMATIC LITERATURE REVIEW**

S. Smallfield, K. Schaefer, A. Myers, Occupational Therapy, The University of South Dakota, Vermillion, South Dakota

Low vision is recognized as a significant, growing health concern in the older adult population. It can be detrimental to health because it impairs the reading necessary for the performance of numerous daily activities. Older adults with low vision are commonly prescribed optical, non-optical, and electronic magnifying devices and are trained to use these devices to aid in reading performance. The purpose of this presentation is to discuss the findings of a systematic literature review designed to evaluate the available evidence regarding the effectiveness of interventions for improving the reading ability of older adults with low vision. The findings of this review suggest that there is scientific evidence to support several types of intervention for improving the reading performance of adults with low vision and it solidifies the role of occupational therapy as a part of a multidisciplinary approach to low vision rehabilitation.

**DRIVING AND COMMUNITY MOBILITY: A SYSTEMATIC LITERATURE REVIEW OF EFFECTIVE LOW VISION INTERVENTIONS FOR OLDER ADULTS**

**OBJECTIVE:** To review the evidence for the effectiveness of interventions within the scope of occupational therapy practice to improve the driving performance and community mobility of older adults with low vision. METHODS: A systematic review of the literature was conducted to evaluate the evidence pertaining to low vision interventions for driving and community mobility for older adults. RESULTS: Initial database search yielded 973 abstracts. Ninety-six abstracts were identified for full text retrieval. Thirteen articles met the inclusion criteria and summarized for evidence. CONCLUSION: Variability of interventions (remediation, compensation) and driving/community mobility outcomes (crash risk, performance) specific to older adults with low vision resulted in limited evidence. Further research is needed with this population utilizing reliable and valid outcomes for driving and community mobility.

**SESSION 1900 (SYMPOSIUM)**

**NEW FINDINGS OF FEAR OF FALLING PROGRAMS: INPUT FOR AN IMPROVED LIFESPAN?**

Chair: G.L. Kempen, Maastricht University, CAPHRI School for Public Health and Primary Care, Maastricht, Netherlands

Co-Chair: G. Zijlstra, Maastricht University; CAPHRI School for Public Health and Primary Care, Maastricht, Netherlands

Discussant: A. Jette, Boston University, School of Public Health, Boston, Massachusetts

Several reviews of the literature have shown that a variety of programs reduce fear of falling or related concepts, such as concerns about falling, balance confidence, and fall-related efficacy. In this symposium we focus on prevention programs that are either explicitly or implicitly aimed to manage fear of falling, i.e. measuring fear of falling as primary or secondary outcome. However, in view of this year’s theme ‘Lifestyle → Lifespan’ we broaden our perspective and will also report on other program outcomes, such as activity engagement, disability and program benefits reported by participants. Knowledge about a program’s effects on multiple outcomes is important for future decisions regarding the implementation of programs. During this symposium researchers from the US, Switzerland and the Netherlands will present new data on the multiple effects of different programs, i.e. outcomes of a meta-analyses on fall-related efficacy and activity engagement, outcomes of a fear of falling and health coaching program on fear of falling and mobility, the role of control beliefs and concerns about falling in disability outcomes after a fear of falling program, perceived benefits of participants and facilitators of a fear of falling program, and the effects of gait training with high tech shoes on fear of falling and gait performance. Our discussant from the US will reflect on the presentations and will facilitate a discussion with the audience on-site.

**THE RELATIONSHIP BETWEEN FALL-RELATED EFFICACY AND ACTIVITY ENGAGEMENT IN COMMUNITY-DWELLING OLDER ADULTS: RESULTS FROM A META-ANALYSIS**

S. Schepens1, A. Sen1,2, J. Painter3, S.L. Murphy1,2, 1. University of Michigan, Department of Physical Medicine & Rehabilitation, Ann Arbor, Michigan, 2. Geriatric Research Education and Clinical Center, Veterans Affairs Ann Arbor Health Care System, Ann Arbor, Michigan, 3. University of Michigan, Department of Family Medicine, Ann Arbor, Michigan, 4. University of Michigan, Department of Biostatistics, Ann Arbor, Michigan, 5. East Carolina University, College of Allied Health Sciences, Occupational Therapy Department, Ann Arbor, Michigan

**OBJECTIVE:** Fear of falling can lead to restricted activity, but little is known about how fear affects different aspects of community-dwelling older adult’s lives. The study’s aim was to examine the relationship between fall-related efficacy (confidence or belief in performing activities without losing balance or falling) and activity and participation. **METHOD:** Meta-analysis of studies comparing community-dwelling older adults’ fall-related efficacy to measures of activity or participation. **RESULTS:** From 20 cross-sectional and prospective studies, a strong positive relationship between fall-related efficacy and activity was found (r=0.528). An insufficient number of studies examining fall-related efficacy and participation were available for analysis. **CONCLUSION:** Low fall-related efficacy may be an important barrier to activity engagement for many older adults which warrants careful consideration by rehabilitation practitioners. Future research should explore interventions that target fall-related efficacy and examine such interventions’ effects on activity performance and participation.

**ACTIVITY OUTCOMES AFTER A FEAR OF FALLING INTERVENTION**

H. Lach, Saint Louis University, St. Louis, Missouri

This pilot study tested an intervention to help older adults develop realistic appraisals of falls, and maintain/increase appropriate activity levels. The intervention group (n=40) participated in the Matter of Balance class compared to a control (n=20) who participated in an alternate health class. The groups were similar at baseline. Intervention group had increased physical activity levels. The intervention group had faster TUG scores at one month (13.28±7.1 vs 10.38±3.1). At the completion of the class, the intervention group showed greater improvements on the SF-12 physical/mental health scores and exercise minutes than the control group, although both groups improved. There were no significant differences, or changes...
in activity types (instrumental, low-demand leisure, high demand leisure, or social activities) or increases in life-space assessment.

DISABILITY AFTER A SELF-MANAGEMENT PROGRAM: THE ROLE OF CONTROL BELIEFS AND CONCERNS ABOUT FALLING

G. Zijlstra, J.C. van Haastregt, T. Ambergen, G.I. Kempen, Maastricht University, School for Public Health and Primary Care, Maastricht, Netherlands.

Results of an RCT showed the effectiveness of a multifaceted cognitive behavioral program on concerns about falling, daily activity, and recurrent falls in community-living older people. The present study explored the program effects on disability and the contributions of changes in control beliefs and concerns about falling herein. The sample comprised 540 community-living older people randomly allocated to the intervention (n=280) or control (n=260) group. Mixed-effects regression analyses showed that participants in the intervention group reported reduced disability at 2, 8 and 14 months (adjusted mean differences: -0.52 (p<.05), -0.78 (p<.05), and -0.60 (p=.07), respectively). Small to moderate significant intervention effects were shown on control beliefs and concerns about falling. These variables, including other psychosocial variables, contributed largely (i.e., 70 to 97%) to the intervention effects on disability. This indicates that positive changes in control beliefs and concerns about falling may be important to reduce disability in older people.

COMPARING PARTICIPANTS’ AND FACILITATORS’ PERCEPTIONS ON BENEFITS OF A CONCERNS ABOUT FALLING PROGRAM

T. Dorrestijn1, G. Zijlstra1, J.C. van Haastregt1, J. Vlaeyen2,3, G.I. Kempen1, 1. Maastricht University, CAPHRI School for Public Health and Primary Care, Maastricht, Netherlands, 2. University of Leuven, Research Group Health Psychology, Leuven, Belgium, 3. Maastricht University, Department of Clinical Psychological Science, Maastricht, Netherlands.

This study compares the perceptions of participants and facilitators regarding participant’s benefits from a multicomponent cognitive-behavioral in-home program to manage concerns about falling. Data on perceived benefits regarding 11 program goals (during an RCT) were collected from 113 intervention participants. Additionally, nine program facilitators reported their opinion on the program’s benefits for each participant they supervised. Participants perceived more program benefits when compared to the opinion of the facilitators. To illustrate, more participants indicated that they were less concerned to fall (62% of the participants vs. 48% of the facilitators, that they had increased self-confidence (72% of the participants vs. 61% of the facilitators, and that they became more physically active (69.0% of the participants vs. 65.4% of the facilitators). Perceived program benefits were similar between participants and facilitators regarding avoiding fewer activities, i.e. 40%. To conclude, participants were slightly more positive about perceived benefits of the program than facilitators.

SMILING RANDOMIZED TRIAL: GAIT PERFORMANCE AND FALLS-EFFICACY AFTER TRAINING WITH CHAOTIC PERTURBATIONS

C. Bula1, I. Melzer1, F. Marcellini1, V. Gabor2, R. Papa1, C. Hoskovec1, M. Belokopytov3, S. Bar Haim1, 1. University of Lausanne Medical Center, Lausanne, Switzerland, 2. Ben-Gurion University of the Negev, Beer-Sheva, Israel, 3. Italian National Research Institute on Aging (INRCA), Ancona, Italy, 4. Geriatric center of St. Luke, Kosice, Slovakia, 5. Assaf Harofeh Medical Center, Tel Aviv, Israel, 6. Step Of Mind, Lid, Tel Aviv, Israel.

Objective: To determine whether a training program with high tech (“SMILING”) or inactive (“dummy”) shoes for 4 weeks of training (biweekly 30-minutes sessions with walking tasks of increasing difficulties). After a 1-week wash-out period, subjects exchanged shoes and completed 4 additional weeks of training. Assessments were performed at baseline, weeks 4, and 8, and included measures of gait performance and falls-efficacy. Results: Sixty-six participants (mean age 72.5±6.2, 80.3% women, 23.6% multiple fallers) completed the training program. Although participants improved in several gait parameters and falls-efficacy after completing the training program, there was no significant difference between periods of training with and without chaotic perturbations. Conclusions: Training with chaotic perturbations might require more intensive programs to achieve improvement in gait performance and falls-efficacy.

SESSION 1905 (SYMPOSIUM)

REP SYMPOSIUM - OPTIMIZING HEALTHY BEHAVIORS TO MAXIMIZE LIFESPAN: INTERSECTIONS OF RESEARCH, EDUCATION, AND PRACTICE

Chair: D. Bakerjian, School of Nursing, University of CA, Davis, Sacramento, California
Co-Chair: T. Monroe, Vanderbilt University, Nashville, Tennessee
Discussant: D. Bakerjian, School of Nursing, University of CA, Davis, Sacramento, California

Historically, much of the research on older adults has focused on illness and pathophysiology. Recently, there has been a greater focus on health and aging. Symposium speakers will present information on exercise, alcohol use, and mild cognitive impairment in aging from the research, education and practice perspectives. Dr. Moore will discuss the often controversial role of alcohol on aging and the role of health care professionals in addressing this issue with patients. Dr. Resnick will present outcomes of research of her Functional Focused Care Intervention (FFC) as viewed through a social ecological model perspective and the effects of use in institutionalized older adults. Dr. Ellison will conclude by discussing the management of age-associated chronic disease and healthy lifestyles. The symposium chair will lead the audience in a lively discussion with symposium speakers.

BENEFITS AND RISKS OF ALCOHOL USE IN HEALTHY AGING

A.A. Moore, University of CA, Los Angeles, Los Angeles, California

Alcohol has long been a controversial issue and the risk factors, benefits and prevalence of alcohol intake in older adults is poorly understood. The epidemiology of alcohol use in older adults, recommended drinking limits, age-related factors that affect alcohol risks, data on alcohol’s benefits and risks, elder-specific issues in alcohol risk and methods for identifying unhealthy drinking in older adults are discussed in this seminar. Healthcare professionals often fail to ask older adults about their alcohol intake. Improved knowledge of these factors will facilitate their ability to properly education their aging patients in the risks and benefits of alcohol intake. Alcohol has benefits and risks for older adults depending on amount of alcohol use, co-morbidity and medication use. The most effective way to ascertain risks and benefits is to ask about alcohol use.

ENGAGING OLDER INSTITUTIONALIZED RESIDENTS IN EXERCISE ACTIVITIES

B. Resnick, University of Maryland, Baltimore, Maryland

It has been well established that older adults in residential settings engage in insufficient amount of exercise. Further we have established that interventions influencing exercise are comprehensive and best delineated using a social ecological model (SEM). Our Function Focused Care Intervention (FFC), guided by a SEM, has been used across a variety of settings to demonstrate that this approach helps to increase time in...
exercise among those living in the sites. FFC is a philosophy of care in which all residents are encouraged and helped during routine care interactions to increase time spent in function and exercise. The intervention is implemented by a Function Focused Care Nursing and incorporates four components: (I) Environment and Policy/Procedure Assessments; (II) Education; (III) Developing Function Focused Goals; and (IV) Mentoring and Motivating. This session will provide findings from our multiple studies implementing FFC Interventions in nursing homes and assisted living facilities.

SUPPORTING OPTIMAL COGNITIVE AGING INDIVIDUAL SYMPOSIUM ABSTRACT
J. Ellison, McLean Hospital, Belmont, Maine

Changes in cognition that predictably accompany normal aging differ both quantitatively and qualitatively from the cognitive changes associated with the diagnosable cognitive disorders of Mild Cognitive Impairment or Dementia. No medication has been shown to improve the course of Mild Cognitive Impairment, and the cognitive benefits of pharmaceutical agents used to treat dementia have been regarded as modest. Nonetheless, while we await more effective medication approaches, physicians can encourage management of age-associated chronic medical conditions and promote healthy lifestyle choices in middle age and beyond that have been associated with decreased risk of subsequent cognitive decline. This presentation will describe the cognitive changes associated with normal aging, differentiate these from Mild Cognitive Impairment and Dementia, and review the evidence supporting beneficial effects of medical disease management, physical activity and exercise, nutritional management, cognitive stimulation, and stress reduction.

SESSION 1910 (SYMPOSIUM)

WALKING IN LATER LIFE: CURRENT “BEST EVIDENCE” FOR CLINICAL PRACTICE
Chair: M. Lusardi, Physical Therapy & Human Movement Science, Sacred Heart University, Middletown, Connecticut

The ability to walk is much more than a key functional task in later life. Tracking an older adult’s usual self-selected and fast walking speeds (SSWS, FWS) provides important predictive information about overall health as well as functional status. Many health professionals do not regularly measure walking speed, however, missing the opportunity to use this powerful and meaningful measure in their clinical decision making. We propose that walking speed is indeed a vital sign that can be used to identify modifiable contributors to slow walking should be undertaken. Those walking less than 1.0 m/sec should trigger further examination and differential diagnosis to identify modifiable contributors to slow walking should be undertaken. Those walking less than .6 m/sec are particularly vulnerable to adverse health outcomes. We challenge physical therapists and other health professionals to routinely measure SSWS for all older adults in their care.

USING WALKING SPEED IN CLINICAL PRACTICE: WHAT DO THE NUMBERS MEAN?
M. Lusardi, Physical Therapy & Human Movement Science, Sacred Heart University, Middletown, Connecticut

Measuring self-selected walking speed (SSWS) is clinically feasible, requiring only a stopwatch and a 6m area to walk. SSWS can be measured in all practice settings: inpatient, outpatient, wellness clinics, subacute and long term care, assisted living, and in the home. SSWS is more informative than use of assistive device, need for physical assistance, or distance walked as an evaluation tool and outcome measure for physical therapy interventions. Once SSWS is measured, the challenge is to interpret what an individual’s SSWS indicates. In this portion of the symposium, we review available information on “norms” for SSWS and fast walking speed (FWS) for community living older adults, as well as the clinometric characteristics of walking speed (e.g., minimal detectable difference and minimal clinically important differences), and apply this information to the development of a plan of care and documentation of intervention efficacy.

WHAT CAN WALKING SPEED TELL US ABOUT FUNCTIONAL RESERVE?
K.K. Chui, Physical Therapy and Human Movement Science, Sacred Heart University, Fairfield, Connecticut

An older individual’s self-selected walking speed (SSWS) emerges from the interaction of the neuromuscular, musculoskeletal, and cardiopulmonary systems as the most energy efficient pattern of locomotion, minimizing the person’s metabolic cost per unit distance walked. The ability to increase walking speed is influenced by the multisystem resources available to the individual and allows the individual to better meet demands of their daily activity and challenges encountered in the environment. As such, measuring fast walking speed (FWS) may provide an index of an older individual’s “functional reserve”. In this portion of the symposium, we review the evidence that the difference between SSWS and FWS is an indicator of functional reserve and may help to identify those older adults at the cusp of functional decline.

WALKING WHILE TALKING AND OTHER DUAL TASK PARADIGMS: ADDING COMPLEXITY TO THE MIX
P. Pohl, Doctor of Physical Therapy Program, The Sage Colleges, School of Health Sciences, Troy, New York

The ability to divide attention (do two or more things at once) becomes more challenging in the later years of life. Another important and ecologically valid strategy to evaluate an older individual’s functional competence is by imposing an additional cognitive or motor task while they are walking, and determining how this impacts on walking speed. This portion of the symposium will describe the various dual task strategies that have been tested in clinical research that may be useful in clinical practice. We will present information about how change in SSWS or FWS may change with dual task conditions in healthy older adults, and discuss implications of change in SSWS for determining risk of falling, risk of functional decline, and early recognition of cognitive impairment.

WALKING SPEED AS PREDICTOR AND OUTCOME MEASURE: APPLICATION TO HIP FRACTURE
S. Fritz, University of South Carolina, Columbia, South Carolina

Hip fracture is frequently a monumental and detrimental health event for older adults. In this portion of the symposium, we will provide an example of how walking speed can be interpreted and guide practice in rehabilitation following hip fracture. We start with a review of incidence and risk factors for hip fracture as a major public health problem. Next, we present evidence from the research literature about how SSWS can
BECAUSE MANY OLDER ADULTS DREAD THE END OF THEIR DRIVING CAREER, FEW PLAN FOR FUTURE TRANSPORTATION NEEDS. THIS LACK OF PREPARATION CAN PLACE A SPECIFIC BURDEN ON ADULT DAUGHTERS, WHO OFTEN PROVIDE CARE FOR AGING RELATIVES. IN 2010, 10 ADULT DAUGHTERS (9 CAUCASIAN, 1 ASIAN; MEAN AGE 55.5, RANGE 50-63) AND THEIR FATHERS (MEAN AGE 83.1, RANGE 70-90) COMPLETED SEPARATE IN-DEPTH QUALITATIVE INTERVIEWS ABOUT EXPECTATIONS AND PLANS FOR THE FATHERS’ DRIVING FUTURE AND CAREGIVING NEEDS.

At the time of the interview, all fathers were active drivers; none had specific plans to stop. Daughters were invited 6 months later to complete a brief survey (online or by telephone) to assess the impact of the interview on discussions and plans with their fathers. The survey encouraged daughters to reflect critically on the impact of the interview and changes it effected via open-ended questions. Response rate was 100%. Eight daughters reported that the interview prompted discussions about their father’s driving future on a range of topics (e.g., shared increased awareness of driving limitations, how routines could be altered to improve safety, openness to discuss future changes and responses as a family). Two fathers had ceased driving completely, 1 having moved to a senior community that provided transportation after family discussions, the other without family input after serious health declines. Findings suggest that discussion-based interviews about driving cessation with parent/adult child dyads may prompt continued family discussion about driving-related topics and planning for the future.

**DO FATHER/DAUGHTER QUALITATIVE INTERVIEWS ABOUT DRIVING cessATION PROMPT CHANGES IN DRIVING, COMMUNICATION, AND PLANNING AT 6-MONTH FOLLOW-UP?**

Because many older adults dread the end of their driving career, few plan for future transportation needs. This lack of preparation can place a specific burden on adult daughters, who often provide care for aging relatives. In 2010, 10 adult daughters (9 Caucasian, 1 Asian; mean age 55.5, range 50-63) and their fathers (mean age 83.1, range 70-90) completed separate in-depth qualitative interviews about expectations and plans for the fathers’ driving future and caregiving needs. At the time of the interview, all fathers were active drivers; none had specific plans to stop. Daughters were invited 6 months later to complete a brief survey (online or by telephone) to assess the impact of the interview on discussions and plans with their fathers. The survey encouraged daughters to reflect critically on the impact of the interview and changes it effected via open-ended questions. Response rate was 100%. Eight daughters reported that the interview prompted discussions about their father’s driving future on a range of topics (e.g., shared increased awareness of driving limitations, how routines could be altered to improve safety, openness to discuss future changes and responses as a family). Two fathers had ceased driving completely, 1 having moved to a senior community that provided transportation after family discussions, the other without family input after serious health declines. Findings suggest that discussion-based interviews about driving cessation with parent/adult child dyads may prompt continued family discussion about driving-related topics and planning for the future.

**BENEFITS OF VOLUNTEERING TO DRIVE FOR A SENIOR TRANSPORTATION PROGRAM**

Background: Previous research documents positive health effects of volunteering. We surveyed volunteer drivers for Independent Transportation Network® (ITN), an automobile-based service for mobility-restricted adults, to learn how volunteering impacts quality of life (QOL). Methods: Between September-November 2009, ITN volunteer drivers from eight communities (n=256) were asked to complete self-administered questionnaires. To investigate benefits, we asked: 1) Since you began volunteering for ITN, how much thought have you given to your own future transportation needs when you may no longer be able to drive? 2) What do you do with your ride credits that accumulate when you volunteer to drive for ITN? 3) Explain how volunteering for ITN has affected your quality of life (we conducted theme analysis of responses). Results: 141 subjects (59.6% female; mean age=62.5+12.7 years; 98.5% White) completed surveys (55% response). Most common QOL responses: felt good to help/give back to community (59.0%); social aspects/rewarding relationships (42.9%); expanded knowledge of aging issues (12.4%); more active lifestyle (9.5%). Most respondents (85.6%) gave at least some thought to their own future transportation needs as a consequence of volunteering, and 39.2% stored ITN ride credits to help finance future transportation needs. Volunteers 65+ were more likely than younger volunteers to think “quite a lot” about future transportation needs, and to store credits for future rides (both p<0.05).

Conclusions: Volunteer drivers for an automobile-based transportation service derive numerous personal and social benefits, and this role enables them to consider and plan for their future transportation needs, especially if they are 65+.
SESSION 1920 (SYMPOSIUM)

CAREGIVING IN ASIAN COUNTRIES AND THE PACIFIC RIM
Chair: F. Ejaz, Benjamin Rose Institute, Cleveland, Ohio
Co-Chair: K. Chee, Texas State University, San Marcos, Texas

This symposium addresses issues and challenges related to caregiving in Asian countries including India, China, Japan, Korea, Taiwan as well as in New Zealand in the Pacific Rim. Findings from these studies point to a number of issues including: a) with the rapidly aging population in developing countries, examining the role of caregivers is becoming increasingly important; b) traditional roles of caregiving are changing with the increase in women working outside the home; c) caregivers, like their Western counterparts, are likely to experience a variety of conflicting emotions such as stress/burden and joy during the process of caregiving; and d) caregiving can occur long-distance through correspondence between family members living in different countries. Findings will be presented from four different research projects. Dr. Gupta will discuss qualitative findings from a survey of 259 randomly selected households in India. Dr. Lou Vivian and her colleagues will discuss quantitative findings related to a study of 716 dyads (older adults and caregivers) in Shanghai province, China. Dr. Katagiri will present findings from a secondary data analysis of 8,120 older adults and their children in four East-Asian countries. Dr. Bradley will present findings from a historical analysis of correspondence records between families in New Zealand and their relatives who migrated to four countries. The chair and co-chair will discuss the importance of the findings in relation to general differences and similarities between caregiving in the U.S. and these countries. Discussion will also center on the implications for changing practice and public policy in these countries.

TRANSNATIONAL CAREGIVING IN THE PACIFIC RIM
D.B. Bradley, Center for Gerontology, Western Kentucky University, Bowling Green, Kentucky

This research presents the analysis of family communications undertaken in a transnational context within a perspective that account for multiple exchanges between migrants and non-migrants, and between historical generations. Data for this presentation are drawn from the correspondence records (1852 – 2000) of the Heath, McBride and Houghton families held in the Hocken Collection Archives, University of Otago, New Zealand. Qualitative methods focused on the ‘actors point of view’ was used to analyze these historical records between relatives who lived in New Zealand and their relatives who migrated to four countries. Families were challenged by the financial, practical, and emotional support aspects of caregiving and employed diverse strategies to manage caregiving over great geographic distances. The most common strategy, present in 65% of the correspondence, was to pay another individual to provide care. Others either moved their older relative in closer proximity (15%) or provided emotional support through correspondence exchange.

CAREGIVERS’ NEEDS AND PSYCHOLOGICAL WELL-BEING IN SHANGHAI, CHINA
V. Lou1, S. Gui2, C. Kwan3, K. Ting4, 1. Social Work & Social Administration, The University of Hong Kong, Hong Kong, Hong Kong. 2. Population Research Institute, East China Normal University, Shanghai, China. 3. Department of Statistics & Actuarial Science, The University of Hong Kong, Hong Kong, Hong Kong. 4. Department of Sociology, The Chinese University of Hong Kong, Hong Kong, Hong Kong

Objective: This study investigates the needs of caregivers in Shanghai, China, and their psychological well-being. Method: Using a multistage sampling strategy, a total of 716 dyads (i.e., older adults and their family caregivers) were interviewed in-person by trained interviewers. Results: About 60% of the caregivers were female; more than 50% were 60 years and older; about 20% provided care for more than 10 hours per day; around 30% had provided care continuously for more than six years. About 20% of the caregivers showed depressive symptoms, which were associated with care receivers’ degree of dependency, and caregivers’ perceived burden, and coping avoidance. About 15% of caregivers were dissatisfied with life. Higher caregiver life satisfaction was associated with lower caregiving burden, greater social support, active coping and higher income. Conclusion: Providing support for the psychological well-being of Shanghai’s caregivers will be discussed in light of its implications for service provision and policy.

SESSION 1925 (SYMPOSIUM)

JOY AND BURDEN OF CARE GIVING IN INDIA: IMPLICATIONS FOR SERVICE PROVIDERS
R. Gupta, San Francisco State University School of Social Work, San Francisco, California

With modernization and an increase in women working, home-based eldercare in India has seen many changes. As a result, researchers have begun to study the impact of caregiver burden on urban households in India. This presentation focuses on results from a cross-sectional survey of 259 randomly selected households in Allahabad city in India. Data are drawn from interviews with primary caregivers on four, opened-ended questions that focused on the joys, burden, transitions and strategies for eldercare. Qualitative data analysis yielded subthemes related to the ‘joy’ of caregiving, i.e., receiving recognition and praise from extended family; feeling able to fulfill the ‘dharma’ (duty) of filial caregiving responsibilities; and reciprocating caregiving responsibilities between generations. Themes related to ‘burden’ included: lack of assistance from siblings; not having time and energy to provide care; and poor physical and mental health of the elder. Implications for social work practice will be discussed in a cultural context.

GLOBAL INITIATIVE FOR NONPHARMACOLOGICAL DEMENTIA TREATMENT
Chair: J. Zeisel, Hearthstone, Woburn, Massachusetts
Co-Chair: C. Camp, Linda-and-Cameron, Inc., Solon, Ohio

For several decades family caregivers and professionals in Alzheimer’s and dementia care have employed nonpharmacological interventions to reduce many symptoms associated with dementia, among these the 4 “A”s: Anxiety, Agitation, Aggression and Apathy. During the same period, research on the effectiveness (or not) of these interventions and approaches has been carried out in underfunded case studies and small pilot trials, in addition to infrequent RCTs. A global initiative started in Europe (Spain and Portugal) has brought together
world-wide experts in small groups to better identify the components of the “nonpharmacological paradigm” including ways to resolve the methodological challenges this new field faces. This symposium reports on this effort, including announcement of a global nonpharmacological web based network. The components of the field so far identified and which will be addressed by participants in the global process include the common nature of such interventions, design as a nonpharmacological intervention, the role of technology in dementia care, ethical questions that arise, and requirements for a new methodological approach necessary to prove or disprove the effects of such interventions. The goal of this symposium is to share the developed model of nonpharmacological approaches and to generate a broader professional discussion of its basic tenets. One of these is that nonpharmacological interventions are not merely a way of organizing “activities” but rather are based on a basic belief in the human nature and rooted in a commitment to supporting the human rights of all those living with dementia.

ETHICS, DEMENTIA AND NONPHARMACOLOGICAL INTERVENTIONS
P. Whitehouse, Case Western Reserve University, Cleveland, Ohio

Ethical deliberations have likely been a part of the human scene for the entire time we have been a verbal species and in other forms before we even came into our current form. Yet homosapiens are not always wise and some would say values and ethics define us more that thoughts and cognition. Ethics have taken many forms emphasizing differently duty, virtue, discourse and narrative. Bioethics as a field was invented in 1970 by Van Potter to be a blend of humanities and science focusing on sustainability. It is now misguided by its cooption by medicine manifest by focused on genetics, technologies and research, primarily using empirical means. Dementia raises many ethical issues including genetic testing, diagnostic disclosure, informed consent, and end of life care. A new ethical framework focusing of mutual caring and responsibility for the future will have us look at dementia and other forms of medicalization of life very differently.

BETTER OUTCOMES FOR PEOPLE WITH DEMENTIA: OPPORTUNITIES AND CHALLENGES IN THE ADOPTION OF ASSISTIVE TECHNOLOGY
M.S. Parsons, Oxford Ageing Research Associates, Oxford, United Kingdom

Assistive technology has emerged as a key component in the transformation of services for people with dementia and their carers in Western society. Increasing prevalence of age related disability and costs associated with rising demand for health and social care have brought assistive technology (AT) to the fore with a plethora of products, devices and equipment offering opportunities to improve the quality of life of many people with dementia and their carers. This potential has yet to be fully realised however as industry, researchers and governmental bodies face challenges in mainstreaming AT. On the challenge agenda are: enhancing the evidence base especially in respect of cost effectiveness of AT, ensuring design is sensitive to the intentions, capabilities, and values of end users who require advice and information, comprehensive assessment of need and ongoing support alongside ongoing issues in commercial development, getting products into market and supply side constraints.

THE DESIGNED ENVIRONMENT AS A NONPHARMACOLOGIC TREATMENT FOR DEMENTIA
M. Calkins, IDEAS Consulting, Inc., Kirtland, Ohio

The past five years has seen significant growth in the evidence that the built environment impacts the psycho-social-emotional well-being and probably physical health of individuals with dementia. Yet effective dissemination and widespread application of this evidence remains weak. A gathering of nine internationally renown experts was held to identify where the design-based evidence is relatively incontrovertible, and where different approaches to design may be equally supported by the research. While there is solid evidence of the positive outcomes associated with smaller and more residential households, especially those with a higher percentage of private rooms, too often outcomes are limited to “reducing challenging behaviors” or maximizing safety. A deeper understanding of meaning and quality of life for individuals living with dementia needs to drive future research and design activities.

NONPHARMACOLOGICAL INTERVENTIONS: AN OVERVIEW
3. Zeisel, Hearthstone Alzheimer Care, Woburn, Massachusetts

Nonpharmacological interventions broadly include all the arts, the designed environment, communication, external memory cues, community programs, physical exercise, and training. What ties them together, however, is not that they do not include drugs as treatment, but rather that they all aim to engage the person, to raise the person’s confidence, and to improve their quality of daily life. Successful nonpharmacological interventions offer choice, respect the person’s decisions, have a purpose and add to that person’s sense of self. Ultimately, all these interventions focus on the person’s right to dignity, independence, self-fulfillment, care, and participation. The global website supporting this effort will help the global dementia community share experiences and research efforts, collaborate where appropriate, learn from each other, find out about best practices and generally raise awareness and legitimacy if the nonpharmacological approach to dementia.

METHODOLOGICAL ISSUES IN DEVELOPMENT OF NONPHARMACOLOGIC TREATMENTS FOR DEMENTIA
C. Camp, Linda-and-Cameron Inc., Cleveland, Ohio

While conducting a Randomized Control Trial (RCT) is one important and meaningful means of determining if a treatment for dementia produces an effect, adherence to this methodology as the only or highest form of evidence-based knowing remains a cultural and potentially political reference and convention. This presentation will focus on methodological issues involved in the development of nonpharmacologic treatment of dementia, emphasizing the need to balance internal and external validity in evidence-based action research, and including discussion of these topics: 1) The most appropriate study methodology to investigate a phenomenon must be the one that has the best ‘fit’ with the phenomenon; 2) When single subject case studies and other methods provide a high level of evidence-based knowledge; 3) The need to report and assess both effect size / clinical significance and statistical significance for treatments for dementia; and 4) The need to use clinically meaningful outcome measures.

SESSION 1930 (SYMPOSIUM)

LONG TERM CARE RESEARCH POLICY: THE FUTURE OF NOT-FOR-PROFIT PROVIDERS

Chair: L. Polivka, Claude Pepper Center, Florida State University, Tallahassee, Florida
Discussant: F.G. Caro, University of Massachusetts-Boston, Boston, Massachusetts

Managed care organizations, mainly for-profit HMOs, have gradually become the dominant providers of publicly supported community-based long-term care services in Florida since 2000. Recent legislation will place the entire long-term care system, including Medicaid nursing home program, under managed care organizations, which is likely to accelerate the marginalization of the 40 year old non-profit aging network of area agencies on aging and service providers. The steady spread of for-profit managed long-term care has not been slowed by the findings from three comprehensive evaluations showing that the community long-term care programs administered by aging network organizations are more cost-effective than those run by HMOs in the managed long-term care program. This presentation will include a description of
"DO SOMETHING, EVEN IF IT'S WRONG", AND OTHER WORDS OF WISDOM THAT CAN GET YOU IN TROUBLE: STATE MEDICAID LONG-TERM CARE REFORM EFFORTS

R. Applebaum, S. Mehdizadeh, Miami University, Oxford, Ohio

Today’s Medicaid challenges, coupled with the baby boom demographics, have every state in the nation recognizing the need to do something different in Medicaid. Although achieving a better balance between institutional and home and community-based services has been an important reform, Medicaid managed long-term care is also a growing option. Designed to both control the acute and long term care costs of older people and individuals with disability, the approach also is directed at linking the two disparate systems. It is not clear however, whether the managed care solution is the correct one. Based on data from Ohio’s Medicaid system, collected over the past 10 years, the financial impact of moving Medicaid recipients in need of long-term services into managed care appear quite limited for older people. The paper will examine Ohio’s efforts for action in these turbulent times, to “do something, even if it is wrong.”

STATE DUAL-ELIGIBLE DEMONSTRATIONS: EVOLUTION OF FULLY INTEGRATED ACUTE AND LONG-TERM CARE MODELS

W. Leutz, Heller School, Brandeis University, Waltham, Massachusetts

This paper describes and presents evaluative data on the three states operating fully integrated acute and long-term care programs - Minnesota, Wisconsin, and Massachusetts. These states contract with both for-profit and non-profit managed care organizations (MCOs) to provide the full range of Medicaid and Medicare funded services. The paper draws on the author’s 2007 evaluation of these programs conducted for CMS, other published research and evaluations, as well as updated reports from federal, state and provider personnel about successes and shortcomings in the areas of enrollment, service integration, payment models, cost-effectiveness, and beneficiary outcomes. Aids and barri- ers to operations and effectiveness in Medicare and Medicaid regulations will also be covered, including impacts of the 2003 Medicare Modernization Act, which the 2007 report found led to “disintegration” and “cost-ineffectiveness,” the 2008 The Medicare Improvements for Patients and Providers Act, and the 2010 Affordable Care Act.

SESSION 1935 (SYMPOSIUM)

RELATIONSHIP OF LIFESTYLES IN LONG-TERM CARE SETTINGS WITH QUALITY OF LIFE AND QUALITY OF CARE

Chair: N. Castle, University of Pittsburgh, Pittsburgh, Pennsylvania

This symposium will examine the relationship of lifestyles in long-term care settings with quality of life (QOL) and quality of care (QOC). Presentations will examine QOL/QOC across different settings and include what can be learned by longitudinal and cross-sectional research, and promising and proven interventions. This symposium will include: (1) an evaluation of a state Money Follows the Person Demonstration program, which transitions people from nursing homes into home and community based settings. QOL interview data from 4 time points pre- and post-transition will be presented; (2) 10 states initiatives in QOC and QOL for all long-term supports and services through the National Balancing Indicator Project will be presented; (3) adjustment to assisted living (AL) focusing on individual and AL community characteristics associated with QOL; and (4) the development and testing of a technol-
of care efforts in ten states amidst new health care reform reporting requirements.

LEADERSHIP PRACTICES OF NURSING FACILITY ADMINISTRATORS AND QUALITY OF CARE

D.G. Wolf, Eastern University, Delran Beach, Florida

Globalization, increased consumer demand, new market technologies and prevalent human resource issues have created an opportunity for leaders to develop from traditional, vertical top-down authoritative leadership behaviors to a more transformative style of management. Effective leadership, at both individual and system levels, has been evidenced to have an effect on quality improvement. Using the Kouzes & Posner (1995, 2007) five practices of exemplary leadership framework along with an existing multivariate conceptual quality of care model, this research identifies key leadership behaviors that have a significant effect on quality of care. By raising awareness of the benefits of exemplary leadership practices and their attributes, administrators can learn to transform themselves and their followers to increase the overall quality of care within their organizations. This quantitative study examines the relationship between the exemplary leadership practices of nursing home administrators (as self-reported and by their direct reports) and the overall quality of care.

PERSONALITY AS A PREDICTOR OF ADJUSTMENT TO ASSISTED LIVING

W.L. Mills1,2, V. Molinari1, C. McEvoy3, J.D. Edwards4, L. Hyer5, D. Gammonley6, L.M. Brown7, 1. Houston Health Services Research & Development Center of Excellence, Michael E. DeBakey VA Medical Center, Houston, Texas, 2. Department of Medicine, Baylor College of Medicine, Houston, Texas, 3. Department of Aging and Mental Health Disparities, University of South Florida, Tampa, Florida, 4. School of Aging Studies, University of South Florida, Tampa, Florida, 5. Georgia Neurosurgical Institute, Macon, Georgia, 6. School of Social Work, University of Central Florida, Orlando, Florida

Adjustment to assisted living (AL) does not always proceed smoothly, making it imperative to identify predictors of transition difficulties, such as personality factors. The sample for this cross sectional study included 64 older adults from ten AL communities. The sample was primarily white, well-educated, and female with an average age of 86 years. Correlation and regression were used to examine relationships between personality factors (neuroticism, extraversion, openness, agreeableness, and conscientiousness) and adjustment (relative quality of life, depression, and feeling of home). The regression analysis revealed that participation in community activities, satisfaction with food quality, and the ability to set one’s own daily schedule were important predictors of adjustment. Above and beyond these predictors, neuroticism was found to predict adjustment, indicating that personality does play a role in determining adjustment to assisted living. Responses to an open-ended question echoed these results and revealed additional issues related to resident perceptions of adjustment.

SESSION 1940 (SYMPOSIUM)

SEXUALITY AND AGING: QUALITATIVE RESEARCH PERSPECTIVES

Chair: R.S. Goldberg-Glen, Center for Social Work Education, Widener University, Chester, Pennsylvania
Discussant: K.M. Hicks, Lehigh University, Bethlehem, Pennsylvania

Little attention has been paid to research on sexuality and aging yet, we know from a life span perspective that individuals are sexual throughout their lives. Perhaps this avoidance is due to the fact that associating intimacy, sexuality and aging is often seen as an “unthinkable” subject. Regardless of this misconception the purpose of this symposium is to introduce the audience to issues related to perspectives on sexuality and older adults. Levaro, Walker and Hooker, focus on women and men over the age of 70 who are pursuing intimate partnerships. Thematic analysis of the in-depth semi-structured interviews reveal the importance of physical attributes, perceived sexual ability, qualities sought and avoided, medication use and pleasure found in late life intimate relationships. Gallegly’s study examines the experience of sexuality and intimacy in relationships where one partner has dementia. Results suggest that sexual expression and intimacy were compromised by the dementia of a partner, couples became more symbiotically bound to each other and physical touching was more likely to be utilitarian in nature rather than physically stimulating or emotionally satisfying. Goldberg-Glen’s research focuses on three life stories of older gay males ranging in age from 65-81. Narrative analysis focused on developing an understanding of how these men made sense of and experienced their life trajectories. Results provide insight regarding how one came out, family challenges, fitting in, the impact of the “boy code”, the importance of social networks, the advantages of being gay and feelings of difference in comparison to younger gay men.

UNDERSTANDING THE LIFE TRAJECTORIES OF OLDER GAY MALES

R.S. Goldberg-Glen, Widener University, Chester, Pennsylvania

By the year 2030 there will be 2 to 6 million GLB adults over the age of 65. Yet, there continues to be a paucity of research designed to help us understand the needs of these seniors. This presentation will focus on the life stories of three gay males ranging in age from 65-81. Narrative analysis focused on developing an understanding of how these individuals made sense of and experienced their lives. Results also provided insights regarding when and how one came out, family challenges, fitting in, the impact of the “boy code” and social construction of males, social networks, privacy, the advantages of being gay and their feelings of difference in regard to younger gay men. Findings suggest that while older gay men may experience life similarly to heterosexual males there are also difference in their life trajectories that need to be considered by practitioners and policy makers alike.

IDENTITY AND INTIMACY IN DEMENTIA: “ALONE TOGETHER”

C.M. Gallegly, Community Health and Human Services, St. Joseph’s College, Patchogue, New York

This descriptive study focused on the unique experience of sexuality and intimacy in relationships where one of the partners has a form of dementia. As part of a larger qualitative study of spousal dementia caregiving, the sample included 40 spousal caregivers, the majority of whom were white females (although 11 were male, and 3 were non-white). Interviews averaged 1.5 hours and included questions about feelings, closeness, gestures, and intimacy as the disease progressed. With one striking exception, most of the caregivers expressed that sexual expression and intimacy were seriously compromised by the dementia of the partner. At the same time as the couples became more symbiotically bound to each other, physical touching was more likely to be practical in nature, rather than physically stimulating or emotionally satisfying. These insights suggest practice applications for health care providers.

“I’M OLD, I’M NOT DEAD”; SEXUALITY, AGE, AND GENDER RELATIONS IN LATE-LIFE DATING

Continued (or regained) sexual drive, functioning, and activity are a definitional component of “successful aging,” yet their expression remains traditionally gendered and ageist. We report findings on the sexual experiences, attitudes, and preferences of 24 heterosexual women and men between the ages of 70 and 92 who were actively pursuing new
intimate partnerships, primarily via Internet ads on Match.com. Transcribed data from in-depth semistructured interviews were analyzed utilizing thematic analysis and perspectives provided by the intersection of age relations and gender relations. We discuss potential partners’ physical attributes and qualities sought and avoided; the salience of perceived sexual ability and desirability to positive gender and age identities; and the impact on both women and men of men’s widespread use of medications for erectile dysfunction on their considerations of younger women as potential dating partners. Particularly those respondents widowed after long caregiving responsibilities reported discovering newly found pleasure in intimate relationships.

SESSION 1945 (SYMPOSIUM)

THE GREAT AMERICAN DEBATE ON THE FUTURE OF SOCIAL SECURITY
Chair: F. Cook, The Institute for Policy Research, Northwestern University, Evanston, Illinois
Discussant: R. Hudson, Boston University, Boston, Massachusetts

In the last thirty years, Social Security has risen on the policy agenda as a topic of national debate at least four times – during the Reagan presidential administration in 1981-83, the Clinton administration in 1998-99, the Bush administration in 2005, and now again in 2010-11. The purpose of this symposium is to analyze this fourth moment of debate. Some members of Congress and political commentators claim that Social Security is substantially adding to the national deficit and dramatic changes must be made to address this problem, while others say this claim is not true and that fairly small incremental changes can make Social Security financially secure for the rest of the century. President Obama’s Deficit Commission has recommended a number of policy changes. In response, Atlantic Philanthropies has funded a massive advocacy campaign on the left entitled “Social Security Works,” while on the right the Peter Peterson Foundation has funded initiatives to push for cuts in Social Security. Speakers will address three sets of questions: What claims are being made about the status of Social Security by various members of Congress, the president, and political commentators, and to what extent are these claims accurate? What exactly is the nature of the advocacy campaigns funded by Atlantic Philanthropies and the Peter Peterson Foundation? Finally, what does the public think? What changes, if any, do members of the public want to see in Social Security, and in which political party do they have most confidence to deal with Social Security?

SUPPORT FOR SOCIAL SECURITY: WHAT THE PUBLIC THINKS
F. Cook, R. Moskowitz, The Institute for Policy Research, Northwestern University, Evanston, Illinois

At a time when political polarization in the U.S. Congress is the highest in 120 years and addressing the U.S. deficit has become extremely politicized, Social Security has again become a topic of debate. It is clear that little consensus can be found between Republicans and Democrats in the U.S. Congress about Social Security. This paper asks how much consensus there is among the public. Results of analyzing hundreds of survey questions from the early 1980s to 2011 show that support for Social Security remains high across age, party, and ideology. Since 1997, Americans have rated Social Security as a priority for the President and Congress to address (66% in 2011). However, Americans continue to be very concerned about Social Security’s future. They have clear preferences about what changes they would like to see but are not enthusiastic about the ability of either political party to deal with Social Security.

MYTH AND REALITY IN THE DEBATE ON SOCIAL SECURITY
T.R. Marmor, Yale University, New Haven, Connecticut

From 1973 until today, the American public has experienced a periodic diet of public handwringing about Social Security. For the last year, there has been a resurgence of concern, launched in part by the recommendations on Social Security of President Obama’s deficit commission. Claims are made that Social Security is a major contributor to the U.S. deficit and that it is going bankrupt. In response, the Atlantic Philanthropy’s Strengthen Social Security Campaign on the left and Peter Peterson Foundation’s advocacy efforts on the right have presented alternative definitions of “problems” of Social Security and “solutions.” When occupational pension protections and other private retirement savings are shrinking, why is the discussion about the future of Social Security framed almost entirely in terms of deficit reduction and/or solvency? This paper attempts to separate the claims made about Social Security from the reality and in so doing to correct some popular misconceptions.

ORGANIZING TO PRESERVE SOCIAL SECURITY: AN ANALYSIS OF THE CAMPAIGN OF 2011-12
E. Kingson, Syracuse University, Syracuse, New York

Responding to a threat to the future of Social Security, 270 national and state organizations – unions, and aging, disability, women’s and human rights organizations – coalesced around the proposition that Social Security did not cause the federal deficit; benefits should not be cut, means-tested or privatized; benefits should be increased for those at greatest risk; and Social Security’s modest funding gap should be closed with progressive revenues. Beginning in mid-2010, the campaign established a lobbying, field and communications presence in Washington, DC and in key states. The campaign challenged the view widely held among elites – that it is “only sensible” for Social Security benefit reductions to be an important part of any effort to reduce federal deficits. This presentation discusses Campaign origins, goals and strategies, and the extent to which changes in the policy frame, positions of policy elites and the policy agenda are a function of the Campaign.

SESSION 1950 (SYMPOSIUM)

CONTRIBUTIONS OF INFLAMMATION AND MUSCLE-RELATED GENE VARIANTS TO FRAILTY AND LATE-LIFE DECLINE
Chair: J.D. Walston, Medicine/Geriatrics, Johns Hopkins University, Baltimore, Maryland
Co-Chair: R. Varadhan, Medicine/Geriatrics, Johns Hopkins University, Baltimore, Maryland
Discussant: J.M. Murabito, Harvard School of Public Health, Boston, Massachusetts

Although lifestyle is a critical factor in the development of aging phenotypes such as frailty, age-related biological changes and genetics contribute substantially. To better understand the biological and genetic underpinnings of frailty and late-life decline, and how lifestyle factors might influence these, we studied the relationship of inflammatory, muscle, and frailty phenotypes to genes that influence aging biology, inflammation, and muscle biology in the Cardiovascular Health Study (CHS), a population of 5600 adults age 65-100. In this symposium, we will first report on the development of an aggregate inflammatory phenotype that includes measurement of TNF alpha receptor-1 and IL-6 and predicts 10 year mortality better than any single inflammatory measure, followed by data that demonstrate a significant relationship between variants in GADPH and DNMT3a genes and this aggregate phenotype. Next we highlight candidate gene variants in the WNT gene family, HIF1AN and DNMTa and their relationship to skeletal muscle and walking speed. Finally, a significant association between the phenotype of frailty itself and variants in the PAX 3 and DNMT3a genes will be presented. Pre-
senter will also discuss how these genetic signals are modified by important lifestyle factors such as smoking and physical activity. At the end of this symposium, investigators should have a clear understanding of phenotype development for genetic studies related to frailty and late-life decline, knowledge of potentially important biological pathways highlighted by genetic results that includes important DNA methylation genes, and a better understanding of the influence of lifestyle on genetic outcomes.

THE DEVELOPMENT OF AN AGGREGATE INFLAMMATORY PHENOTYPE

R. Varadhan1, W. Yao2, K. Bandeen-Roche3, A. Matteini1, A. Reiner2, D. Fallin1, J.D. Walston1, 1. Geriatric Medicine, Johns Hopkins Center on Aging and Health, Baltimore, Maryland. 2. University of Washington, Seattle, Washington

Although elevations in serum markers of inflammatory mediators are highly associated with numerous adverse outcomes in older adults, no one measure is known to be the most robust predictor of these outcomes. In order to identify the best predictors of mortality, and in order to have a robust phenotypic measure for genetic studies, we measured several inflammatory mediators previously implicated in association studies in the Cardiovascular Health Study population and developed analytical models that included a weighted summary score, a principal components score and a mortality risk score. In age-adjusted analyses, the mortality risk score that included IL-6 and TNF-a R1 was most predictive of mortality, (hazard ratio 1.65, 95% CI 1.57-1.72). It performed better than any single or other aggregate measure, and almost as well as age in this population. These results and the potential impact of lifestyle on activation of inflammatory pathways in older adults will be discussed.

CANDIDATE GENES AND INDICATORS OF PHYSICAL FUNCTION IN OLDER ADULTS

A.Z. Moore1, P.H. Chaves2, D.E. Arking2, D. Fallin1, A. Matteini2, Q. Xue2, J.D. Walston1, 1. Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland, 2. Johns Hopkins University School of Medicine, Baltimore, Maryland

It is hypothesized that genetic variation may contribute, through alterations of skeletal muscle, to heterogeneity in late life physical function. This project explores the influence of markers in genes related to inflammation, apoptosis, and mitochondrial function on trajectories of grip strength and walking speed in older adults. The study participants came from the Cardiovascular Health Study. 1360 SNPs (MAF>0.01, HWE p>0.001) were analyzed. Genetic effects on trajectories of physical function were assessed through likelihood ratio tests comparing mixed effects models with and without terms for individual SNPs and interactions between SNPs and trajectory parameters (e.g. time slope). Genes in the WNT family were associated with grip strength in both groups (lowest p<0.001 in white strata). In participants identifying as white, HIF1AN also influenced the trajectory of strength and DNMT3A was associated with walking speed. Validation of these observations in other populations and exploration of related skeletal muscle pathways is warranted.

CANDIDATE GENES OF FRAILTY IN OLDER ADULTS

A. Matteini1, W. Yao1, R. Varadhan1, B. Psaty2, A. Reiner2, A.B. Newman1, J.D. Walston1, 1. Geriatric Medicine, Johns Hopkins Medical Institute, Baltimore, Maryland, 2. University of Pittsburgh, Pittsburgh, Pennsylvania

Frailty is a syndrome of physiologic decline that associates with increased inflammatory markers and adverse health outcomes. In order to better understand biological underpinnings of frailty, we performed a candidate gene study using previously collected and validated frailty definition in Cardiovascular Health Study. Genes related to inflammation, mitochondria function and apoptosis were selected and common single nucleotide polymorphisms (SNPs) were genotyped. Discrete time-to-event Cox models were built to evaluate the association between these SNPs and incident frailty, stratified by race and adjusted for age, gender. Measures of physical activity were used to test for gene by environment effects. Common significant results across races were observed in SNPs within PAX3 (p-value = 0.006) and DNMT3A (p-value = 0.00014) genes, although significant SNPs per gene varied by race. PAX3 and DNMT3A are involved in mitochondrial function and transcription regulation, respectively and may influence one’s risk of frailty, possibly via increased inflammation.

GENETIC ASSOCIATION OF INFLAMMATORY ENDOPHENOTYPE IN CHS OLDER ADULTS

W. Yao1, R. Varadhan1, A. Matteini1, A. Reiner2, Q. Xue2, J.D. Walston1, 1. Johns Hopkins Medical Institutions, Baltimore, Maryland, 2. University of Washington, Seattle, Washington

Serum markers of inflammation are highly associated with the development of adverse health outcomes in older adults. Inflammatory pathway activation is a heritable trait, and therefore these measures can be used to study genetic predictors of inflammation. Using a candidate gene approach and a validated aggregate inflammatory phenotype developed in CHS that best predicts mortality, we analyzed the association between 1536 SNPs in 100 candidate genes. A general linear model was utilized to assess the genetic association of inflammatory endophenotype with candidate SNPs coded in additive model, and stratified by race. SNPs in the DNMT3B and GAPDH genes were found to be significantly associated in increased mortality risk score in both races. A common significant SNP in DNMT3B was observed in both races, with lowest P = 0.0017 in African American. DNMT3B is thought to play a role in DNA methylation, which can be a trigger of the inflammatory process.

SESSION 1955 (SYMPOSIUM)

FUNCTIONAL NEUROIMAGING OF AUTOBIOGRAPHICAL MEMORY

Chair: P.L. St. Jacques, Psychology, Harvard University, Cambridge, Massachusetts
Co-Chair: R. Spreng, Psychology, Harvard University, Cambridge, Massachusetts
Discussant: M. Moscovitch, University of Toronto, Toronto, Ontario, Canada

Functional neuroimaging studies of autobiographical memory and their changes with advancing age have rapidly increased in the last year. This work expands our understanding of age-related changes to memory by examining the integration of episodic and semantic memory, the rich recollection memory, and memory’s link to theory of mind and planning for future events. These components make personal memories meaningful but are difficult to study in the context of learning lists of items, as is typical in laboratory based studies of memory. The current symposium will showcase recent functional MRI (fMRI) studies examining age-related changes in autobiographical memory. The first talk (St-Laurent) uses a multivariate approach to highlight the converging and differential effects of aging on autobiographical, episodic and semantic memory retrieval. The second talk (St. Jacques) employs a novel camera technology to examine the impact of photographs for retrieval support in the recollection of autobiographical memories in young and older adults. The third talk (Rosenbaum) examines the relationship between autobiographical memory retrieval and other mental states by considering both patient and neuroimaging data. Finally, the fourth talk (Spreng) investigates the domain of autobiographical planning, and the functional brain networks involved, in both young and older adults.
AGE-RELATED EFFECTS ON THE NEURAL CORRELATES OF AUTOBIOGRAPHICAL MEMORY RETRIEVAL UNDER VARYING LEVELS OF RETRIEVAL SUPPORT

P.L. St. Jacques¹, M.A. Conway², R. Cabeza³, ¹. Harvard University, Cambridge, Massachusetts, 2. University of Leeds, Leeds, United Kingdom, 3. Duke University, Durham, North Carolina

Age-related changes in recollection of autobiographical memory (AM) are linked to decreased recruitment of the hippocampus and PFC, and these behavioral effects are attenuated under conditions of retrieval support. The current fMRI study examined age-related effects on the neural correlates of AM while varying retrieval support. We used a novel camera technology to prospectively collect personal photographs (high support) to elicit AM during functional scanning compared to verbal descriptions (low support). The fMRI results revealed age-invariant neural correlates of AM while varying retrieval support. We tested healthy young and older adults on a functional magnetic resonance imaging paradigm that allowed a direct comparison between the neural correlates of autobiographical, semantic, and episodic memory. A multivariate analysis was conducted to identify patterns of activity characterizing the groups across conditions. We identified brain regions activated by all three memory conditions, relative to a control condition, which were activated equally in the age groups, suggesting that the activation of a common memory retrieval network is maintained with age. We also identified regions whose activity differentiated between the memory conditions. These patterns of differentiation were expressed less strongly in the older adults, relative to the young adults. Further analysis showed that this age-related dedifferentiation was significant in the autobiographical and episodic memory tasks, but not in the semantic memory task. These results may be linked to aging-related changes in episodic autobiographical memory, and relative preservation of semantic memory.

UNDERSTANDING AUTOBIOGRAPHICAL MEMORY IMPAIRMENT: LESSONS FROM PATIENT AND NEUROIMAGING STUDIES

R. Rosenbaum¹, ², H. Abdi³, H. Burianova³, C. Grady⁴, ¹. Psychology, University of Toronto, Toronto, Ontario, Canada, 2. Rotman Research Institute, Toronto, Ontario, Canada, 3. Macquarie University, Sydney, New South Wales, Australia, 4. The University of Texas at Dallas, Dallas, Texas

We tested healthy young and older adults on a functional magnetic resonance imaging paradigm that allowed a direct comparison between the neural correlates of autobiographical, semantic, and episodic memory. A multivariate analysis was conducted to identify patterns of activity characterizing the groups across conditions. We identified brain regions activated by all three memory conditions, relative to a control condition, which were activated equally in the age groups, suggesting that the activation of a common memory retrieval network is maintained with age. We also identified regions whose activity differentiated between the memory conditions. These patterns of differentiation were expressed less strongly in the older adults, relative to the young adults. Further analysis showed that this age-related dedifferentiation was significant in the autobiographical and episodic memory tasks, but not in the semantic memory task. These results may be linked to aging-related changes in episodic autobiographical memory, and relative preservation of semantic memory.

SESSION 1960 (PAPER)

ENHANCING KNOWLEDGE AND SKILLS OF HEALTH AND LTC PROFESSIONALS

INTERDISCIPLINARY CAREPLANS: TEACHING HEALTH PROFESSION STUDENTS THE STRENGTHS OF WORKING IN TEAMS

A.G. Rothrock¹, C. Ford¹, P. Sawyer¹, P. Bosworth¹, C. Ritchie¹,², ¹. University of Alabama at Birmingham, Birmingham, Alabama, 2. Birmingham/Atlanta VA GRECC, Birmingham, Alabama

Optimal care of patients requires inclusion of multiple health professionals. Health systems are encouraging providers to participate in interdisciplinary team meetings to gain a full perspective on patient care and to provide their insights and recommendations that allow for the most comprehensive, collaborative care. The University of Alabama at Birmingham Geriatric Education Center’s Interdisciplinary Team Training (IDT) experience has been held four times over the past three years for students from 9 health professions (dentistry, medicine, nursing, nutrition, occupational therapy, optometry, pharmacy, physical therapy, social work). The goal is for students to experience participating on interdisciplinary teams and developing a plan of care in collaboration with other health care professionals, based on information learned through the interviewing of an older adult. Participation in the first two pilot IDTs was voluntary. Due to their success from both student and faculty perspectives, the program is now held twice per year and is mandatory for students in 6 of the 9 disciplines, including 180 second year medical students. Evaluations show (range = 1 to 5) that as a result of participating in the activity, students are more aware of multiple perspectives to consider when caring for older adults (M=4.4), have a greater understanding of how their disciplines contribute to the interdisciplinary perspective (M=4.3) and are more confident in participating on interdisciplinary teams (M=4.3). After attending this presentation, participants will be able to discuss lessons learned regarding curriculum development, unique challenges with interdisciplinary training of large numbers of students, program implementation and evaluation.

THE GERONTOLOGICAL SOCIETY OF AMERICA

AGING AND THE NEURAL CORRELATES OF AUTOBIOGRAPHICAL, EPISODIC AND SEMANTIC MEMORY RETRIEVAL

M. St-Laurent¹, H. Abdi², H. Burianova³, C. Grady¹,⁴, ¹. Psychology, University of Toronto, Toronto, Ontario, Canada, 2. Rotman Research Institute, Toronto, Ontario, Canada, 3. Macquarie University, Sydney, New South Wales, Australia, 4. The University of Texas at Dallas, Dallas, Texas

We tested healthy young and older adults on a functional magnetic resonance imaging paradigm that allowed a direct comparison between the neural correlates of autobiographical, semantic, and episodic memory. A multivariate analysis was conducted to identify patterns of activity characterizing the groups across conditions. We identified brain regions activated by all three memory conditions, relative to a control condition, which were activated equally in the age groups, suggesting that the activation of a common memory retrieval network is maintained with age. We also identified regions whose activity differentiated between the memory conditions. These patterns of differentiation were expressed less strongly in the older adults, relative to the young adults. Further analysis showed that this age-related dedifferentiation was significant in the autobiographical and episodic memory tasks, but not in the semantic memory task. These results may be linked to aging-related changes in episodic autobiographical memory, and relative preservation of semantic memory.

AUTOBIOGRAPHICAL AND VISUOSPATIAL PLANNING IN YOUNGER AND OLDER ADULTS: AN FMRI STUDY

R. Spreng, D.L. Schacter, Harvard University, Cambridge, Massachusetts

There is a growing body of evidence to suggest a shared functional neuroanatomy between autobiographical memory and future-oriented thinking in young adults. The current study extends this work to examine autobiographical planning in younger and older adults. Participants formulated personally relevant plans in response to goals, such as managing finances, scheduling health care visits, and volunteering. Brain activity underlying planning in younger and older adults was compared with a traditional laboratory measure of planning, the Tower of London. Analyses determined large-scale network integrity and interactivity within and between the default (e.g. posterior cingulate, medial prefrontal cortex, posterior inferior parietal lobule, hippocampus) attention (e.g. superior parietal lobule, frontal eye fields) and control (e.g. rostral prefrontal cortex, anterior inferior parietal lobule) networks of the brain, with differential patterns of activity between the age groups.
The impact of health literacy to optimal patient care and outcomes has become increasingly recognized in recent years. There are a growing number of training programs for consumers and practicing providers. However, few programs exist to reach health profession students or faculty. In 2009, the Geriatric Education Center of Michigan [GECM] developed and implemented one of the nation’s first train-the-trainer programs aimed at increasing health literacy curricula used by multidisciplinary health profession schools in Michigan public universities. Thirty faculty members and administrators representing 8 disciplines from 13 universities participated in 25 hours of training which included an opportunity to develop an individualized curriculum that could be integrated into their home institution’s program. All participants expressed satisfaction with the course and follow-up surveys indicated significant potential for translation of lessons learned into actual classroom instruction. Based on this pilot program, over 70% stated they planned to introduce health literacy as a core competency requirement for graduation and 26% had already integrated new health literacy content into their current courses. This success will have a direct impact on preparing greater numbers of upcoming health professionals to address health literacy in their future practices. Plans are underway to expand and formally evaluate the program. Session Objectives: Participants will be able to 1) discuss key concepts related to health literacy curriculum in health profession education and 2) identify specific strategies for designing and implementing a health literacy faculty development program in their own communities.

EXBELT: THE IMPACT OF A RESTRAINT REDUCTION PROGRAM ON NURSING HOME STAFF ATTITUDES
M. Gulpers 1, M. Bleijlevens 1, E. van Rossum 1, E. Capezuti 2, J. Hamers 2, 1. Department of Health Care and Nursing Science, Maastricht University / school CAPHRI, Maastricht, Netherlands, 2. Zuyd University of Applied Sciences, Research Centre on Autonomy and Participation, Heerlen, Netherlands, 3. New York University, Hartford Institute for Geriatric Nursing, New York, New York

Background: Educational interventions to reduce restraint use have shown mixed results in changing staff attitudes and practice. A multi-component intervention program, ‘EXBELT,’ that includes an educational intervention for staff, a policy change (belt use is prohibited by the nursing home management), availability of a nurse specialist consultant, and availability of alternative interventions, has demonstrated a major reduction of restraints in 13 Dutch nursing homes. This paper will examine the effect of EXBELT on staff attitudes and opinions regarding physical restraints and their decision to use restraints. Methods: The Maastricht Attitude Questionnaire (MAQ) on attitudes regarding restraints (subscales: reasons, consequences and appropriateness of restraint use) and opinions regarding the restrictiveness of restraint measures and discomfort in using them, was administered prior and at 2 weeks and 8 months following the educational part of the intervention. Results: A total of 95 (40,2 years (sd=10,97); 76% women) of 161 nursing home staff members completed the MAQ at all three time points. Staff attitudes towards the use of physical restraints changed from 2.88 (SD=0.51) to 2.62 (SD=0.49) over the 8 months period, indicating more negative attitudes regarding restraint use (p<0.001). In addition, nursing home staff reported physical restraint usage as more restrictive (p<0.05) and experienced more discomfort in using these measures (p<0.001). Conclusion: Implementation of the EXBELT intervention resulted in a desired and meaningful change of nursing home staff attitudes and opinions. These results underline the importance of changing staff perceptions towards physical restraint that can contribute to the reduced usage of these measures.
research databases (PsychARTICLES, socINDEX, and MEDLINE). Keyword search terms were used in various combinations, which included ‘childhood trauma,’ ‘child abuse,’ ‘earlier life trauma’ and ‘older adults.’ A data extraction tool was created by the research team to organize information related to the methods and major findings of the research studies. Two coders were trained to extract relevant information and 100% agreement was achieved for interrater reliability checks. These collective findings suggest that earlier life trauma is associated with later life mental health (including substance abuse), physical health, and re-victimization or elder abuse (e.g., Shmotkin & Litwin, 2009). The types of lifetime traumatic and stressful life experiences linked to the physical and mental health of older adults range from a single event to the accumulation of multiple traumatic and stressful life events that have occurred in childhood or adulthood. Drawing firm conclusions must be tempered by common methodological limitations in research design, data collection procedures, sampling strategies, and measurement used across studies. These results have implications for social work practice with older adults. Potential avenues for assessment, prevention, and intervention with older adults with past and present histories of traumatic and stressful life experiences. Accurate assessment for trauma and PTSD assessment and multidisciplinary practice with older adults are reviewed.

RELIABILITY AND VALIDITY OF THE LIFE EVENTS ASSESSMENT PROFILE: A NEW TOOL FOR STRESS RESEARCH

E. Wethington1, B.P. Anderson2, T. Kamarck3, I. Human Development, Cornell University, Ithaca, New York, 2. University of Pittsburgh, Pittsburgh, Pennsylvania

Life course research on stressor exposure has been hampered by the lack of reliable and valid assessments. Personal interview measures assessing exposure to stressors (e.g. Life Events and Difficulties Schedule (LEDS): Brown & Harris, 1972), are believed to be more reliable and valid than typical self-report measures because they more precisely estimate severity and duration of stressor exposure. Yet the LEDS is also extremely time-consuming to use (> 16 hours per interview). We developed a new instrument, the Life Events Assessment Profile (LEAP), which reproduces important LEDS features but reduces the time required to administer. We field-tested the LEAP with 55 men and women, ages 30-50 years, literate in English and not currently receiving treatment for psychiatric disorder. Thirty subjects were randomly administered either the LEDS or LEAP, followed by the other interview one week later; 25 were interviewed with the LEAP twice, six weeks apart. There were no age or gender differences in reported stressor exposure over a one year retrospective period. The LEAP and the LEDS did not differ in the number of severe and non-severe events assessed. Correspondence between LEDS and LEAP was good (r=.84 for severe events, r =.75 for total number of severe chronic stressors). Test-retest reliability of the LEAP was excellent for total events (r=.99), and severe events (.90). LEAP recall falloff was not significant over a 12 month period. Severe chronic stressors measured by the LEAP were significantly associated with higher scores on the CES-D (p<.02) and the Cohen Perceived Stress Scale (p<.01).

DOES CHILDHOOD REALLY HAVE A “LONG ARM?” ACCUMULATIVE LIFE COURSE PROCESSES IN LATE-LIFE FUNCTIONAL DISPARITIES

J. Kelley-Moore, J. Lin, D. Dannefer, T. Bhatta, Sociology, Case Western Reserve University, Cleveland, Ohio

Studies examining the “long arm” of inequality have found that childhood socioeconomic conditions influence late-life health net of adult conditions. However, this work treats early-life and mid-life characteristics as independent and exogenous predictors, rather than accounting for the accumulative character of life course processes. Guided by cumulative disadvantage theory, we used 8 waves (1994-2008) of the Health and Retirement Study to re-examine the “long arm” thesis. Utilizing a novel statistical methodology that incorporates endogenous variables in latent growth curve models, we examined whether childhood conditions actually have an independent effect on late-life functional limitations once the mid-life pathways (instrumented endogenous variables) are incorporated. We find that while childhood health and educational attainment originally had a direct effect on late-life functional limitations, they actually only influence mid-life morbidity and mortality risk, which in turn influence late-life function. Alternatively, the influence of childhood SES on late-life functional limitations is significantly attenuated after accounting for its influence on mid-life health and mortality risk. Our findings demonstrate that late-life health disparities are the product of accumulative but modifiable life course processes. We discuss the theoretical and statistical consequences of considering indicators of early-, mid-, and late-life circumstances as independent influences on health in older adulthood.

THE GENDERED LIFE COURSE AND HEALTH IN LATER LIFE: MODELING WORK AND FAMILY LIFE COURSE EXPERIENCES

L. Corna, University of Toronto, Toronto, Ontario, Canada

There is a well-established relationship between socioeconomic position (SEP) and health among older adults, but a short-coming of existing research is its failure to link the SEP-health relationship in later life to the gendered histories of work and family life or the social contexts in which these histories unfold. Drawing on life course and welfare state theory, this research investigates the dominant patterns of labor market and family experiences over the life course (19-64 years) for current cohorts of older adults in Britain using a two-stage latent class analysis. The data come from the British Household Panel Survey and respondents born between 1927 and 1940 were included in this sample (N=1552). Detailed retrospective histories of labor market attachment, occupational class, marriage(s), and dependent children were used to model life course experiences. Four latent life paths characterized the experiences of the older adults in this sample. Consistent with the social policy context in Britain in the post-World War II years, there was evidence of distinct gender patterns in role configurations at various points across the life course and in the life paths that link these experiences over time. The two-stage latent class model provides an innovative way of summarizing detailed and complex life course experiences. The relationship between these gendered life paths to SEP and health dynamics in later life is discussed in the context of our current understanding of health inequalities among older adults.

THE CONTINUED ECLIPSE OF DIVERSITY IN GERONTOLOGICAL AND DEVELOPMENTAL RESEARCH

M. Stone, J. Lin, P. Zhang, D. Dannefer, Case Western Reserve University, Cleveland, Ohio

Do age peers become increasingly diverse, dissimilar or heterogeneous as they grow older? This paper extends and updates the analysis of Nelson & Dannefer’s widely cited article containing that 1) questions of age-based variability are infrequently reported or discussed in studies of aging and human development, and 2) when reported, they tend to show an increase in variability. This paper updates and extends their analysis by examining articles published in leading gerontological and developmental journals. Articles (N = 185) from Journals of Gerontology, Psychology & Aging, Research on Aging, Developmental Psychology, Developmental Review and Human Development appearing 2000-200X were examined to determine whether with-in age variability was reported and/or discussed. We also classified the trajectories of intra-age variability (increasing, decreasing, fluctuating or stable). Our findings indicate that although a large proportion of gerontological and developmental studies report with-in age variability, few discuss it. This finding is considered in the context of the growing attention in gerontology to this issue and related topics such as age-based...
inequality and cumulative dis/advantage. An analysis of variability trajectories constructed for those studies who reported it revealed a somewhat more complex pattern than the earlier analysis, although a linear increase in variability remained the modal pattern. We will provide potential reasons for this apparent neglect of age-based variability, as well as stimulate a discussion about the possible solutions surrounding the lack of attention given to the problem.

SESSION 1970 (PAPER)

LONGEVITY

FORECASTING THE FUTURE OF HEALTH AND LONGEVITY

Commonly used metrics such as age-specific death rates and life expectancy may be accurate predictors of the future if they are sensitized to the health conditions of those still alive. However, because current reporting metrics do not take the latent effects of the health of the living into account, they can (and have) led to inappropriate public policies linked to improving health. Using the looming impact of the obesity epidemic as an example, we suggest that the health and mortality prospects of younger generations are considerably worse than indicated by recent trends in national vital statistics. Moreover, because recent birth cohorts are susceptible to obesity early in the life course, it is critical to use a forecasting method capable of accounting for cohort variability in lifestyle and obesity-related health complications. To illustrate, we show that recent reversals in heart disease mortality among younger generations are missed by a widely-used projection technique, but are accurately predicted by a methodology accounting for variability among birth cohorts. Both the extant literature and our empirical findings suggest that predicting future health and longevity will require the utilization of projection techniques sensitized to high rates of obesity among young Americans.

ESTIMATING AND EMPLOYING SURVIVAL WEIGHTS FOR LIFE COURSE ANALYSES OF REPEATED CROSS-SECTIONAL DATA

S.M. Lynch, D. Alwin, S. Brown, Sociology, Princeton University, Princeton, New Jersey

Sample weighting has become increasingly common in analyses of repeated cross-sectional data. Yet, most weighting schemes re-weight data to represent the population of those who have survived to particular ages. For life course analyses of cross-sectional data, such weights are not necessarily desirable. Instead, for analyses that model life course processes, we should, perhaps, be weighting individuals at given ages by their propensity to survive to the ages at which they are observed. In this paper, we develop and discuss the benefits of “survival weights,” that is, weights for individuals based on their probability of surviving to the ages at which they are observed in cross-sections. Using data from the General Social Survey (GSS), we show (1) that survival probabilities can be estimated from cross-sectional data based on fixed covariates, and (2) that life course analyses based on data weighted using these survival probabilities yield different results than analyses based on usual weights. The particular focus in our work is on the life course pattern in the relationship between education and health. Extant research has found an inverted-U-shaped pattern, such that education’s maximum effect is observed just beyond midlife. However, we argue that this pattern is due to selective survival. With data properly reweighted to compensate for differential survival by education level, we find a different pattern. Specifically, the effect of education on health appears to increase well beyond the age found in previous research. Implications and extensions of our “survival weighting” approach are discussed.

NEW ESTIMATES OF MORTALITY TRAJECTORIES AT EXTREME OLD AGES

N.S. Gavrilova, L.A. Gavrilov, NORC and the University of Chicago, Chicago, Illinois

A growing number of persons living beyond age 100 emphasizes the need for accurate measurement and modeling of mortality at advanced ages. Earlier studies indicate that exponential growth of mortality with age (Gompertz law) is followed by a period of mortality deceleration with slower rate of growth. This study challenges earlier conclusions with new data and methods. In contrast to many earlier reports based on analysis of mixed cross-sectional data for people belonging to different generations, we studied real cohort survival data for people with the same year of birth. For this purpose we obtained data from the U.S. Social Security Administration Death Master File to measure mortality in single-year 1881-1895 extinct birth cohorts. We found that mortality deceleration is far less pronounced when it is measured for shorter monthly age intervals rather than for traditional annual intervals. This indicates that traditional measures of mortality (like the Nelson-Aalen hazard rate estimate) underestimate mortality force at extreme old ages. We also found that mortality deceleration is far less pronounced when datasets with higher data accuracy (age reporting) are analyzed. Mortality modeling found that the Gompertz model demonstrates better goodness-of-fit in age interval 88-106 years compared to mortality deceleration (logistic) model for data of good quality studied in monthly age intervals. Earlier reports of mortality deceleration for ages below 106 years appear to be a result of age exaggeration and use of improper estimates of hazard rate. This study was supported by the National Institute on Aging (R01 AG028620 grant).

SESSION 1975 (PAPER)

TECHNOLOGY USE FOR INDEPENDENCE AND WELL-BEING

I AM OLD BUT A NEW SELF: POST-CANCER SELF-REAPPRAISAL AMONG OLDER ADULTS SURFING THE CYBER WORLD OF SOCIAL SUPPORT

G. Seckin, UMBC, Baltimore, Maryland

The Internet is a fascinating social context to study coping and health support for seniors. Adults aged fifty five and older are the fastest growing Internet users since early 2000s. The present study investigates perceived impact of online support on alternative appraisals of cancer and interaction of these variables on post-diagnosis self-reappraisal among older survivors. Sample of the present study (N = 157) represent a subsample of a larger study of adults living with cancer. The average age of the respondents was 57.0 years, with a range from 50 to 79. Respondents completed the survey in a web-based format. Ordinary least-squares (OLS) regressions entered the variables in five hierarchical blocks: (a) demographic and medical variables; (b) psychosocial variables; (c) online support; (d) appraisal variables; e) interaction terms between online support and appraisal variables. Within each block, the simultaneous entry procedure was used. This hierarchical approach tested the independent and cumulative effects of blocks of variables on post-diagnosis self-transformation. The results showed that there is a significant interaction between online support and trauma appraisal of cancer. Perceived benefits of online support increased in proportion to the degree to which cancer experiences were appraised traumatic. Findings of the study point out potentially modifiable variances associated with cognitive appraisals of cancer and underscore the significance of online support communities on positive reappraisal of illness experiences in old age.
AN INNOVATIVE APPROACH THAT SUPPORTS INDEPENDENCE AND SAFETY IN DRESSING
M. Calkins, IDEAS, Kirtland, Ohio

Roughly 72% of nursing home residents need some assistance with dressing. Most dressing research focuses on the ability to don clothing. However, accessing clothing from the wardrobe/closet/dresser is a necessary precursor to independence in the full act of dressing. This research evaluated the impact on safety and autonomy of nursing home and AL residents of an innovatively designed wardrobe system. Based on Universal Design principles and other design characteristics to specifically address dressing deficits in this population, this multi-phased pre-post design examined the impact of “wardrobe” and “wardrobe with training” conditions. Dressing was digitally recorded (audio-visual) for 6 weeks. IRB issues will be discussed. Dressing performance was assessed using the WISS: Wardrobe Independence and Safety Scale. Safety, ease, and use of supportive features increased significantly (p<0.000 for all three), and safety and ease further improved with training (p<0.019 and p<0.021 respectively). Differences by cognition and functional ability were also examined. Overall, it made less of a difference for individuals with more severe physical impairments, who seldom accessed anything in their wardrobes either with their original wardrobe or with the assistive wardrobes. The wardrobe, however, was effective for individuals with lower cognitive abilities, and individuals with little to no cognitive impairment, but greater physical disability.

COMPUTER SKILLS FOR HEALTHY AGING: STUDENTS MENTORING OLDER ADULTS ONLINE
S.S. Wexler1, L. Drury2, J. Coppola3, B. Appelbohm Thomas4, I. Lienhard School of Nursing, Pace University, New York, New York. 2. Westchester Community College, Valhalla, New York. 3. Seidenberg School of Computer Science and Information Systems, Pace University, New York, New York

Online communication is increasingly necessary for full participation in modern life. Older adults who lack computer skills or equipment are at risk for social isolation and resulting cognitive decline. Our research program equips clients aged 65+ with a refurbished computer and Internet access. Each client is matched with one nursing and one computer science student who work together coaching the older adult into online networking. Nursing students evaluate the physical and psychosocial needs of each client while computer students adapt the hardware and software accordingly. Students make weekly home visits to provide one-to-one assistance in using email, Skype, and web searches. “Virtual visits” continue online allowing students to monitor their client’s progress and to determine when further home visits or referrals for additional services are needed. Outcomes for participating clients and controls are measured in a pretest/posttest design using the Montreal Cognitive Assessment (MOCA), Experiences and Attitudes to Aging Questionnaire, Older Adult Survey of Computer Anxiety and Assistive Technology, and demographic data instruments. The mean age of participants is 77.76 years, with a range of 55-100 years of age. Analysis of Paired t-tests reveals significant improvement (p<.001) in MOCA scores. Qualitative data suggest improvement in clients’ functional status and increased engagement in activity outside the home. The next phase of the study will use standardized instruments to measure these dimensions.

A WEB-BASED INTERVENTION FOR IMPROVING THE PSYCHOLOGICAL WELL-BEING OF MALE STROKE SURVIVORS AND THEIR SPOUSAL CAREGIVERS
G.C. Smith, N. Egbert, M. Delmann-Jenkins, K.M. Nanna, LifeSpan Development, Kent State University, Kent, Ohio

The efficacy a web-based intervention for improving the psychological well-being of male stroke survivors (SS) and their caregiver (CG) wives was examined in a randomized clinical trial study. In the treatment condition (n= 15 dyads), CGs received twice weekly group ses-

SESSION 1980 (PAPER)

TRAJECTORIES OF COGNITIVE FUNCTIONING

PROGNOSTIC SIGNIFICANCE OF CLOX COGNITIVE PHENOTYPES ON MORTALITY AND FUNCTION
1. Birmingham/Atlanta VA GRECC, Birmingham, Alabama. 2. University of Alabama at Birmingham, Birmingham, Alabama. 3. University of Texas Health Science Center at San Antonio, San Antonio, Texas

Purpose: To examine the prognostic implications of CLOX phenotypes for mortality and function over 8.5 years. Methods: Community-dwelling Medicare beneficiaries aged 65 years and older completed baseline in-home assessments including socio-demographics, medical conditions, depressive symptoms, and everyday function (ADLs, IADLs, and life-space). The CLOX tool was used to determine clock drawing phenotypes (no impairment, type 1 and type 2). Follow-up telephone interviews were used to assess function and vital status every six months over 8.5 years. Deaths were confirmed by the National Death Index. Survival analysis and longitudinal mixed models were used to examine mortality and functional trajectories, respectively. Models were adjusted for age, race, gender, marital status, rural residence, education, income, depressive symptoms, and baseline co-morbidity. Results: Participants (N=863) had mean age of 74.8 (SD=6.3); 50% were male and 47% African American. 15% demonstrated Type 2 (executive dysfunction) impairment while 32% had Type 1 (global dysfunction). Type 1 had significantly higher mortality than the referent (49.8% vs 30.3%, HR=1.43, p<.01); Type 2 did not (38.9%). The main effect of the Type 1 phenotype was significant on life-space, with Type 1 participants having a lower life-space than those with no impairment or the Type 2 Phenotype. Type 1 phenotype had accelerated rates of new ADL and IADL difficulty over time in comparison to participants with no impairment or Type 2. Conclusions: Compared with the non-impaired CLOX phenotype, older adults with Type 1 are at increased risk for mortality and functional decline. Type 2 phenotype was not.
INTRAINDIVIDUAL VARIABILITY AND AGING: SELF-INCONSISTENCY AND COGNITIVE DECLINE
D. Finkel, N. Ram, School of Social Sciences, Indiana University Southeast, New Albany, Indiana

Intraindividual variability is often associated with lower levels of emotional and physical well-being, as well as cognitive functioning (Baird et al., 2006; Chow et al., 2007; Ong & Allaire, 2005; Ram, et al. in press). Collection of burst (repeated) measurements during on-going longitudinal studies is now allowing us to investigate the extent to which long-term developmental processes may influence and/or be influenced by short-term variability in function. During the fifth wave of the on-going 19-year Swedish Adoption/Twin Study of Aging, 42 participants (aged 54 to 67) completed up to 10 days of repeated assessments of neuroticism, extraversion, depression, life satisfaction, and locus of control. Integrating quantifications of intraindividual variability and multi-phase growth curve models, we used this data to elaborate the antecedent, correlate, and consequent associations between day-to-day variability and decade-to-decade change. Specifically, we examined how measures of short-term self-inconsistency in personality were associated with concurrent levels of cognitive function and both prior and later cognitive decline in verbal, spatial, memory, and speed domains. Results indicate that greater inconsistency in extraversion is generally associated with lower overall levels of cognitive performance and that higher levels of intraindividual variability were associated with steeper rates of decline for the verbal and speed factors, particularly as a potential indicator of forthcoming declines. Our study expands the methodological frameworks for layering short-term and long-term processes and how they may contribute to our understanding and identification of early markers of development and senescence.

EARLY IDENTIFICATION OF NEUROPSYCHOLOGICALLY-DEFINED MILD COGNITIVE IMPAIRMENT (MCI): A STUDY OF MIDLIFE TWINS
W.S. Kremen1, A. Jak1, M.S. Panizzon3, C.E. Franz3, A. Dale1, C. Fennema-Notestine1, L. Eyler1, M. Lyons1, J. University of California, San Diego, La Jolla, California, 2. VA San Diego Healthcare System, La Jolla, California, 3. Boston University, Boston, Massachusetts

Early identification of MCI is important. Most studies focus on age 65+, and include clinically-referred patients without actual premorbid cognitive ability data. Furthermore, the heritability of MCI (proportion of phenotypic variance due to genes) is unknown. We assessed 1168 community-dwelling male twins in the Vietnam Era Twin Study of Aging (VETSA). All but 4 were in their 50s. Neuropsychological assessment covered multiple tests in 5 domains. Adapted Petersen-Morris Criteria=impairment based on ≥1 measure in a domain ≥1.5 SDs below normative expectations. Comprehensive Criteria=impairment based on ≥2 measures in a domain ≥1.0 SD below normative expectations. Comprehensive Criteria=impairment based on ≥2 measures in a domain ≥1.5 SDs below normative expectations. Premorbid general cognitive ability was based on testing at age 20. 44.18% met Adapted Petersen-Morris Criteria; 20.18% met Comprehensive Criteria; and 11.3% met Comprehensive Criteria. Heritability was 0.32 for the Adapted Petersen-Morris, 0.28 for the Comprehensive, and 0.46 for the Comprehensive Criteria. In analyses based on Comprehensive Criteria, participants classified as having multiple-domain MCI had the lowest premorbid cognitive ability, followed by single-domain, and then cognitively normal participants. Hippocampal volume was smallest in multiple-domain MCI, and remained so after adjusting for premorbid cognitive ability. Findings suggest that: 1) neuropsychologically-defined MCI can be identified even among non-clinically referred adults in their 50s; 2) being heritable, neuropsychologically-defined MCI is an appropriate phenotype for genetic association studies; 3) premorbid cognitive ability is a risk/protective factor, but analyses controlling for premorbid ability suggest additional processes. Ongoing follow-ups will determine the utility of different MCI definitions.

AGE DIFFERENCES IN ADAPTIVE DECISION MAKING: GAINS VS. LOSSES
Y. Chen, R. Kirk, O.L. Pethel, J. Wang, A.E. Kietner, Psychology Department, Bowling Green State University, Bowling Green, Ohio

Throughout human development, the ability to make adaptive decisions is crucial for survival and well-being. However, decisions may become increasingly difficult when there is uncertainty of the outcome. Risky decision making refers to decisions in which the outcome is unknown. Past research has found that people make different risky decisions when the decision involves gains vs. losses. It is well-known that losses loom larger than gains (Kahneman & Tversky, 1979): individuals are more likely to take a risk to avoid potential losses than to achieve potential gains. This tendency is not necessarily maladaptive as the traditional framing effects typically represent equal probability of gains vs. losses. The present study used the Cups task (Levin, Weller, Peder-son, & Harshman, 2007) to manipulate probabilities of gains and losses so sometimes it was advantage to take the risk and sometimes it was disadvantage to take the risk. Levin and colleagues (2007) found that children were more likely to make risky choices than their parents especially when risky choices were disadvantageous. But little is known about adult age differences in the ability to make advantageous decisions. Thus, the major objective of the current study was to investigate young and older adults’ abilities to make adaptive decisions in gain vs. loss domains. Forty young (18-25 years old) and 40 older adults (over 65 years old) completed the risky decision making task on a computer (i.e., the Cups task). The Cups task consisted of 54 trials representing 3 trials each of all combinations of two domains (gain vs. loss), 3 levels of probability (.20/.33/.50) and 3 levels of outcome magnitude for risky options (2/3/5 dollars) compared to 1 dollar for sure. In addition, participants completed a cognitive battery including measures of crystallized intelligence (e.g., Wechsler Adult Intelligence Scale) and fluid intelligence (e.g., processing speed). It was found that overall young adults were more likely than older adults to make risky choices in the gain domain whereas the two age groups did not differ in risk-taking in the loss domain. In addition, both young and older adults were sensitive to probability change across the two domains and made adaptive decisions. The current study made important contributions to our understanding of adult age differences in risky decision making. The findings also have practical implications. Older adults may benefit more from increasing their advantageous risky taking in order to achieve potential gains.

AGE-INVARIANT MEMORY FOR GENERAL, BUT NOT SPECIFIC, SOCIAL INFORMATION
A.H. Gutchess, J. Coleman, M. Limbert, Brandeis University, Waltham, Massachusetts

While some evidence indicates that memory for socioemotional information can be preserved with age (e.g., Rahhal, May, & Hasher, 2002), a large body of literature investigating nonsocial information suggests age-related declines in memory, particularly in memory for specific details. We investigated the possibility that memory for general social information (e.g., whether someone had a good or bad character) could be intact with age, while memory for behavioral details would be impaired with age. Sixteen young and 16 older adults encoded faces paired with sentences containing character information, and then completed tests assessing general and specific aspects of memory. Results indicate that young and older adults are well-equated on general social memory but young perform better than older adults on specific memory trials. These results indicate that while memory for socioemotional information can be preserved under some circumstances with
age, memory of social information continues to be vulnerable to losses with age.

SESSION 1985 (SYMPOSIUM)

CROSS-NATIONAL VARIATION IN WORK OUTCOMES AMONGST OLDER ADULTS: THE GENERATIONS OF TALENT STUDY

Chair: M. Pitt-Catsouphes, Graduate School of Social Work, Boston College, Sloan Center on Aging & Work, Chestnut Hill, Massachusetts
Co-Chair: N. Sarkisian, Boston College, Department of Sociology, Chestnut Hill, Massachusetts
Discussant: N. Sarkisian, Boston College, Department of Sociology, Chestnut Hill, Massachusetts

Work in the 21st century has been affected by the globalization of human resource/talent management strategies and dramatic shifts in the age composition of the workforce. The impact of these trends on employee’s employment experiences has posed new opportunities and challenges to employees, employers, and public policy-makers. To date, however, there has been limited effort to examine how employment experiences vary by country and for employees of different ages—particularly older adults. The Sloan Center on Aging & Work (SCAW) at Boston College collaborated with 7 multinational companies operating in 11 different countries around the world (Brazil, China, India, Japan, Mexico, Netherlands, South Africa, Botswana, Spain, the United Kingdom, the United States) to conduct the Generations of Talent Study (GOT). This study collected data from over 11,000 employees on several dimensions of quality of employment as experienced by today’s multigenerational workforces. The papers presented in this symposium are based on the data collected for this study. The first presentation in this symposium provides an overview of the study aims, design, and methods. The second through fourth presentations focus on analytical papers based on the GOT data. The primary aim of these papers is to explore cross-national variation in work outcomes—specifically job satisfaction, work engagement, and work embracement—amongst older adults. Findings reveal interesting differences and similarities within and across employee, organizational and national contexts. A discussant will reflect on the contribution of this work to knowledge building around the work experiences of older adults in various national contexts.

VARIATIONS ACROSS WORKSITES IN RELATIONSHIPS WITH JOB SATISFACTION FOR MULTI-NATIONAL ORGANIZATIONS

E. Besen, C. Matz-Costa, R. Bhave, Boston College, Chestnut Hill, Massachusetts

The world population is aging, as are the workforces in many nations. In response to this trend, researchers have begun investigating how the experience of work for older workers differs from that of younger workers. This research has largely been US based and has not focused on multi-national organizations with worksites around the world. As economic globalization continues and workforces become more globally diverse, it is becoming increasingly important to understand how the impact of age on work experiences may vary cross-nationally. One important work experience that has been found to differ across the lifespan is job satisfaction. We examine how relationships with job satisfaction vary between older and younger workers. Analyses reveal that job satisfaction is greater for older than younger workers and this does not vary across worksites/countries. Findings will be discussed regarding implications for multi-national organizations with diverse workforces regarding age.

THE EMBRACEMENT OF WORK IN OLDER ADULTHOOD: THE IMPACT OF JOBS, ORGANIZATIONS, AND CULTURAL CONTEXTS

C. Matz-Costa, S. Sweet, M. Pitt-Catsouphes, 1. Graduate School of Social Work, Boston College, Sloan Center on Aging & Work, Chestnut Hill, Massachusetts, 2. Ithaca College-Department of Sociology, Ithaca, New York

Prior studies show that expectations to work and participation in work varies remarkably over the life course, between organizations, and between societies. In this paper we seek to extend understandings of work attachment amongst older adults by considering the psychological embracement of work—meaning the extent that one perceives work as meaningful, interesting, and as an important part of their identity. We will share findings that explore the impact of personal attributes, employment characteristics, care responsibilities, household work commitments, work-family balance, and retirement expectations on the work embracement of adults age 50 and older. By considering the contexts in which work is embraced (or conversely those that correspond with detachment from work) our study contributes to understanding how values are nested within systems that give shape not only to the opportunity to work in older adulthood, but also aspirations that intersect with job, career, and family role performance.

THE GENERATIONS OF TALENT STUDY: STUDY DESIGN AND METHODS

R. Carapinha, N. Sarkisian, M. Pitt-Catsouphes, 1. Boston College, Chestnut Hill, Massachusetts, 2. Sloan Center on Aging and Work, Boston College, Chestnut Hill, Massachusetts

The Generations of Talent Study (GOT) was conducted from May 2009 through November 2010. Seven multinational companies participated in the study through their operations in 11 different countries including Brazil, China, India, Japan, Mexico, Netherlands, South Africa, Botswana, Spain, the United Kingdom, and the United States. Data were collected using a 30-minute web-based survey that was translated from English to four other languages that focused on employees’ perceptions of their work experiences, workplace-based resources, demographic information, and their assessments of their health and well-being (at work and in their lives, in general). In total, 11,297 individual employees of these multinational companies responded to the survey, 1,325 of which were over age 50. This presentation will provide an overview of the overall study design, data collection mechanisms, and sampling procedures employed in the GOT study. General analytic strategies relevant to the papers in this session will also be discussed.

CRITICAL JOB RESOURCES TO PROMOTE WORK ENGAGEMENT AMONG OLDER EMPLOYEES

J. Lee, R. Carapinha, M. Pitt-Catsouphes, Boston College, Chestnut Hill, Massachusetts

The dramatic shifts of age demographics in the workforce and the global economic crises present opportunities and challenges for global employers who are managing multi-generational and multi-national talent. Promoting employee work engagement as a global talent management strategy is related to positive benefits for both employers and employees. However, in order to address the global aging of the workforce in tough economic times, employers need to specifically identify the critical predictors of work engagement among older employees (50 years and older). In this paper, we examine the relationship between older employee’s satisfaction with job resources (such as training and development) and work engagement to identify the resources that has the greatest impact among older employees cross-nationally. Analyses reveal that some job resources are more important than others to promote work engagement among older employees. Best strategies to promote work engagement among older employees cross-nationally will be presented.
SESSION 1990 (SYMPOSIUM)

GRANDPARENT CAREGIVERS: UTILIZATION AND EFFECTIVENESS OF SERVICES AND SUPPORT PROGRAMS
Chair: C.A. Fruhauf, Human Development & Family Studies, Colorado State University, Fort Collins, Colorado
Discussant: T.A. LaPierre, University of Kansas, Lawrence, Kansas

Understanding the effectiveness of services and support programs utilized by grandparent caregivers is increasingly important as the number of grandparents raising grandchildren continues to grow. Despite the recognition of the vital role programs and services play in the lives of grandparents raising grandchildren, questions remain to be answered. In this symposium, empirical investigations addressing the impact services have on grandparents, service providers’ reports of program needs, and grandparents’ views of working with social workers will be discussed. In particular, the first paper by Whitley, Kelley, and Campos focuses on the varying coping behaviors of custodial grandmothers as a response to a multi-disciplinary service program. Using focus groups and surveys, the second paper by Kolomer and colleagues will address results from a supplemental food program that has been added to the Healthy Grandparents program in Northeast Georgia. In the third paper, Rhynes, Hayslip, and Ingman will discuss benefits custodial grandparents report from activities and services based on senior center attendance. The final two papers will address service providers’ needs and their engagement with grandparent caregivers. Fruhauf and Bundy-Fazioli will report data gathered from telephone interviews with service providers on their needs in order to better assist grandparent caregivers. Additionally, Gladstone will end the symposium addressing grandparent involvement in the child welfare system, relationships with social workers. The discussant, LaPierre, will integrate the findings from these papers, address future research needs, and provide implications for professional practice with grandparent caregivers.

ADDRESSING FOOD INSECURITY IN GRANDPARENT HEADED-HOUSEHOLDS
S. Kolomer1, S. Himmelmanber1, S. McKinney2, C.J. Elward1, J. University of Georgia School of Social Work, Athens, GA, 2. Athens Community Council on Aging, Athens, Georgia

Background: A major challenge for grandparent headed-households is confronting how to provide for the food needs of an instant family of dependents. One response to the needs of grandparent caregivers in the Northeast Georgia area has been Healthy Grandparents. Recently, supplemental food assistance has been added to the services provided through the Healthy Grandparents Program. Method: Through multiple focus groups and surveys, food insecurity levels among grandparent caregivers in the Northeast Georgia area were explored to identify what sources of food assistance are being utilized, what obstacles exist to accessing services, and to assess the effectiveness in the provision of supplemental food through the Healthy Grandparents Program. Results: Grandparent headed-households have several external and personal strategies for coping with food insecurity. Discussion: Grandparent headed-households are greatly impacted by the weak state of the economy. Participants will be able to identify program and policy initiatives regarding food insecurity.

HOW TO BETTER SERVE GRANDFAMILIES: RECOMMENDATIONS FROM SERVICE PROVIDERS
C.A. Fruhauf1, K. Bundy-Fazioli1, 1. Human Development & Family Studies, Colorado State University, Fort Collins, Colorado, 2. School of Social Work, Colorado State University, Fort Collins, Colorado

Grandparent caregivers often need support services. Yet, little is known about what service providers need in order to better serve grandfamilies. As a result, we conducted telephone interviews with professional service providers (N = 16) from agencies serving grandfamilies. Participants answered questions such as: (1) when you come in contact with grandparent caregivers what services do you provide, and (2) what do you need to better serve grandfamilies? Data were transcribed verbatim and transcripts were analyzed using an inductive, constant comparison approach. Findings revealed service providers’ desire to better understand the available resources in the community for grandfamilies. Participants fully supported continual funding for the kinship navigator position, and discussed the importance of community providers sharing a common voice and working together. It is important that professionals who serve grandparent caregivers are knowledgeable and willing to collaborate with other providers to meet the needs of grandfamilies.

ENGAGING GRANDPARENTS IN THE HELPING PROCESS: A VIEW FROM CHILD WELFARE
J. Gladstone, McMaster University, Hamilton, Ontario, Canada

Custodial grandparents are often involved with child welfare agencies who offer services intended to support the family. The question addressed in this paper is: What do service providers need to consider in order to engage grandparents in the helping process? Data were gathered through in-depth qualitative interviews with 33 grandparents who were raising their grandchildren and involved with the child welfare system. Findings show that grandparent engagement is related to 4 factors: (1) relationships between grandparents and social workers attached to these agencies; (2) workers’ relationships with children and older adults in the middle generation; and (3) workers’ relationships with the middle generation. Findings are discussed in relation to Yatchmenoff’s (2002) conceptualization of engagement which includes 4 dimensions: receptivity, buy-in, working relationship, and mistrust. Our conclusion is that engaging grandparents in child welfare services is a multidimensional process that needs to look beyond dyadic relationships.

SENIOR CENTER ATTENDANCE BENEFITS GRANDPARENTS RAISING GRANDCHILDREN
B. Hayslip, L. Rhynes, S. Ingman, Psychology, University of North Texas, Denton, Texas

While senior centers provide many benefits for those who partake of its services, such effects have not been examined among custodial grandparents. One-hundred thirty such persons completed measures of quality of life, well being, loneliness, caregiver burden, and role satisfaction. A MANOVA (F = 2.72, p < .01) wherein senior center attendance impacted the above measures as a set, and ANOVAs suggested that quality of life, caregiver burden, well being, and role satisfaction were impacted positively by senior center attendance. Grandparent caregivers who were currently attending were also twice as likely to report doing so relative to when they were not raising grandchildren, while among those not currently attending, this pattern was reversed (X21 = 13.1, p < .05). These findings substantiate the unique benefits for grandparent caregivers of becoming involved in the activities and services senior centers provide, key to such persons’ well-being and satisfaction with life.

FAMILY COPING PATTERNS AMONG CUSTIODIAL GRANDMOTHERS RAISING GRANDCHILDREN: A PRELIMINARY ANALYSIS
D. Whitley, S.J. Kelley, P.E. Campos, Georgia State University, Atlanta, Georgia

Many custodial grandparents have difficulty in maintaining a cohesive home setting because of challenging parental responsibilities. Stabilizing the home environment requires family members to develop appropriate coping behaviors. This presentation reports on the preliminary findings of the coping behaviors of 191 grandparents who participated in a 12-month program designed to strengthen their social, physical and emotional states. All participants are African American.
grandmothers or great-grandmothers, raising an average of 2.3 grandchildren. The Family Crisis Oriented Personal Evaluation (FCOPES) and the Family Adaptability and Cohesion Evaluation Scales (FACES) measured multiple dimensions of family coping, cohesion and adaptability. Pre/Post comparative analysis suggest participants experienced improved perceptions of coping over time. However, younger, more educated, employed grandmothers, with fewer grandchildren had higher cohesion and adaptability scores than their counterparts, but their scores appear to decline over time. This presentation highlights these findings and the implications for community-based service interventions.

SESSION 1995 (SYMPOSIUM)

LATINO FAMILY CAREGIVING: LIFE COURSE, LIFE STYLES, AND LIFESPAN
Chair: D.W. Coon, College of Nursing & Health Innovation, Arizona State University, Phoenix, Arizona
Discussant: J. Montoro Rodriguez, California State University, San Bernardino, San Bernardino, California

Latinos are the fastest growing segment of our aging population, and substantive numbers of these older adults are expected to need ongoing care as a result of debilitating chronic health conditions. These changes already translate into burgeoning numbers of Latino family members accepting the additional role of family caregiver. Such rapid growth is spurring the need to explore not only existing and emerging configurations of Latino family care, but also the demand for sustainable, culturally responsive caregiver interventions for effective delivery across the caregiving trajectory. Consonant with this year’s theme of Lifestyle → Lifespan, this symposium and its individual presentations use complementary qualitative and quantitative approaches to enrich our understanding of cultural and contextual factors (e.g., familismo, SES, gender, coping styles) that influence Latino family caregiving as framed within a life course perspective. An NIH funded longitudinal mixed methods study of 110 Latino caregiving families provides the backdrop for two presentations, with one focusing on multiple caregiving experiences in Latino families (compound caregiving, serial caregiving and the domino effect), and the other describing the unique emerging role of Latino sons breaking cultural proscriptions to provide personal care for aging mothers. The third presentation describes a project funded by the Alzheimer’s Association that evaluates the impact of a fotonovela designed to help Latino families manage caregiver stress. The fotonovela was developed through a series of focus groups with caregivers and professionals by uncovering cultural and contextual factors to carefully guide content development and delivery.

AN EMERGING LIFESPAN PHENOMENON: MEXICAN-AMERICAN SONS CARING FOR THEIR MOTHERS
B.C. Evans, M. Belyea, E. Ume, D.W. Coon, F. Castro, Arizona State University, Phoenix, Arizona

Despite robust cultural taboos, the emerging phenomenon of personal care by Mexican-American sons for their aging mothers represents a newly identified caregiving approach in such families. Of the 110 enrolled caregivers in our NIH funded, descriptive, longitudinal, mixed methods study, 10% are sons who cope with personal care in this way. This presentation describes one such case of personal caregiving by a son and traces the evolution of his coping skills, rooted in childhood, over time. The study, Momento Crucial, uses life course perspective to integrate disparate explanations for differences in caregiver stressors, gain, and cultural expectations, and facilitate derivation of testable propositions. Completed at 10-week intervals over 15 months, standardized instruments and semi-structured interviews provide insight into how this son came to be a personal caregiver, pinpoint adaptive strategies for reconciling his activities with cultural expectations, and consider the impact of socioeconomic status and acculturation on his experience. This study was funded by NINR, National Institutes of Health (5R01NR0101541).

EMERGING LIFESTYLES OF MEXICAN AMERICAN FAMILIES: MULTIPLE CAREGIVERS AND MULTIPLE CARE RECIPIENTS
D.W. Coon, B.C. Evans, E. Ume, M. Belyea, F. Castro, College of Nursing & Health Innovation, Arizona State University, Phoenix, Arizona

An understudied phenomenon in caregiver research with Mexican American families is that of multiple caregiving: multiple caregivers caring for one or more care recipients at a time (compound caregiving), caring for one family member after another (serial caregiving), or receiving care from others while themselves providing care (domino effect). Most multiple caregivers participating in our federally funded, descriptive, longitudinal, mixed methods study are low-income, married, and have little more than a high school education. The purpose of this presentation is to describe the emerging lifestyles of families whose cumulative disadvantage, collective ethos, socioeconomic status, or familismo lead them to provide care for older family members in groups. Multiple caregivers view caring as normative and affording familial bonds; are committed to intensive, long term, reciprocal involvement; take pleasure in providing care with family members and friends; experience mutuality in the caregiver-care recipient relationship, and articulate caregiver gain from these activities.

DEVELOPMENT OF A NEW FOTONOVELA FOR LATINO DEMENTIA FAMILY CAREGIVERS TO HELP MANAGE STRESS

Latino family caregivers are a fast-growing segment of the US caregiving population. Prior research found that there is a general lack of accurate information about dementia and caregiving stress and high rates of depressive symptoms, pointing to a need for a culturally sensitive method to deliver accurate information. Our research team developed a new Fotonovela to address this need. Ten focus groups were held (4 with Latino caregivers, 6 with Latino health care professionals, with 32 and 34 participants, respectively) to obtain content input grounded in cultural and contextual factors including values such as familismo. Involving everyone in a whole family in the Fotonovela was primary, as was an emphasis on developing skills to manage care recipient behavior problems and caregiver stress and depression. Preliminary results indicate the Fotonovela is highly valued, highly rated for relevance, and frequently shared with family members.

SESSION 2000 (SYMPOSIUM)

RELATEDNESS, FRIENDSHIPS AND SOCIAL INTERACTIONS: EXPLORING WHAT'S POSSIBLE IN THE MILIEU OF DEMENTIA LONG-TERM CARE
Chair: K. de Medeiros, Miami University, Oxford, Ohio

Long-term care settings for people with dementia are viewed as a transitional place, a temporary residence somewhere in between what was once “home” and ultimate death. Although “friendships” among residents are something family and loved ones continually stress as important for people with dementia, there have been few investigations to explore what this notion really means. For example, are staff members “friends” simply because they know a resident’s name? Is it possible to form new friendships even in advanced stages of dementia? How do conversational markers help us better stand how friendship is constructed and understood linguistically? The purpose of this symposium is to present research specifically related to the notion of friendship and social interactions among people with dementia. Topics covered
include exploring the possibility of friendships among residents with dementia, navigating relationships in the social world of dementia long-term care, exploring the notion of relatedness and social cognition relative to friendships, and taking a close look at social interactions. Overall, research presented in this symposium addresses an important gap in the literature on dementia: the importance of friendship.

FRIENDSHIP BETWEEN DEMENTIA RESIDENTS IN LTC: IS IT POSSIBLE?
P. Saunders, K. de Medeiros, 1. Georgetown University School of Medicine, Washington, DC, District of Columbia. 2. Miami University, Oxford, Ohio.

Researchers have shown that the communicative function of persons with dementia influences interactions with other people. For example, persons with dementia (PWD) may take longer to respond than non-impaired persons. Also PWD may be outpaced when others speak too quickly. This paper examines how conversational attempts at friendship are impacted by communicative practices of staff members in the long-term care setting. Ethnographic observations were conducted. Conversations were among PWD and staff members were recorded and transcribed. Findings show that PWD use language in conversational interactions including pronominal reference and alignment to manage relationships. Findings also reveal practices by staff members that may hinder and/or support PWDs’ attempts at conversational interactions.

In summary, PWD in long-term care settings may suffer from isolation and loneliness due to the nature and communicative practices of institutional facilities. Understanding how people construct social relationships and how staff impact this process is important to PWDs’ quality of life.

RELATEDNESS AMONG PEOPLE DIAGNOSED WITH DEMENTIA: SOCIAL COGNITION AND THE POSSIBILITY OF FRIENDSHIP
S. Sabat, J.M. Lee, Georgetown University, Washington, DC, District of Columbia.

In this study, we examined the social relatedness of people in the moderate stage of dementia as defined by their performance on standard tests and clinical examination. The individuals herein were observed in the natural social environment of an adult day center that they attended on weekdays. A number of important aspects of mutually desired, independently initiated, supportive social relationships were observed to exist, through which the principals revealed semiotic, or meaning-driven, behavior that would not be predicted by their meeting the criteria that contributed to their diagnosis. Losses in social functioning described in the DSM and the clinical diagnosis of dementia appear not to be directly caused by the losses that lead to the diagnosis, but by social dynamics involving healthy others. Implications for the non-pharmacological treatment of people with dementia are explored and discussed within the context of Kitwood’s idea of positive person work.

NAVIGATING RELATIONSHIPS WITHIN THE SOCIAL WORLD OF A DEMENTIA CARE SETTING: THE CASE OF A PARTICULARLY ‘FRIENDLY’ RESIDENT
P.J. Doyle, K. de Medeiros, P. Saunders, 1. Center for Aging Studies, Department of Sociology and Anthropology, University of Maryland, Baltimore County, Baltimore, Maryland. 2. Miami University, Oxford, Ohio. 3. Department of Neurology, Georgetown University, Washington, Distric of Columbia.

There is a great deal of complexity that exists in the social environments of long-term care settings especially those that focus on people with dementia. In these settings, social networks form and over time the members change and new dynamics and relationships arise. However, previous research has demonstrated that friendship, as traditionally defined, is difficult to identify between people with dementia. Cognitive and physical impairments that can occur in this group limit the researchers’ ability to identify “friendships.” This paper will focus on one male resident, Dr. Mitchell. Ethnographic fieldwork over two years documented this resident; having multiple intimate relationships with female residents, regularly sitting with a group of male residents, and being friendly with the staff. Dr. Mitchell was an outlier in regard to his social engagement. Understanding the factors that may have contributed to this will give insight into how social engagement could be improved in these settings.

THE SOCIAL DYNAMICS OF DEMENTIA CARE UNITS: EXPLORING THE NATURE OF INFORMAL SOCIAL INTERACTION
M. Campo, H. Chaudhury, Department of Gerontology, Simon Fraser University, Vancouver, British Columbia, Canada.

Despite recognizing the importance of socialization as contributing to well-being and quality of life for institutionalized seniors with dementia, little research has been conducted that comprehensively examines the social dynamics within dementia care settings. The purpose of this study was to explore the nature of informal social interactions that occur in special care units. An ethnographic approach using in-depth interviews with staff and resident observations was employed. Findings from this investigation revealed that despite spending a majority of time not interacting with anyone, when residents did engage with others, the behaviors expressed were varied and included several types of informal social interactions: active and brief verbal communications; touching; gesturing; glancing; attention seeking; and other non-verbal communications. The findings discussed highlight the diversity and complexity in social patterns expressed by people with dementia and underscores the importance of developing policies within special care units that recognize and promote informal social interaction.

SESSION 2005 (SYMPOSIUM)

REPRESENTATIONS OF OLDER ADULTS AND AGING IN POPULAR AND PUBLIC MEDIA
Chair: B. Carpenter, Psychology, Washington University, St. Louis, Missouri.

Older adults and the issues important to them appear in a wide variety of media. These representations can have a powerful effect on both personal and public opinion about what the experience of aging is like. This symposium includes five presentations that explore representations of older adults and their potential impact in a range of media. The first presentation (Sakai) describes how older adults with Alzheimer’s disease are portrayed in children’s picture books, focusing on primary characters, plot features, and the depiction of Alzheimer’s disease. The second presentation (Jarrott) uses a contact theory framework to examine attributes of intergenerational relationships among characters in adolescent fiction. The third presentation (Mason, Kuntz, & McGill) explores characterizations of older adults and aging in texts published between 1800 and 2000, using state-of-the-art text analysis software. The fourth presentation (Roberto, McCann, & Brossoie) presents results from an analysis of media reports on intimate partner violence among older adults, highlighting common types of violence and contributing factors. And the final presentation (Goldstein & Miller) documents the media’s influence on state health policy agenda, with a focus on how media presentations altered the balance of long-term care services in four states. As a set, these presentations demonstrate the multiple ways...
in which depictions of older adults can influence private and public discourse about aging.

OLDSTERS AND NGRAMS: REPRESENTATIONS OF OLDER ADULTS IN 19TH AND 20TH CENTURY ENGLISH LITERATURE
S. Mason, C. Kuntz, C. McGill, Niagara University, Niagara University, New York

Older adults tend to be underrepresented, or represented negatively, in the media. While the images and words presented in the media can shape our attitudes and contribute to stereotyping and ageism, media portrayals can also reflect views that are prevalent at the time. To better understand how attitudes have changed over time, we used Google Books Ngram Viewer and studied changes in the words used to describe older adults and aging. Ngram Viewer searches over five million books published between 1800 and 2000 and plots trends in word usage. With this tool, we demonstrated that older adults, particularly older women, have been underrepresented in the literature for the past 200 years. We compared the usage of such terms as “oldster”, “senior citizen”, and “elder”, and found when these terms were introduced and when they were most popular. Finally, we examined stereotypes by plotting the use of different adjectives to describe young and old adults.

MEDIA REPORTS OF INTIMATE PARTNER VIOLENCE IN LATE LIFE
K.A. Roberto1, B. McCann2, N. Brossie1, 1. Ctr for Gerontology, Virginia Tech, Blacksburg, Virginia, 2. University of Louisiana - Monroe, Monroe, Louisiana

The media is influential in shaping public perceptions and policies as it often prints items that mirror the cultural values and interests of its readership. When relatively “invisible” and less palatable topics such as intimate partner violence (IPV) are brought to light, the social biases and assumptions embedded in the reporting style influence the public’s response and future consideration of the issue. Using a feminist intersectional framework, we analyzed 100 articles published nationally to understand how the media conceptualized IPV among older adults. Most stories involved violence against women, with murder and murder-suicide being the types most commonly reported. Caregiver stress, alcohol use, and the poor health of the victim were frequently named as factors contributing to the violence. Findings raise awareness about the types and outcomes of IPV in late life and suggest the need for community prevention and intervention programs tailored specially to older adult victims and perpetrators.

WHAT’S WRONG WITH GRANDMA?: THE PORTRAYAL OF ALZHEIMER’S DISEASE IN CHILDREN’S PICTURE BOOKS
E.Y. Sakai, Psychology, Washington University, St. Louis, Missouri

While Alzheimer’s disease (AD) affects older adults most directly, other family members, including young children, can be indirectly affected by the disease. Yet, there has been limited information about the disease for young children who encounter AD in their lives. Picture books are one accessible way to educate children about AD. In this study, we evaluated 33 children’s picture books that addressed AD. Analyses focused on character profiles, plot features, and the depiction of AD symptoms. Common features of the books include children as main characters, interacting with an older adult with AD, usually a grandparent. Children are portrayed as trying to make sense of AD symptoms, turning to parents for information. A narrow range of AD symptoms is depicted, focusing on cognitive symptoms (e.g., memory impairment) and, less frequently, emotional symptoms (e.g., anger). Picture books may help children learn about AD, although they offer circumscribed portrayals of the disease.

THE ROLE OF THE MEDIA IN LONG-TERM CARE REBALANCING: A COMPARATIVE STATE ANALYSIS
R.H. Goldstein1, E.A. Miller2, 1. Massachusetts General Hospital, Boston, Massachusetts, 2. McCormack Graduate School of Policy and Global Studies, University of Massachusetts, Boston, Massachusetts

Few studies examine role of the media in long-term care (LTC). This study analyzes the media’s role in state efforts to rebalance LTC away from institutions toward home- and community-based services (HCBS). Changes in media reporting on rebalancing in four case study states—Connecticut, Minnesota, Oregon, and Utah—were examined using data drawn from content analysis of all nursing home-related articles reported in each state’s capital newspaper from 1999 to 2008. Changes in state policy agendas toward rebalancing were examined using Medicaid HCBS spending and legislative bills proposed. Ordinary least squares regression was used to assess the relationship between the media and policy agendas, controlling for other potentially confounding variables. Findings reveal a relationship between states’ rebalancing policy agendas and total nursing home coverage, negative coverage, and coverage of rebalancing issues, specifically. They also confirm the relationship between states’ rebalancing policy agendas and states’ economic, political, and programmatic characteristics.

SESSION 2010 (SYMPOSIUM)

THE AGING SELF IN CONTEXT: LIFE-SPAN CHALLENGES AND POTENTIALS
Chair: J. Wagner, Humboldt-University of Berlin, Berlin, Germany
Co-Chair: M.K. Rohr, Friedrich-Alexander-University of Erlangen-Nuremberg, Erlangen, Germany
Discussant: K. Fingerman, Purdue University, West Lafayette, Indiana

Irrespective of numerous challenging physical, psychological, and social role changes in late life, the majority of old adults illustrate patterns of successful aging. Flexibility and adaptive competencies of the self may play a pivotal role in maintaining well-being and functionality in everyday life. The major objective of this symposium is to bring together a collection of empirical papers that examine specific challenges of diverse aging-related contexts highlighting the important role of flexible self-regulation. J. Wagner, F.R. Lang et al. deal with lifelong dynamics and challenges in the context of self-esteem as well as their age-specific constraints and risks, M.K. Rohr & F.R. Lang address the role of personality and relationship risks within the transition to care, F. Infurna, D. Gerstorf, and S. Zarit examine key components of caregiving change in relation to placement of care recipient in a nursing home, and L. Pitzer & C. Bergeman present data on positivity and resilience after traumatic events, especially looking at the role of the social network. The discussion by K.L. Fingerman will integrate the four empirical papers, emphasize the importance of considering self-related dynamics across the entire life span, and discuss possible future directions that research should take.

SELF-ESTEEM ACROSS ADULTHOOD: THE ROLE OF AGE-SPECIFIC CONTEXTS

Research on self-esteem has often focused on the second and third decades of life. More recent studies, using age-heterogeneous samples, point to a possible destabilization and decrease in later adulthood and old age. Extending such findings, we explored mean-level differences in self-esteem from ages 17 to 90 in two cross-sectional studies. In addi-
tion, we examined intradividual changes in self-esteem in two longitudinal studies with young and old adults. The findings of Studies 1 and 2 supported the previously reported inverted U-shaped trajectory only in the context of the online assessment, which was based on a selective sample, but not in representative face-to-face interviews. The stability indices of Studies 3 and 4 also indicated high consistency of self-esteem across 4 and 8 years. Thus, findings point to a general robustness of self-esteem across the life span, but also suggest that challenges to self-esteem are reflective of age-specific constraints and risks.

THE ROLE OF PERSONALITY IN THE TRANSITION TO CARE
M.K. Rohr, F.R. Lang, Institut of Psychogerontology, University Erlangen-Nuremberg, Erlangen, Germany

Current research on caregiving discloses great individual variations in the experience of stress and burden as well as the acknowledgment of positive aspects. However, findings regarding the topic are still limited and it remains unclear how individual differences impact the entrance into the caregiving role: Who does become a caregiver? How does personality shape the care experience within the first years? And when do we observe growth? Combining longitudinal data from the Socio-Economic Panel (SOEP, N = 14579) with a complementary web based approach (N = 485) we monitor the role of personality within the transition to care. Preliminary results point to the impact of neuroticism on care decisions and mirror the importance of gain-loss-dynamics in the care experience. Based on an action-theoretical background we discuss the interplay between stable personality traits and individual resources on the mastery of care transitions.

CHANGES IN ROLE OVERLOAD AND MASTERY OF CAREGIVERS WITH THE PLACEMENT OF A CARE RECIPIENT: THE ROLE OF CAREGIVER AND CARE RECIPIENT CHARACTERISTICS

Major life events and transitions often trigger psychological change processes. Using prospective longitudinal data from the Caregiving Stress and Coping Study (N=271; M age=63; 70% women), we target how role overload and mastery change in caregivers with the placement of the care recipient into an institution and examine whether caregiver and care recipient characteristics serve as risk and protective factors. Results revealed that caregivers experienced increasing role overload preceding placement, followed by a substantial decline at placement. Likewise, caregivers experienced declines in mastery preceding placement, followed by significant increases around placement and further increases thereafter. More caregiver depressive symptoms and care recipient ADL/ADL dependencies were each associated with larger declines in role overload and increases in mastery at placement. Our findings suggest that key variables involved in caregiving processes show substantial changes leading up to and after placement and illustrate the importance of examining change across salient life transitions.

A LONGITUDINAL EXPLORATION OF POSTTRAUMATIC GROWTH: RESULTS FROM A SAMPLE OF OLDER ADULTS
L. Pitzer, C.S. Bergeman, Univ Notre Dame, Notre Dame, Indiana

Some adults experience positive psychological change after a highly stressful event. This posttraumatic growth is often characterized by enhanced perceived quality of life (e.g., appreciation of life, closer relationships), yet this phenomenon has not been examined over time. Using 450 older adults from the Notre Dame Study of Health and Well Being, this study investigates trajectories of positive growth after different stressful events (e.g., death or major deterioration in the quality of life) across five waves of data. Multilevel growth curve models revealed significant quadratic change in the association between stressful events and posttraumatic growth. This study also considered effects of the social network and personality traits. For people who experienced the death of a loved one, rate of change and curvature in posttraumatic growth differed by level of neuroticism, agreeableness, openness, and optimism. Discussion focuses on the developmental implications of growth over time after stressful events.

SESSION 2015 (SYMPOSIUM)

THE MANY FACETS OF AGE-RELATED EMOTION REGULATION
Chair: H. Fung, Department of Psychology, Chinese University of Hong Kong, Hong Kong, China
Discussant: F.R. Lang, Friedrich-Alexander-University Erlangen-Nuremberg, Erlangen, Germany

This symposium summaries the many facets of emotion regulation and discusses how they differ by age and culture. According to Gross's Model of Emotion Regulation, the process of emotion regulation can be divided into (1) situation selection, (2) situation modification, (3) attention deployment, (4) cognitive change and (5) emotion response. The first paper by You and colleagues is about situation selection and situation modification. In contrast to Western findings that daughters shoulder the bulk of care-giving responsibilities, You and colleagues found from a large-scale, representative sample of Chinese that older Chinese mainly sought support from their spouse and sons; rarely from their daughters. The implications of this finding for providing “culturally competent and sensitive support” to older adults will be discussed.

The second paper by Isaacowitz and Choi is on attention deployment and cognitive change. Addressing the mood – health behavior trade-off, Isaacowitz and Choi tested whether paying less attention to negatively-valenced but important health information might have negative behavioral consequences for older adults. The third to fifth papers are all about emotion responses. Sit and Fung examined whether, compared with younger adults, older adults showed stronger physiological reactions towards images of aging of different valence. Sims and colleagues tested whether the co-occurrence of positive and negative emotions were differentially related to well-being among European Americans and Chinese Americans across the adult life span. Yeung and colleagues examined whether the use of suppression correlated positively with the subjective well-being of younger and older workers. Finally, Frieder Lang will discuss the implications of these findings for socio-emotional aging.

THE PATTERN OF SOCIOEMOTIONAL SUPPORT SEEKING AMONG ELDERLY CHINESE
J. You1, H. Fung2, J. Li3, 1. Department of Psychology, University of Houston, Houston, Texas, 2. Chinese University of Hong Kong, Hong Kong, Hong Kong, Hong Kong, 3. Institute of Psychology, Chinese Academy of Science, Beijing, China

Support seeking, as an important coping strategy, has been greatly disvalued by Chinese. This study aims to investigate whether and how elderly Chinese adopt support seeking to satisfy daily socioemotional needs. Data was derived from the 2005 nationwide survey on health status. The sample includes 15,638 elderly Chinese aged from 63 to 120 years (M = 86.16, 42.8% male). Participants were asked to report the first person to whom “they talk frequently”, “they talk first when wanting to share thoughts”, “they ask for help when having problem/difficulties”. More than half of elderly Chinese tended to seek socioemotional support from their spouse and sons, and 10% of them relied on their daughters. However, males and married individuals tended to seek support from their spouse; females, windowed individuals, and those from rural areas mainly relied on their sons. Findings have implications for providing culturally competent care-giving for elderly Chinese.
I. Yen, Medicine, University of California, San Francisco, San Francisco, California

You take the good, you take the bad: Cultural differences and age-related change in mixed emotions

T. Sims1, H. Ersner-Hershfield2, S. Scheibe1, L. Carstensen1, J.L. Tsai1, J. Stanford University, Stanford, California, 2. Northwestern University, Evanston, Illinois, 3. University of Groningen, TS Groningen, Netherlands

Researchers have become increasingly interested in “mixed emotions” (i.e., the co-occurrence of positive and negative affect). One body of research suggests that the experience of mixed emotions increases with age. Another body of research suggests that East Asian contexts promote mixed emotional experience more than European American contexts. No studies, however, have examined whether culture and age exert independent effects or interact to produce mixed emotional experience. Using experience sampling methodology, we measured the co-occurrence of positive and negative affect among European Americans and Chinese Americans across the adult life span. Analyses revealed that mixed emotions increased with age and were higher for Chinese Americans than European Americans, suggesting that culture and age independently influence mixed emotional experience. We explore possible mediators of these differences and their consequences for well-being.

Emotional suppression and work performance: An experience sampling study in younger and older workers

D. Yeung1, H. Fung2, 1. City University of Hong Kong, Hong Kong, Hong Kong, 2. Chinese University of Hong Kong, Hong Kong, Hong Kong

Past studies have revealed that increasing age is associated with different preferences for emotion regulatory strategies; but the psychosocial consequences of these age differences remain largely unclear. The present study adopted an experience sampling methodology to examine whether momentary emotional suppression and its impacts on emotions and work performance would differ by age. Eight-seven Chinese insurance workers (18-61 years) participated in a five-day sampling study. Their affective responses at work and momentary task performance were recorded. Results showed that unlike their younger counterparts, older workers’ use of suppression at work was not associated with higher intensity of negative emotions. Moreover, greater use of suppression over the sampling period was significantly predictive of post-sampling sales productivity of older workers, but such a positive association was not shown in younger workers. These findings reveal that the use of suppression at work may be more effective for older workers than for younger workers.

Session 2020 (Symposium)

Tracking physical activity: Using GPS & other technologies to collect data and design interventions

Chair: I. Yen, Medicine, University of California, San Francisco, San Francisco, California
Co-Chair: O. Duru, University of California, Los Angeles, Los Angeles, California
Discussant: Y.L. Michael, Drexel University, Philadelphia, Pennsylvania

Literature on neighborhood influences on health among older people has generally not include more distant locations where people spend time in addition to their immediate neighborhood. For example, older adults may work or volunteer outside of their residential neighborhood. Knowing where older adults spend time and how they get to these regular destinations could be useful for both policy makers and practitioners. City and transportation planners would learn which design features attract older people. Practitioners could use the travel pattern information to design targeted interventions, for example to increase physical activity. For researchers, the first task is ascertaining where people spend time and what features of these locations support their activities. This session features the development and use of GPS and other GIS technologies that bring together information on travel patterns, the use of the GPS-collected data to design physical activity interventions, and the connections between physical and social features of the environment and walking behavior. The presentations are: 1) report of the a pilot project using GPS devices to collect travel pattern data from 40 older adults in San Francisco and Los Angeles; 2) the development of a device integrating a GPS, an accelerometer, and ANT (a proprietary wireless sensor network) functionality to collect data from adults and children in Montreal; 3) the application of GPS to design individualized physical activity interventions for older adults in San Francisco and Los Angeles; and 4) the association of community resources, green spaces, and walking behavior in the Montreal VoiSiNuAge study.

Using GPS and survey data to individualize a physical activity intervention

O. Duru1, K.C. Kayekjian2, S. Movahedi1, J. Ven1, 1. UCLA, Los Angeles, California, 2. UCSF, San Francisco, California

Evidence shows that individualized physical activity interventions are more effective than group interventions. However, existing pro-
programs are generally tailored to differing physical abilities without accounting for other individual and neighborhood characteristics. The current project incorporates individual daily schedules and resources of the built environment into the intervention design. Within a pilot study of participants 50 years and older living in Los Angeles and San Francisco, GPS and survey data were collected over 7 days from 8 sedentary individuals, in order to design individualized physical activity interventions. Interventions were delivered to participants after baseline data collection. Preliminary analysis of 6-month follow-up data suggests that participants increased their physical activity levels. Individualized exercise interventions using GPS data may effectively improve physical activity in older adults. After this session, attendees will be able to understand how GPS data, community-resource information, and survey data can be incorporated to design an individualized physical activity intervention.

PEOPLE-PLACE INTERACTIONS AND HEALTHY AGING: CONTRIBUTIONS OF A NOVEL MULTISENSOR DEVICE

Y. Kestens\textsuperscript{1}, L. Gauvin\textsuperscript{1}, M. Thériault\textsuperscript{1}, T. Barnett\textsuperscript{1}, M. Daniel\textsuperscript{1}, A. Chevallier\textsuperscript{2}, M. Sawan\textsuperscript{2}, J. Montreal University, Montreal, Quebec, Canada, 2. École Polytechnique, Montréal, Quebec, Canada, 3. Laval University, Quebec City, Quebec, Canada, 4. University of South Australia, Adelaide, South Australia, Australia

A better understanding of mobility patterns, corresponding exposure to multiple environments, and their impact on the health of seniors has eluded researchers at least partially because of the absence of an appropriate measurement and data collection technology. Ubiquitous wearable sensors allow for collecting relevant data on mobility and health behavior. Combined with complementary environmental data sources within a geographic information system, such tools offer new opportunities to tackle novel research questions and support community-based interventions for healthy aging. We introduce a novel wearable device designed for continuous data collection in situ. The device combines a GPS, an accelerometer, an AN module allowing for integration of supplemental sensors, and a GPS phone that allows for over-the-air, real-time data transmission. Data collected with the device and applicability for research among older adults are illustrated through presentation of ongoing research projects. Implications for use in the crafting of interventions are also outlined.

ASSOCIATION OF COMMUNITY RESOURCES AND GREEN SPACES TO TRANSPORTATION AND RECREATIONAL WALKING IN THE MONTREAL VOISINÂGE STUDY

L. Gauvin\textsuperscript{1,2}, L. Richard\textsuperscript{1,2}, Y. Kestens\textsuperscript{1,2}, M. Daniel\textsuperscript{1,2}, B. Shatenstein\textsuperscript{2,5}, H. Payette\textsuperscript{1}, 1. Research Center of the University of Montreal Hospital Center, Montreal, Quebec, Canada, 2. Université de Montréal, Montréal, Quebec, Canada, 3. Institut de recherche en santé publique de l’Université de Montréal, Montréal, Quebec, Canada, 4. University of South Australia, Adelaide, South Australia, Australia, 5. Institut Universitaire de Gériatrie de Montréal, Montreal, Quebec, Canada, 6. Institut universitaire de gériatrie de Sherbrooke, Sherbrooke, Quebec, Canada

We examined how walking for transportation and recreational motives is associated with accessibility to local services and density of green spaces. A sample of 423 adults (44.9% female) from the VoisinÂge study (M=78.6 years, SD=4.1) completed a modified version of the International Physical Activity Questionnaire and other interviewer-administered instruments. Information about the distance between their home and 16 services and the density of green spaces were derived from a geographic-information system. Overall 9.0% and 21.7% of the sample walked at least 30 minutes, 5 times per week for transportation and recreational purposes respectively. Logistic regression analyses adjusted for age, sex, health, and socio-demographic characteristics showed that likelihood of recreational walking was associated with living in an area with greater green space density and that transportation walking was most strongly associated with greater proximity to services. Using combined data sources, we conclude that different types of walking are associated with unique environments.

USING GPS DEVICES TO TRACK OLDER ADULTS’ TRAVEL PATTERNS: PILOT STUDY RESULTS

I. Ye\textsuperscript{1}, K.C. Kayekjian\textsuperscript{2}, S. Movahedi\textsuperscript{2}, O. Duru\textsuperscript{2}, 1. Medicine, University of California, San Francisco, San Francisco, California, 2. University of California, Los Angeles, Los Angeles, California

We conducted a pilot study in Los Angeles and San Francisco to test the use of GPS devices to track travel patterns of older adults and to compare the GPS data to survey data. A multi-ethnic group of 40 volunteers (ages 50 to 99; 23 women) had a GPS device for 7 days. 26 (65%) of the 40 were able to collect 7 days of data (some days, people forgot to wear or turn on their devices); at least 5 days of data were collected for everyone. After the 7 days, we asked them about the previous week and their regular travel. GPS data showed a mean of 4 trips/day, mean trip distance 7.6 km. Survey data indicated that people commonly made trips for 4 activities (e.g. volunteering, work, visiting friends or family) at least once each week. Women and men did not differ in the number of trips for activities.

SESSION 2025 (SYMPOSIUM)

UNDERSTANDING AGE-RELATED CHANGES IN AVIATION PERFORMANCE: THE ROLES OF EXPERTISE, COGNITION, BRAIN MECHANISMS, AND GENETICS

Chair: Q. Kennedy, Stanford University/Department of Veterans Affairs Palo Alto Health Care System, Palo Alto, California
Discussant: J. Becker, Dept. of Psychiatry, School of Medicine, University of Pittsburgh, Pittsburgh, Pennsylvania

Consistent findings indicate that age-related decrements in aviator performance and decision making do occur. In this symposium, we describe some of these age-related differences, then present findings that demonstrate that flight expertise, cognitive ability, brain mechanisms, and genetics play a role in aviator performance and decision making and how they moderate or mediate these age-related differences. Dr. Tsang’s presentation will examine the interactive effects of age and time-sharing expertise on performance on tasks that pose cognitive demands similar to those of piloting among middle-aged (40–59 years) and older (60–70 years) pilots and nonpilots. Dr. Morrow will describe results showing that expert pilots make better decisions when collaborating than when alone, while novice pilots make worse decisions (collaborative inhibition), and how these results suggest the potential of collaboration for moderating age effects in pilot performance. Dr. Taylor’s overview of the longitudinal Stanford/VA Aviation Study will highlight findings on the influence of APOE e4 on age-related brain changes observed in this healthy cohort, the extent to which APOE e4 impacts skilled real-world performance as measured in flight simulation, and how fluid abilities can predict age-related decline in longitudinal flight simulator performance. Dr. Kennedy’s presentation will describe the roles of age, flight expertise, cognitive ability, and COMT status on simulated tasks of flight control and decision making. Dr. Adamson will review findings on the extent to which brain regions impact flight simulator performance in relation to aviation expertise, and age-related brain changes in aviator decision-making during a land/no land decision task.

AGE, EXPERTISE, AND SPEEDED DECISIONS IN MULTIPLE-TASK PERFORMANCE

P.S. Tsang, Psychology, Wright State University, Dayton, Ohio

The study examines the interactive effects of age and time-sharing expertise on multiple-task performance. A group of middle-aged subjects (40–59 years of age) and an older group (60–70 years of age) are
compared. To examine naturally developed time-sharing expertise that is inherent in piloting aircraft, half of the subjects are airplane pilots. Subjects simultaneously perform three tasks that pose cognitive demands similar to those of piloting: a continuous flight control task, a task that requires remembering two call signs, and a spatial collision decision task. In addition to examining subject’s control of their attention management, older subject’s ability to quickly issue collision decisions when encouraged to is examined. Results suggest that both older and middle-aged subjects could respond adaptively and strategically to varying task demands. In addition, older pilots exhibit smaller age effects than older nonpilots in several aspects of their performance.

EXPERTISE AND AGE DIFFERENCES IN PILOT DECISION MAKING
D. Morrow, University of Illinois at Champaign-Urbana, Champaign, Illinois

Decision making in complex domains such as aviation involves identifying problems and determining appropriate responses in the face of often ill-defined and dynamic conditions. While age-related changes in fluid mental abilities (e.g., working memory capacity) may impair decision making processes, experience-related gains in knowledge and skill may offset these declines to maintain performance in older pilots. In a previous study, older and younger expert and novice pilots read at their own pace scenarios describing flight situations, and then discussed the scenario problem and how they would respond. Experts in this study made better decisions than novices about the flight-related problems, in part by developing more accurate representations of the problem situation. There was some evidence that age differences in identifying problems were reduced for the experts. Because pilots often work together as a crew when flying, collaboration may be an important component of expertise. Therefore, we followed up this study by examining collaborative processes involved in pilot decision making. In this study, young expert pilots, novice pilots, and nonpilots read the scenarios from the first study and then performed the decision making task either alone or in pairs. The expert pilots made better decisions when collaborating than when performing alone, while novices and nonpilots made worse decisions when collaborating (collaborative inhibition). Collaborative benefits for expert pilots appeared to reflect better problem representations. We conclude by considering the potential of collaboration for mitigating the effects of age on decision making processes such as developing and using problem representations.

OVERVIEW OF LONGITUDINAL RESULTS FROM THE STANFORD/VA AVIATION STUDY
J.L. Taylor², Q. Kennedy², M.M. Adamson¹, G. Murphy¹, M.W. Weiner³, J. Yesavage¹,¹, 1. Stanford University, Stanford, California, 2. VA Palo Alto Health Care System, Palo Alto, California, 3. UCSF and SFVA Medical Center, San Francisco, California

Although APOE ε4 is a risk factor for dementia, lifestyle factors may moderate the impact of APOE ε4. In this overview of longitudinal results from the Stanford/VA Aviation Study, we will first summarize APOE ε4-related effects on measures of brain and neuropsychological function. Although APOE ε4 effects are evident in this cohort of healthy 40-70 year-old pilots, pilots with advanced training (expertise) did not show indications of an APOE ε4 effect on flight simulator performance. These results suggest that relevant training and activity may help sustain real-world performance. In addition to expertise, longitudinal simulator performance was predicted by cognitive ability measures. Faster processing speed (at baseline) predicted less decline in flight performance. However, faster speed was not advantageous unless executive function was also adequate (Speed × Executive Function interaction). In conclusion, these longitudinal data have implications for assessment and training interventions in other arenas of mobility such as driving.

INDIVIDUAL DIFFERENCE FACTORS IN FLIGHT CONTROL AND DECISION MAKING PERFORMANCE
Q. Kennedy², J.L. Taylor¹, J. Yesavage¹, A. Noda, M.M. Adamson¹, G. Murphy¹, J.M. Zeitzer², 1. Stanford University/ Palo Alto VA, Palo Alto, California, 2. Stanford University School of Medicine, Stanford, California

In two studies, we explored the roles of age, flight expertise (measured by FAA ratings), cognitive ability, and genetic factors on simulated tasks of flight control and decision making. In one study (n = 172), we investigated whether findings regarding COMT, a gene associated with executive performance, processing speed, and attention, extend to flight control. A COMT x expertise interaction was found for traffic avoidance, in which met/met carriers benefited from flight expertise to a greater extent than other participants. In a second study (n = 72), we explored aviators’ decision to land or not under weather conditions that varied in levels of fog. Regardless of flight expertise level, older pilots and those with faster processing speed were more likely to land when visibility was inadequate. Future directions include using eyetracking to determine if visual scan patterns at key points in the simulated flight provide greater insight into these results.

THE IMPACT OF AGE-RELATED BRAIN CHANGES ON FLIGHT SIMULATOR PERFORMANCE AND DECISION-MAKING
M.M. Adamson¹, D. Heraldez³, Q. Kennedy¹, J.L. Taylor¹, J. Yesavage¹, 1. Stanford University, Stanford, California, 2. VA Palo Alto Health Care System, Palo Alto, California

Age-related decline in cognitive abilities and brain structures, crucial for aircraft navigation and decision making, may lead older pilots to perform poorly in a flight simulator task and can also influence their decision-making abilities. Studies also report the compensatory role of expertise in cognitive decline. We previously reported an interaction of brain size with aviation expertise in predicting flight simulator performance. We also reported that older pilots were more likely than younger pilots to take risks during landing in bad weather. These findings led to our current study that evaluates the role of age-related changes in the decision-making network during performance of a real-world skilled task: a pilot’s crucial decision to land or not under difficult weather conditions. Understanding how older adults make crucial time-pressed real-world decisions, in relation to acquired expertise and age-related brain changes, have implications for their assessment of risk and safety in every-day life.

SESSION 2030 (PAPER)

CAREGIVING

DOES HAVING A SPOUSE WITH COGNITIVE IMPAIRMENT INCREASE YOUR OWN RISK OF DEATH?: THE HEALTH AND RETIREMENT STUDY
T. Okura¹, K. Langa¹, 1. Baykoon Clinic, Tokyo, Japan, 2. University of Michigan, Ann Arbor, Michigan

(Objectives) We hypothesized that, among older adults, having a spouse with cognitive impairment might increase one’s own risk of death due to chronic psychological stress and difficulty maintaining a healthy lifestyle associated with a high level of caregiving burden. (Methods) We identified 1,957 older married couples (both aged 65 or older) living in the community in the 2002 wave of the Health and Retirement Study (HRS). Level of cognitive impairment was characterized according to quartile of scores on the 35-point HRS cognitive scale (HRS-cog). We ascertained date of death from the follow-up surveys of the HRS. (Results) Older adults in the highest cognitive quartile (best cognitive function) whose spouses were in the lowest cognitive quartile were more likely to die, compared to individuals whose spouses were in the highest cognitive quartile during the 7-year study period, even
after controlling for demographics, cognitive function, and medical comorbidities (hazard ratio (HR), 1.73; 95% CI, 1.01-2.95). This association was not significant for individuals whose own cognitive function was not in the highest cognitive quartile (a lower level of cognitive function). (Conclusions) Among community-dwelling older adults with the highest level of cognition, having a spouse with significant cognitive impairment may increase the risk of death. Cognitive assessment of both partners in an older couple may be important to identify those at especially high risk for death and to better target interventions to prevent negative health outcomes.

EFFECTS OF CAREGIVING ON CAREGIVERS’ SELF-RATED CHANGE IN HEALTH: FINDINGS FROM THE REACH-II STUDY

Background Caregiving for a person with dementia is stressful and can strongly impact caregivers’ (CGs) overall health status. This study investigated the impact of the Resources for Enhancing Alzheimer’s Caregiver Health II (REACH II) intervention on CG’s self-rated change in health, controlling for both negative and positive caregiving experiences using the REACH II randomized clinical trial data. Method: The study included caregivers randomly assigned to intervention and control groups who had complete data at both Baseline and 6-month follow-up for the variables of interest (N=461). CG self-rated change in general health from baseline to 6-month follow-up, rated on a scale from 0 (“much better now”) to 4 (“much worse now”), was the outcome variable. Primary independent covariates in addition to demographic variables, included Zarit Burden, Memory and Behavior Problem Checklist (RMBPC), CES-D, and Positive Aspect of Caregiving (PAC). To measure the impact of the intervention, we included a treatment dummy variable (coded 1 for intervention group, and 0 for control group), a time dummy variable (0 for baseline, and 1 for follow-up), and an interaction term between treatment and time variables. Generalized linear model was used for the data analysis. Results Compared with the control group, caregivers in the intervention group were more likely to report an improvement in their self-rated health at follow-up (Odds Ratio [OR] = 20.69 with 95% CI: 1.35 to 276.44). Change in the two burden variables, CES-D, and PAC scores were not associated with improvements in CG’s self-rated change in health. The intervention’s significant impact on CG’s self-rated change in health was associated with greater than high school education. Conclusion Although the multisite REACH II intervention did improve caregiver’s self-rated change health, this improvement was not impacted by changes in positive or negative experiences reported by the caregivers. Rather, education seems to play a significant role in CG’s self-rated change in health.

CORTISOL, ESTROGEN, AND COGNITION IN ELDERLY FEMALE CAREGIVERS AND NON-CAREGIVERS

B.B. Sherwin, S. Jitter, Psychology, McGill University, Montreal, Quebec, Canada

This cross-sectional study examined the cortisol awakening response (CAR), acute cortisol levels, estrogen use, and cognitive function in healthy, 69-year-old female caregivers (n=15) and in a group of non-caregivers (n=15) matched for age, education, socioeconomic status, and exposure to estrogen therapy (ET). It was hypothesized that (1) caregivers would have an elevated CAR and poorer performance on cognitive tests compared to the matched non-caregivers and (2) that the current estrogen-users (E-users) and women who had ever taken ET (Ever-users) would perform better on tests of verbal and working memory than women who had never taken ET after the menopause (Never-users). There were no significant differences in the CAR between groups. However, caregivers’ scores were significantly higher than those of the non-caregivers on tests of verbal and working memory (p=.034), Digit Span total standard score (p=.035) and on spatial memory (p=.018), Spatial Span total standard score (p=.01), and Block Design test (p=.034). When the groups were collapsed, the E-users and Never-users performed significantly better on tests of working memory compared to the Never-users (p=.02). In this sample therefore, physiological stress responses were not different for the high-functioning, well-educated group of caregivers. However, our hypothesis that women who had ever taken ET after their menopause would perform better on tests of verbal and working memory was supported.

ENHANCING RESOURCEFUL SKILLS ON CAREGIVER’S RESOURCEFULNESS, ANXIETY, DEPRESSION AND PREPAREDNESS

E.W. Gonzalez, C.F. Lippa, M. Polansky, I.Q. healthcare, Radboud University Medical Centre, Nijmegen, Netherlands, 2. Bradford Dementia Group, Bradford, United Kingdom, 3. Fiennes Centre, Oxford, United Kingdom

Purpose: This study examined the effects of enhancing resourceful skills on caregiver resourcefulness, anxiety, depression, and preparedness while caring for people with dementia. Theoretical rationale: Enhancing resourceful skills in family caregivers is postulated to enable caregivers to achieve goals by self-regulation of negative emotions, apply problem-solving skills, cognitively reframe the caregiving issues and maintain confidence to function at an optimal level. Methodology: A stratified randomized clinical trial (ethnicity and resourcefulness level) was used to compare the effectiveness of enhancing resourceful skills versus the standard care in 105 family caregivers. Outcomes were measured at baseline, 6 weeks and 3 months post-intervention. Resourcefulness was measured using Rosenbaum’s (1982) Self-Control Scale. Depression was measured using the CES-D (1977) CEDS. Anxiety was measured using the State-Trait Anxiety Inventory – State subscale (Spieberger et al., 1982). Caregiver preparedness was measured using Preparedness for Caregiving Scale (Archbold et al., 1990). Results: The ANCOVA analysis showed that after controlling for baseline resourcefulness, family caregivers who received the intervention demonstrated a higher resourcefulness immediately post-intervention (6 weeks) F(1,99) = 15.74, p<.001 compared to those in the control group. Additionally, after controlling for baseline anxiety, depression, and preparedness there was a significant difference between the groups immediately after the intervention (6 weeks) for anxiety F(1,99)=6.86, p<.01, but not for depression F(1,99)=21.21, p=.005, or preparedness F(1,99)=32.32. At 3 months follow-up, no significant differences were noted between groups in resourcefulness, anxiety, depression, and preparedness. However, anxiety in the intervention group decreased (mean= 35; SD=11.5) while those in the control (mean= 40.4; SD=11.7) group increased.

COGNITIVE REFRAMING FOR CARERS OF PEOPLE WITH DEMENTIA

M. Vervoort, M. Downs, J. McCleery, Draskovic, 1. I.Q.healthcare, Radboud University Medical Centre, Nijmegen, Netherlands, 2. Bradford Dementia Group, Bradford, United Kingdom, 3. Fiennes Centre, Oxford, United Kingdom

Background Multi-component tailor made interventions appear to be the most effective psychosocial interventions for carers of people with dementia. These interventions involve multiple working mechanisms. In order to narrow down the number of possible working mechanisms the aim of this study was to evaluate the effectiveness of cognitive reframing interventions with carers of people with dementia. Cognitive reframing refers to reframing of self-defeating or distressing cognitions into those that reduce stress and support adaptive behaviours. Methods The trials were identified by searching the Specialized Register of the Cochrane Dementia and Cognitive Improvement Group on
Regional anesthesia is associated with decreased inpatient mortality after hip fracture surgery in older adults

Background: Hip fracture is a common, morbid, and costly event among older adults, occurring 340,000 times each year in the U.S. Available data are inconclusive regarding the potential for epidural or spinal (regional) anesthesia to improve outcomes after hip fracture. Methods: We examined data on discharges from general acute-care hospitals in New York between January 1 and December 31, 2007. Patients undergoing hip fracture surgery were identified by ICD-9-CM diagnosis and procedure codes. Use of regional anesthesia was determined by variables indicating anesthesia type included in the study database. We used logistic regression to test the association of anesthesia type with mortality, controlling for age, sex, fracture characteristics, surgery type, race, and comorbidities, and carried out separate conditional logistic models to control for individual hospital effects. Results: Of 9,982 patients undergoing treatment for hip fracture, 70.7% received general anesthesia. Compared to patients receiving general anesthesia, those receiving regional anesthesia were older, more often had chronic obstructive pulmonary disease or dementia, and less frequently had diabetes, pathological fracture, or a history of malignancy. Unadjusted analyses showed no mortality differences according to anesthesia type (1.9% (regional) vs. 2.5% (general), p=0.069). However, regional anesthesia was associated with a lower odds of inpatient mortality after adjustment for patient-level confounders (OR 0.724, 95% CI 0.527–0.996, p=0.047) and hospital effects (OR 0.602, 95% CI 0.407–0.892, p=0.011). Conclusions: Regional anesthesia was associated with a 28% lower adjusted odds of inpatient mortality after hip fracture relative to general anesthesia.

Hip Fracture Recovery

Regional Anesthesia is Associated with Decreased Inpatient Mortality After Hip Fracture Surgery in Older Adults

L.A. Beaupre1,2, A. Jones3, D.C. Johnston4, D.M. Wilson4, S.R. Majumdar3, 1. Physical Therapy, University of Alberta, Edmonton, Alberta, Canada, 2. Department of Surgery, University of Alberta, Edmonton, Alberta, Canada, 3. Department of Medicine, University of Alberta, Edmonton, Alberta, Canada, 4. Faculty of Nursing, University of Alberta, Edmonton, Alberta, Canada

Purpose: Little is known about recovery after hip fracture in those admitted from nursing homes. Our purpose was to examine function and mortality following hip fracture in nursing home patients. Methods: Nursing home subjects who were ambulatory before hip fracture were consecutively enrolled in a prospective cohort study. Pre-fracture function and comorbidities were obtained via patient/proxy interviews. Cognitive status was measured using the Mini-Mental State Examination. Functional status was re-assessed at 3- and 6-months using the Functional Independence measure (FIM). All-cause mortality was determined at 6-months. Results: Of 91 eligible subjects, 61(67%) were enrolled. The average age was 86.7[SD 8.1], 42(69%) were female, and 44(73%) had three or more comorbidities at time of fracture. Most subjects (85%) had moderate-to-severe cognitive impairment. By 6-months, 20(33%) subjects had died. All patients were ambulatory prior to fracture and most (46(75%) walked without assistance. By 6-months post-fracture, only 7/33(21%) were walking without assistance and 16/33(48%) were no longer ambulatory. The average pre-fracture functional status according to the FIM was low pre-fracture (47.5[18.2]) and dropped substantially and significantly post-fracture (3-months (27.3[17.7]; p<0.001 for difference from baseline) and 6-months (30.2[18.5]; p<0.001 from baseline). Discussion: One-third of patients who are admitted from nursing homes with hip fracture and survive to hospital discharge are dead within 6-months. Among those who survive to 6-months, 48% are no longer ambulatory and the remainder have a very marked loss of function. Recovery may be improved with better

Functioning Status and Mortality in Nursing Home Patients After Hip Fracture: A Prospective Cohort Study

The Gerontological Society of America
attention to post-discharge rehabilitation, although this hypothesis has not been formally tested.

THE ASSOCIATION BETWEEN BODY MASS INDEX, WEIGHT LOSS AND PHYSICAL FUNCTION FOLLOWING HIP FRACTURE

L. Reider1, W. Hawkes2, J.R. Hebel3, C. D’Adamo4, R.R. Miller1, D. Orwig1, J. Magazine1, D. Alley1. 1. University of Maryland, Baltimore and Baltimore County, Doctoral Program in Gerontology, Baltimore, Maryland, 2. Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland, 3. University of Maryland School of Medicine, Department of Epidemiology and Public Health, Baltimore, Maryland, 4. University of Maryland School of Medicine, Department of Family and Community Medicine, Baltimore, Maryland

Little is known about the relationship between body mass index (BMI) and physical function after hospitalization for an acute event. The purpose of this study was to determine whether BMI at the time of hospitalization for hip fracture or weight change in the period immediately following hospitalization (3-10 days) predict physical function in the year after fracture in older women (n=136). Mixed effects models were used to examine the associations between BMI, weight change, and physical function, measured using the lower extremity gain scale (LEGS), walking speed and grip strength at 2, 6 and 12 months following fracture. LEGS score and walking speed trajectories did not differ across BMI tertiles. However, grip strength trajectories were significantly different (p<0.029), with underweight women having lower grip strength than normal weight women at all three time points. Women experiencing severe weight loss (>4.8%) had significantly lower LEGS score at all time points, slower walking speed at 2 and 6 months, and weaker grip strength at 12 months post-fracture relative to women with more modest weight loss. After controlling for potential confounders, overall differences in functional trajectories were not significant, but differences at 12 months post-fracture remained significant. Underweight women were weaker than normal weight women (-2.8 kg, p=0.049), and women with severe weight loss had an average grip strength 9.8 kg lower than in women with modest weight loss (p=0.003). Results suggest that weight loss after fracture is associated with weakness during hip fracture recovery and is a stronger predictor of strength than BMI.

PROGNOSTIC VALUE OF HANDGRIp STRENGTH IN OLDER PATIENTS HOSPITALIZED FOR HIP FRACTURE SURGERY

E. Savino1, S. Volpato1, I. Pedriali2, A. Zagatti2, G. Zuliani1, A. Zarco1. 1. University of Ferrara, Ferrara, Italy, 2. S. Anna Hospital, Ferrara, Italy

Background: Handgrip strength, an objective measure of physical function, can be assessed in a supine position, representing a potential prognostic tool for bedridden older patients. Objectives: We investigate the value of grip strength as predictor of length of hospital stay (LOS) and risk of death in the year following hospitalization for hip fracture surgery. Methods: Prospective cohort study of 209 patients aged 70 years and older admitted to the hospital for hip fracture. Multidimensional geriatric evaluation and handgrip strength were assessed at hospital admission, before surgical intervention, and patients were evaluated after surgical treatment every 3 months for 1 year by telephone interviews to assess vital and functional status. Results: The mean age was 85.4 years, 82% were women; before hospital admission 46% had BADL difficulty, mean handgrip strength was greater in men (β: 6.8±1.20, p<0.001). There was a direct relationship of grip strength with cognitive function (SPMSQ p<0.001) and ADL difficulty (p<0.001), whereas we found an inverse correlation with age (p<0.001), depressive symptoms (GDS score, p=0.004), Charlson Index (p=0.060), and C-reactive protein (p=0.022). In multiple regression analysis, after adjustment for confounders including age, gender, comorbidity, functional and cognitive status and APACHE II severity of illness score, higher grip strength was associated with shorter LOS (β -0.46; p=0.008) and reduced risk of death over the follow-up (HR 0.93; 95% CI 0.88-0.98). Conclusions: Grip strength evaluation before hip fracture surgery might provide important information for patients risk stratification and long term prognosis.

RESEARCH METHODS

BAYESIAN JOINT MODELING OF LONGITUDINAL, ORDINAL DATA AND INTERVAL-CENSORED SURVIVAL TIMES

T.E. Murphy, L. Han, H. Allore, P. Peduzzi, T.M. Gill, H. Lin, Yale University School of Medicine, New Haven, Connecticut

Analyses of longitudinal studies of gerontological outcomes must account for dependence with death as well as the changing nature of the cohort. Most joint modeling work involves the use of linked random effects between the longitudinal and survival models, i.e., the sub-models, and is recommended to reduce bias. While the literature has recently expanded to include investigations employing binary and count outcomes, there is little history of joint modeling based on ordinal outcomes. In this article Bayesian joint modeling of a longitudinal, ordinal outcome and interval-censored survival times is explored. The estimated regression coefficients of important covariates yielded by sub-models based on both fixed and random effects will be compared to those yielded by a joint model formulation with a common set of random effects. Results show the relative contributions of the random effects, both with and without the joint modeling paradigm. All modeling is demonstrated using longitudinal and survival data from the Precipitating Events Project using OpenBUGS software.

MODELING LONGITUDINAL FUNCTIONAL DISABILITY IN PRESENCE OF DEATH

Y. Li, H. Allore, H. Lin, Yale University, New Haven, Connecticut

Longitudinal aging research typically has both missing data and death. Previous research has shown that it is important to distinguish whether data truncated by non-ignorable reason, such as death, in the analysis because this informative truncation may be highly correlated with the longitudinal response. To address this we modeled the joint probability of longitudinal functional disability (as measured by Activities of Daily Living, ADL) and survival. Disability was a multinomial response with levels Non-disabled, Mild (1-2 disabled ADLs), Severe [3-4 disabled ADLs]. This differs from modeling the probability having a disability level based on surviving subjects in partly conditional model (such as in Kurland and Heagerty, 2005). Our method allows inferences using all subjects and estimates the probability of being alive at one disability level on given covariates. This inference translates to estimating the probability that an elder can survive beyond age 80 and be non-disabled rather than the probability that an elder is non-disabled if they survive beyond age 80. An extended marginalized random effect model with estimating equations is presented that uses the longitudinal multinomial response in presence of death. We apply this new method using 9 years of the Precipitating Event Project data with fixed covariate sex, and time-dependent covariates age, physical frailty, depressive symptoms, cognitive impairment, number of chronic conditions. We present the results of scenarios of stable non-disability, worsening disability and recovery of functional disability for age, physical frailty, depressive symptoms, cognitive impairment, number of chronic conditions. Simulation models results are presented as a validation.
IMPACT OF MISSING DATA ON ANALYSIS OF POSTOPERATIVE COGNITIVE DECLINE (POCD)  

S. DeCrane, L.P. Sands, K.M. Young, *Purdue University, West Lafayette, Indiana*  

Background: Missing data can lead to biased results when the ‘reasons for missingness’ are associated with the outcome of interest. Missing data are common when assessing patients for early POCD, but prior research has not described the extent to which missing data bias estimates of POCD. Method: Missing data from neurocognitive tests (Word List, Verbal Fluency, and Digit Symbol) of 439 postoperative patients were coded for ‘reason for missingness’ using adjectives including ‘confused,’ ‘incapable,’ ‘stuporous,’ ‘comatose.’ Those adjectives that indicated the patient was incapable were used to rescore patients’ neurocognitive test performance from ‘missing’ to ‘zero.’ Determination of significant change from pre-operative to post-operative test performance the first and second day after surgery was determined for each test. Results: Using imputed data, the change in diagnosis of patients with POCD from Preoperative to Day 1 of the study increased using Word List (38% to 51%), Verbal Fluency (34% to 51%), and Digit Symbol (58% to 79%). The change in diagnosis of patients with POCD from Preoperative to Day 2 also increased using Word List (31% to 46%), Verbal Fluency (27% to 44%), and Digit Symbol (55% to 75%). Conclusion: Imputing scores of zero for incapable patients in neurocognitive testing may provide a reasonable solution for reducing bias in estimates of POCD.

BIAS FROM PROXY RESPONDENTS IN AGING RESEARCH: EPIDEMIOLOGICAL AND ANALYTICAL SOLUTIONS  

M. Shardell1, R.R. Miller1, G. Hicks2, D. Alley3, J. Magaziner1, J. University of Maryland School of Medicine, Baltimore, Maryland, 2. University of Delaware, Newark, Delaware  

Epidemiological studies of older adults often include participant self-assessment on subjective constructs such as perceived disability. In some studies, when participants are unable or unwilling to provide self-reports, proxies (e.g. relatives or other care givers) are recruited to provide reports in place of the study participant. Proxies are usually not approached to provide reports for study participants who respond for themselves; thus, for each study participant, data from only one of the study participant or proxy are collected. Typically, proxy reports are simply substituted for missing study participant self-reports, and standard complete-data statistical analyses are performed. However, this approach may introduce bias and produce incorrect results. Although the purpose of including proxies is to solve the problem of missing participant data by improving generalizability, statistical methods for incomplete data have not been used with proxy data. Also, some studies recruit validation proxies (proxies for study participants who do provide self-reports) to quantify proxy-participant agreement, but validation proxies have not been leveraged in statistical analyses as a bias reduction tool. The objectives of this talk are to show session participants how to correct for bias from proxy responses by 1) adapting multiple imputation (a method originally designed to address missing data) to handle proxy data and 2) using data from validation proxies in statistical analyses. A cohort study of elderly hip-fracture patients is used to motivate and exemplify the methods.

RECOGNIZING DIVERSITY IN PATIENT POPULATIONS: A K-MEANS CLUSTER ANALYSIS OF REHABILITATION SERVICE USERS WITHIN THE HOMECARE SECTOR OF ONTARIO  

J.J. Armstrong, M. Zhu, J. Hirdes, P. Stolee, *Health Studies and Gerontology, University of Waterloo, Waterloo, Ontario, Canada*  

BACKGROUND: The home health care system in Ontario provides rehabilitation therapies (physical therapy and occupational therapy) to a large number of older adults, yet little is known about the existing patterns of individual differences that can be found within this patient population. Researchers and policy makers have long recognized that home care populations are heterogeneous, yet little research has focused on this diversity. As the number of older home care clients receiving rehabilitation services is steadily increasing, it is important that we develop an improved understanding of these elderly patients in order to effectively and efficiently deliver home health care services to them. The development of such knowledge is possible through the use of data mining techniques in the available health assessment data. METHODS: Clinical assessment data was collected on 150,253 homecare clients in Ontario using the provincially mandated RAI-HC data system. A K-means cluster analysis was performed using 37 variables (i.e. disease diagnoses, functional abilities) from their initial home care assessment. RESULTS: The K-means cluster analysis resulted in identifying seven homogeneous subgroups that differed significantly in a variety of ways. Patient profiles were created to illustrate the diversity of this population. Results from predictive analyses on 1 year post-assessment outcomes further emphasize the importance of recognizing heterogeneity within this patient population. CONCLUSION: Our findings support the view that rehabilitation users in home care are a heterogeneous population that can be broken down into homogeneous subgroups based upon baseline assessment data. These findings are exploratory and require further validation.

SESSION 2045 (SYMPOSIUM)  

DIMENSIONS OF HEALTH AND AGING IN ASIA  

Chair: S. Vasunilashorn, Population Studies, Princeton University, Princeton, New Jersey  
Co-Chair: E. Crimmins, University of Southern California, Los Angeles, California  
Discussant: J. Lee, RAND Corporation, Santa Monica, California  

Population aging is quickly becoming a global phenomenon. Nowhere in the world is this demographic transition more pronounced than in Asia. By historical standards, an unprecedented increase in the number of older adults is projected to occur over the next fifty years, with an expectation that Asia will become the oldest region worldwide. This rapid demographic transition is met with a dramatic economic transformation in several parts of Asia. These rapid demographic, economic, and social changes will undoubtedly influence the health and well-being of the older adult population. This underscores the importance of evaluating the determinants and correlates of health and the aging process in Asia. Since health is influenced by a multitude of factors ranging from social, psychological, physical, and environmental circumstances, this symposium will address some of these influences in determining the state of health among older adults residing in several rapidly aging countries across Asia. Cross-sectional and longitudinal methods will be employed to examine trends, transitions, and determinants of health in China, Singapore, and Taiwan. At the end of the session, participants will be able to describe the state of health and define the trends in functioning among older adult populations of Asian descent.

PERCEIVED STRESS AND MORTALITY IN A TAIWANESE OLDER ADULT POPULATION  

Perceived stress has been documented as being associated with a number of outcomes, including negative affect, increased susceptibility to the common cold, and cardiovascular disease; however, the consequences of perceived stress on mortality have received much less attention. This study characterizes the relationship between a summary measure of perceived stress and 8-year mortality in a population of Taiwanese adults age 54+. We calculated a composite measure based...
on 8 items pertaining to the health, financial situation, and occupational stress of the respondents and their families. Proportional hazards models are used to determine whether the perceived stress summary measure predicts mortality. Preliminary results suggest that perceptions of stress contribute to differences in survival among older adults: the perceived stress score is positively associated with the probability of dying during the 8-year follow-up period, even when the score excludes questions pertaining to the respondent's own health.

**DIVERSITY IN AGING: WHAT WE CAN LEARN FROM THE CHINESE HEALTH AND RETIREMENT STUDY (CHARLS) ABOUT CHANGING PATHS TO AGING**

E. Crimmins, L. Zhang, J. Kim, University of Southern California, Los Angeles, California

CHARLS is a new nationally representative study of aging in China. It allows us to gain insight into variability in aging in a country undergoing dramatic social, economic, and demographic change. We examine how life style and health differ across persons in rural and urban divisions of richer and poorer states to suggest how modernization changes behavior, physiology and mental well-being for older persons. Overall we find very high levels of hypertension and raised cholesterol in the sample; with urban dwellers and women having more hypertension and raised cholesterol. Obesity is related to higher levels of both hypertension and cholesterol. On the other hand, higher education appears to be related to somewhat lower levels of these markers. Life style changes related to modernization, change the path of aging.

**TRENDS IN DISABILITY RATES AMONG OLDER ADULTS IN BEIJING CHINA OVER A SEVENTEEN YEAR PERIOD**

Z. Zimmer1, X. Fang2, Z. Tang2,1, University of Utah, Salt Lake City, Utah, 2. Beijing Xuanwu Hospital, Beijing, China

While studies in the United States point to a decline in long-term disability rates among elders, evidence in Asia is weaker and contradictory. Recent examples from Indonesia, Japan, Philippines, Korea and Taiwan indicate everything from increases to decreases plus little change in disability, and most of these studies include few data points and span a short time period. This study uses a unique dataset from Beijing (the BMLSA) with eight observation points over seventeen years (1992 to 2009). The study design includes a panel follow-up survey plus an add-on sample at four points in time. Measures of disability were collected at each data point, allowing for one of the longest term analyses of disability rates among older adults yet undertaken. The current study will monitor population trends in disability over the BMLSA’s seventeen years and determine whether changes have been a function of transformation in individual socio-economic characteristics.

**ASSOCIATION BETWEEN HANDGRIP STRENGTH AND MORTALITY AMONG ELDERLY IN SINGAPORE**

Y. Saito1, V. Yong1, A. Chan1,3,1, Nihon University, Tokyo, Japan, 2. National University of Singapore, Singapore, Singapore, 3. Duke-NUS Graduate Medical School, Singapore, Singapore

Handgrip strength, a proxy measure of overall muscular strength, has been found to be a good predictor of all-cause mortality among the elderly in several countries. In this study, we used longitudinal data from the Social Isolation, Health and Lifestyles Survey (SHLSS) in Singapore (2009-2011) to examine the association between handgrip strength and mortality of Singaporeans aged 60+ (N=5,000). Measurements of handgrip strength at baseline were taken twice alternatively from the subjects’ right and left hand. Almost 90% of the sample provided measurements. Mortality data were collected at follow-up (data pending). The majority of the subjects (85%) normally use their right hand. Preliminary analysis showed that mean maximum handgrip strength for males is 28.7kg (SD=6.8) and for females 16.6kg (SD=4.8). It is 22.0kg (SD=9.1), 22.2kg (SD=6.0), 21.8kg (SD=5.9), 23.0kg (SD=10.4) for Chinese, Malays, Indians, and Others, respectively. There is significant difference between sex but no significant difference among ethnic groups.

**SESSION 2050 (SYMPOSIUM)**

**GETTING OUT AND STAYING OUT: VA DEMONSTRATION PROJECTS TO PREVENT HOSPITAL READMISSION**

Chair: J.L. Rudolph, Geriatric Research, Education, and Clinical Center, VA Boston Healthcare System, Boston, Massachusetts, Harvard Medical School, Boston, Massachusetts

Discussant: J.L. Rudolph, Geriatric Research, Education, and Clinical Center, VA Boston Healthcare System, Boston, Massachusetts

Discharge from the hospital is a critical time in the function of older patients, because the burden of illness, decreased function, and increased care requirements transition to the patient and caregiver. As a result, this transition is critical to prevent readmission and ultimately, preserve independent function. Because the process of transition has many steps, there are multiple targets for improvement in the process of transition from the hospital can reduce the readmission rate, allowing the healing process to occur in a patient’s environment. This symposium will describe five VA clinical quality improvement projects that are targeting different aspects of the transition process. The first project targets patients with cognitive impairment who are discharged home and intervenes with pharmacist telephone medication reconciliation and clinic assessment. The second project uses at-home educational coaches for patients and caregivers to improve outcomes. The third presentation describes a caregiver assessment and education project for patients with cognitive impairment who are discharged home. The fourth project intervenes with home-based transitional care visits by a kinesiotherapist and nurse team to reinforce discharge plan and home safety to prevent readmission. The fifth project targets older patients discharged from a rehabilitation unit with a post discharge clinic model to improve adherence and prevent readmission. Each of these programs reduces readmissions and represents different models that learners might develop at their own institutions. As payment reform places more emphasis on readmission as a negative health event, the financial value of these programs could become viable for more healthcare systems.

**PILL CLINIC: A POST-DISCHARGE MEDICATION SERVICE FOR OLDER VETERANS**

A.M. Paquin1,2, J.L. Rudolph1, N. Quinlan1, M. Salow1,2,1, Geriatric Research Education and Clinical Center (GRECC), VA Boston Healthcare System, Boston, Massachusetts, 2. Department of Pharmacy, VA Boston Healthcare System, Boston, Massachusetts

The Pharmacological Intervention in Late Life (PILL) clinic is a quality improvement project developed to address medication complexity, inappropriate prescribing, and patient education in cognitively impaired elders upon discharge from the hospital. This transition is a critical time complicated by numerous medicines, toxicities, regimen changes, and discrepancies. The goal of PILL is to keep patients functioning longer at home after a hospitalization by use of telephone follow-up and expansion of our collaborative pharmacist-pharmacist medication clinic. Patients ≥65 years old with evidence of cognitive impairment who were discharged home were called by a pharmacist who performed medication review and reconciliation. In cases of severe difficulty, an in-person PILL clinic visit was scheduled. The primary outcome for this project is acute care visits (i.e. urgent care, admissions) during 60 days post-hospitalization. Additionally, information about medication adherence, discrepancies, and adverse drug effects was collected. The PILL clinic appears to reduce acute care visits.
WASHINGTON DC VAMC TRANSITIONAL COACHING
Catholic University, Washington, District of Columbia

Hospitalization represents a critical time for older patients with serious, chronic illnesses. The objective of this program was to improve utilization outcomes in these chronically ill patients. Two nurse practitioners, titled “Transitional Coaches” (TC), joined the Geriatrics Clinic Team to provide short-term, home-based, intensive case management, comprehensive assessment, education, collaborative care planning, and identification of resources for care. In addition to improving patient satisfaction, the TC program sought to improve medication adherence and cost, reduce utilization of emergency department and readmission, and improve advanced care planning. The TC program found increased patient satisfaction and improved medication adherence. The impact of the TC program on utilization is pending. Person-centered education about how to access existing resources may be among the most important aspects of this intervention. Thus, TC has the promise of improving the ability of patients and their families to more successfully cope with serious chronic illness.

COMING HOME FROM THE HOSPITAL: SUPPORT FOR VETERANS WITH COGNITIVE IMPAIRMENT
E. Archambault, J. Hill, K. Lawrence, B. Kelly, L.J. Rudolph, Geriatric Research, Education, and Clinical Center, VA Boston Healthcare System, Boston, Massachusetts

When veterans return home from the hospital, they and their caregiver face challenges to remain independent while recovering from the acute illness leading to hospitalization. Because of cognitive impairment, these veterans and their caregivers may need alternate education to preserve independence. The “Coming Home Project” provides support to veterans with cognitive impairment and their caregivers after a hospitalization. The three step process includes: 1) Identification of inpatient veterans with cognitive impairment; 2) Administration of a standardized brief social functioning assessment conducted with the patient and caregiver that is documented in the medical record pre-discharge; and 3) Distribution of caregiver educational materials. The goals of the project were to improve caregiving abilities as measured by reduced 60-day acute care and readmission rates. This presentation will detail the highly requested caregiving materials, the patient and caregiver disparity in social functioning, and the impact of the program on clinical outcomes.

HOME BASED TRANSITIONAL CARE PROGRAM: THE TAMPA VA PATIENT CENTERED SOLUTION FOR FRAIL ELDERLY READMISSIONS
D.M. Davis, K. Keys, S. Arondel De Hayes, E.I. Sanchez, A. Black, Geriatrics and Extended Care, James A. Haley VA, Tampa, Florida

Hospital readmissions in this population may be reduced by home visits. The Home-Based Transitional Care Program (HBTCP) was developed to support frail elders during the first 28 days after a hospitalization. Upon referral, HBTCP provides an in-home visit by a nurse and kinesiotherapist within 4 days of discharge from an inpatient setting. At the home visit, the nurse addresses medication adherence, reinforces the discharge plan, and identifies clinical needs. The kinesiotherapist provides a home safety evaluation assessing the environment, fall risk, and functional status. They work in coordination with the hospital and primary care teams to ensure the patient’s medical care needs are met. HBTCP found a high need for equipment (100%), supplies (22%), new services (17%), and medications (25%). HBTCP reduced 14-day readmissions by 57% and 30-day readmissions by 38%. HBTCP with a nurse and kinesiotherapist team, focused on care coordination and safety may reduce hospital readmissions.

BRIDGING THE GAP THROUGH POST-DISCHARGE CLINIC
H.C. Park, J. James A Haley Tampa VA Hospital, Tampa, Florida

To provide comprehensive care coordination for veterans transitioning from skilled nursing facilities (SNF) to VA primary care, a post discharge clinic (PDC) was developed. Prior to implementation of PDC, care coordination was fragmented with urgent care clinic, social work, home care, and primary care each coordinating a piece. The PDC targets veterans discharged from post-hospitalization SNF care to independent living settings such as home or assisted living facilities. This clinic seeks to bridge the gap between the SNF and VA primary care. The program has 4 key components a) medication reconciliation, including timely provision of medications, medical supplies, and durable medical equipment, b) care coordination for home health services, c) patient education, and d) coordination of follow-up appointments. The outcomes are measured with 30-day emergency/urgent care utilization and VA readmission. The outcomes are compared to data from SNF discharges prior to implementation of PDC.

SESSION 2055 (SYMPOSIUM)

PHYSICAL ACTIVITY AS A BUFFER AGAINST ADVERSE OUTCOMES IN OLDER ADULTS: ANALYTIC SOLUTIONS
Chair: K. Bandeen-Roche, Biostatistics, Johns Hopkins University, Baltimore, Maryland
Discussant: M. Glymour, Harvard University, Boston, Massachusetts

Physical activity is a basic, and modifiable, behavior that evidences salutary effects on multiple aspects of the human organism. As such, it may be a potent buffer against frailty and disability in older adults. Learning whether it is, and identifying factors that promote it, are challenged by considerable methodological challenges including measurement, time-dependent confounding, and feedback relations. This session addresses these. A first presentation proposes a latent-class based method for defining trajectories of persons’ self-reported physical activity engagement over time and evaluates its utility for predicting mortality. The method envisages subpopulations of older adults with similar longitudinal activity patterns. A second presentation employs marginal structural models (MSM) to evaluate the effect of pain on self-reported levels of physical activity. MSMs aim to acknowledge that restricted physical activity may affect pain as well as account for time-dependent confounders and so approximate a causal inference comparing physical activity engagement for potentials of being pain-free, versus in pain, throughout the time period. A third presentation evaluates a potential feed-forward relationship in which physical activity and energy are hypothesized to be mutually enhancing (or antagonizing). The session concludes with discussion. It advances discovery as to the relationship of physical activity to pain and energy. More broadly it highlights methodologies available to address complexities of studying effects of elective behaviors on health outcomes thus aims to improve the associated science.

FEED-FORWARD LOOP BETWEEN ENERGY LEVEL AND PHYSICAL ACTIVITY
A. RoyChoudhury1, Q. Xue1, L.P. Fried1, R. Varadhan2, 1. Biostatistics, Columbia University, New York, New York, 2. Johns Hopkins University, Baltimore, Maryland

A feed-forward relation may exist between energy level and physical activity in older adults. Physical activity is known to increase muscle mass, muscle strength and efficiency in biological systems, which boost energy level and makes it possible to heighten physical activity. Here we present statistical evidence for feed-forward relation between energy level and physical activity measures in older women. As the energy level measure, we used self reported energy level (1-10) by the subjects. As the physical activity measures, we used observations such
as hours of physical activity per week, energy (kcal) spent per week, and also some standard measures such as HABC, CDC/ACSM criteria. We categorized the feed-forward relations as strong and weak. We found evidence for strong relation with HABC exercise and lifestyle measures, and evidence for week relation with Kcal/Wk, Frailty, Mins. of activity/Wk, Kcal/Day-Kg, CDC/ACSM and NHIS tertile measures.

TRAJECTORIES OF CHANGE IN PHYSICAL ACTIVITY AND ALL-CAUSE MORTALITY: THE WOMEN'S HEALTH AND AGING STUDY (WHAS) II

Q. Xue1, K. Bandeen-Roche1, T. Mielcz2, W. Yao3, R. Varadhan3, P.H. Chaves4, L.P. Fried5, I. Medicine, Johns Hopkins University, Baltimore, Maryland, 2. Columbia University, New York, New York

The benefits of physical activity (PA) for older adults are evident. However, interventions designed to achieve the recommended levels of PA have met limited success. We hypothesize that the ability to maintain some level of moderate PA over time, even if below the recommended levels, is associated with lower risk of adverse outcomes. Using 10-year follow-up data from WHAS II, we identified four distinct PA trajectories based on latent class analysis: (1) always active (16.5%), (2) always moderately active (32.8%), (3) fast declining (19.7%), (4) always sedentary (31.0%). While there was a step-wise increase in mortality risk from the always active to the always sedentary with the fast decliners having immediate risk (p<0.05), there was no meaningful survival advantage for being always active compared to being moderately active (p=0.56). These findings suggest that suboptimal but persistent moderate level of activities may be a realistic target for older women to adopt.

DO PAIN LEVELS HAVE A DIRECT CAUSAL EFFECT ON PHYSICAL INACTIVITY WITHOUT MEDIATION BY FUNCTION?

T. Mielcz1, J. Tian2, K.J. Alvarez3, K. Ornstein1, J.M. Guralnik1, L.P. Fried1, K. Bandeen-Roche1, Q. Xue1, I. Epidemiology, Columbia University Mailman School of Public Health, New York, New York, 2. Johns Hopkins University, Baltimore, Maryland, 3. University of Maryland School of Medicine, Baltimore, Maryland

Literature suggests widespread pain is independent of the pathway to disability via physical impairments. We assessed whether levels of pain have a direct causal effect on physical inactivity in WHAS II participants in pathways not mediated by time-dependent confounding. Over a 7.5-year period, we applied weighted analysis of pooled multinomial logistic regression of three physical activity categories (sedentary, moderately active and very active) from the National Health Interview Survey on four levels of pain (widespread, moderate lower extremity, other and none/mild). We adjusted for one time-dependent confounder (short physical performance battery) and time-independent confounders (depression, comorbidities and demographics). Compared to women with no reported pain, women with widespread pain had 1.9 times the odds of being inactive vs. very active (p=0.12) and 2.6 times the odds of being inactive vs. moderate active (p=0.06). The current study suggests that pain, especially widespread pain, may have a direct effect on physical inactivity.

SESSION 2060 (SYMPOSIUM)

SOLVING MYSTERIES ABOUT REPEATED ED USE IN OLDER ADULTS

Chair: J. Mentes, University of California Los Angeles, Center for the Advancement of Gerontological Nursing, Los Angeles, California
Discussant: E.R. Beattie, Queensland University of Technology, Brisbane, Queensland, Australia

Older adults are more frequent users of emergency department (ED) services, with oldest adults, those 75 years and older, accounting for the greatest number of visits (62 vs 39 per 100 persons over-all) according to the 2007 Emergency Room Summary of the National Hospital Ambulatory Medical Care Survey. Additionally, studies show that when compared with younger adults, older adults are more likely to be misdiagnosed, discharged to home with untreated conditions resulting in adverse events and multiple repeat visits to the ED. This symposium focuses on “demystifying” some of the difficulties with ED transitions to home that may account for this repeated ED use. The first paper describes those older adults who have clustered repeat visits, 8 or more ED visits during a two year period with at least 3 visits clustered within a two month period. The second paper, using a group-based trajectory method of analysis (GBTM), describes the probability of older adults who visit the ED belonging to a group and the characteristics of the older adults in those groups with a view to predicting who is most likely to have frequent ED visits. The third paper characterizes the most prevalent diseases or conditions co-occurring with a diagnosis of dehydration in older adults with repeated ED visits. The last paper compares different patterns of repeated ED use: clustered repeaters, non-clustered repeaters and single users. Our goal is to develop ED-based interventions that address the distinct needs of older adults, ultimately decreasing repeated ED use in this population.

ONE SIZE DOES NOT EVEN FIT MOST: COMPARING TYPES OF REPEATERS

L.R. Phillips1, M. Cadogan1, J. Mentes1, D.L. Woods1, S. Takayanagi2, H. Aronow1, N. Salem3, 1. UCLA School of Nursing, Los Angeles, California, 2. Cedars Sinai Medical Center, Los Angeles, California

Clearly understanding what brings older adults to the ED is the first step in tailoring services to meet their needs. While information is available about the medical diagnoses associated with their visits, less is known about the influence of geriatric syndromes on elders’ decisions to seek care. Little is known about patterns of use, particularly with regard to the frequency of visits and time between visits. This paper focuses on comparing three patterns of ED use including: clustered repeaters, those who visited more than 8 times and had at least 3 visits within a two month period; non-clustered repeat users, those who visited more than 3 times in the two years but with no clustered visits; and single users, those who used the ED only once. Statistical tests were applied to determine differences in variables such as age, gender, ethnicity, presence of geriatric syndromes, and discharge disposition.

HOW DRY I AM! REPEATED ED USE AMONG OLDER ADULTS WITH DEHYDRATION

J. Mentes1, M. Cadogan1, L.R. Phillips1, D.L. Woods1, H. Aronow2, S. Takayanagi1, K. Skrine Jeffers1, 1. University of California Los Angeles, Center for the Advancement of Gerontological Nursing Science, Los Angeles, California, 2. Cedars Sinai Medical Center, Los Angeles, California

Dehydration is often a precursor to other systemic conditions such as urinary tract and other infections, adverse drug reactions, falls and delirium that precipitate visits to the ED for older adults. Because preventing the precursor event, dehydration, is not addressed during these ED visits, older adults are likely to be repeat users of the ED. We used ED data over a two-year period from a large urban hospital that included 6455 adults over 65 years who had repeat visits to the ED. This data serve as the basis for characterizing older adults who had a primary or secondary diagnosis of dehydration and are clustered (59/143, 41%) and non-clustered (1298/6312, 20%) repeat users of ED services with special attention to co-occurring conditions and with a goal to inform interventions to prevent repeated ED use for this ambulatory care sensitive outcome indicator.
UNEXPLORED ENCOUNTERS: CLUSTERED ED VISITS AMONG OLDER ADULTS

Emergency Department (ED) use among older adults is increasing, however little is known about patterns of ED use within this population. Using data from a larger study of 31,664 ED visits among adults age 65 and older to an urban Level I trauma center, this presentation will focus on 143 patients whose 1454 ED encounters represent 8 or more ED visits during a two year period, of which at least 3 visits clustered within a two month period. The relationships among age, gender, symptoms and diagnoses, discharge disposition from ED, and intervals between clustered visits will be presented. Identification of factors associated with clustered ED visits will be highlighted with recommendations for potential areas of intervention to decrease ED use among this population.

PROBING POSSIBILITIES OF OLDER ADULT ED USE: AN INNOVATIVE ANALYSIS
D.L. Woods, L.R. Phillips, J. Mentes, M. Cadogan, S. Takayanagi, A. Ing, University of California, Los Angeles, Los Angeles, California

Analyzing the patterns of Emergency Department (ED) use among older adults to predict who may be more at risk for repeated use is challenging. Using group-based trajectory modeling trajectory (GBTM), this paper focuses on identifying and describing the distinct trajectories or patterns of change that exist using 31,664 ED visits among adults age 65 and older over a 2-year period, those who have only one ED visit, those who have repeat visits (N = 1454), and those who have clustered visits (N = 143). GBTM has an advantage for investigators trying to identify patterns in heterogeneous groups, such as vulnerable older adults. Factors associated with each group membership will be highlighted, possible predictors of ED use identified and interventions suggested.

SESSION 2065 (SYMPOSIUM)

THE USE OF ACCELEROMETRY TO ASSESS PHYSICAL ACTIVITY IN OLD AGE: METHODOLOGICAL CONSIDERATIONS
Chair: A. Koster, National Institute on Aging, Bethesda, Maryland, Maastricht University, Maastricht, Netherlands
Co-Chair: P. Caserotti, National Institute on Aging, Bethesda, Maryland
Discussant: T.B. Harris, National Institute on Aging, Bethesda, Maryland

Accelerometry is widely used to objectively measure physical activity across the full range of activity intensities. This symposium will explore some of the methodological challenges around the use and interpretation of accelerometer data in older individuals. Due to a reduction in maximal physiologic capacity with aging, the amount of high-intensity activity may concomitantly decrease. It may therefore not be appropriate to classify high-intensity activity based on accelerometer cutpoints derived from younger populations. Dr. Caserotti will present a new method on how individual cut-points for moderate to vigorous physical activity could be derived and applied to accelerometer data. While high-intensity activity decreases with age, sedentary time increases. There is growing interest in the effect of sedentary time as an independent health risk factor. Dr. Visser compared a sedentary questionnaire to assess total sedentary time with accelerometer-derived sedentary time. Accelerometry data are also used to estimate total energy expenditure and validation studies in older adults are necessary. Dr. Manini will show how an artificial neural network approach could be used to estimate physical activity energy expenditure and activity type from a hip-worn accelerometer. Dr. Mackey will show the results of a study where energy expenditure estimated from the Sensewear armband is validated against doubly labeled water. Dr. Glynn has used the Sensewear armband data to show the impact of fatigability and function on physical activity levels in older adults. This symposium provides a better understanding of the use of accelerometry to assess physical activity in older adults and some methodological challenges involved.

ABSOLUTE versus INDIVIDUAL CUT-POINTS FOR MODERATE-TO-VIGOROUS PHYSICAL ACTIVITY
P. Caserotti1, A. Koster1,2, D.R. Van Dolen1, K. Chen1, R.J. Brychta1, N.Y. Amadottir1, T.B. Harris1, J. Staudenmayer2, M. Lorow2, J. Knaggs2, K. Larkin2, M. Visser1,3, T.B. Harris1,2,1

The goal of this research was to validate a statistical approach for processing data from a single hip-worn accelerometer. Participants (N = 45, 76.3 ± 5.1 yrs) completed 17 daily activities that were catego-
Valuation of an Armband to Measure Daily Energy Expenditure in Older Adults

Valid methods to measure daily energy expenditure in older adults are needed. Participants from Health ABC (N=19, 82±3.3 (SD) years) wore a SenseWear armband (SWA, v6.1, BodyMedia, Pittsburgh, PA) for 12.5±1.1 days. Criterion values for total energy expenditure (TEE) were assessed with doubly labeled water (DLW), and for resting metabolic rate (RMR) with indirect calorimetry. Agreement between SWA and criterion measures of TEE and AEE. Individual values were highly correlated between methods (r=0.89, p<0.01) and demonstrated strong agreement (ICC=0.90). Mean AEE values from SWA were lower by 26.8% than criterion values (427±304 vs. 583±242 kcal/day, p=0.01); however, individual values were highly correlated between methods (r=0.76, p<0.01) and demonstrated moderate agreement (ICC=0.65). Bland-Altman plots identified no bias for TEE or AEE. Results demonstrated acceptable agreement between SWA and criterion measurements of TEE and AEE.

Impact of Fatigability and Function on Activity Patterns of Older Adults

To guide the design of intervention studies, understanding fatigability and function in relation to physical activity (PA) is important. Study of Energy and Aging-Pilot participants (N=36, mean±SD age 78.3±4.9 yrs) wore a SenseWear armband for ≥5 days to measure sedentary time (SED), moderate/vigorous PA (MODVIG) and steps. High (N=15) vs. low (N=21) fatigability (Rating of Perceived Exertion ≥9 vs. ≤10 at end of 5 min treadmill walk at 6.8 m/s) had greater SED (mean±SE, 1364±16 vs. 1324±14 min/d, p=0.06), less MODVIG (42±11 vs. 81±9 min/d, p=0.01), and steps (4803±687 vs. 7045±590 steps/d, p=0.02). Gait speed <1.0 m/s (N=7) vs. >1.0 m/s (N=29) was associated with higher SED (1397±26 vs. 1330±11 min/d, p=0.02) and lower MODVIG (28±19 vs. 71±8 min/d, p=0.04) and steps (2822±1078 vs. 6746±448 steps/d, p=0.002). Data were age and sex adjusted. Reducing fatigability by increasing PA may be a possible mechanism to improve function in older adults.

SESSION 2070 (PAPER)

Challenges and Opportunities in Community Living for Special Populations

Low-Income Senior Housing Residents with Dementia: An Academic-Community Partnership Education and Intervention

D. Morhardt¹,², M. Spira³, 1. Social Work, Loyola University, Chicago, Illinois, 2. Northwestern University Feinberg School of Medicine, Chicago, Illinois

As senior-housing providers experience the aging of their residents, they face the needs of an increasingly frail and cognitively impaired population. A national senior housing management firm providing affordable housing for seniors approached a university school of social work to review their protocol addressing residents with dementia in a local urban area. Following review of the protocol, a need for further dementia education was identified and a community/academic partnership was formed. School of social work faculty partnered with a National Institute on Aging Alzheimer’s disease center to provide education to housing administrators, social service coordinators and maintenance staff. Two 4-hour workshops were held for 80 staff. The lecture consisted of an introduction to dementia and communication strategies followed by discussion of barriers and next steps. After each lecture, social work faculty and graduate interns conducted 3 focus groups to explore questions concerning the perception of their role, challenges and needs. Field-notes were documented by interns. Participants were given the opportunity to discuss concerns and complete written evaluations. Overall, the educational intervention was well received. Focus group data analysis revealed internal organizational barriers, minimal informal and formal support services, and limited knowledge of dementia. Contributed to difficulty addressing the challenges of the cognitively impaired in senior housing. Strengths included firm’s commitment to safety and overall welfare of tenants, continued development of appropriate methods to manage challenging situations and provision of ongoing staff education. Three and six month post follow-up is planned.

Inclusive Design and Environmental Docility: The Case of the Kitchen

S.M. Peace¹, J. Percival¹, C. Nicolle², M. Maguire², R. Marshall², R.E. Sims², C. Lawton², 1. Faculty of Health & Social Care, The Open University, Milton Keynes, United Kingdom, 2. Loughborough Design School, Loughborough University, Loughborough, United Kingdom

Across the life course, the kitchen can be a central hub of activity. Long discussed as a gendered space, in ageing populations, the kitchen provides a perfect case study for re-considering press-competence, testing environmental docility and considering proactivity through inclusive design; central issues in environmental gerontology. The paper reports on research involving social gerontologists and ergonomists which studied people’s lives in relation to the kitchen. Following detailed pilot work, two interviews were conducted with 48 older participants (aged 61 to 91 years) in the UK. The first interview, using an oral history approach, recorded people’s experiences of kitchens throughout their lives. The second concerned their current kitchen and how well it met their needs. Other tools gathered housing histories, personal demographic details, routine activities, and photographs recorded aspects of the kitchen that were particularly liked or disliked. This approach for gathering data from and working with older people will be described, including discussion of Person-Environment fit (practical design issues and behavioural needs). It is concluded that a multi-disciplinary approach has been productive in producing a greater user understanding that will help promote more inclusive design while extending theoretical perspectives in environmental gerontology. It forms a useful case study.
for producing guidelines for the design of more inclusive kitchens that will be useful to people as they get older and their abilities change.

**HOARDING, HYGIENE AND ENVIRONMENTAL HAZARDS IN A COMMUNITY-DWELLING POPULATION OF OLDER ADULTS**

Background: Self-neglect is associated with increased morbidity and mortality. We examined the prevalence of self-neglect and its specific behaviors of hoarding, hygiene and other environmental hazards in a community-dwelling elderly population. Methods: Population-based cohort study conducted from 2007 to 2010 of a community-dwelling residents who were participating in the Chicago Healthy and Aging Project (CHAP), a population-based epidemiological study of residents over 65 years of age. Participant’s personal and home environment was rated on hoarding, personal hygiene, house in need of repair, unsanitary conditions, and inadequate utility. Prevalence estimates were presented across age, gender, health status, physical and cognitive function. Results: There were 4,627 older adults (1,645 men and 2,982 women) in the cohort from 2007-2010. The prevalence of overall personal and environmental hazards did not significantly change across age groups (Men: 9.5% for 65-74, 9.2% for 75-84 and 10.1% for >85; Women: 8.5% for 65-74, 7.9% for 75-84 and 7.5% for >85). Prevalence of the personal and environmental hazards increased with lower levels of health status in both men (4.7% in very good/excellent, 7.9% in good and 14.9% in fair/poor) and women (4.5% in very good/excellent, 7.9% in good and 10.6% in fair/poor). For those with MMSE <20, the prevalence of personal and environmental hazards was 18.8% in men and 13.6% in women. For those with > 3 Katz impairments, the prevalence of personal and environmental hazards was 12.8% in men and 13.8% in women. Conclusion: Hoarding, poor hygiene, and other environmental hazards are prevalent, especially among those with lower health status, physical and cognitive function.

**PATHWAYS OUT OF ELDER HOMELESSNESS: PERCEIVED BARRIERS AND POTENTIAL SOLUTIONS**

K. Mills-Dick1, J.G. Gonyea1, 1. School of Social Work, Boston University, Boston, Massachusetts, 2. University of Hawaii School of Social Work, Honolulu, Hawaii

Despite existing federal and state policies focused on promoting the well-being of older adults, many of the most vulnerable elders in our communities continue to struggle to meet basic needs. With over 75,000 homeless elders in the U.S. today, and an increase expected due to population aging, it is critical to better understand the facilitators and barriers to maintaining safe and secure housing for older adults. This paper will present findings from a qualitative study that utilized a constructionist, phenomenological approach to explore how older adults and outreach workers define and mitigate problems associated with urban elder homelessness. A series of in-depth interviews and field observations with 20 urban homeless elders and 6 outreach workers were utilized to illuminate the perspectives of those on the frontlines and understand not only causal factors, but also pathways out of homelessness. Interpretive phenomenological analysis revealed themes of cumulative inequality manifested over the life course and the interplay between institutional arrangements and individual life trajectories. Excerpts from participant narratives illustrate the perceived role of social structures as both barriers to and resources for resolving the problem of elder homelessness, as well as their interaction with, and impact on, individual agency. Elder homelessness presents complex challenges given the range of contributing factors and multiple systems involved. This paper will present “street level” perspectives and their implications for the development and implementation of programs and policies to address elder homelessness.

**THE STATE OF ADULT DAY SERVICES: FINDINGS FROM THE 2010 METLIFE NATIONAL ADULT DAY SERVICES STUDY**

H. Dabelko-Schoeny, K.A. Anderson, College of Social Work, The Ohio State University, Columbus, Ohio

With roughly 4,600 programs serving over 260,000 persons each day, adult day services (ADS) continues to be an important and growing sector within the long-term care industry. While researchers have begun to shed light on the effectiveness of ADS, information on the national profile of the industry is largely based upon decade-old information (2002). In this national-level study, the researchers collected descriptive and programmatic data on a randomly selected sample (N = 557) of ADS facilities across the United States. Results indicated substantial changes in the following: facility characteristics (e.g., size, staffing); participant characteristics (e.g., age, care needs); service provision (e.g., psychosocial, nursing, and medical services); and financing and funding (e.g., rates, reimbursement). Data suggest that ADS is not only a growing source of long-term care services, but also has increased capacity to serve as a provider of comprehensive health care and as a platform for chronic disease management. Future challenges and concerns are also discussed in light of pending policy proposals.

**SESSION 2075 (SYMPOSIUM)**

**CARING FOR FAMILY CAREGIVERS: FINDINGS FROM A MULTI-STATE INITIATIVE**

Chair: D.J. Sheets, University of Victoria, Victoria, British Columbia, Canada
Co-Chair: M. Marcus, University of Victoria, Victoria, British Columbia, Canada
Discussant: P. Liebig, University of Victoria, Victoria, British Columbia, Canada

The Harry and Jeanette Weinberg Foundation is providing nearly $8 million in funding to develop the capacity of non-profit organizations to support family and informal caregivers. This symposium presents findings from non-profit organizations in 3 states in their second year of funding under this 3 year initiative. The projects highlight innovative approaches to addressing the needs of rural, urban and diverse caregiver populations. One presenter evaluates the impact of using trained volunteers to provide respite care and other services to low income caregivers of medically frail or demented older adults in an ethnically diverse county in New York. Another presenter evaluates the impact of the coordination of caregiver resources in two rural counties in Maine. Findings from pre- and post-service evaluation data indicate that coordination of caregiver resources has: forestalled institutionalization; reduced caregiver burden; and increased self-efficacy. The third presenter assesses the Caregiver Ombudsman Outreach Program (Co-Op), which supports ethnically, racially and culturally diverse family caregivers in an underserved New York neighborhood through the . training of community members as advocates and the offer of limited respite care. The Co-Op also developed Elderpedia, a comprehensive, WIKI database of caregiver resources that provides everyday solutions to real-life issues, such as finding a laundry with deliver y service. Panelists will focus on key evaluation findings relevant to public policy and the development of family caregiver programs and services.

**IMPACT OF A VOLUNTEER INTERVENTION IN REDUCING CAREGIVER BURDEN**

M. Wolf, L. Breuer, Nerenker Center for Research, Parker Jewish Institute, New Hyde Park, New York

The Willing Hearts, Helpful Hands program is dedicated to easing the many burdens associated with being a caregiver of an older adult. Willing Hearts, Helpful Hands, is an innovative community program designed to meet the needs of overburdened caregivers by connecting them with a circle of trained volunteers who provide an array of respite services.
services. Caregivers are experiencing high levels of stress: 60% had moderate depression; 78% reported high levels of strain and burden. 87% of caregivers care for a family member with dementia. Evaluation of the program revealed: (1) a reduction in caregiving burden (80% of caregivers reported a reduction in their caregiving burden at the 6 month follow up; (2) less than 10% sought nursing placement during enrollment in the program. There were no significant changes in depressive symptoms. Findings show that brief respite by a trained volunteer corps can help caregivers cope with the burden of caregiving.

ASSESSING THE EFFICACY OF A NORTHERN NEW ENGLAND RURAL CAREGIVER SUPPORT SYSTEM
J. Crittenden1, L.W. Kaye1, N.L. Merrill1, D. Poulton1, 1. UMaine Center on Aging, Bangor, Maine, 2. Eastern Area Agency on Aging, Bangor, Maine

Maine’s Rural Caregiver Network Project, supported by the Weinberg Foundation, is a service collaborative targeting caregivers in two of Maine’s most rural counties. Pre- and post-service evaluation data indicate the coordination of caregiver resources has resulted in a system that: forestalls institutionalization (50% of caregivers have maintained relatives at home at the 4-month follow-up); reduces caregiver burden and risk (100% and 43% of caregivers experienced a decline in burden and risk scores respectively); and increases in self-efficacy. One-quarter of caregivers report increased use of partnering agency services (hospice, adult day care, care management) and 91% report learning about at least one new community resource they can turn to (63% used those resources at one month post-training). All caregivers who received training learned at least one new practical skill and used those skills within one month. Findings speak to the importance of rural community provider collaboration in responding to caregiver needs.

LEVERAGING COMMUNITY RESOURCES TO SUPPORT CAREGIVERS: THE CAREGIVER OMBUDSMAN OUTREACH PROGRAM
C. Gelman1, T.A. Sokoloff2, 1. Hunter College School of Social Work, New York, New York, 2. Isabella Geriatric Center, New York, New York

Seeking to provide support to ethnically, racially, and culturally diverse caregivers in an underserved New York City neighborhood, 8 agencies and a School of Social Work collaborated to develop The Caregiver Ombudsman Outreach Program (Co-Op). The Co-Op trained community members as advocates to provide information and referrals to existing resources to maximize utilization, and offered limited respite in the form of home health aide hours and vouchers for social day care in an effort to bridge need while helping families plan for more permanent solutions. The Co-Op has also developed Elderpedia, a comprehensive, new knowledgebase of caregiver resources created using a wiki format – both by and for professionals, caregivers, seniors, their families and friends – containing not just health and social service programs, but everyday solutions to real-life issues, such as laundries with delivery service. Evaluations at 6-month intervals of participating caregivers indicate a statistically significant reduction in caregiver burden.

SESSION 2080 (SYMPOSIUM)

EXAMINING THE SOURCE OF SOCIAL DISPARITIES IN MOBILITY IN LATER LIFE
Chair: M. Choi, Department of Epidemiology and Community Health, Virginia Commonwealth University, Richmond, Virginia
Co-Chair: B. Mezuk, Department of Epidemiology and Community Health, Virginia Commonwealth University, Richmond, Virginia
Discussant: K.B. Adams, Case Western Reserve University, Cleveland, Ohio

Mobility is a critical component of wellbeing over the lifespan, and recent research has drawn attention to the role of transportation for quality of life for older adults. However relatively few studies have examined mobility issues from a health disparities framework. This symposium examines the source of social disparities in mobility in later life with a focus on driving behaviors. The first two papers address gender differences in driving behaviors. Mollard and colleagues discuss the mechanisms underlying gender differences in self-regulatory driving. Classen and colleagues examine gender differences in traffic violations and driving errors using administrative data from Florida Traffic Crash Records Database. The final two papers examine gender and racial disparities in driving behaviors and mobility. Mezuk and colleagues examine whether gender and racial disparities in driving cessation widen over the lifespan. Finally, Choi discusses the health trajectories and health disparities among older adults who have never driven an automobile using data from the Health and Retirement Study. The health disparities framework embraces an interdisciplinary approach to studying transportation issues, and this symposium will examine factors that contribute to social disparities in mobility in order to remedy these differences.

TRAFFIC VIOLATIONS VS. DRIVING ERRORS: IMPLICATIONS FOR OLDER FEMALE DRIVERS
S. Classen, University of Florida, Gainesville, Florida

We examined violations from a Crash Database (CD) (N= 5,345 older drivers). From a standardized road course we selected driving errors underlying failing a road course. Three expert raters classified violations from the CD into six types of driving errors. Using SAS version 9.1 we calculated the probability (p<0.05) of the rater experts’ endorsement to classify a violation as a specific type of error; and computed descriptive information, chi-square relationships among the main predictors (age, gender, error type) of injury (p<0.05), and with Fisher’s exact test the effects of gender in traffic violations and driving errors. Female drivers (2,445, 45.7%) had significantly more failed to yield, failed to obey traffic control and speed related violations predictive of crash-related injuries. Injured female drivers made more yielding (p<0.001) speed regulation and gap acceptance errors (p<0.05) and emerge as a high risk group for sustaining injuries from crashes and driving errors.

A STUDY OF GENDER IN SELF-REGULATION OF DRIVING AMONG OLDER ADULTS
L.J. Mollard1,2, D.W. Eby1,2, J. Langford3, J. Charlton1, S. Roberts3, 1. University of Michigan Transportation Research Institute, Ann Arbor, Michigan, 2. Michigan Center for Advancing Safe Transportation throughout the Lifespan, Ann Arbor, Michigan, 3. Monash University Accident Research Centre, Melbourne, Victoria, Australia

Self-regulation of driving by older adults (i.e., reducing overall driving exposure or avoiding specific driving situations) shows promise for extending safe driving. Previous studies have generally found greater self-regulation of driving among women than men. However, findings are mixed on other factors that may influence self-regulation and/or explain gender differences. This study examined gender differences in self-regulation, using a sample of older drivers with clinically-determined impairments in functional abilities, as well older adults from the general population (n=137). While few gender differences were found in self-regulation, this was not the case for self-perceived driving comfort, a construct thought to influence avoidance of certain driving situations. Women reported lower comfort than men for driving on high-traffic roads, in unfamiliar areas, at night in bad weather, in rush hour traffic, on the expressway, and backing up. Reasons why this did not translate into reporting more avoidance of these circumstances are discussed.
GENDER AND RACIAL DISPARITIES IN DRIVING CESSION AMONG OLDER ADULTS: EVIDENCE FROM THE ADVANCED COGNITIVE TRAINING FOR INDEPENDENT AND VITAL ELDERLY (ACTIVE) STUDY

Objective: To longitudinally examine gender and racial disparities in driving cessation among older adults. Methods: Data come from the ACTIVE Study (n=1,789; 74.8% female; 77% White). Generalized estimating equations were used to identify predictors of driving cessation; stratified analysis were used to determine whether predictors differed by gender and race. Results: Overall, 205 (11.5%) participants stopped driving. Being married was associated with lower risk of cessation for men (OR=0.18, 95% CI=0.06–0.56) but unrelated to cessation for women (OR=1.00; 95% CI=0.56–1.80). Higher education was associated with greater risk of cessation for men (OR=1.40, 95% CI=1.10–1.78) but lower risk for women (OR=0.90; 95% CI=0.82–0.98). Results were consistent with the hypothesis that racial disparities in cessation widen with age. Discussion: Racial disparities in cessation in later life may widen with age. Transportation policy should reflect social determinants of, and aim to address disparities in, mobility in later life.

HEALTH TRAJECTORIES OF OLDER ADULTS WHO HAVE NEVER DRIVEN: EVIDENCE FROM THE HEALTH AND RETIREMENT STUDY (HRS)

M. Choi, B. Mezuk, Virginia Commonwealth University School of Medicine, Richmond, Virginia

We aim to explore 15-year health trajectories of older adults who have never driven. Data come from four waves (1993, 1998, 2002, and 2008) of HRS. Health status of adults who had never driven a car in 1993 was compared to that of current/former drivers (n=8,110). About one out of eight (11.8%) participants had never driven a car in 1993. They were more likely to be women, older, and non-White than current/former drivers. CES-D scores, obesity, and mortality were consistently higher for never-drivers than current/former drivers at all four time points. Never-drivers were more likely to have diabetes than current/former drivers in 1993, 1998 and 2002. In conclusion, never-drivers consistently had poorer psychosocial wellbeing and higher morbidity than former/current drivers. Driving history and ability may be an indicator of social disadvantage in later life. Future research should explain the role of access to care in this relationship.

SESSION 2085 (SYMPOSIUM)

NURSING HOME CAPACITY TO DELIVER QUALITY CARE: A CLOSER LOOK AT TOP MANAGEMENT

Chair: E.O. Siegel, Betty Irene Moore School of Nursing, UC Davis Health System, Sacramento, California
Co-Chair: N. Castle, University of Pittsburgh, Pittsburgh, Pennsylvania

Discussant: J. Calkin, University of Calgary, Calgary, Alberta, Canada

Nursing home administrators and directors of nursing, as the top management team in nursing homes, are in key positions to influence an organization’s capacity to deliver quality nursing home care. With overarching responsibilities for administrative, operational, and clinical activities, top management teams are critical to ensuring effective and efficient care delivery practices. With ongoing concern for quality nursing home care, this symposium highlights a growing body of research focused on the top management team in these settings, examining issues of job tenure and past experience, turnover, job satisfaction, leadership, and education, training, and experience. Collectively, the insights gained from this symposium will provide a foundation for better understanding characteristics of management teams that support quality care and quality work environments in nursing homes. Our first paper describes associations between director of nursing tenure and past experience and nursing home quality measures. The second paper examines factors associated with turnover among long term care administrators and directors of care in Ontario Canada nursing homes. The third paper examines administrator transitions to other positions and related characteristics associated with job satisfaction. The next paper describes various education, training, and experiences that prepare administrators for their first position and their ongoing professional development. The final paper examines the relationship between exemplary leadership practices of nursing home administrators (as self-reported and by their direct reports) and the overall quality of care. The presentations will be followed by a facilitated discussion of the implications of the research findings and directions for future research.
moving to another industry). For example, approximately 3% of NHAs quit the industry every 6-months. Second, job satisfaction characteristics will be presented. For example, NHAs working in the same facility were most satisfied with rewards and work skills and least satisfied with work demands; those moving to another nursing home were most satisfied with rewards and work skills and least satisfied with coworkers; those leaving the industry were most satisfied with rewards and least satisfied with work demands, coworkers and work load.

NURSING HOME ADMINISTRATORS: EDUCATION, TRAINING, AND EXPERIENCE TO SUPPORT ROLE PERFORMANCE
E.O. Siegel1, H.M. Young1, M.C. Leo2, I. Betty Irene Moore School of Nursing, UC Davis Health System, Sacramento, California, 2. Oregon Health & Science University, Portland, Oregon

Licensed nursing home administrators (NHA) are responsible for care delivered in nursing homes, with roles and responsibilities centered around five job domains: human resources, finance, leadership/management, resident-centered care, and environment. This study explored education, training, and experiences that support NHAs’ development of competencies in these five job domains. NHAs (N=175) were randomly recruited from nursing homes in five states, with data collected using a mailed self-report questionnaire. Data analysis included descriptive statistics, correlations, and ANOVA. Overall, respondents ranked on-the-job training and previous work experience as most important to their actual development of competencies needed for the NHA position. Respondent rankings for ‘ideal’ ways to develop role competencies suggested NHA preferences for more formalized opportunities (e.g. education, administrator-in-training programs, mentoring) and less reliance on previous work experience and on-the-job training. The findings provide a basis for further exploration into optimal learning opportunities to support effective and efficient role performance of NHAs.

LEADERSHIP PRACTICES OF NURSING FACILITY ADMINISTRATORS AND QUALITY OF CARE
D.G. Wolf, Eastern University, Delray Beach, Florida

Globalization, increased consumer demand, new market technologies and prevalent human resource issues have created an opportunity for leaders to develop from traditional, vertical top-down authoritative leadership behaviors to a more transformative style of management. Effective leadership, at both individual and system levels, has been evidenced to have an effect on quality improvement. Using the Kouzes & Posner (1995, 2007) five practices of exemplary leadership framework along with an existing multivariate conceptual quality of care model, this research identifies key leadership behaviors that have a significant effect on quality of care. By raising awareness of the benefits of exemplary leadership practices and their attributes, administrators can learn to transform themselves and their followers to increase the overall quality of care within their organizations. This quantitative study examines the relationship between the exemplary leadership practices of nursing home administrators (as self-reported and by their direct reports) and the overall quality of care.

SESSION 2090 (SYMPHOSIUM)

POLICY SERIES: CONGRESSIONAL AGING ISSUES UPDATE
Chair: B. Lindberg, Consumer Coalition for Quality Health Care, Washington, DC, District of Columbia

Capitol Hill staff, including the Senate Special Committee on Aging, will discuss this year’s legislative developments and plans for aging and health policy for 2012. Topics will include the Older Americans Act reauthorization, income security, and health care reform implementation. Brian Lindberg, a Washington, DC, policy consultant, will moderate this session.

SESSION 2095 (SYMPOSIUM)

THE MEDICARE MEDICAL ADULT DAY CARE DEMONSTRATION: EVALUATION FINDINGS
Chair: W. Leutz, Heller School, Brandeis University, Waltham, Massachusetts
Discussant: W.D. Clark, Centers for Medicare and Medicaid Services, Baltimore, Maryland

This Symposium presents the findings of an independent evaluation of the Centers for Medicare & Medicaid Services’ (CMS) Medical Adult Day Services Demonstration, which was conducted by five home health agencies in five states from 2006-2009. It examined the effects of allowing Medicare home-health services to be delivered in medical adult day-care (MADC) centers rather than only in a beneficiary’s home, as is required under current law. The Demonstration showed that it is possible to provide Medicare home health services in MADC centers and that a significant minority of new home health patients may be interested in this model. Those who chose the Demonstration reported high rates of satisfaction with both attending MADC and receiving their home health in the MADC center. However, in relation to matched comparison groups at the three sites with enough enrollees for quantitative analysis, overall Medicare expenditures were increased at one site, and home health quality was lower at another. These expenditure and quality findings should be interpreted with caution due to small study groups; and they should also be weighed against the positive satisfaction reported by beneficiaries, family members, and home health and day care staff members.

THE IMPLEMENTATION OF THE MEDICAL ADULT DAY SERVICES DEMONSTRATION
W. Leutz, Heller School, Brandeis University, Waltham, Massachusetts

This presentation evaluates the implementation of the CMS Medical Adult Day Services Demonstration, which allowed Medicare home health (HH) services to be delivered in medical adult day-care (MADC) centers rather than only in a beneficiary’s home, as is required under current law. Implementation was assessed through reviews of site records, interviews with site staff and beneficiaries, and analyses of enrollment and claims data. Results: The demonstration did not increase HH referrals to sponsors, and most sites fell short of enrollment goals. Sites generally used existing HH staff to deliver HH services in MADCs, and half of HH were delivered in participants’ homes. None of the changes in service delivery was difficult for HH agencies or MADC centers to address, but the changes did involve new and extra work. A significant minority of new HH patients may be interested in this model, particularly for socialization and caregiver respite provided by MADC.

BENEFICIARY SATISFACTION AND EXPERIENCE
D. Gurewich, W. Leutz, Brandeis University, Waltham, Massachusetts

This presentation covers the results of a survey administered to individuals who participated in (n=197) and who declined participation in (n=253) the Medicare Medical Adult Day Services demonstration. The survey assessed the experiences and satisfaction of participants and decliners with home health (HH) services delivered in the home. Separate survey questions asked only of participants covered satisfaction with HH services delivered in the MADC, as well as satisfaction and experiences with MADC services. Results indicate that HH patients that were older and in poorer health were more likely to decline participation in the demonstration. Participants were highly satisfied with the MADC demonstration services, and their satisfaction with HH services was similar to beneficiaries who declined to participate in the demonstration. Participants overwhelmingly expressed a desire to continue at the MADC center after their episode of care.
COST AND QUALITY OUTCOMES OF THE MEDICARE MEDICAL ADULT DAY SERVICES DEMONSTRATION
C.E. Bishop, G. Ritter, W. Leutz, Heller School for Social Policy and Management, Brandeis University, Waltham, Massachusetts

Statistical analyses of beneficiary data assessed cost and quality outcomes for the Demonstration. Data were drawn from the Outcome and Assessment Information Set (OASIS), home health (HH) agency Medicare claims and HH agency patient data. For three sites with sufficient participants, use and cost of HH services were measured for participants and matched comparison subjects residing in the same market areas but served by other agencies. There was no difference in expenditures at two sites and substantial increases in expenditures at the third, associated with large increases in HH utilization. Analyses did not discern greater improvement or less decline in Demonstration beneficiary functional status or selected health conditions. There was no evidence that the Demonstration had a positive financial effect on HH agencies or MADC centers. Findings should be interpreted with caution due to small sample sizes at two sites and unusually high episodes per patient at one site.

SESSION 2100 (SYMPOSIUM)

THE NEXUS OF AGING AND DIVERSITY IN THE U.S. AND MEXICO: A BILATERAL DEMOGRAPHIC DESTINY
Chair: F. Torres-Gil, University of California, Los Angeles, Los Angeles, California, University of Southern California, Los Angeles, California
Co-Chair: J.L. Angel, University of Texas, Austin, Austin, Texas
Discussant: K. Markides, University of Texas, Medical Branch, Galveston, Texas

Latinos in the United States will become the largest minority while they are experiencing increased longevity and while Mexico undergoes a demographic reversal. Research has focused on the status of “elderly” Latinos and their social, health, and economic conditions. What has not been explored is the multifaceted nature of demographic trends facing the emerging Latino population and bilateral-relationships with their host countries, primarily Mexico. This symposium examines the methodological, research, and policy dynamics of a more robust process of Hispanic aging and presents a more nuanced set of questions and implications facing the U.S. and Latin America. The symposium builds on a seminal set of U.S-Mexico bi-national meetings. Presenters will examine crucial issues that present a more robust research and policy agenda on health and retirement security. This includes the methodological and data requirements for obtaining a more analytical understanding of Hispanic demographics, the aging of the Latino Baby Boomers, the nature of US-Mexico gerontological relationships, the demographic imperatives of a Mexico growing older with declining fertility rates, and the implications for moving toward a broader research framework for addressing an array of policy issues such as immigration and entitlement reform in the U.S. and social change in Mexico. Taken together, these papers advance research on both the complex dynamics of a population having major influence on the demographic transformation of the United States and Mexico. Information about Individual Papers to Date: The Economic Security of Latino Boomers & Beyond: The Role of Citizenship among Generational Cohorts by Kate Wilber, Ph.D., Zachary Gassounis, Fernando Torres-Gil, Ph.D. (USC); Implementing Effective and Sustainable Health Care Programs for Latino Aging by William Vega, Ph.D. (USC); Mapping the Future: Aging, Migration, and the Widening of Ethnic Inequalities by Rubén G. Rum-baut, Ph.D. (UC Irvine); Mexico’s Aging Population: Establishing a Paradigm for a Youthful Nation Growing Older by Maria Elena Aguilar Aldrete, Ph.D. (University of Guadalajara, Mexico); Caring for an Aging Mexican-American Population: The Institutional Challenges by Jacqueline L. Angel, Ph.D. (UT Austin), Angelica P. Herrera, Dr.P.H. (UCLA), Fernando Torres-Gil, Ph.D. (UCLA), Kyriakos Markides, Ph.D. (UT Medical Branch).

THE ECONOMIC SECURITY OF LATINO BOOMERS & BEYOND: THE ROLE OF CITIZENSHIP AMONG GENERATIONAL COHORTS
Z.D. Gassounis1, K. Wilber1, F. Torres-Gil2, 1. Davis School of Gerontology, University of Southern California, Los Angeles, California, 2. University of California, Los Angeles, Los Angeles, California

The foundation for economic security in retirement is laid during one’s working life; yet, many Latino workers are falling considerably behind their non-Latino counterparts. Marked distinctions also exist within the Latino population, with non-citizen Latinos showing wealth and income far below Latinos who were born citizens or have naturalized. This presentation uses Census data to reveal trends in immigrant naturalization among various generational cohorts. In 1990, 26% of Latino baby boomer immigrants had naturalized; in 2009, when Generation X was of a comparable age, 37% of Latino GenX immigrants had naturalized. Using data from the Census and the Health and Retirement Study, we highlight income and wealth disparities of these cohorts based on citizenship status and identify the direct effect of naturalization on the change in income over the worklife. Our findings emphasize the importance of naturalization in bolstering economic security in adulthood and helping to provide a financially secure retirement.

IMPLEMENTING EFFECTIVE AND SUSTAINABLE HEALTH CARE PROGRAMS FOR LATINO AGING
W. Vega, University of Southern California, Los Angeles, California

Aging Latinos contend with chronic physical conditions and diseases that increase as they grow older. Using a disablement framework, this presentation addresses the need for provision of an adequate health care support system for Latino aging. The goal is to examine the service and organizational elements needed to minimize progression into disablement and promote quality “aging in place”. This presentation examines the physical decline of Latino elders over 65 and focuses on the 50% of elder Latino social security recipients living near poverty status. The presentation addresses the service mix that can sustain them through provision of cost-effective and community-focused services. Recommendations for federal and state policies will be discussed.

MEXICO’S AGING POPULATION: ESTABLISHING A PARADIGM FOR A YOUTHFUL NATION GROWING OLD
M. Aguilar Aldrete, University de Guadalajara, Mexico, Guadalajara, Mexico

With a total of 112 million, Mexico is eleventh in the world in terms of population size, and it has been widely viewed as a young nation. Yet it is experiencing a dramatic demographic transition. Fertility rates have declined from 7.0% to 2.05% between 1960 and 2010. In 2011 the population over 60 years of age reached 8.7%, and it will be 17% by 2030. Thus, Mexico is becoming an older nation and its youth population...
will stabilize. This aging process presents a “demographic bonus” for responding to the needs of its young. Mexico, however, is not prepared for an elderly population with limited services for its elderly and minimal pension coverage. This paper examines these dilemmas, presents recommendations, and suggests a bilateral gerontological partnership between the U.S. and Mexico.

CAN OLDER MEXICAN AMERICANS AGE IN PLACE? THE NEXUS BETWEEN FAMILY AND COMMUNITY-BASED LONG-TERM CARE
J.L. Angel1, A.P. Herrera2, K. Markides4, F. Torres-Gil1, 1. University of Texas at Austin, Austin, Texas, 2. University of California, Los Angeles, Los Angeles, California, 3. University of California, Los Angeles, Los Angeles, California, 4. University of Texas Medical Branch Galveston, Galveston, Texas

Community resources are important for an older person’s ability to successfully age in place, yet minimal research exists on the relationships of home and community based long-term care to a growing older Hispanic population. We investigate ethnic-based patterns of home and community-based services and reliance on informal sources of support using longitudinal data from the Hispanic Established Populations for the Epidemiologic Study of the Elderly (H-EPESE) and the National Surveys of Older Americans Act (Title III) Service Participants. Identifying risk factors associated with supportive service suggest a substantial amount of unmet long-term care creating a dependency burden on Hispanic families. Mexican Americans reported a high prevalence of functional disability but low to moderate use of Title III home and community-based services. The paper discusses new public initiatives aimed at providing cost-effective community services for frail and disabled elders.

SESSION 2105 (SYMPOSIUM)
THEORETICAL APPROACH OF LONGEVITY: FONDATION IPSEN PRIZE AWARDING CEREMONY
Chair: Y. Christen, Fondation Ipsen, Boulogne-Billancourt, France
Co-Chair: G. Martin, Fondation Ipsen, Boulogne-Billancourt, France
Yves Christen (Paris) & George Martin (Seattle): Introduction

Caleb Finch (Los Angeles): Presentation of Tom Kirkwood, laureate of the Fondation Ipsen Prize 2011 Tom Kirkwood (Newcastle): Longevity - what do we really know, and what do we really want? The Fondation Ipsen Prize is awarded to a researcher -biologist, geneticist, gerontologist, psychologist, anthropologist, demographer, statistician, etc.- in recognition of an outstanding contribution in the field of longevity. This year, Tom Kirkwood (Institute for Ageing and Health) has been selected for his theoretical approach of longevity.

SESSION 2110 (SYMPOSIUM)
VA GRECC SYMPOSIUM: OXIDATIVE STRESS AND INFLAMMATION: ROLE IN THE PATHOPHYSIOLOGY OF AGE-RELATED DISEASES (MUSI)
Chair: N. Musi, GRECC, San Antonio, Texas

The free radical and mitochondrial theories of aging suggest that aging and age-related diseases are caused by accumulated oxidative damage to macromolecules (DNA, proteins, lipids) and by associated decreases in mitochondrial function. Also, it has been proposed that oxidative stress and mitochondrial dysfunction lead to a pro-inflammatory state. This symposium will begin by presenting data from a study that utilizes a unique model in which the antioxidant enzyme superoxide dismutase has been overexpressed in transgenic rats, and the impact that this genetic intervention has on lifespan, glucose tolerance, and insulin sensitivity. The following presentation will discuss the role that oxidative stress and protein aggregation play on the pathogenesis of amyotrophic lateral sclerosis. Next, a presentation will be given which will describe how impaired aldehyde detoxification contributes to the aging process and Parkinson’s disease. Lastly, a new model for the temporal evolution of Alzheimer’s disease pathology will be proposed based on combined autopsy data with latent growth curve models of cognitive performance. Overall, this session will highlight the importance of oxidative stress and inflammation on the pathogenesis of several age-related diseases and prove evidence that modulating oxidative damage can alter the course of some of these pathologies.

IS THE LIFE-EXTENDING ACTION OF CU/ZNSOD OVEREXPRESSION IN MAMMALS OBESITY DEPENDENT?
Y. Ikeno1,2, A. Salmon1, N. Musi1,2, L. Cortez1, S. Lee1, G.B. Hubbard2, H. VanRemmen1,2, A. Richardson1,2, 1. GRECC, Audie Murphy VA Hospital, San Antonio, Texas, 2. UTHSCSA, San Antonio, Texas

Recently, our laboratory made the surprising observation that overexpressing Cu/ZnSOD [Tg(hSOD1)+/0] in Sprague Dawley (SD) rats resulted in a significant increase in lifespan and a reduction in age-related pathologies. The purpose of this study is to determine whether overexpressing Cu/ZnSOD increases lifespan in SD rats. The Tg(hSOD1)+/0 rats showed lower levels of oxidative damage to DNA and lipids in vivo, and higher resistance to oxidative stress in vitro. Both Tg(hSOD1)+/0 and wild-type rats showed an age-related increase in body fat, and the Cu/ZnSOD overexpression did not attenuate adiposity. Interestingly, Tg(hSOD1)+/0 rats showed a significant increase in insulin sensitivity at a young age, and lower plasma glucose levels at an old age. We propose that the increase in longevity in SD rats is due to obesity, which characterizes this strain of rats. Therefore, the overexpression of Cu/ZnSOD could be more protective against oxidative stress under obese conditions in mammals. (Supported by grant from the VA Merit Review, American Federation for Aging Research, and Glenn Foundation)

MODELING THE TEMPORAL EVOLUTION OF ALZHEIMER’S DISEASE PATHOLOGY WITH AUTOPSY DATA: IMPLICATIONS FOR AD’S PATHOGENESIS

Background: The tempo-spatial evolution of Alzheimer’s disease (AD) pathology cannot be easily determined. We’ve combined autopsy data with latent growth curve (LGC) models of cognitive performance to estimate the temporal development of AD lesions. Methods: Autopsy data from the Honolulu-Asia Aging Study (HAAS) were combined into a LGC model of 10-year change in cognitive performance. Results: Change in cognition fully mediated the association between baseline performance and NFT counts. In contrast, change in cognition was not a mediator of the association between baseline cognition and NFT counts. Conclusion: This analysis successfully dates temporal evolution of HAAS’ cognitive surveillance. It also suggests that NFT and NP are not spatially co-localized, this defies the “amyloid cascade” hypothesis.

MISFOLDED GAPDH: A COMMON TARGET PROTEINS DETECTED IN TWO DISTINCT F-ALS MOUSE MODELS
A. Chaudhuri, 1. San Antonio Geriatric Research, Education and Clinical Center (GRECC), San Antonio, Texas, 2. University of Texas Health Science Center in San Antonio, Dept of Biochemistry and Barshop Institute, San Antonio, Texas

Change in protein surface hydrophobicity can lead to loss of activity or induce protein aggregation. Because protein misfolding/aggregation have been considered as causative factor in neurodegeneration including amyotrophic lateral sclerosis (ALS), we monitored protein
ROLE OF IMPAIRED ALDEHYDE DETOXIFICATION IN AGING AND PARKINSON’S DISEASE
E. Fernandez1,2,3, M. Wey1,2, P.A. Martinez1,2, X. Bai1,2, R. Strong1,2,3, I. Geriatric Research, Education and Clinical Center (GRECC), VA hospital, San Antonio, Texas, 2. Barshop Institute for Longevity and Aging Studies, San Antonio, Texas, 3. Department of Pharmacology, University of Texas Health Science Center, San Antonio, Texas

Parkinson’s disease (PD) is a progressive, age-related, neurodegenerative disorder manifested by motor dysfunction and loss of nigrostriatal dopamine neurons. Elevation of biogenic aldehydes has been consistently observed post-mortem in brains from PD patients. Aldehyde dehydrogenases (ALDH) play a major role in detoxifying biogenic aldehydes in the brain. Therefore, we tested the hypothesis that deficiency in ALDH results in behavioral deficits, and neuropathological manifestations characteristic of PD. To test this hypothesis, we developed a line of Aldh1a1/−/−X Aldh2/−/− mice. Age-associated deficits in Aldh1a1/−/−X Aldh2/−/− mice were observed in rotarod performance and gait analysis. L-DOPA treatment temporarily ameliorated the motor deficits. Age-related decreases were observed in striatal dopamine and metabolites in Aldh1a1/−/−X Aldh2/−/−/−, consistent with the impaired motor function. These data provide evidence that impaired aldehyde detoxification may play a role in age-related motor dysfunction and supramotor function. These data provide evidence that impaired aldehyde detoxification in Aldh1a1/−/−X Aldh2/−/− mice, consistent with the impaired deficits. Age-related decreases were observed in striatal dopamine and metabolites in Aldh1a1/−/−X Aldh2/−/−/−, consistent with the impaired motor function. These data provide evidence that impaired aldehyde detoxification in Aldh1a1/−/−X Aldh2/−/− mice, consistent with the impaired deficits. Age-related decreases were observed in striatal dopamine and metabolites in Aldh1a1/−/−X Aldh2/−/−/−, consistent with the impaired motor function. These data provide evidence that impaired aldehyde detoxification may play a role in age-related motor dysfunction and supramotor function.

SESSION 2115 (PAPER)

DEMENTIA AND DEMENTIA CAREGIVING
AD CAREGIVERS: HEALTH CARE UTILIZATION AND COST OVER 18 MONTHS
R. Schulz1, T. Cook2, G. Hunt3, 1. University of Pittsburgh, Pittsburgh, Pennsylvania, 2. Cleveland Clinic, Cleveland, Ohio, 3. National Alliance for Caregiving, Bethesda, Maryland

Self-report caregiver health service utilization data were collected at four measurement points at six month intervals over 18 months from 583 caregivers providing care in their home to individuals with moderate to severe impairment due to Alzheimer’s disease (mean MMSE = 13.5). At each measurement point caregivers were asked to report the number of hospital stays, emergency department visits and physician office visits for the caregiver experienced during the prior month. Caregivers were on average 60.8 years old, predominantly female (82%), and had been providing care on average for 4.5 years. We compared utilization rates for caregivers with rates for US females of similar age. Utilization rates for hospital stays, emergency department visits and physician visits among caregivers were 2 to 3 times higher than they were for US females of similar age. For example, utilization rates for emergency department visits were 5.5 per month per 100 AD caregivers compared to 2.6 per month per 100 US females aged 45-64. Repeated measures analysis showed significant increases over 18 months for hospital use (β=0.017), and physician office visits (β=0.018), and marginally significant increases in emergency department visits (β=0.069). Multivariate regression models showed that the strongest baseline predictor of physician office use at the 18 month follow up was self-rated health. Interaction analysis showed that caregivers who rated their health as poor or fair and whose care recipient experience significant declines in ADL functioning were more likely to have high levels of physician visits. Converting utilization rates to costs shows significantly higher costs for AD caregivers by a factor of 2.

PREDICTIVE VALUE OF EMOTIONS IN THE POSITIVE ASPECTS OF CARE GIVING AMONG DEMENTIA CAREGIVERS
N. Galdona, J. Yanguas, I. Etxeberria, E. Barbero, E. Aldaz, R+D, Fundación Ingema, San Sebastian, Spain

Recent studies have focused their attention on the Positive Aspects of the Caregiving Process. Some scientific literature has addressed the relevance of socio-demographic characteristics as predictors of Caregiving Satisfaction, but there is a lack of research investigating other possible predictors. The aim of this study was to analyse the predictive value of Positive and Negative Emotions on the Positive Aspects of Caregiving. Method: The sample was composed of 117 Family Caregivers of Elderly people with Dementia. Socio-demographic data were collected and participants were evaluated using the following measures: the Positive and Negative Affect Schedule (PANAS) (Watson et al., 1988), and Caregiving Satisfaction Scale (Lawton et al., 1989). Results: Pearson Correlation Coefficient was used to analyze the relationship between the independent and dependant variables. Emotions that showed significant correlations (p<0.05) were introduced in a post step-wise regression analysis in order to determine the weight and relationship among variables. Results show a significant regression equation (F (3, 113) = 8.576, p<0.001) with R2 Adjusted= 0.164. The emotions that predicted the Positive Aspects of Caregiving were: Pride (β= -0.23, p=0.01), Excitement (β= -0.25, p=0.00) and Embarrassment (β=0.17, p=0.04). Those emotions explained 16 per cent of the caregivers’ Care giving Satisfaction variance. Conclusions: These results show that emotions, as caregivers’ resources to cope with the caregiving process, should be taken into account as they can predict satisfaction with care.

THE DIFFERENTIAL IMPACT OF UNIQUE PATIENT BEHAVIORAL SYMPTOMS FOR THE DEMENTIA CAREGIVER

The behavioral and psychological symptoms associated with dementia (BPSD) are highly burdensome to caregivers. Although BPSD consist of a wide variety of behaviors including depression, aggression and delusions, it remains unclear whether specific symptoms have a differential impact on caregivers. The aims of this study were to assess how BPSD symptom clusters impact depressive symptoms for dementia caregivers and to test the pathways by which BPSD symptom clusters impact caregiver depressive symptoms. We examined four symptom clusters derived from the Columbia University Scale for Psychopathology in Alzheimer’s Disease (CUSPAD) based on their likely impact on the caregiver: patient depressive symptoms, accusatory/aggressive behaviors, non-threatening psychotic symptoms, and difficult to manage behaviors. Using data from a longitudinal study of dementia patients and their caregivers, we analyzed the relationship between BPSD symptom clusters and caregiver depressive symptoms among 160 patient-caregiver dyads in up to six years of follow-up. Using multivariate GEE logistic models, we found mild associations between all four symptom clusters tested and caregiver depression (OR range: 1.03-1.55). Only the presence of patient depressive symptoms was sig-
music therapy to add life quality to expanded life spans: a model program for dementia care

A. Clair, T. Turner, J. Memt, University of Kansas, Lawrence, Kansas, 2. Central Plains Geriatric Education Center Landon Center on Aging University of Kansas Medical Center, Kansas City, Kansas

The health care system offers much to extend life in those with dementia far beyond their abilities to typically engage in daily activities. Life quality becomes an important and controversial issue as cognitive, social, and emotional life functions erode. With good physical health persons in moderate and late stage dementia are locked into lengthy life spans while intractable disease processes erode social, cognitive, and emotional life functions vital for a fully human experience. Pharmacological interventions show some promise but cannot fully stave off deterioration. Music therapy is the application of music designed to have desirable and measurable non-musical outcomes that contribute to life quality. Music therapy can lead to increased social engagement that reduces isolation through carefully structured group participation, enhanced attention to interactions through instrumental rhythm playing, and mood shifts that promote engagement through responses to gently stimulating music. This paper describes the experience of a music therapy intervention nested within small group living memory care environments in an established suburban neighborhood. Engagement, the appropriateness of ongoing contextual behaviors, and social outcomes prior to, during, and following music therapy sessions will be noted and the comfort afforded family members to join sessions will be discussed. The potential exists for training care providers to integrate music sessions into existing structured routines while building their musical confidence. This session will introduce a model program for dementia care design that evolved from the applied clinical experience of the presenters.

forever: feasibility of life review in early dementia: veterans' experiences remembered

B.R. Williams, L.L. Woody, P.S. Goode, T. Blizzard, K.L. Burgio, 1. VA Medical Center, Birmingham, Alabama, 2. University of Alabama at Birmingham, Birmingham, Alabama

Purpose: Loss of self is a salient concern for early dementia patients as they experience declines in short-term memory and become increasingly dependent on recall of past accomplishments for sustaining a sense of mastery and meaning. The FOREVER Project engages veterans with early dementia in a life review process to enhance self-understanding and promote a sense of personal continuity. METHODS: Veterans, age 65 and older, with early dementia are recruited from the Birmingham Veterans Affairs Medical Center geriatric clinics. A Hospice Foundation of America life-review workbook is used to facilitate 2-3 face-to-face sessions with each veteran and to assist veterans with recalling memorable accomplishments and other experiences from the past. Sessions are tape-recorded and transcribed into workbooks which are given to participants at the end of their participation in the life review process. RESULTS: Life review is well-received by veterans with early dementia, with veterans and caregivers showing an appreciation for the worthwhileness of the activity. Older veterans are thoughtful and purposeful about the need for transmitting life lessons and values. The life review process evokes a range of emotional responses among veterans related to life experiences in general, and military service, in particular. As such, it is providing a window into the affective world of early dementia patients. Potential barriers to veteran participation include patient multimorbidity and caregiver resistance. CONCLUSIONS: Life review is feasible with early-dementia patients and offers an opportunity for veterans to create legacies for loved ones, preserving long-term memories before they are lost to advancing illness.

session 2120 (paper)

issues in long-term care

advanced pressure ulcers that develop in nursing home residents despite “best care”

Older neglect is the failure of caregivers to provide for basic needs of vulnerable older (age 65+) adults. Some suggest that pressure ulcers (PUs) are from neglect. Others suggest that, while not all PUs are from neglect, advanced pressure ulcers (APUs) (Stage III or IV) are a “red flag” for elder neglect. There is a paucity of data to support these assertions. Study aims were to examine whether APUs can develop in vulnerable older adults despite “best care” and evaluate characteristics of APUs that develop despite “best care.” Twenty-four participants had 26 facility-acquired APUs. Two participants had a second APU, but only the larger PU was included in analysis. All participants had mobility limitations. Morbidities included cardiovascular conditions (N=24); current or recently-diagnosed infections treated with antimicrobials (N=20); dementia (N=20); depression (N=13); chronic pain (N=12); and diabetes (N=4). APUs were generally small (cm2: mean/SD=6.8/9.2; range 0.1-35.8; median 4.1; mode 0.25); in expected/explainable locations; with distinct or well-defined edges; with rare undermining; with rare non-purulent exudate; and rare peripheral tissue edema/induration. Eight ulcers had no necrosis; eight had eschar that covered 75-100% of the wound. Six of 8 eschar-covered APUs were heel ulcers, an expected finding. Study limitations include small convenience sample and no controls. These data provide evidence that APUs can develop without neglect by professional caregivers. Results suggest characteristics of APUs that develop despite “best care.” Future research will explore APUs in suspected neglect situations.

cultivating knowing and relationships: a grounded theory of quality of death in the nursing home

R. Trotta, University of Pennsylvania School of Nursing, Philadelphia, Pennsylvania

Understanding quality of death in the nursing home is mandated both by demographics and morality in an aging society. Nursing home residents are among the oldest and most physically and mentally frail members of our society. Today, approximately 40% of people die in nursing homes in the United States. Despite being a relatively commonplace event, death in the nursing home, and the quality of it, are understood in limited terms. My recent dimensional analysis on palliative care in the nursing home poses “quality of death” as an outcome that could improve the experience of death in the nursing home for all involved. Quality of death assumes explicit acknowledgement of death as the event of interest, and embraces dying as an imperceptible time period that precedes it. This emergent mode grounded theory study applied qualitative event analysis techniques to prospectively verify and refine this emergent concept by delineating dimensions embedded in quality of death. Through observations, interviews, and document review, events in the lives of residents receiving palliative care were analyzed using grounded theory methods. By focusing on events of residents’ deaths, the Grounded Theory “Cultivating Knowing and Relationships” emerged from the
data. This theory describes a process whereby certified nursing assistants come to know and understand their residents and develop personal relationships with them. These findings provide critical insight into what constitutes quality in death and can guide future inquiry aimed at improving current care processes for those who die in nursing homes.

PERSON-CENTERED ATTITUDE, JOB DEMANDS AND RESOURCES OF STAFF: THE RELATION WITH STAFF WELLBEING

B.M. Willemsen, Q. Visser, D. Smit, J.D. Lange, A. Pol. 1, 2. 1. Program on aging, Netherlands institute of mental health and addiction, Utrecht, Netherlands. 2. VU University, Amsterdam, Netherlands

Objective: Person-Centered Care Is Not Only Assumed to Increase the Quality of Life of Residents with Dementia, but also the Well-Being of Healthcare Staff. It Is Assumed That A More Person-Centered Attitude Has a Positive Effect on Job Satisfaction. On the Other Hand, Organizational Barriers Can Cause Strain When Staff Cannot Do What They Think Is Best for the Residents. We Studied the Relationship of the Person-Centeredness of Healthcare Staff Providing Nursing Home Care for People with Dementia and their Perceived Demands and Resources, on Staffs’ Wellbeing (Job Satisfaction, Intention to Leave, Emotional Exhaustion and Personal Accomplishment). Methods: This Study Uses Data from a Study of a Wide Range of Arrangements (N=136) Providing Nursing Home Care for People with Dementia. A Total of 1147 Healthcare Staff (59%) Participated. Results: Multilevel Regression Analysis Showed that a More Person-Centred Attitude of Healthcare Staff is Related to More Job Satisfaction and More Personal Accomplishment. On the other hand, Results Showed That Staff with a More Person-Centred Attitude Experience More Exhaustion at High Levels of Demands and Are More Likely to Leave the Job When They Experience Low Levels of Social Support From Their Supervisor than Staff with a Less Person-Centred Attitude. Conclusion: This Indicates the Importance of Creating a Work Environment in Which Healthcare Staff Feels Supported by Their Supervisor and Do not Experience too much Pressure to Maintain Healthy Staff with a Person-Centered Attitude in order to Successfully Provide Person-Centered Care for People with Dementia.

SAFETY CULTURE OF ASSISTED LIVING FACILITIES

Further understanding of patient safety in healthcare is still needed. This is especially evident than in long-term care settings, where relatively little information exists. In this research, patient safety issues in assisted living (AL) will be examined. The Patient Safety Culture (PSC) of a large sample of AL facilities is examined. The Nursing Home Survey on Patient Safety Culture (NHSPSC) was modified and used to examine PSC. Respondents for the modified survey were AL administrators and Direct Care Workers (DCWs). A random sample of AL settings were selected to participate from all 50 states. The applied proprieties of the instrument were examined. A summary score for administrators and DCWs for each NHSPSC item is presented. These summary scores have a range from 0 to 100. The modifications to the survey were minor, and comprised of small wording changes. Information was received from 572 administrators (response rate = 57%) and 3,620 DCWs (response rate = 51%). The scores (using a 0-100 scale) fell into the 48-72 range for administrators and the 40-68 range for DCWs. Overall, the scores are similar to those found in nursing homes. AL is recognized as one of the fastest-growing institutional components of the long-term care industry. This study provides us with important information that some areas of PSC could be higher (i.e., more favorable). This study provides a first step towards examining patient safety in this under-examined setting.

LET’S GET ENGAGED! DIRECT CARE WORKERS AND ORGANIZATIONS: HOW ENGAGEMENT OPTIMIZES OUTCOMES

D. McCaughey, G. McGhan, E. Walsh. 1. HPA, Penn State University, State College, Pennsylvania. 2. Penn State University, School of Nursing, State College, Pennsylvania

Purpose: The direct care workforce (DCW) is among the fastest growing occupations in America. Fueled by an aging population, the need for nursing assistants in the long term care setting is expected to outpace the supply of workers, resulting in high levels of burnout and disengagement. Employee engagement, the opposite of employee burnout, is linked to lower turnover, improved safety, and higher productivity and efficiency. Currently, the healthcare sector lacks a publicly available scale to evaluate DCW engagement. To address this gap, this study proposes a tool to measure employee engagement among the DCW workforce. Methods: Using two nationally representative databases, items from the National Health Care Surveys were examined to determine if an employee engagement scale could be derived from the existing workplace environment items. Results: Factor analysis identified 5 items that loaded as one scale (34% of variance) representing employee engagement. Correlation analysis found the engagement scale is correlated with supervisor support (r= .60) and job satisfaction (r= .53). Using regression analysis employee engagement was positively related to lower levels of DCW injury rates (β=.203, p-value <.001), negatively related to turnover intention (β=-.311, p-value <.001), and positively related to DCW’s willingness to recommend the organization (β=.460, p-value <.001) Conclusions: Study results identified a reliable and valid scale to measure employee engagement. Employment engagement is related to positive DCW outcomes (lower turnover intent, lower injury rates and better perceptions of offered care). The validation of this scale offers healthcare organizations access to a public instrument for measuring engagement.

SESSION 2125 (PAPER)

METHODOLOGICAL ISSUES IN AGING RESEARCH

YOUNGER AND OLDER AMERICANS’ SOCIOPOLITICAL ATTITUDES: APC COMPONENTS OF SOCIAL CHANGE

N. Danigelis, S. Cutler, M. Hardy. 1. Sociology, Univ Vermont, Burlington, Vermont. 2. Pennsylvania State University, University Park, Pennsylvania

Recent evidence (Danigelis, Hardy & Cutler, 2007) has shown surprising intracohort aging differences between older and younger individuals regarding a wide range of sociopolitical attitudes. Most noteworthy are significantly greater liberal intracohort trends for the older group for a number of attitudes. Left unanswered is whether such trends are due simply to aging (A) itself or whether they are attributable to period (P) or cohort (C) or some combination. Following Littlel et al. (2006; see also Yang, 2008), we employ a generalized linear mixed models approach to disentangle fixed aging and random period and cohort effects for two separate age groups in the 1972 – 2008 General Social Surveys: ages 25 – 39 (minimum N = 5,440) and ages 60+ (minimum N = 4,036). With composition effects controlled, in the younger group aging had a significant liberal effect 25% of the time, with no significant conservative effects. Fifteen percent of period effects were significant, mostly from conservative 1970s effects; and 17% of cohort effects were significant, showing different patterns of both liberal and conservative effects depending on the particular attitude. By contrast, the older group showed no significant aging effects, while cohort was significant only 8 percent of the time. Period effects were significant 25 percent of the time, reflecting conservative period effects for the 1970s for 10 out of 16 attitudes, and liberal 2000s effects for six out of 16 attitudes. Results illustrate the importance of placing age group differences in proper historical context and are discussed accordingly.
CIRCADIAN CORTISOL RHYTHMS: METHODOLOGICAL APPROACHES TO IDENTIFY ASSOCIATIONS WITH SOCIAL FACTORS
C.J. Donohoe1, E. Crimmins1, E.M. Friedman2, T. Seeman2. 1. University of Southern California, Los Angeles, CA, California, 2. University of California Los Angeles, Los Angeles, California

Disruptions in the hypothalamic-pituitary-adrenal axis (HPA) have been associated with many psychosocial factors such as chronic stress and childhood adversity, as well as psychological factors such as depression and post-traumatic stress disorder. This study examines how psychosocial and psychological factors contribute to differences in diurnal cortisol production, an indicator of HPA function, and contrasts the results of two statistical approaches to modeling these associations: growth curve modeling and group-based trajectory modeling. Growth curve modeling relies on the assumption that individuals follow a similar pattern of change over time, and is predictor focused, examining pre-defined groups for variation around the mean. Group-based trajectory modeling is outcome focused and identifies clusters of individuals (i.e., latent groups) following the same trajectories of an outcome, followed by identifying risk factors that alter the probability of membership in a trajectory. We analyze data from the Survey of Midlife in the US (MIDUS), a cohort of US adults aged 35-86. Using growth curve modeling, we found marital conflict and depression to be associated with flatter diurnal rhythms, and chronic stress to be associated with a steeper nighttime rise. Using group-based trajectory modeling, four distinct trajectories of cortisol were observed. One unexpected trajectory was found and was characterized by high values that increased throughout the day. Members of the four trajectories differed considerably in depressive symptoms, chronic stress, and marital satisfaction and conflict. We highlight the advantages of using multiple methods to characterize and identify diurnal patterns of change, and understand how social factors influence these changes.

ISSUES OF TREATMENT FIDELITY IN A LARGE, MULTISITE CLINICAL TRIAL: THE MTRAIN STUDY
M. Stolder1, K. Lane1, A. Bossen1, J. Specht1, P. Mobily1, J. Russell1, D.A. Reed1, 1. Nursing, University of Iowa, Iowa City, Iowa, 2. University of North Carolina, Chapel Hill, North Carolina

Treatment fidelity refers to several components that improve the reliability and validity of behavioral interventions. Though often not addressed and evaluated sufficiently, a lack of treatment fidelity will affect both internal and external validity, effect size and statistical power of a clinical trial and can result in non-significant findings that are not due to the research design itself. This presentation will focus on challenges to treatment fidelity encountered in the Multilevel Translation Research Application in Nursing Homes (MTRAIN) project, a four-year large-scale translational research study testing the effects of an intervention to promote the use of evidence-based practice (EBP) for the management of pain and urinary incontinence (UI) in nursing homes (NHs). With respect to treatment fidelity, strategies built in the study design included the use of an expert nurse consultant, an intervention component based on the conceptual framework guiding the study design; the use of a detailed intervention manual and standardized protocols; training classes delivered in small group sessions at convenient locations; and adherence monitoring per nurse consultant through direct observation. Despite efforts to ensure treatment fidelity and advance the aims of the study, there were multiple challenges that needed to be addressed. These included the dosing of the expert nurse consultant, competing demands of leaders in NHs, the availability of NH staff to participate in training sessions, and subject selection. There continues to be a need to find ways to maintain treatment fidelity in a feasible and cost-effective manner when carrying out translation research in NHs.

VALIDATION OF AN INSTRUMENT TO MEASURE UNDERSTANDING OF CURATIVE, PALLIATIVE AND HOSPICE CARE
D.J. Schulman-Green1, K. Fennie1, R. McCorkle1,4, E. Bradley1, H. Prigerson1,3, T. Knobf1, M. DiGiovanna1, J. Dixon1, 1. Yale School of Nursing, New Haven, Connecticut, 2. Harvard University, Cambridge, Massachusetts, 3. Dana Farber Cancer Institute, Boston, Massachusetts, 4. Yale School of Medicine, New Haven, Connecticut, 5. Yale School of Public Health, New Haven, Connecticut

Treatment decision-making may be hindered by lack of knowledge about curative, palliative and hospice care. The purpose of this study was to develop and validate the Knowledge of Care Options (KOCO) instrument to measure understanding of these care options. KOCO was developed in 4 steps. In Step 1, we identified 3 knowledge domains—curative, palliative and hospice care—and generated 22 true-false items based on their common definitions. Editing for redundancy and clarity resulted in 13 items. In Step 2, experts evaluated items for relevance and suggested edits. We calculated Content Validity Indexes (CVI) for each item and for the total scale (S-CVI). Eliminations left 11 items. In Step 3, a convenience sample completed KOCO and cognitive interviews. In Step 4, a purposive sample of women with metastatic breast cancer completed KOCO as part of a feasibility study that tested educational materials on self-management, including content on care options. Frequencies, correlations and Wilcoxon signed rank tests were calculated. Thirty-one experts reviewed KOCO. Content validity testing yielded an S-CVI of 83.3% (CVIs >80% = valid). Interviews with 4 men and 6 women aged 51-80 with various types and stages of cancer indicated KOCO to be clear and acceptable. Twenty-three women aged 40-81 years participated in the feasibility study. KOCO was correlated with chronic disease management self-efficacy and captured change in knowledge of care options (signed rank test = -3.26, p<.005, SD=1.19). The KOCO is able to detect changes in knowledge of care options and should be tested in a larger sample.

QUALITY MEASURES FOR ALZHEIMER’S/DEMENTIA RESIDENTS LEAD TO IMPROVED OUTCOMES AND QUALITY OF LIFE
C. Teigland1, Z. Pulungan, Foundation for Long Term Care, Latham, New York

This session presents findings from a study funded by the Alzheimer’s Association that addressed the lack of sensitive measures to identify quality of care problems in residents with Alzheimer’s/Dementia (AD). Analysis of Minimum Data Set (MDS) data for 670+ NH’s revealed serious problems using CMS Quality Measures (QMs) to identify quality of care/quality of life issues for AD residents. Aggregate QMs mask underreported pain (they are 2.5x less likely to have reported pain even after risk adjustment for conditions causing pain), 4-5x more likely to have adverse outcomes such as functional decline and depression. We evaluated the impact of making available dementia specific QMs to 55 NH’s using a “difference in difference” method to compare the change in outcome rates in the intervention group before and after access to the AD-centered QMs to the change in a control group. This approach controls for changes in outcomes in similar residents and NHs over the same time period due to other effects, such as state and federal quality improvement initiatives. The model also adjusts for characteristics such as facility size and staffing levels. The results showed a significant impact on reported rates of pain, a 4.2 percentage point reduction in undetected pain, a 6 percentage point reduction in use of restraints compared to the control group, and a 5.5 percentage point lower rate of functional decline in AD residents.
PARENT-CHILD RELATIONSHIPS

“SHE’S ALWAYS BEEN MY CLOSEST”: STABILITY AND CHANGE IN MOTHERS’ FAVORITISM TOWARD ADULT CHILDREN
J. Suitor1, K. Pillemer2, 1, West Lafayette, Indiana, 2, Cornell University, Ithaca, New York

Despite a powerful norm of equal treatment of offspring, research has demonstrated convincingly that parents often differentiate among their children in such domains as closeness, support, and control. Portrayals of favoritism in literature, history, and popular culture are presented, implicitly or explicitly, as a stable aspect of the parent-child relationship, typically beginning and continuing through the child’s adulthood. However, there has never been empirical confirmation that patterns of favoritism are, in fact, stable. In the present paper we use 7-year panel data collected from 420 older mothers about their relationships with 1,584 adult children as part of the Within-Family Differences Study to describe changes in favoritism across time. Specifically, we describe and explain patterns of favoritism regarding emotional closeness, confiding, and expectations for later caregiving. Findings revealed patterns of both stability and change in mothers’ preferences across these relational domains. Mothers tended to name the same children as confidants and as preferred caregivers at T1 and T2; however, the majority of children named as those to whom the mothers were most close at T2 had not been named in this context at T1. Multivariate and qualitative analyses were consistent in indicating that changes in mothers’ favoritism were fueled by new circumstances in children’s lives (divorce, illness, residential moves) rather than in the mothers’ lives (illness, widowhood, etc.). While demonstrating that mothers continue to favor some children over others as they move through the later years, the findings call into question whether the same children remain favored across time.

DOES BELIEF OF FILIAL PIETY MAKE DIFFERENCES ON COPING STRATEGY OF PARENT-CHILD CONFLICT AMONG YOUNG AND MIDDLE-AGED CHINESE?
D. Wang, Institute of Developmental Psychology, School of Psychology, Beijing, China

The purpose of this study was to examine to what extent young and middle-aged adults hold traditional belief of filial piety (TBFP), and the relationship between TBFP and coping strategies of filial dilemmas. The sample included 215 white-collar employees (147 female, 92 middle-aged) ranged in age from 22 to 59 years (mean = 38). The Scale of Filial Piety Belief (Yang et al., 1989) was used to test TBFP with four dimensions, namely Suppress one’s own desire and obey to parents (SO), Protect and honor parents (PH), Take care parents and worship them after their death (TW), and Respect and love parents (RL). The Questionnaire of Dilemmas of Filial Piety Decision was developed to examine participants’ coping strategy when confronting filial piety dilemmas. Six typical parent-child conflicts were presented one by one to the participants and each was followed with questions as “what do you think Xiao Zhan will do in this situation?” and “why do you think so?” The results indicated that male participants held stronger belief of PH than female, and young adults had stronger belief of TW than the middle-aged. In light of their responses of open-end questions, the participants’ coping strategies were grouped into three types, i.e. Self-sacrifice, Comprising or Reframing, and Ego-centered. However, no uniting pattern of coping strategy across 6 dilemmas was found, which implied that the decision making of filial piety might be specific to situations.

Nonetheless, those identified more with TBFP preferred self-sacrifice to other strategies.

DRIFTING APART OR BONDING TOGETHER? CHANGES IN PARENT-ADULT CHILD RELATIONSHIPS OVER TIME
M.J. Hogerbrugge1, M. Silverstein2, 1, Faculty of Social and Behavioral Sciences, Utrecht University, Utrecht, Netherlands, 2, USC Davis School of Gerontology, Los Angeles, California

In the past years, research on intergenerational relations has seen a number of methodological and conceptual advances. First, utilizing the model of intergenerational solidarity and latent class analysis, recent studies have started to simultaneously include multiple characteristics of intergenerational relations, such as contact, affection, patterns of help exchange and conflict, allowing for the development of typologies in which different relationship types are distinguished. Second, research has increasingly employed longitudinal data to study changes in characteristics of intergenerational relations over time. These two advances have thus far not been combined; Typologies that were based on multiple characteristics of the relationship were developed employing cross-sectional data, while research employing longitudinal data focused merely on one, or maybe two, characteristics of intergenerational relations. Fortunately, latent transition analysis (LTA) offers a methodological solution for handling the complexity of inter-generational relations, while allowing the researcher to model transitions into different family types between time points. In this study, we conduct a LTA on panel data from the Longitudinal Study of Generations (LSOG), spanning a total of 17 years. Using a variety of theories and theoretical frameworks from gerontology and the social sciences, we elaborate on which transitions between types of intergenerational relations are most likely to occur and explore these expectations with our longitudinal panel data. We end with a discussion on possible directions for future research.

CHILDREN’S MARITAL QUALITY AND PSYCHOLOGICAL WELL-BEING: MODERATING EFFECTS OF MOTHER-CHILD RELATIONS
S. Kim1, J. Suitor1, J. Sechrist1, K. Pillemer2, 1, Sociology, Purdue University, West Lafayette, Indiana, 2, Cornell University, Ithaca, New York

The relationship between mothers and children is one of the most consequential and enduring bonds in individuals’ lives. Research on intergenerational relations has demonstrated that mothers continue to serve as an important source of expressive and instrumental support to their children even after offspring enter adulthood and establish their own households. Given the role of mothers’ in their adult children’s lives, it is remarkable how little attention has been given to the way mothers shape their children’s adjustment following negative events. In the present paper, we ask: Can the relationship between mothers and their adult children moderate the association between children’s stressors and psychological well-being? Specifically, can support or strain in the mother-child relationship moderate the association between children’s marital distress and psychological well-being? To examine these questions, we used data collected from 423 adult children nested within 229 families collected as part of the Within-Family Differences Study. Multivariate analyses revealed that expressive support from mothers did not buffer the effects of marital distress on depressive symptoms or positive affect for either sons or daughters. In contrast, strain in the mother-child relationship had a direct effect on positive affect. Separate examination by child’s gender indicated that strain exacerbated the effects of marital distress on depressive symptoms for both daughters and sons; however, the effect on daughters was much stronger. These findings suggest that strain in adult children’s relationships with mothers decreases children’s positive affect, particularly when experiencing marital problems.
A QUALITATIVE STUDY OF FILIAL PIETY AND WELL-BEING AMONG COMMUNITY-DWELLING CHINESE OLDER ADULTS IN CHICAGO CHINATOWN

E. Chang¹, M.A. Simon², E. Wong², B. Wong², X. Dong³, J. Rush
University Medical Center, Chicago, Illinois, 2. Northwestern University Medical Center, Chicago, Illinois, 3. Chinese American Service League, Chicago, Illinois

Background: As a core value of Chinese culture, filial piety (Xiào) strictly dictates children’s obligatory roles and caregiving responsibilities to aging parents. Despite its significance, changes are taking place in the context of immigration which may disrupt traditional filial piety practices. However, few studies have examined the impact of its modification on the well-being of U.S. Chinese older adults. Methods: This NIH-funded community-based participatory research (CBPR) study explores the perception of filial piety practice and its relationship to the health and well-being of U.S Chinese older adults. Qualitative data were collected from semi-structured interviews with 78 community-dwelling Chinese older immigrants residing in Chicago Chinatown.

Results: Qualitative data analysis demonstrates existing filial piety discrepancy between expectations and actual care receipt from the standpoint of older adults. The lack of desired filial support was associated with feelings of distress and helplessness. In addition to worsening psychological well-being, participants expressed concerns in social well-being, including social isolation, loneliness and feelings of getting bored. Quality of life may be jeopardized in the forms of worsening health conditions, exacerbation of chronic conditions, and cognitive function impairment. Consequences that fall into the category of elder mistreatment were also reported. Last, the lack of filial support may deepen older adults’ barriers to health care services. Discussions: Adult children’s improved understanding of older parents’ healthy aging needs in relation to filial piety is needed. This study has elder care programs and policy implications for communities, social service deliveries as well as public policy makers.

SESSION 2135 (PAPER)

PHYSICAL ACTIVITY AND HEALTH STATUS

TRAJECTORIES OF REGULAR EXERCISE AND ITS RISK FACTORS AMONG TAIWANESE ELDERLY

L. Pan¹, H. Hsu², W. Chang³, 1. Bureau of Health Promotion, Department of Health, Taiwan, Taipei City, Taiwan, 2. Department of Health Care Administration, Asia University, Tai-Chung City, Taiwan, 3. Institute of Health Policy and Management, National Taiwan University, Taipei City, Taiwan

Purpose: Physical activity plays a protective role on health of elderly and on keeping them to live independently. Little is known relative to the patterns of physical activity and which factors influence the change over time. This study aimed to: (1) identify the patterns of regular exercise among Taiwanese elderly, and (2) investigate the risk factors related to the patterns. Methods: Data of 5,333 elder people followed from year 1996 to 2007 (four waves) by a national-representative longitudinal study, TLSA, were used. The definition of regular exercise is doing exercise at least 3 day per week and lasting for at least 30 minutes each time. Trajectory groups of regular exercise and their risk factors were identified by using group-based trajectory analysis. Results: Four trajectory groups of regular exercise have been identified: Sedentary (44.97%), decreasing (15.91%), increasing (19.53%), active (19.59%). Gender, years of education, age at baseline year and self-rated health at baseline year were found to be related to the trajectory groups. For those who were male, younger or with better self-related health, were less likely to be classified into “inactive” trajectory group significantly. Compared to the inactive group, having longer years of education were more likely to be in active group. Marital status, satisfaction of economic status and numbers of chronic diseases at baseline were not associated with the trajectory groups. Conclusion: Still around 40% of subjects remained active or increasing the probability of regular exercise. Gender, age and self-rated health were significantly related to these patterns.

IMPACT OF TELEPHONE REINFORCEMENT ON PREDICTORS OF PHYSICAL ACTIVITY MAINTENANCE IN OLDER ADULTS WITH OSTEOARTHRITIS

P. Desai, S.L. Hughes, University of Illinois at Chicago, Chicago, Illinois

Currently, little is known about the impact of telephone reinforcement (TR) on maintenance of physical activity among older adults. This study examined the impact of TR provided as a follow up maintenance intervention to the Fit and Strong! program on factors believed to mediate exercise maintenance out to 18 months. Participants were older adults with lower extremity osteoarthritis (n=486) who were randomly assigned to one of four follow up treatments. Participants assigned to negotiated follow up, worked with their instructor to develop a maintenance plan of their choice before the program ended. Persons assigned to the meanstreamed arm were referred to an ongoing physical activity program at the same site that offered Fit and Strong!. Within the two study arms participants were assigned randomly to TR or no TR. TR calls were provided bi-weekly during months 3-6 and tapered to once a month during months 7-18. Total sample and group differences were examined. Random effects modeling found that participants in the Mainstreamed with TR arm showed the most improvement in decisional balance (b=.06, p=.02) and physical activity barriers (b=-.05, p=.04) over time whereas participants in the Negotiated no TR arm showed the most improvement in stage of change (b=-.27, p=.01) over time. Main findings and interactions with covariates will be reported. These findings will contribute to tailoring TR strategies that target physical activity maintenance among diverse older adults with OA in the future.

64th Annual Scientific Meeting
they have significantly better health in middle and old age than average Americans, controlling for income and education levels. We utilize lifespan developmental theory to consider several factors beyond the physical exercise value of TGQ that may be responsible for the exercise group differences.

PERCEIVED HEALTH, PHYSICAL ACTIVITY PARTICIPATION AND THE STAGES OF EXERCISE BEHAVIOR CHANGE IN OLDER ADULTS

M. Seo, R.M. Lyle, 1. SUNY Oswego, Oswego, New York, 2. Purdue University, W. Lafayette, Indiana

This study examined differences in perceived physical and mental health status across five stages of exercise behavior change as well as relationships between physical activity participation and stages of exercise behavior change. Older adults (N=188; mean age = 71.1, SD = 8.5) living in a Midwestern community completed a questionnaire that included demographic information, Stages of Exercise Behavior Change (SEBC), 12-Item Short Form Health Survey Instrument (SF-12), and the Physical Activity Scale for the Elderly (PASE). Data were analyzed using descriptive statistics, Pearson’s r, one-way ANOVA and the Tukey HSD test. Results showed that perceived physical and mental health status differed across SEBC (F =9.3, p < .000, F = 10.1, p < .000, respectively). Older adults in the preparation, action and maintenance stages had higher scores on perceived physical health than those in the precontemplation and contemplation stages, while perceived mental was higher in the maintenance stage compared to other stages. Overall PASE scores [F (4, 182) = 6.67, p < .00] and mean scores of strenuous sport and recreational activity [F (4, 184) = 7.43, p < .000] also differed across SEBC. Older adults in the maintenance stage were more engaged in strenuous sport, recreational activities, muscle strength and endurance activities than those in the precontemplation, contemplation, and preparation stages. These findings should be considered when developing effective stage-based intervention strategies in order to increase the probability that older adults will move from a lower to a higher stage and maintain the stage shift.

PERCEIVED HEALTH STATUS AND PHYSICAL ACTIVITY IN OLDER ADULTS

A.N. Szabo, E.A. Olson, R.W. Motl, E. McAuley, Department of Kinesiology and Community Health, University of Illinois, Urbana, Illinois

Self-report health status (HS) is composed of several physical factors as well as mental or psychosocial factors. Psychosocial factors that may influence HS include fatigue, sleep quality, stress and cognitive ability. Although physical activity (PA) level has also been shown to be associated with HS, it is unclear as to whether this association differs by PA intensity. Older adults (N=242; Mage=71.2, SD=5.1) were screened for cognitive ability (Telephone Interview of Cognitive Status-Memory; TICS-M) and HS by telephone and completed measures of fatigue, sleep quality, and perceived stress via questionnaire. Participants wore an accelerometer for 7 days to assess PA. A total PA score was calculated by summing the counts from the valid days (>10 h of wear time). We conducted a series of hierarchical linear regression analyses to determine the independent contributions of the psychosocial factors and PA to HS. SEX and age were analyzed as covariates. Results showed that total PA (β=.285, p=.000) was an independent predictor of HS above fatigue, sleep interference, stress, cognitive ability, and demographics, F(2, 236)= 5.145, R2=.14. In subsequent analysis, the independent contributions of sedentary, light, and moderate to vigorous PA were examined. In this analysis, moderate to vigorous PA (β=.256, p=.002) and sex (β=.132, p=.047) were the best predictors of HS. Although total PA is related to HS in older adults, it appears that moderate to vigorous PA may play a more influential role in this relationship. This has implications for current public health recommendations for older adults.

PREPARING FOR DRIVING CESSION: DOES HEALTH OR PERSONALITY MAKE A DIFFERENCE?

N.W. Mullen, 1. Lakehead University, Thunder Bay, Ontario, Canada, 2. St. Joseph’s Care Group, Thunder Bay, Ontario, Canada

Background/Objective. Preparing in advance for driving cessation may help older drivers with the transition to nondriver status. This project was conducted to determine whether health or personality affect older drivers’ preparedness or intentions to retire from driving. Method. 180 (84 male, 96 female) older drivers (mean age = 71.2 years) completed a questionnaire package that included measures of demographics, health (SF-12), personality (NEO-FFI Neuroticism and Extraversion), intentions to cease driving in the next 2 or 5 years, and whether drivers had thought about how they would get around following driving cessation. Results. Drivers who were older or in poorer health had greater odds of intending to cease driving (OR for a 10-year increase in age: 5.48, 95% CI: 2.44-12.32; OR for a 10-point increase in MCS = 1.80, 95% CI = 1.06-3.07). Conclusion. Although older drivers’ physical and mental health did not affect their driving frequency or driving distance, their mental health was associated with their satisfaction with the amount of driving they did. Future research should investigate this discord between driving patterns and driving satisfaction, with the goal of developing interventions to prevent the decline in driving satisfaction in older drivers with poorer mental health.

SESSION 2140 (PAPER)

SAFETY AT THE WHEEL

OLDER DRIVERS’ DRIVING PATTERNS AND SATISFACTION

N.W. Mullen, G. Kafka, M. Bedard, 1. Lakehead University, Thunder Bay, Ontario, Canada, 2. St. Joseph’s Care Group, Thunder Bay, Ontario, Canada

Background/Objective. The objective was to examine older drivers’ driving patterns, their satisfaction with these patterns, and whether these patterns were affected by health. It was hypothesized that driving patterns would be associated with satisfaction, and that health would affect both driving patterns and satisfaction. Method. 139 (64 male, 75 female) licensed older drivers (mean age = 71.5 years) living in an urban area of >100,000 people completed a questionnaire package that included measures of demographic variables, driving frequency, distance driven per week, satisfaction with their amount of driving, and health (SF-12). Results. Driving satisfaction was not associated with driving frequency or distance driven per week. Three regression models examined whether health measures predicted driving patterns and driving satisfaction, after controlling for gender and age. Health measures predicted neither driving frequency nor driving distance. However, the Mental Component Score (MCS) of the SF-12 was a significant predictor of driving satisfaction, such that healthier older drivers had greater odds of being satisfied with the amount of driving they did (OR for a 10-point increase in MCS = 1.80, 95% CI = 1.06-3.07). Conclusion. Although older drivers’ physical and mental health did not affect their driving frequency or driving distance, their mental health was associated with their satisfaction with the amount of driving they did. Future research should investigate this discord between driving patterns and driving satisfaction, with the goal of developing interventions to prevent the decline in driving satisfaction in older drivers with poorer mental health.
CONSTRUCT VALIDITY OF THE SAFE DRIVING BEHAVIOR MEASURE
Y. Wang, S. Classen, C.A. Velozo, B. Brumback, M. Bedard, S. Winter, D.N. Lanford, J. University of Florida, Gainesville, Florida, 2. Lakehead University, Thunder Bay, Ontario, Canada

Objective: To test the construct validity of the self- and proxy report Safe Driving Behavior Measure (SDBM), a tool developed to quantify older adults’ driving behaviors based on item response theory. Methods: We report on a convenience sample of 107 older drivers (mean age = 73.0, standard deviation [SD] = ±5.3, range = 65-85; male participants = 51.4%) and 107 family members/caregivers (mean age = 65.4, SD = ±13.4, range = 25-85; male participants = 27.1%) recruited from Florida, United States and Ontario, Canada. Two evaluators collected data. We examined the rating scale, item/person-level psychometrics, item hierarchy, and match between person and item calibrations of the SDBM ratings for three rater groups (driver, family member/caregiver and evaluator) using Rasch analysis. Results: Across the three rater groups, the analyses show good item separation (≥3.88), person separation (≥3.14), item reliability (≥0.94), person reliability (≥0.91), person strata (≥0.52), and Cronbach’s alpha (≥0.97); few infit misfitting items (≤15.9%); and mild ceiling effects (12.1% family member/caregiver). The average person measure (≥3.74 logits) is higher than the mean item calibration (anchored at 0) indicating a high functioning group of older drivers. Conclusions: The SDBM’s item hierarchy generally matches the conceptually hypothesized order of item difficulty (easiest to hardest items). The SDBM shows promise across raters to classify the drivers into 4 - 6 ability levels and to identify their unsafe driving behaviors, but more older drivers of a lower ability level need to be tested to complete the instrument calibration.

NATURALISTIC DRIVING EXPOSURE AND PATTERNS IN OLDER DRIVERS WITH PARKINSON’S DISEASE COMPARED TO AGE-MATCHED CONTROLS
A. Crizzle, A. Myers, Health Studies and Gerontology, University of Waterloo, Waterloo, Ontario, Canada

Symptoms of Parkinson’s disease (PD) can impair the ability to drive safely as has been shown in multiple studies examining performance via simulators and road tests. Survey studies have also shown higher crash rates (adjusted for mileage) in drivers with PD versus controls. However, exposure (km driven) has been based on self-report. Although a few studies have suggested that drivers with PD may self-regulate (e.g., by reducing exposure or avoiding challenging situations), all have been based on self-report. The primary goal of this study was to objectively examine driving practices in older drivers with PD compared to an age-matched group of healthy drivers by monitoring their driving over a two-week period using in-vehicle devices. The sample consisted of 27 drivers with PD (mean age 71.6±6.6, 78% men) and 20 controls (mean age 70.6±7.9, 80% men). Compared to objective measures, self-estimated km were inaccurate for both groups. According to the electronic vehicle data, the PD group drove significantly less overall (distance, duration and trips), at night, on week-ends and in bad weather. The PD group also had significantly slower response times on a brake test, higher depression scores, lower driving comfort scores and poorer perceptions of their driving abilities. Almost three-quarters of the PD group had mild cognitive impairment according to the Montreal Cognitive Assessment (MoCA), as did 45% of the controls. This finding is particularly noteworthy as many of the prior studies on PD and healthy older drivers have not assessed cognitive impairment.

SESSION 2145 (SYMPOSIUM)

AGEING, THE BODY AND SOCIETY: EMBODIED THEMES; CRITICAL PERSPECTIVES
Chair: W. Martin, School Of Health Sciences and Social Care, Brunel University, Uxbridge, United Kingdom
Co-Chair: J. Twigg, University of Kent, Canterbury, United Kingdom
Discussant: S. Katz, Trent University, Ontario, Ontario, Canada

There has been a wealth of work recently on the subject of the body across the humanities and social sciences. Most has, however, focused on younger, implicitly ‘sexier’ bodies. Social gerontology has, moreover, tended to avoid the subject of the body, in its struggle to assert the social and cultural determinants of ageing, as against the reductionist bio-medical accounts that dominate professional and popular discourses of age. This means, however, that the body in old age has remained largely untheorised and unexplored. The aim of this symposium is to bring together academics and researchers (members of the active and internationally recognised British Sociological Association (BSA) Ageing, Body and Society study group) whose work focuses on ageing and embodiment to explore and debate different theoretical perspectives and empirical findings on the social, cultural and biological dimensions of our bodies as we grow older. Higgs and Gilleard aim to move the debate regarding the ageing body forward by more clearly connecting ageing embodiment to discourses of distinction. Through an exploration of empirical research, Martin highlights the idea of an increasing sense of embodied vulnerability as people grow older. Dickinson examines how the older body is maintained in hospital through the provision of food and mealtimes. Twigg highlights the significance of fashion, consumption and the body by exploring how the UK High Street conceptualises older women. The symposium will conclude by highlighting and debating interconnections between the corporeality of ageing bodies and the socio-cultural context in which we live.

THE AGEING BODY AND THE CORPOREAL DISCOURSES OF IDENTITY
P. Higgs, C.J. Gilleard, Research Strategy, UCL, London, United Kingdom

Our concern in this paper is to move the debate regarding the ageing body forward through more clearly connecting ageing embodiment to discourses of distinction. By interrogating sociological approaches to the body and their relevance to the embodied identities of age, disability, gender and race we will argue that the corporeal features that typically define these important sources of social difference are mostly passed over in favour of textual readings of power relations which rarely connect with their bodily referents. Paradoxically, people of all sorts engage in body work as sources of gendered, racialised or age related identity. Much of this work done to skin, hair, size, shape and musculature has corporeal significance. To regard these practices as epiphenomena of cultural discourses is a mistake. Developing this theme allows for insights into the ageing body where its cultural interpretation engages with the socially mediated processes of disease, deficiency and decay.

EMBODYING VULNERABILITY: AGEING, BODIES, GENDER AND EVERYDAY LIFE
W. Martin, School Of Health Sciences and Social Care, Brunel University, Uxbridge, United Kingdom

The aim of this paper is to explore the complexities of an increasing sense of embodied vulnerability as people grow older. Whilst embodied vulnerabilities, ‘ontological security’, can be predominately dealt with by developing and sustaining daily routines, the ability to manage daily norms and practices can become increasingly problematic as people grow older as everyday routines are more frequently and, at times, unpredictably disrupted. Disruptions to daily routines and biographical identities include bodily changes; ill-health, bereavement and divorce; and increased perceptions and experiences of risks, such as, falls, safety

64th Annual Scientific Meeting

575
and security and mobility difficulties. The integrity and logic of the ageing body and everyday practices are questioned; the taken for granted nature of embodiment challenged. Through illustrations from empirical research the paper will show how perceptions and experiences of embodied vulnerabilities are related to chronological age, gender, social networks, living arrangements, and time and space.

**PATIENT EXPERIENCES OF HOSPITAL FOOD PROVISION: MAINTAINING THE OLDER BODY IN HOSPITAL**

A. Dickinson, Centre for Research in Primary and Community Care, University of Hertfordshire, Hatfield, Hertfordshire, United Kingdom

Food is vital to the maintenance of the physical body, but also has social and psychological roles important for health and well-being. Malnutrition and poor nutritional care of older patients in Westernised hospital settings have long been a concern. However, less well understood is how patients’ experience eating in this setting. This paper draws on interviews conducted with patients (n=81) during an action research study to explore their mealtime experiences. Patients undertake work in order to make the best of the hospital situation and ‘survive’ often through engaging in ‘self-sufficiency’ behaviour. Adaptations are made to adjust to the alien environment and foods, fit in with institutional constraints, and avoid asking for assistance. Patients also experience weight loss, varying impacts of disease and altered appetite. Despite these difficulties, mealtimes are important to patients, maintaining a sense of normality and providing temporal signals as well as providing nutrients essential for recovery.

**FASHION, CONSUMPTION AND AGE: HOW DOES THE HIGH STREET CONCEPTUALISE OLDER WOMEN?**

J. Twig, Sociology and Social Policy, University of Kent, Canterbury, United Kingdom

With changing demography and - for some at least - rising levels of disposable income, older people represent an increasingly significant segment of the market for consumer goods. Retailers and manufacturers are keen to address this silver market, but they face problems in doing so, partly as a result of their own preconceptions, but also as result of the values and prejudices held more widely in society, including by older customers themselves. The paper takes the area of fashion and dress to explore how the High Street conceptualises the older market. Drawing on interviews with a range of UK clothing retailers, it explores their responses to older customers. In doing so it addresses arguments about the interplay between cultural and bodily ageing, and role of consumption in the potentially changing character of later years.

**SESSION 2150 (SYMPOSIUM)**

**ATTACHMENT DYNAMICS IN LATER LIFE**

Chair: S. Nelis, Psychology, Bangor University, Bangor, United Kingdom

Discussant: J.R. Oyebode, University of Birmingham, Birmingham, United Kingdom

Attachment theory recognises that seeking and maintaining attachment bonds occurs across the lifespan. There is growing recognition of the importance of attachment in the lives of older adults, including the suggestion that attachment may affect adjustment to ageing and well-being in old age. Two papers will examine the importance of attachment for older adults. Cicirelli will discuss the importance of attachment figures and the strength of attachment in older adults. Nelis, Clare, Whitaker & Quinn will examine the sequelae of secure and insecure attachment in older people and the relationship between different attachment styles and social and emotional well-being. Attachment theory offers a framework for understanding issues relating to care receiving and caregiving. Two papers will discuss the importance of attachment representations for people with dementia and their caregivers. Clare, Nelis & Whitaker will examine the relationship between attachment and the subjective emotional experiences of people with dementia and their primary caregiver. Dr. Jan Oyebode, with research interests in attachment and relationship continuity in carers of people with dementia, will act as discussant for the symposium.

**ATTACHMENT STYLES OF OLDER ADULTS AND THE SPOUSE AS AN ATTACHMENT FIGURE**

V. Cicirelli, Purdue University, West Lafayette, Indiana

Recent studies reported that a majority of elders have dismissing attachment styles (desiring independence and avoiding close relationships). This study examined spousal relationships of those with a dismissing style. Participants were 86 elders, aged 60-92 (half married, half widowed). Attachment styles were derived from the RSQ. Participants named individuals who were attachment figures for the functions of proximity seeking, safe haven, secure base, and separation protest; strength of attachment to the spouse was obtained from the spouse’s position as an attachment figure. In chi-square analyses, married and widowed participants did not differ in the four attachment styles. Secure and dismissing married participants did not differ in the strength of attachment to a spouse; however, in ANOVAs secure participants had greater self ratings of energy level and mental health and less depressive symptomatology compared to dismissing participants (p < .05). Results are interpreted in relation to Carstenson’s socioemotional selectivity theory.

**ATTACHMENT ORGANIZATION AND THE SOCIAL AND EMOTIONAL WELL-BEING OF OLDER ADULTS**

S. Nelis, L. Clare, C.J. Whitaker, C. Quinn, Psychology, Bangor University, Bangor, United Kingdom

Attachment theorists have viewed old age as a period of reorganisation of the attachment system to meet the changes occurring with age, and there is a growing recognition of the importance of attachment in the lives of older people. Five hundred older adults were surveyed on their attachment behaviour and feelings using the Relationship Questionnaire. They also completed measures of social support, well-being, and adjustment to ageing. The dominant attachment style reported was dismissing. Securely attached older adults reported more frequent social contact and greater satisfaction with their current social relationships than insecurely attached respondents. Attachment security was also related to lower levels of anxiety and depression, and with a more positive attitude to ageing. Individuals with different attachment styles may be differentially prone to certain interpersonal problems such as depression, anxiety, and social isolation in later life.

**ATTACHMENT REPRESENTATIONS IN PEOPLE WITH DEMENTIA AND THEIR CAREGIVERS: IMPLICATIONS FOR WELL-BEING**

L. Clare, S. Nelis, C.J. Whitaker, Psychology, Bangor University, Bangor, United Kingdom

Attachment may have implications for the experience of giving and receiving care in dementia. This study examines the relationship between attachment and the subjective emotional experiences of people with dementia (PwD) and their primary caregivers. One hundred PwD chose their best fitting attachment style and rated their mood, sense of identity and quality of life. Caregivers rated their attachment style and completed measures of stress and well-being. Secure and dismissing attachment styles were the most prevalent for both PwD and carers. There was little concordance in attachment styles within the dyads. Attachment security was related to anxiety, quality of life and a stronger sense of identity in PwD. Carers of PwD with insecure attachment were more stressed and reported poorer relationship quality. The attachment styles of both partners may be particularly salient and attachment security may have implications not only for the PwD but also for caregivers.
SESSION 2155 (SYMPOSIUM)

HEALTH TECHNOLOGY DESIGN FOR OLDER ADULTS: FINDINGS FROM CREATE
Chair: T.L. Mitzner, Georgia Institute of Technology, Atlanta, Georgia
Discussant: K. Insel, University of Arizona, Tucson, Arizona
The Center for Research and Education on Aging and Technology Enhancement (CREATE) is a consortium of three universities: The University of Miami, Florida State University and Georgia Institute of Technology. CREATE is a collaborative center that brings together multidisciplinary researchers dedicated to improving technology design for older adults. This symposium will highlight several CREATE projects that address design issues relevant to older adults’ use of health technologies. Health technologies have the potential to facilitate older adults in performing health-related tasks, such as finding health information and disease monitoring. However, older adults must adopt and be able to use these technologies to maximize their potential benefits. Participants in this symposium will discuss usability and needs assessment research regarding health technologies for older adults. Czaja and colleagues will examine the perceived utility of Ehealth information, and the factors influencing website choices and trust of information contained on websites. Charness and colleagues will present findings concerning several aspects of reliability related to the use of a home health monitoring system that continuously captures and transmits physiological and environmental data (e.g., heart rate, blood pressure, weight). Boron and colleagues will explore older adults’ likes and dislikes related to their use of health technologies and health technology training. Mitzner and colleagues will examine the challenges that professional caregivers encounter when working with older adults and the potential of technology to alleviate these challenges. After this symposium, attendees will be able to discuss implications regarding health technology design and training for older adults.

ASSESSING THE RELIABILITY OF A HOME HEALTH MONITORING SYSTEM
N. Charness1, M. Fox1, C.A. Crump2, A. Papadopoulos1, 1. Psychology, Florida State University, Tallahassee, Florida. 2. AFrame Digital, Reston, Virginia
We present reliability analyses for data from a mobile monitoring study. AFrame Digital’s home monitoring system was deployed for 2 weeks in 9 Tallahassee households headed by seniors aged 75+. The system consisted of a wearable watch-like device collecting physiological and environmental data (e.g., heart rate, blood pressure, weight), and a touchscreen questionnaire device. Participants performed daily data collection tasks, kept information in journals, and completed aesthetics and comfort questionnaires. We discuss 4 measures of reliability: system reliability, data concurrence, study effectiveness, and system usability. Aside from pulse-oximetry values and fall detection (false alarms), reliability scores typically exceeded 80%. We discuss lessons learned.

CHALLENGES EXPERIENCED BY HOME HEALTH CARE PROVIDERS AND THE POTENTIAL FOR TECHNOLOGY SUPPORTS
T.L. Mitzner, S.E. McBride, J.M. Beer, W.A. Rogers, Georgia Institute of Technology, Atlanta, Georgia
Home health care supports aging in place and offers many benefits over institutionalized care, including reduced costs and reduced exposure to nosocomial infections. However, home health care providers may experience challenges because most homes are not designed as settings to administer health care. Furthermore, home health providers may need to use medical equipment and devices that were not designed for home use. The goal of this study was to investigate the difficulties encountered by home health care providers. We conducted structured interviews with eight registered nurses and eight certified nursing assistants to gain an understanding of the challenges they encounter when performing health care tasks for older adults. The tasks caregivers discussed included bathing, toileting, transfer, device use, medication management, and wound care. Our results will be discussed within the framework of human factors interventions, including the potential for technology supports.

OLDER ADULTS AND THE USE OF E-HEALTH INFORMATION
S.J. Craja1, S.N. Nair2, J. Shari3, H. Profita4. 1. Psychiatry and Behavioral Sciences, University of Miami Miller School of Medicine, Miami, Florida. 2. University of Miami Miller School of Medicine, Miami, Florida. 3. University of Miami Miller School of Medicine, Miami, Florida. 4. Georgia Institute of Technology, Atlanta, Georgia
There has been an enormous growth in consumer oriented health information technology applications to support health self-management tasks. However, the usability of many of these applications, such as health websites, is uneven across user groups such as older adults. One concern is the ability of consumers to identify reliable health information given the enormity and variety of health websites available. This paper will present data from a diverse sample of 60 adults (18 to 82 yrs.), who completed Internet based health information seeking tasks, regarding their use of health websites, trust in information found on these websites and factors influencing website choice and trust. Data on Internet self-efficacy and ratings of importance of website features and design factors will also be provided. In addition, age group differences on these issues will be presented. We will also discuss the implications of the findings for training and website design.

TECHNOLOGY USE FOR HEALTH CARE: OLDER ADULTS’ LIKES, DISLIKES, AND TRAINING PREFERENCES
J. Blaskewicz Boron1, T.L. Mitzner2, C.B. Faust1, A.E. Adams2, W.A. Rogers1. 1. Psychology, Youngstown State University, Youngstown, Ohio. 2. Georgia Institute of Technology, Atlanta, Georgia
Many older adults manage chronic diseases and take an active role in preventative health monitoring. Incorporating health-related technologies into daily life has become increasingly common. The ability to manage one’s health at home is advantageous. However, this does not suggest that use of health care related technologies is without difficulty. We conducted 12 focus groups with older adults aged 65-85 years to determine likes, dislikes, and training preferences for health care related technologies. On average, each focus group discussed seven different technologies (Range=3-16). The most frequently discussed technologies were blood glucose monitors, blood pressure monitors, telephones, computers, and the internet. Although the majority of comments were favorable regarding technology use (60%), there were also dislikes mentioned (35% of comments). Discussion will focus on likes and dislikes of specific health care technologies, as well as training preferences. These data have implications for improved design of and training for health care technology.

SESSION 2160 (SYMPOSIUM)

LIFESTYLE, HAPPINESS, AND WELL-BEING: DO GLOBAL EVALUATIONS AND DAILY EXPERIENCE DIFFER?
Chair: J. Smith, Institute for Social Research, University of Michigan, Ann Arbor, Michigan
Discussant: S.T. Charles, University of California, Irvine, California
Evidence about mind-body interactions, especially associations between positive affect and longevity, have contributed to a search for new methods to assess individual well-being. Traditional self reports
of satisfaction with specific domains and life-as-a-whole provide global information about subjective well-being but may not reflect daily life experiences associated with health outcomes. For example, whereas most older adults report high life satisfaction, they may be less positive about their actual daily experiences. Speakers in this session address gaps in our knowledge about the relationships between global evaluations, day-to-day affective experiences, and the time spent each day in activities that afford pleasure and misery. They describe findings from studies that examine experienced well-being (EWB) in the contexts of daily life using methods designed for use in large surveys. Smith and colleagues compare findings from two new short measures of yesterday’s activities, time use, and affective experiences (ROBUST project). Ryan and Gonzalez discuss sources of variability in these measures (e.g., activity participation, response bias) and the implications for theories that distinguish global and experienced well-being. Whereas the ROBUST project examines experienced well-being in the context of activities, Stawski and colleagues employ an end-of-day diary to assess the affective experiences associated with daily stressors (NSDE project). The methods described by all presenters complement momentary assessment techniques and detailed 24-hour day reconstruction diaries that are costly to use in large surveys and burdensome for older adults. Charles concludes with an integrative discussion of the processes underlying global and experienced well-being in midlife and old age.

THE ROBUST STUDY: FINDING WAYS TO SURVEY EXPERIENCED WELL-BEING
J. Smith, L.H. Ryan, Lark, Institute for Social Research, University of Michigan, Ann Arbor, Michigan
Kahneman and colleagues (2004) devised the Day Reconstruction Method which adapts detailed time use diaries to assess experienced well-being. They found interesting discrepancies between this measure of yesterday’s experiences and evaluations of well-being over longer time periods. We present findings from the ROBUST project in which we tested new survey measures of experienced well-being. Following a brief reconstruction of “yesterday”, we assess experienced well-being with an activity-linked measure and multiple Yes/No items about overall experiences yesterday. Data come from two studies, a computer-assisted in-person interview with a local sample (N = 320) and a computer-assisted telephone interview with participants recruited nationally using random digit dialing (N = 640). Samples are stratified by age decade (50s, 60s, 70s, 80s) and gender. We present results for age and subgroup differences in experienced well-being (activities, affect, and the time spent on these activities) and associations with global well-being and health.

DO ACTIVITIES MATTER FOR WELL-BEING YESTERDAY: FINDINGS FROM THE ROBUST STUDY
L.H. Ryan, J. Smith, Institute for Social Research, University of Michigan, Ann Arbor, Michigan
Recent developments in the theory and evaluation of daily experienced well-being (EWB) are providing new insight into individuals’ overall subjective well-being. The current study investigates the extent to which positive and negative EWB are associated with interindividual versus intrindividual variability, as well as associations with specific daily activities in a newly collected sample of older adults using a modified version of the DRM (N=960; age range = 50 - 94). Participants reported on up to 10 activities yesterday and feelings of well-being associated with each activity. Analyses were run using SAS PROC MIXED with activities nested within individuals. Intraclass correlations indicate that 51% of the variance in positive EWB is associated with between-person differences, whereas only 37% of the variance in negative WB was attributed to between-person differences. Finally, significant differences in the magnitude and direction of associations among daily activities with positive and negative EWB are identified.

DAILY EXPERIENCE, WELL-BEING AND LIFE SATISFACTION ACROSS THE LIFESPAN: METHODOLOGICAL IMPLICATIONS
R. Gonzalez, L.H. Ryan, J. Smith, University of Michigan, Ann Arbor, Michigan
We consider models accounting for age differences in life satisfaction and activity-based well-being in the ROBUST sample (ages 50-94). We generate several models, including one where age differences are due to differential scale responding versus differences in contextual effects on global and activity-based well-being. The analyses suggest activity-based well-being follows a different trajectory than global assessments, such that the age differences in life satisfaction may be due to discrepancies in scale use rather than an actual change in one’s evaluated life satisfaction. The activity-based measures suggest a different judgment mechanism that is not tied to age differences in response scale. These analyses allow us to test well-being processes, such as whether it is driven by positively evaluated activities, the absence of negatively evaluated activities, a combination of the two, and mechanistic differences by age. We discuss implications for well-being measurement and for theory development in this fledgling field.

EXPERIENCED NEGATIVE AFFECT AND DAILY STRESSORS THROUGHOUT ADULTHOOD AND OLD AGE
R.S. Stawski1, K.E. Cichy2, D. Almeida1, 1. University of Michigan, Ann Arbor, Michigan, 2. Kent State University, Kent, Ohio. 3. Pennsylvania State University, University Park, Pennsylvania
Recent research on well-being has emphasized the need to complement traditional assessments of global subjective well-being (SWB) with measures of experienced well-being (EWB). However, much research on EWB has relied on anchoring experienced emotions to respondent’s time use and activities. We seek to complement the existing EWB research by examining the negative emotions experienced as a result of daily stressors. Respondents included 2,022 adults (Mean Age = 57, SD = 12, Range = 33-84, 56% Female) from the second wave of the National Study of Daily Experiences. Participants completed eight consecutive nightly telephone interviews and reported on their daily stressors (i.e., interpersonal tensions, overloads, and network stressors) and four negative emotions (angry, anxious, sad, and shameful) they experienced as a result of these stressors. Preliminary analyses reveal considerable variability in the negative emotions experienced across different types of stressors, suggesting daily stressors may have unique emotional signatures.

SESSION 2165 (SYMPOSIUM)

PROMOTING AND MAINTAINING HEALTHY LIFESTYLE CHOICES: THE RHODE ISLAND SENIOR PROJECT
Chair: P. Clark, Gerontology, University of Rhode Island, Kingston, Rhode Island
Discussant: P. Clark, Gerontology, University of Rhode Island, Kingston, Rhode Island
The SENIOR (Study of Exercise and Nutrition in Older Rhode Islanders) Project, funded by the National Institutes of Health, is a large-scale, two-phase community-based multibehavioral health promotion intervention study of older adults, focusing on increasing and maintaining regular physical activity and fruit and vegetable consumption. The original study (N=1276), based on the Transtheoretical Model of Health Behavior Change and developed by an interdisciplinary research team, designed stage-tailored manuals, newsletters, expert system assessments, and telephone coaching protocols. Outcome data using a comprehensive set of measures were collected at baseline, 12, and 24 months. A follow-up study (N=470), focusing on the active maintenance of healthful behaviors, uses a similar intervention but is based on the concept of resilience in the face of potential setbacks associated with aging. The first paper in this symposium reports findings on the negative...
PHYSICAL ACTIVITY AND OBESITY ARE RELATED TO FUNCTIONAL STATUS IN OLDER ADULTS

D. Riebe, B. Blissmer, G.W. Greene, K. Stamm, F. Lees, P. Clark
Kinesiology, University of Rhode Island, Kingston, Rhode Island

Older adults are the least physically active of all age groups with 22% of people >65 years engaging in regular physical activity (PA). Further, 31% of older adults are classified as obese. This study investigated the effects of physical activity and obesity on functional status in 402 older adults (age = 79.8±5.5 yr). After controlling for age and gender, subjects who participated in regular PA had lower timed Up & Go (TUG) scores and higher levels of flexibility, strength, and cardiorespiratory fitness compared to sedentary individuals. Sedentary individuals were nearly four times as likely to have abnormal TUG scores (>14 sec) compared to those who were physically active (25.9% vs. 6.5%). Individuals who were obese had higher TUG scores and lower levels of cardiorespiratory fitness compared to individuals who were normal weight and overweight and were nearly twice as likely to have abnormal TUG scores (27.1% vs 12.0% and 13.9%, respectively).

IMPACT OF AGE, OBESITY, AND PHYSICAL ACTIVITY ON QUALITY OF LIFE IN OLDER ADULTS

B. Blissmer, P. Burbank, D. Riebe, G.W. Greene, F. Lees, K. Stamm, P. Clark
Kinesiology, University of Rhode Island, Kingston, Rhode Island

Improving health-related quality of life (HRQOL) for older adults is the ultimate goal of many lifestyle interventions. This study analyzed the unique and joint impact of age, obesity status, and physical activity behavior on components of HRQOL using data from 818 older adults (M age = 77.3) participating in a healthy lifestyle intervention. Multivariate analyses controlling for gender, marital status, and intervention condition found main effects for age, activity, and obesity status on the SF-36 composite scores and subscales. Generally, being older and obese negatively impacted physical health, being active improved physical health, and being obese was linked to improved mental composite scores. A three-way interaction suggests that younger, obese, inactive individuals suffered significant decrements in mental composite scores relative to other groups. Similar patterns were found in the SF-36 subscales. Discussion includes implications for understanding the unique and combined effects of aging, staying active, and avoiding obesity on HRQOL.

CHARACTERISTICS OF LONG-TERM MAINTAINERS OF FRUIT AND VEGETABLE INTAKE IN OLDER ADULTS

G.W. Greene, D. Riebe, B. Blissmer, K. Stamm, F. Lees, P. Clark
Nutrition and Food Sciences, University of Rhode Island, Kingston, Rhode Island

Maintaining a high intake of fruits and vegetables (FV) has been associated with improved health outcomes. This study compared older adults (mean age 81±5.6 yrs, BMI 29.2±6.8 kg/m2, 76% female) who had maintained consumption ≥5 servings FV/day for 6.5 years (n=156) to those who failed to maintain this intake over the time period but had reached the target at 24 months (n=233). Those who increased intake to target over the initial 24 months were less likely to be maintainers (29%) than those who maintained target intake (53%). At 6.5 years, maintainers had higher self-efficacy, social support, FV intake, years of education, and were more likely to live with others and be married than non-maintainers. There was no difference by age, BMI, depressive symptoms, gender, race, or history of falls. Future qualitative and quantitative research is needed to learn how older adults can maintain a high FV intake.

LONGITUDINAL PATTERNS OF GOAL MAINTENANCE AND RESILIENCE IN OLDER ADULTS

M. Milanesi1,2, K. Saint3, F. Lees1, J. Saint1, J. Mulligan3, 1. VA Boston Healthcare System, Boston, Massachusetts, 2. Harvard Medical School, Boston, Massachusetts, 3. University of Rhode Island, Kingston, Rhode Island

Adherence to dietary and exercise goals was examined in 234 older adults across 19 months. Participants received biannual phone coaching calls designed to assist them in maintaining healthy behaviors in the face of age-related stressors. Latent class growth analysis was utilized to identify trajectories of goal maintenance over time. As predicted, four classes emerged: (1) maintainers, those meeting goals and having few stressors (30.3%), (2) resilient, those meeting goals despite stressors (25.2%), (3) stuck, those who are having more difficulty meeting goals as stressors emerge (23.5%), and (4) low motivation, those who have been unable to maintain their goals whether or not stressors were present (20.9%). Results suggest that most older adults are able to maintain goals over time, but additional intervention may help a subgroup navigate life stressors in order to improve their resilience.

SESSION 2170 (SYMPOSIUM)

PSYCHOSOCIAL PREDICTORS OF COGNITIVE DECLINE AND END-OF-LIFE PLANNING FROM THE WISCONSIN LONGITUDINAL STUDY (WLS)

Chair: S.A. Beaudreau, Palo Alto VA Health Care System/ Sierra Pacific Mental Illness Research Education and Clinical Centers (MIRECC), Palo Alto, California, Stanford University School of Medicine, Stanford, California
Co-Chair: J. Fairchild, Palo Alto VA Health Care System/ Sierra Pacific Mental Illness Research Education and Clinical Centers (MIRECC), Palo Alto, California
Discussant: C. Roan, University of Wisconsin, Madison, Wisconsin

This symposium presents three complementary investigations on the impact of psychosocial variables on late-life behavioral outcomes from the Wisconsin Longitudinal Study (WLS). Two presentations focus on predictors of cognitive decline from mid- to late-life, one on the role of the Big 5 personality traits on delayed memory, verbal fluency, and abstract reasoning, the other on exercise frequency and intensity as predictors of decline on these three cognitive measures. The third presentation examines the role of caregiving on end-of-life choices, and the impact of personality on these end-of-life decisions. The Discussant, a scientist on the WLS project since 2005, will provide her insights regarding use of this large longitudinal study to disentangle critical issues of aging. She will also discuss how these three studies using the data from the Wisconsin class of 1957 inform the larger gerontological literature.

IMPACT OF CARE-RECEIVING ON END-OF-LIFE PREPARATIONS

J. Ha1, M. Pai2. 1. University of Chicago, Chicago, IL, 2. Kent State University, Kent, Ohio

This study examines: (1) the association between being a care recipient and end-of-life care planning, and (2) the extent to which personality traits moderate the relationship between receiving care and engagement in end-of-life treatment preparations. Findings based on data from Wisconsin Longitudinal Study (WLS), a study of Wisconsin High school graduates from 1957 to 2004, reveal that care receivers are more likely to plan for end-of-life medical treatment, appoint a durable power of

This study examines the impact of personality on cognitive impairment and decline from mid-life to late-life. Participants were 9,031 Wisconsin high school graduates (class of ‘57) enrolled in the Wisconsin Longitudinal Study (WLS). Based on prior research, neuroticism was predicted to be detrimental to cognitive functioning. Conscientiousness, openness, extraversion, and agreeableness were predicted to protect against decline in cognitive functioning. Openness to new experiences predicted less decline in memory recall, verbal fluency, and attention. Extraversion or sociability, and conscientiousness also predicted less decline in memory recall and attention. Agreeableness was associated with less decline in memory recall, but greater decline in verbal fluency and attention. Counter to prediction, neuroticism was not associated with cognitive decline on any of the cognitive measures. Findings suggest that interventions aimed at strengthening specific behaviors associated with personality, such as openness, are a potential avenue for improving late-life cognitive functioning.

Exercise at Midlife: What Role Does it Play in Cognitive Aging?

EXERCISE AT MIDLIFE: WHAT ROLE DOES IT PLAY IN COGNITIVE AGING?
J. Fairchild, S.A. Beaudreau, K. Rashid. 1. Palo Alto VA Health Care System / MIRECC, Palo Alto, California, 2. Stanford University, Stanford, California, 3. Palo Alto University, Palo Alto, California

Using data from the Wisconsin Longitudinal Study (WLS), the authors examined the impact of exercise at midlife on cognitive outcomes at a ten-year follow-up. Participants were grouped based on intensity (light and vigorous) and frequency (3 or more times a week; 1-2 times a week; 1-2 times a month, < 1 a month) of self-reported exercise. For verbal fluency, there was not a significant difference for the frequency of light exercise; however, those who did more frequent vigorous exercise performed better than those who did less frequent vigorous exercise. Persons who did more frequent light exercise performed better on measures of delayed verbal recall, though this was not replicated for vigorous exercise. Finally, those who reported more frequent light exercise and more frequent vigorous exercise performed better on measures of abstract reasoning. These findings support the benefit of exercise at midlife for cognition.

SESSION 2175 (SYMPOSIUM)

THE IOWA HEALTHY AND ACTIVE MINDS STUDY (IHAMS): A RANDOMIZED CONTROLLED TRIAL TO IMPROVE COGNITIVE FUNCTIONING IN OLDER ADULTS
Chair: F. Wolinsky, Health Management and Policy, University of Iowa, Iowa City, Iowa
Discussant: M. Merzenich, Posit Science Inc., San Francisco, California

Gradual cognitive decline across several domains including information processing speed, memory, orientation, attention, abstract thinking, and perception is a normal part of the aging process. IHAMS is a second-generation RCT building on the multi-site ACTIVE (Advanced Cognitive Training for Independent and Vital Elderly) findings that speed of processing training led not only to improved cognitive function, but also to statistically significant reductions in predicted medical expenses, the risk of global decline in the SF-36, the risk of worsening depressive symptoms, the risk of the onset of suspected clinical depression, and improvements in self-rated health over 1-5 years post-training. ACTIVE, however, had two serious design flaws (a no-contact vs. attention control group, and booster training conditioned on adherence) which were corrected in IHAMS. Moreover, IHAMS used a commercially available, user-friendly, second-generation of the speed of processing training software (Road Tour) used in ACTIVE, which has considerable promise for widespread implementation. Furthermore, IHAMS includes six different cognitive outcomes assessed at baseline and one-year follow-up (Useful Field of View [UFOV] also repeated post-training, Symbol Digit Modalities Test, Trail Making Tests A & B, Controlled Oral Word Association Test, Digit Vigilance Test, and the Stroop Color and Word Test), rather than just the UFOV as in ACTIVE. IHAMS enrolled and randomized 681 participants into four arms: on-site Road Tour training without booster (154), on-site Road Tour training with booster (148), on-site Crossword-Puzzle training (188), and take-home Road Tour training (191). This symposium presents the IHAMS design, and the post-training and one-year follow-up results.

FACTOR ANALYSIS OF THE COGNITIVE OUTCOMES IN THE IOWA HEALTHY AND ACTIVE MINDS STUDY (IHAMS)

IHAMS assessed six cognitive outcomes: the Useful Field of View (UFOV; 3-task PC version), the Symbol Digit Modalities Test (SDMT), the Trail Making Tests A and B (TMT), the Controlled Oral Word Association Test (COWAT), the Digit Vigilance Test (DVT), and the Stroop Color and Word Test (Stroop). Exploratory factor analysis (EFA) using principal components and oblique rotation revealed a simple structure (no factorial complexity) consisting of three factors at baseline that explained 66% of the variance in the six tests with all communalities > 0.50. The first factor reflected divided attention, and had principal (> 0.50) factor loadings for the UFOV, SDMT, and TMT A and B. The second factor reflected sustained attention, with the DVT total time and DVT error components loading on it. The third factor reflected processing speed, with the Stroop (word, color, and color-word components) and the COWAT loading on it.

POST-TRAINING AND ONE-YEAR FOLLOW-UP RESULTS IN THE IOWA HEALTHY AND ACTIVE MINDS STUDY (IHAMS)

On-site training involved 10 hours delivered in five 2-hour sessions over five-weeks. Take-home participants were asked to train for at least 10 hours over five-weeks, although the delivery of that training was left to their discretion, and they were allowed to train for more hours, and to train beyond five-weeks. Post-training UFOV testing occurred, on average, at 6-8 weeks post-baseline, with scores available for 616 participants. Logistic regression was used to model UFOV composite improvements > 100 ms, adjusting for the baseline UFOV composite score. Compared to the on-site crossword puzzle (attention-control) group, the on-site Road Tour training without booster, on-site Road Tour training with booster, and take-home Road Tour training groups had statistically significant (p < 0.001) adjusted odds ratios of 4.01, 5.52, and 5.15, respectively, with substantially greater improvement rates observed in the younger age strata. One-year follow-up results for all outcomes will be presented at the GSA meeting.
The design of the Iowa Healthy and Active Minds Study (IHAMs)

IHAMs is a second-generation, four-arm RCT building on the multi-site ACTIVE findings using the commercially available Road Tour software for speed of processing training, and the commercially available cross-word puzzle program (Boatload of Crosswords) for attention-control. We consented, enrolled, and randomized 681 patients from UI’s GIM and FP clinics, stratifying on ages 50-60 vs. 61-87. The four IHAMS arms were on-site Road Tour training without booster (154), on-site Road Tour training with booster (148), on-site Crossword-Puzzle training (188), and take-home Road Tour training (191). On-site training consisted of 10 hours in five sessions, and booster training at 11 months was 4 hours in two settings. Six different cognitive outcomes were assessed at baseline and one-year follow-up (Useful Field of View [also repeated post training], Symbol Digit Modalities Test, Trail Making Tests A & B, Controlled Oral Word Association Test, Digit Vigilance Test, and the Stroop Color and Word Test).

SESSION 2180 (SYMPOSIUM)

The Many Faces of Old Age: Images of Aging Across Contexts, Domains and Targets

Chair: C. Bowen, Jacobs Center on Lifelong Learning and Institutional Development, Bremen, Germany
Discussant: M.L. Hummert, University of Kansas, Lawrence, Kansas

This symposium showcases recent work concerning psychological images of aging. Psychological images of aging are associated with aging adults’ attitudes, behavior and cognitive performance, interpersonal interactions, as well as developmental patterns over time. In recent years great strides have been made to further distinguish and specify the rich, multi-faceted nature of images of old age and aging. For instance, images of aging are known to vary across cultures and racial/ethnic groups. Furthermore, people have perceptions of their own aging that are distinct from their general perceptions of aging and older people which may differentially affect immediate and long-term outcomes. Finally, both images of one’s own aging as well as general images of aging and older people are known to vary considerably across domains (e.g., cognition, health, personality). Chasteen and Kang as well as Bowen present their results on how images of older people vary depending on context (across racial groups and across countries, respectively). Diehl and colleagues present results revealing the multi-dimensional nature of how people view their own aging, specifically, their perceptions of age-related change. Finally, Komnadt and Rothermund present results which illustrate the differential relationships that images of one’s own aging and images of aging in general can have, in this case, on preparations for old age. Together the presentations in this symposium demonstrate how images of aging vary by context, domain, and target.

How Images of Aging Influence Reactions to Multiply-Categorizable Individuals

A. Chasteen, 1 S. Kang, 2. Psychology, University of Toronto, Toronto, Ontario, Canada; 2. University of Toronto Mississauga, Mississauga, Ontario, Canada

How do images and stereotypes of aging influence reactions to older individuals who belong to more than one stigmatized group? In two studies, we explored whether stereotypes of older adults interact with racial stereotypes. In Study 1, we examined young and older adults’ perceptions of anger and happiness on the faces of young and old Black and White men. In Study 2, we investigated current and projected trait-related perceptions of young and old Black and White men at various points across the lifespan. Across these studies, we found that age-based stereotypes combined with race-based stereotypes. Specifically, older Black and White men were characterized according to the age old stereotypes which most strikingly contrast them against their younger counterparts. Compared to the corresponding young targets, this results in relatively positive evaluations of older Black men, but relatively negative evaluations of older White men.

Thinking About the Future: How Age Stereotypes and Personal Aging Expectations Affect Preparations for Old Age

A.E. Komnadt, K. Rothermund, Department of Psychology, Friedrich-Schiller-University Jena, Jena, Germany

Preparing oneself for old age is a task that already starts in younger years, and that has a positive effect on well-being and adjustment in later life. In our study, we wanted to examine the role of stereotypes and personal views on aging for preparation across the life span. Therefore, preparations for “third age” (e.g., social relations, activities) and “fourth age” (e.g., care needs, living arrangements) were assessed in a large age-heterogeneous sample of German participants (N = 769; aged 30-80). The amount of preparations increased with age, but this age dependency was much stronger for “third age” preparations. Furthermore, negative personal views of one’s own aging negatively affected preparations for an active “third” age, whereas no such effects emerged for “fourth age” preparations. Our results thus speak in favor of a multidimensional conceptualization of preparation for old age and highlight the role of personalized views on aging.

Awareness of Age-Related Change: A Multimethod Approach to Measurement Development

M.K. Diehl, 1 H. Wahl, 2 K. Konieczny, 2 M. Schmoezl, 2 L. Linke, 1 R.T. McGrath, 1 Human Development & Family Studies, Colorado State University, Fort Collins, Colorado; 2. University of Heidelberg, Heidelberg, Germany

Diehl and Wahl (2010) defined the Awareness of Age-Related Change (AARC) as a person’s awareness of what they perceive as performance, or ways of experiencing life have changed as a consequence of having grown older. In this paper, we report on our efforts toward measuring AARC. For this purpose, focus group discussions with 47 individuals aged 40 years and older were conducted and a pilot version of a 60-item questionnaire was administered. The scales of the questionnaire represented the five conceptually postulated dimensions of AARC (health, cognition, social relations, social-cognitive functioning, and lifestyle). The preliminary measure was given to a sample of 300 adults. Findings underscore that individuals experience their aging in a multi-faceted way that goes beyond health and cognitive issues. Additional findings revealed that negative and positive AARC show consistent but opposite patterns of associations with personality traits and indicators of life satisfaction and successful aging.

Indicators of Older Adults’ Productivity and Perceptions of Older People

C. Bowen, Jacobs Center on Lifelong Learning and Institutional Development, Bremen, Germany

There are many ways in which older people can be “productive”, for instance, by doing paid or volunteer work, participating in political life, and as friends and grandparents to the younger generation. In the current research we investigated whether indicators of older people’s productivity (in this wider sense) were associated with the perceived status of older adults. We used the European Social Survey, a survey including over 50,000 participants across 28 countries, to investigate predictors of status perceptions on the individual-, regional- and country-level. Results indicate that approximately 15% of the variance between status perceptions of older people was on the country-level. Differences between countries could not be completely accounted for by differences in GDP or average life expectancy. First results suggest
that certain indicators of older adults’ productivity are indeed related to
the perceived status of older people.

SESSION 2185 (SYMPOSIUM)

WITNESS TO SIGNIFICANT OTHERS’ SUFFERING:
CONSEQUENCES FOR ADULTS’ BELIEFS, BEHAVIORS,
AND EMOTIONS
Chair: D. Carr, Institute for Health, Health Care Policy, and Aging
Research, Rutgers University, New Brunswick, New Jersey
Discussant: W.E. Haley, University of South Florida, Tampa, Florida

In the past decade, social scientists have become increasingly inter-
eted in the concept of “suffering.” This symposium explores how sig-
nificant others’ suffering affects the well-being and behaviors of older
adults. We conceptualize both caregiving and participation in end of life
decision making as processes that entail both witnessing a significant
other’s suffering, and efforts to ameliorate that suffering. However, both
of these processes may compromise the well-being of the caregiver.
Boerner and Mock examined the impact of amyotrophic lateral sclero-
sis (ALS) patients’ suffering on their caregivers. Results showed that
caregiver outcomes were differentially affected by psychological and
physical components of suffering; the impact of suffering was also mod-
erated by how supportive the patient was of the caregiver. Carr finds
that older adults who witnessed the painful or prolonged death of a sig-
nificant other are significantly more likely to engage in formal and infor-
mal advance care planning, although these effects do not differ signific-
tantly by race and ethnicity. Macdonald and colleagues find that
emotional adjustment to a significant other’s death is shaped by the
extent to which the survivor feels responsible for the patient’s suffer-
ing due to errors in administering complex at-home medications and
treatment. Monin, Schulz and Cook examined caregiving spouses’ ver-
bal accounts of partner suffering and its association with stress react-
ivity. They found that caregivers who tried to understand and were more
emotionally positive about their partners’ suffering experienced less car-
diovascular stress. We discuss the implications of our results for health
care policy and practice, including the use of hospice service and the
“off-loading” of professional caregiving to family caregivers.

LINGUISTIC MARKERS OF EMOTION REGULATION AND
CARDIOVASCULAR REACTIVITY IN OLDER
CAREGIVING SPOUSES
J. Monin1, R. Schulz2, T. Cook2, 1. Yale School of Public Health, New
Haven, Connecticut, 2. University of Pittsburgh, Pittsburgh,
Pennsylvania

This study examined the word content of caregiving spouses’ verbal
accounts of partner suffering and its association with stress reactivity.
Fifty-three individuals were audio-taped while they privately disclosed
an instance of their partner’s suffering and a typical interaction (i.e. a
meal with the partner). Cardiovascular reactivity (systolic and diastolic
blood pressure, SBP and DBP, and heart rate, HR) and self-reported
distress were measured during each account. Linguistic analyses deter-
mined emotion and cognitive processing word use. Results revealed that
using more positive words was associated with lower DBP, HR, and dis-
tress in general. Using more cognitive processing words (e.g. because,
think, realize) in the suffering account, but not in the typical interaction
account, was associated with lower HR. Results of this study have impor-
tant implications for identifying caregivers who have difficulty regu-
late their emotions in both stressful and typical partner interactions,
placing them at greater risk for negative health consequences.

I DON’T WANT TO DIE LIKE THAT...: IMPACT OF
SIGNIFICANT OTHERS’ SUFFERING ON ADVANCE CARE
PLANNING
D. Carr, Institute for Health, Health Care Policy, and Aging
Research, Rutgers University, New Brunswick, New Jersey

Dying patients often receive treatments that are futile, costly, and
unwanted. Through the use of formal (i.e., living wills and health care
proxies) and informal (i.e., discussions) advance care planning (ACP),
can patients control the treatments they accept or reject. However, only
half of older Americans engage in ACP, and scholars continue to iden-
tify psychological and structural obstacles to ACP. I hypothesize that
persons who witnessed the painful or prolonged deaths of significant
others will be more likely to do ACP. Using quantitative and qualita-
tive data from the New Jersey End of Life study (N=305), I find that
persons who witnessed others’ painful and prolonged deaths are 1.5-2.2
times more likely to do any of the three types of ACP. Patterns do not
differ significantly by race, although women who witnessed suffering
are more likely than men to engage in planning. Qualitative data pro-
vide explanations for the motivations behind ACP.

THE IMPACT OF PATIENT SUFFERING ON CAREGIVER
WELLBEING
K. Boerner1, S.E. Mock2, 1. Jewish Home Lifecare/Mount Sinai School
of Medicine, New York, New York, 2. University of Waterloo,
Waterloo, Ontario, Canada

This study of 52 patients with Amyotrophic Lateral Sclerosis (ALS)
and their caregivers examined the impact of two suffering components,
physical symptoms and distress (patient ratings), as well as patient sup-
port (caregiver rating of support from patient), on caregiver outcomes
(i.e., negative/ positive affect, and benefit finding). Regression analy-
ses were conducted with significant main effects found for patient dis-

tress in predicting caregiver negative affect, patient support in predict-

caring positive affect, and patient symptoms and support in predict-

caring benefit finding. We also found a significant two-

tive symptom and support by: Benefit finding was
not only more likely with greater physical suffering and patient support,
but it was also the case that caregivers who perceived the care recipi-
ent as unsupportive could only find benefit when this person experi-
enced intense physical suffering. Findings have important implications
for optimizing the design of caregiver support services.

SELF-BLAME AND TRAUMA IN BEREAVEMENT: THE
IMPACT OF HEALTHCARE OFFLOADING ON BEREAVED
CAREGIVERS
C. Macdonald, Sociology, University of Wisconsin, Madison,
Wisconsin

We use data from a two-year, ethnographic longitudinal study of
adult cancer patients and their family members providing complex med-
care at home. Caregivers were required to perform complex nurs-
ing tasks, including running IV medications, flushing catheter lines,
administering multiple daily medications, monitoring side effects and
complications, and deciding when to call the doctor. One-third of the
patients died during the study, enabling us to explore caregivers’ bereave-
ment outcomes. All of the care-giving family members (n=17) who
experienced bereavement expressed self-blame and responsibility for
the death, even when the death was unrelated to the quality of their care.
However, only those who witnessed suffering during death exhibited
post-traumatic stress disorder (PTSD) symptoms post-loss. We conclude
that shifting care from professional facilities to private homes, and from
trained nurses to untrained family members has profound implications
for caregiver bereavement, including self-blame. We discuss implica-
tions for health care policy and practice.
SESSION 2190 (PAPER)

BODY COMPOSITION AND BMI

IS PRENATAL GROWTH ASSOCIATED WITH BODY COMPOSITION IN LATE LIFE? FINDINGS FROM A BRITISH COHORT

D. Bann1, R. Cooper1, A.K. Wills1, J. Adams2, D. Kuh1, T. and Muscle Ageing Group1, 1. MRC Unit for Lifelong Health and Ageing; Division of Population Health, University College London, London, United Kingdom, 2. Clinical Radiology, Manchester Royal Infirmary, Manchester, United Kingdom, 3. MRC Human Nutrition Research, Cambridge, United Kingdom

The composition of the body has important implications for health and physical functioning and may be influenced by factors in early life. We examined whether prenatal growth, indicated by birthweight, influences fat and lean mass in later life. Included were 531 participants aged 60–64 from the MRC National Survey of Health and Development who attended two out of the six regional clinics where data collection and body composition measurement (dual x-ray absorptiometry) were completed 2006-11. Findings on this subsample show that birthweight was positively associated with lean mass in both men (β per kg increase in birth weight: 1.71kg; 95% CI: 0.24 to 3.17) and women (β: 2.42kg; 95% CI: 1.07 to 3.76). These associations remained after adjustment for childhood socio-economic circumstances, but were largely attenuated after adjustment for adult height in men (β: 0.35kg; 95% CI: -0.98 to 1.68), but not women (β: 1.29kg; 95% CI: 0.12 to 2.45). Birthweight was not associated with fat mass in either sex, before or after adjustments. These findings, if confirmed in the full dataset (n=1700, available June), suggest that pre-natal growth affects lean but not fat mass, in later adulthood. A high birthweight may reflect a greater number of muscle fibres attained at birth, which then track into adulthood. Attenuation of effect after adjustment for height suggests that this association is largely driven by increased body size in men, and additional factors in women. Optimal growth before birth may protect against the detrimental impacts of low muscle mass in later life.

THE JOINT EFFECT OF PHYSICAL ACTIVITY AND BODY MASS INDEX AT MID-LIFE ON COGNITIVE FUNCTION IN LATE LIFE: AGE GENE/ENVIRONMENT SUSCEPTIBILITY - REYKJAVIK STUDY

Background: Physical activity (PA) and body mass index (BMI) are associated with cognitive function, however the long-term joint effect of mid-life PA and BMI on cognition has not been extensively examined among older population. We examined the joint effect of midlife PA and BMI on midlife cognition. Methods: A population based cohort (born in 1907–1935) of men and women who participated in the Age, Gene/Environment Susceptibility - Reykjavik Study with an average age of 79 years (range: 70-88). The cohort was the subsample of the nation-wide Icelandic Longitudinal Health Study from Reykjavik. All participants completed a comprehensive neuropsychological test battery. Results: Analyses were based on 4777 participants (women = 58%) after excluding dementia cases. Compared with NPAO group (reference), PAO and PAN groups had significantly faster SP (PAO, β = 0.19; PAN, β = 0.25, p < 0.001), higher MEM (PAO, β = 0.14; PAN, β = 0.20, p < 0.001) and EF (PAO, β = 0.11; PAN, β = 0.12, p < 0.001), after controlling for demographic, behavioral, cardiovascular factors and apolipoprotein E genotype. However, no significant difference was found with NPAN group. Conclusion: Being physically active at mid-life even in persons who were overweight or obese BMI contributed to better cognitive function 26 years later.

REDUCED QCT ATTENUATION INDICATES INCREASED TRUNK INTRAMUSCULAR FAT IN WOMEN AND OLDER ADULTS

D.E. Anderson1,2, J. D’Agostino1, A. Bruno1,2, M.L. Boussein1,2, D.P. Kiel1,4, 1. Beth Israel Deaconess Medical Center, Boston, Massachusetts, 2. Harvard Medical School, Boston, Massachusetts, 3. Harvard-MIT Health Sciences and Technology Program, Cambridge, Massachusetts, 4. Institute for Aging Research, Hebrew SeniorLife, Boston, Massachusetts

Multiple factors contribute to age-related sarcopenia, including loss of muscle mass, decreased innervation of motor units, and decreased activity levels. Another possible factor is increased fat infiltration into muscle, which is indicated by reduced attenuation of muscles in quantitative computed tomography (QCT) scans. In the lower extremity, reduced muscle attenuation is associated with reduced knee extensor strength and poorer lower extremity performance independent of muscle size, as well as increased risk of hip fracture independent of bone mineral density. The purpose of this study was to examine trunk muscle attenuation for age and sex differences in QCT scans from the Framingham Heart Study Offspring and Third Generation Multidetector CT Study. A sample of 100 men and women was taken from the cohort, representing younger (ages 35-50) and older (ages 75+) age groups. Muscle attenuation was determined for 11 muscle groups at the T8 and L3 vertebral levels and multiple regression analysis was performed. Muscle attenuation was 15-75% lower in older adults (p < 0.001), and reduced in women for most muscles (p < 0.02), but not psoas major (p = 0.06) or external oblique (p = 0.94). Furthermore, age x sex interactions were not significant. These data suggest that intramuscular fat increases with age throughout the trunk, and that while intramuscular fat is higher in women than men, age-related changes are not sex-dependent. The increased fat infiltration of trunk muscles with age may contribute to postural instability and/or alter the loads applied to the spine during activities of daily living.

WAIST CIRCUMFERENCES AND DISABILITY AMONG OLDER ADULTS IN LATIN AMERICAN AND THE CARIBBEAN

S. Nam, K. Markides, S. Al Snih, University of Texas Medical Branch, Galveston, Texas

Objective: To examine the relationship between waist circumference (WC) and disability among older adults living in Latin America and the Caribbean. Methods: Data are from the Health, Well-Being and Aging in Latin America and the Caribbean Study (SABE). This study included 5,796 subjects aged 65 and older from the capital cities of six Latin America and Caribbean countries (Bridgetown, Sao Paolo, Santiago, Havana, Mexico City, and Montevideo) during 1999-2000. Sociodemographic variables, smoking status, medical conditions (arthritis, diabetes, heart attack, hypertension, stroke, or cancer), body mass index (BMI), WC, and activities of daily living (ADL) were obtained. Logistic regression analysis was used to estimate the odds of disability. Results: Mean of WC ranged from 89.4 cm in Havana to 96.2 cm in Santiago. Prevalence of high WC (> 102 cm in men and > 88 cm in women) ranged from 35.7% in Havana to 53.8% in Mexico City. Prevalence of ADL disability among those with high WC ranged from 15.2% in Bridgetown to 28.1% in Santiago. Logistic regression analysis using WC as a continuous variable showed that each one cm increase in WC was significantly associated with increased ADL disability after adjusting by age, gender, BMI, marital status, education, and smoking status.
across all cities except in Bridgetown and Santiago. When medical conditions were added in the equation, the relationship between WC and ADL disability was not longer significant in Sao Paolo and in Havana. Conclusion: Obesity measured by waist circumference was associated with ADL disability among older adults living in Latin America and the Caribbean. KEY WORDS: Obesity, BMI, WC, Disability, Older adults, Latin America, and the Caribbean

ADIPOSEITY AND ISOLATED SYSTOLIC HYPERTENSION IN OLDER ADULTS: DIFFERENTIAL ASSOCIATIONS BY SEX AND TREATMENT STATUS

Background: Obesity is associated with increased aortic stiffness with aging. However, it is unclear if isolated systolic hypertension (ISH), largely a consequence of aortic stiffness, is related to adiposity. Methods: We determined the association between adiposity and ISH in 2,067 participants (mean±SD age: 74±3 yrs, 53.1% female, 38.3% Black, 52.8% on anti-hypertensive medications) from the Health, Aging and Body Composition study who had ISH (systolic blood pressure [BP] ≥140 mmHg and diastolic BP <90 mmHg) or were normotensive/controlled (BP <140/90 mmHg). Participants with diastolic BP ≥90 mmHg were excluded. Adiposity was measured using anthropometry, dual energy x-ray absorptiometry, and computed tomography. Cardio-femoral pulse wave velocity was used to assess aortic stiffness. All analyses were stratified by sex and treatment status. Results: We identified 329 men (56.8% treated) and 388 women (67.8% treated) with ISH. Among treated men only, those with ISH had greater total and abdominal adiposity than men with controlled BP (p’s<0.05). In logistic regression models adjusted for age, race, education, site, smoking, alcohol, and physical activity, 1-SD increments in BMI (OR:1.25, 95%CI: 1.03-1.52); total body fat (OR:1.27, 95%CI: 1.04-1.55), abdominal subcutaneous fat (OR:1.25, 95%CI: 1.03-1.52), and abdominal visceral fat (OR:1.34, 95%CI: 1.10-1.64) were associated with ISH among treated men. Further adjustment for aortic stiffness only slightly attenuated these associations (p’s<0.05). No significant associations were found in women or untreated men. Conclusions: In older men on anti-hypertensive medications, adiposity was positively associated with ISH among treated men and abdominal visceral fat area and total sedentary time, and directly related to moderate physical activity time. Visceral fat area was the only independent predictor using stepwise regression models of these variables. Conclusions: Monocyte sensitivity to insulin has been shown for the first time to be related to conventional measures of IR as well as potentially modifiable risk factors for IR. Immune function deficits in diabetes could be attributable in part to monocyte insensitivity to insulin.

RELATIONSHIPS BETWEEN SKELETAL MUSCLE C-JUN N-TERMINAL KINASE (JNK) AND HEALTH STATUS INDICATORS IN OLDER ADULTS WITH TYPE 2 DIABETES

Q. Guo, Y. Wang, K.A. Anderberg, Y. Mavros, M. Kay, D. Simar, N.A. Singh, M.A. Fiatarone Singh, 1. The University of Sydney, Sydney, New South Wales, Australia, 2. University of New South Wales, Sydney, New South Wales, Australia, 3. Tufts University, Boston, Massachusetts

Background Insulin resistance (IR) in skeletal muscle accounts for most metabolic disturbances in type 2 diabetes (T2D), c-Jun N-terminal kinase (JNK) is a stress-related factor which impairs insulin sensitivity. It is necessary to better understand how JNK is related to health status indicators related to insulin resistance in T2D cohort, so as to identify potential ways to beneficially modify JNK activity. Methods The Graded Resistance Exercise And Type 2 Diabetes (GREAT2DO) study was a randomized double-blind, sham-exercise controlled trial designed to assess the efficacy of power training in the GREAT2DO study cohort. Potential relations between baseline health status indicators and skeletal muscle JNK were assessed, including age, burden of chronic disease and habitual physical activity level, by validated questionnaires. Skeletal muscle JNK was measured by Western Blots in biopsy after an acute bout of resistive exercise, a stimulant for JNK in some prior studies. Results Results were available for 35 subjects (67.8±6.2 years, 46% female). Total number of medications/day was 5.1±2.9. The Physical Activity Scale for the Elderly (PASE) score, an indicator of habitual activity level, was 125.3±60.5. The average JNK protein level was 0.5±0.4 arbitrary units. Total JNK tended to be associated with poorer health status: higher numbers of medications/day (r=0.304, p=0.080) and lower physical activity level (r=-0.333, p=0.055). No significant relationship was found between JNK and age. Conclusion This was the first study to analyze relationships between skeletal muscle JNK and health status indicators in an older T2D cohort. As hypothesized, higher JNK tended to be related to worse health status, but larger studies are needed to confirm this. JNK-dependent insulin resistance may be a modifiable pathway by which exercise can influence glucose uptake and metabolism, but remains to be tested.

SESSION 2195 (PAPER)

DIABETES

GLUCOSE TRANSPORTER-4 EXPRESSION IN MONOCYTES IS CORRELATED TO INDICES OF INSULIN RESISTANCE IN OLDER ADULTS WITH TYPE 2 DIABETES

M.A. Fiatarone Singh, Y. Mavros, D. Simar, K.A. Anderberg, M. Kay, Y. Wang, N.A. Singh, A.O'Sullivan, 1. University of Sydney, Lidcombe, New South Wales, Australia, 2. University of New South Wales, Sydney, New South Wales, Australia, 3. Balmain Hospital, Sydney, New South Wales, Australia, 4. Hebrew Senior Life, Boston, Massachusetts, 5. Jean Mayer USDA Human Nutrition Research Center on Aging, Tufts University, Boston, Massachusetts, 6. St George Hospital, Sydney, New South Wales, Australia

Objective: Monocytes may be a clinically relevant model to investigate the relationships between insulin signalling and glucose transporter 4 (GLUT-4) translocation in vivo, as monocytes have a key role in immunity, and impairments in glucose metabolism may affect their function. Only one previous study has investigated the GLUT-4 translocation in monocytes in participants with type 2 diabetes. However, there are no data correlating GLUT-4 translocation in monocytes to conventional measures of insulin resistance (IR), body composition or physical activity in any cohort. Method: Baseline data from 51 older adults with type 2 diabetes participating in a randomized trial of exercise were analysed for this cross-sectional study. The abundance of GLUT-4 on the monocyte membrane was determined using flow cytometry. Fasting glucose, insulin, c-peptide, HbA1c and adiponectin were measured and Homeostatic Model of Assessment 2 (HOMA2) indices were calculated using the HOMA2 calculator. Body composition was measured via computed tomography and bioelectrical impedance analysis. Results: As hypothesized, GLUT-4 expression on the monocyte membrane relative to circulating insulin was inversely related to HOMA2-IR and HOMA2-%B, as well as visceral fat area and total sedentary time, and directly related to moderate physical activity time. Visceral fat area was the only independent predictor using stepwise regression models of these variables. Conclusions: Monocyte sensitivity to insulin has been shown for the first time to be related to conventional measures of IR as well as potentially modifiable risk factors for IR. Immune function deficits in diabetes could be attributable in part to monocyte insensitivity to insulin.
SKELETAL MUSCLE AND SUBCUTANEOUS ADIPOSE TISSUE ADAPTATIONS TO POWER TRAINING IN OLDER ADULTS WITH TYPE 2 DIABETES: A DOUBLE BLIND, RANDOMIZED SHAM-EXERCISE CONTROLLED TRIAL

Y. Wang1, D. Simar2, K.A. Anderberg1, Y. Mavros3, M. Kay1, B. Baune4, N.A. Singh1,4,5, M.A. Fiatarone Singh1,4, J. The University of Sydney, Sydney, New South Wales, Australia, 2. The University of New South Wales, Sydney, New South Wales, Australia, 3. The University of Adelaide, Adelaide, South Australia, Australia, 4. Balmain Hospital, Sydney, New South Wales, Australia, 5. Royal Prince Alfred Hospital, Sydney, New South Wales, Australia, 6. Tufts University, Boston, Massachusetts

Objective: Exercise has been shown to improve insulin resistance, but the mechanisms are not completely understood. We hypothesized that high intensity power training would improve insulin signaling pathway components and anti-inflammatory state in thigh skeletal muscle and subcutaneous adipose tissues in older adults with type 2 diabetes. Method: We conducted a double-blind, randomized, sham-exercise controlled trial of high velocity, high intensity resistive training 3 times/week for 12 months vs. sham exercise. Fifty of the 103 participants enrolled in this trial had muscle and adipose tissue biopsies performed with blinded measurements of components of the insulin signaling cascade and inflammatory markers via protein studies. Results: Participants [67.8±6.2 years old, 47.9% female, and BMI 30.6 (22.8-54.6)] were similar at baseline between groups. There were no significant effects of time or group assignment on any of the insulin signaling pathway components, inflammatory or growth factors in skeletal muscle and subcutaneous adipose tissue, nor on glucose homeostasis, insulin resistance, systemic inflammation, or whole body composition. Expectedly, Interleukin 6 in adipose tissue decreased significantly in both groups over time. Unexpectedly, heat shock protein 72 in skeletal muscle and adiponectin in adipose tissue decreased significantly in both groups over time. Insulin resistance improved in direct proportion to decreases in percent body fat and thigh skeletal muscle tumor necrosis factor-α. Conclusions: Insulin resistance improves related to improvements in body fat and inflammation in adipose tissue. Future studies need to identify ways to augment this adaptation to exercise in this cohort.

CLINICALLY COMPLEX ADULTS WITH DIABETES - FOUR-YEAR MORTALITY IN THE HEALTH AND RETIREMENT STUDY

P. Lee, C. Cigolle, C. Blaum, Internal Medicine, University of Michigan, Ann Arbor, Michigan

It is often recommended that management of complex patients with diabetes be based on life expectancy. Our previous research classified adults ≥51 years of age with diabetes into clinical groups: relatively healthy (RH), diabetes self-management difficult (DSMD), and limited benefit from diabetes management (LB). We hypothesized that those in the DSMD and LB groups would have higher 4-year mortality than RH adults. We analyzed data from waves 2004-2008 of the Health and Retirement Study, a longitudinal, nationally representative survey of adults aged ≥51 years. Respondents with diabetes (n=3,506) were classified as RH (few comorbidities), DSMD (≥3 comorbidities, mild cognitive and/or visual impairment, IADL difficulty), or LB (multiple comorbidities and/or severe cognitive and/or visual impairment, ADL dependency, and/or in long term care facilities). Cox proportional hazard regression models were used; death was obtained from the National Death Index. At four years, 641 respondents (18%) died: 11%, 23%, and 49% from RH, DSMD, and LB groups, respectively. Among respondents aged ≥76 years old, the mortality rates were 21%, 37%, and 69% for the RH, DSMD, and LB groups, respectively. Adjusting for demographics, the hazard ratios (95% confidence interval) for death were 1.88 (1.46 - 2.42) and 4.57 (3.75 - 5.56) for the DSMD and LB groups respectively, compared to the RH group. We conclude that many people with complex health status, either poor self-management ability or potential limited benefit, survived after 4 years. Targeted diabetes management interventions for these complex patients are needed to improve diabetes care and functional status.

METABOLIC SYNDROME, INCIDENCE OF DIABETES AND MORTALITY AMONG ELDERLY

M. Noale, S. Maggi, F. Limongi, G. Romanato, G. Crepaldi, CNR, Institute of Neuroscience, Padova, Padova, Italy

The aim of the present work is to investigate if Metabolic Syndrome (MetS) can predict incidence of diabetes and all-cause mortality among elderly subjects. The analyses were based on data from the Italian Longitudinal Study on Aging which enrolled 5,632 subjects aged 65-84 years, between 1992 and 1996. The prevalence of MetS according to NCEPATP III, was calculated among subjects without diabetes at baseline. Logistic regression models were defined to study the influence of MetS on incidence of diabetes, adjusting for MetS components and confounders. Cox Proportional Hazard Models were defined to determine the death risk attributable to the synergic association of MetS and diabetes, classifying subjects into four groups: (1) those without MetS and diabetes (reference group); (2) those with diabetes but without MetS; (3) those with MetS but without diabetes; (4) those with MetS and diabetes. MetS was strongly associated with risk of incident diabetes (OR=3.00, 95% CI 1.14-7.85). Adjusting for possible confounders, MetS maintain an important role (OR=3.93, 95% CI 0.97-16.03), together with fasting glucose component. During the follow-up, subjects with diabetes but without MetS had a borderline risk of all-cause mortality (HR=2.26; 95% CI 0.95-5.41); subjects with MetS but without diabetes did not have a significant risk of death. Elderly participants with co-presence of MetS and diabetes had an almost threefold risk of death than the reference group (HR=2.68; 95% CI 1.10-6.55). MetS is associated with incidence of diabetes, and the synergic association MetS-diabetes is an important risk factor for all-cause mortality among elderly subjects.

SESSION 2200 (SYMPOSIUM)

ASHES! ASHES! WE ALL FALL DOWN!—BUT WHO GETS HURT?

Chair: G.A. Pepper, College of Nursing, University of Utah, Salt Lake City, Utah
Discussant: J.F. Wyman, University of Minnesota, Minneapolis, Minnesota

Although up to one-third of adults over 65 years fall each year, this rate is not necessarily higher than for younger adults. What makes falls by older adults a continuing priority of Healthy People 2020 is the greater rate and severity of injury resulting from falls. Over 1.6 million U.S. elders per year suffer serious injuries requiring emergency room admission following a fall. Falls account for 25% of hospital admissions of older adults, 40% of nursing home admissions, and 40% of those hospitalized for a fall do not return to independent living, with up to 25% dying within a year of the fall. Yet the majority of descriptive research on falls by elders has focused on risk for all falls, rather than specifically on injurious falls which make up a minority of the total falls. Greater emphasis on description of injurious falls could increase the effectiveness of interventions to prevent injuries. This symposium features three descriptive studies of risks for injurious falls. While previous meta-analytic studies support the association of psychotropic drugs and falls, the first study is unique in focus on the association of hip fracture and psychotropics, differentiating newer antipsychotic and antidepressant drug groups that are reputed by some to be less prone to cause falling. The second study analyzes characteristics of falls by older adults treated in a trauma service. Finally, using a mixed methods design, risk factors for falls by subjects in an exercise intervention study resulting in no-injury, minor injury, and major injury were compared.
PSYCHOTROPIC-RELATED HIP FRACTURES AROUND THE WORLD: A META-ANALYSIS

L.H. Oderda1, C.V. Asche1, J. Young1, G.A. Pepper2, 1. Dept of Pharmacotherapy, University of Utah College of Pharmacy, Salt Lake City, Utah, 2. University of Utah College of Nursing, Salt Lake City, Utah, 3. University of Utah College of Health, Salt Lake City, Utah

Objective: To evaluate the association of psychotropic agents and risk of hip fracture in older adults. Methods: A PubMed search (1966-2010) was conducted with key words including [antipsychotic agents; psychotropic drugs; or antidepressive agents] and [hip fracture; fractures]. Studies included those with mean age ≥ 65 years and statistical adjustment by age/gender. Those excluded were studies where hip fractures were not distinguished from other fracture types. A random effects model was used to calculate summary odds ratios. Results/Conclusions: Of 166 studies identified, 8 antipsychotic-related studies and 15 antidepressant-related studies met the inclusion criteria representing over 85,000 hip fracture cases from four continents. Preliminary summary odds ratios include (95% confidence interval): conventional antipsychotics 1.66 (1.39, 1.98), atypical antipsychotics 1.29 (1.12, 1.48), tricyclic antidepressants 1.53 (1.28, 1.82), and selective serotonin reuptake inhibitors 1.94 (1.37, 2.76). All classes considered are associated with an increased risk of hip fracture in older adults.

DISCERNING RISKS FOR FALL INJURY: A MIXED METHODS STUDY

G.A. Pepper1, B. Wong1, J. Macintosh1, L. Dibble2, R. Marcus2, S. Latimer1, P. LaStayo2, 1. University of Utah College of Nursing, Salt Lake City, Utah, 2. University of Utah College of Health, Salt Lake City, Utah

Background/Objective: Most fall risk screening tools predict non-injury falls. The purpose of this exploratory mixed methods study was to identify factors associated with injury falls. Methods: A sample of 81 older adults (mean age =81; males=29.6%) with fall history and multiple co-morbidities sampled from an exercise intervention comparison study were divided into groups of non-fallers (n=29), non-injury fallers (n=19), minor-injury fallers (n=20), and serious-injury fallers (n=11) based on up to one year follow-up. Groups were compared quantitatively on baseline functional balance, timed-up-and-go, and timed walk. Themes emerging from qualitative analysis including prodromal symptoms, environmental hazards; pre-fall activity, location, and sensory impairment were compared by category. Results/Conclusions: Exploratory analysis suggests trends toward prodromal dizziness as a protective factor and visual impairment and poor functional balance (p=16) as contributors to serious injury requiring medical intervention. Current typologies do not distinguish injury falls. Additional research with larger samples is warranted.

TRAUMATIC FALLS IN OLDER ADULTS

S. Holt, J.F. Cortez, B.A. Winters, L.S. Edelman, College of Nursing, University of Utah, Salt Lake City, Utah

Introduction: Falls are a leading cause of injury and death for older adults. Falls are the predominant mechanism of injury of older adult trauma patients. Method: Records of adults aged 50+ years admitted to a Level 1 Trauma Service during 2007-2010 with injuries resulting from falls were reviewed. Falls were categorized as ground level (GL) or from a different level. Results: Sixty percent of falls treated by the trauma service were GL and the proportion increased with age. Women accounted for 52% of falls patients and were more likely to experience a GL fall than men. The mortality for GL falls was 3% compared to 9% for falls from a different level. Conclusion: The majority of falls treated by the trauma service are GL. Development of treatment and discharge protocols that facilitate older fall patients returning to pre-injury level of independence and quality of life is warranted.

SESSION 2205 (SYMPOSIUM)

CURRENT AND FUTURE APPROACHES TO MAINTAINING INTELLECTUAL VITALITY AND BRAIN HEALTH

Chair: G.J. McDougall, School of Nursing, University of Texas at Austin, Austin, Texas

Researchers and clinicians are facing a growing demand for information on cognitive aging and ways in which both patients and family can stay intellectually vital throughout their lifetimes. This symposium will provide an update on the current science of cognitive aging and brain health. We will review what steps can be taken to manage and perhaps reduce the effects of aging on intellectual function. Data from three unique studies of cognitive engagement will be presented as evidence for these trends. The presentation will conclude with future treatments to promote brain health. This symposium has five specific objectives and their relevant studies. First, we will evaluate the relationship between lifestyle components and cognitive function from twenty years of evidence. Next we will illustrate the differential benefits of memory training among Caucasian, Hispanic, and African-American older adults from the SeniorWISE study. Third, we present the findings from a randomized trial of a community-based, lay health educator delivered cognitive intervention. Fourth, we present the findings from one study testing Socioemotional Selectivity Theory and how this effects time and language use among older and younger adults. Finally, evidence from outreach programs teaching brain health are evaluated. An opportunity exists to bring research outcomes to community members for their quality of life and intellectual vitality. Program feedback reflects the relevance and novelty of this information, as expressions like “Use it or Lose It” and “Brain Fitness” have an increased presence in the media and commercial product marketing.

AN EVIDENCE-BASED INTEGRATED FRAMEWORK FOR BRAIN HEALTH

C.R. Green, Mt. Sinai School of Medicine, New York, New York

Clinicians face a growing demand to be knowledgeable and serve as a resource for information on cognitive aging and scientifically sound clinical approaches to maintaining intellectual vitality and dementia prevention. We conducted a comprehensive review of the scientific literature across multiple health science disciplines from 1990-2010 to determine what lifestyle behaviors, such as physical activity, mental activity, intellectual engagement, medical co-morbidities, social engagement, etc. have been significantly associated with maintained or improved intellectual performance across multiple neuropsychological abilities and reducing dementia risk. We will present the results of this literature review, and the resultant scientifically grounded, best practices model which clinicians can use to effectively evaluate programs and services for memory wellness and brain health promotion in seniors. The session will also provide discussion of the limitations of the current scientific literature on intellectual vitality, as well as consideration of future clinical approaches to prevention and treatment.

TIME FLIES WHEN IT’S RUNNING OUT: TIME HORIZONS AND EVENT AGENCY IN TEMPORAL LANGUAGE USE AMONG OLDER ADULTS

M.S. McGlone, Department of Communication Studies, The University of Texas at Austin, Austin, Texas

Socioemotional selectivity theory (SST; Carstensen, 1998) maintains that perceiving lifetime as limited has important implications for seniors’ motivation. Although the theory accounts for numerous motivational phenomena, researchers have not persuasively demonstrated that they are mediated by perception of shrinking time horizons. The reported study investigated this issue by exploring differences in senior and younger adults’ use of temporal language. In structured online interviews about future plans (N = 106), we observed that senior adults assigned grammatical agency to events (e.g., Thanksgiving is approach-
**DIFFERENTIAL BENEFITS OF MEMORY TRAINING AMONG COMMUNITY ELDERS**

G.J. McDougal1, H.A. Becker2, K. Pituch1, P.W. Vaughan1, T.W. Acee3, C.L. Delville1, 1. School of Nursing, University of Texas at Austin, Austin, Texas, 2. Texas State University, Austin, Texas

Cognitive training improves mental abilities in older adults, but the benefit to minority elders is unclear. In this secondary analysis we examined this issue. SeniorWISE was a Phase III randomized trial that enrolled 265 non-demented, community-dwelling older adults 65 years of age and older between 2001-2006. Participants were randomly assigned to 12 hours of either memory or health training. The sample was 79% female, 17% Hispanic and 12% African-American. Memory performance on the Rivermead Behavioural Test changed differently over time depending on the demographic characteristics of participants. Both Hispanics and Blacks performed better than whites on visual memory; and Blacks performed better over time on instrumental activities of daily living (IADLs). On all performance measures, lower pretest scores were associated with relatively greater improvements over time. Our analyses suggested that minority participants received differential benefits from the memory training and needs further exploration. Trial Registration ClinicalTrials.gov NCT00094731

http://www.clinicaltrials.gov/ct/show/NCT00094731

**A RANDOMIZED TRIAL OF A COMMUNITY-BASED, LAY HEALTH EDUCATOR DELIVERED COGNITIVE INTERVENTION**

C. Beck1, J. Kleiner-Faussett1, R. Krukowski1, C. Cornell1, T. Prewitt1, H. Felix1, D. West1, G.J. McDougal1, 1. College of Medicine, University of AR for Medical Sciences, Little Rock, Arkansas, 2. University of Texas at Austin, Austin, Texas

This cluster randomized trial of a cognitive intervention was conducted in 16 senior centers in which lay health educators delivered the 12-week intervention. Two-hundred and twenty-eight senior adults were recruited from senior centers randomized to either the cognitive or control weight loss intervention. Three Repeated Measures for the Assessment of Neuropsychological Status (RBANS) indices were examined (immediate memory, delayed memory and attention) as the primary outcome; a difference of 1.1 points (95% CI, 1.6-3.7) between arms was not significant. However, after adjusting for baseline delayed memory, gender, and baseline BMI, seniors in the cognitive arm had a 2.7 times higher odds of a 0.7 SD improvement (clinically significant) in delayed memory from baseline compared to the control arm (95% CI, 1.3-5.6, p=.011). Improvement on cognitive measures is comparable to other community based cognitive interventions, demonstrating that cognitive interventions can be effectively delivered in the community by lay health educators.

**EVIDENCE FROM OUTREACH PROGRAMS: IMPROVING QUALITY OF LIFE THROUGH COMMUNITY BRAIN HEALTH INITIATIVES**

D.A. Raybold, A.J. Estrada, R. Cox, Memorial Hospital of South Bend, South Bend, Indiana

Hospitals and community based programs are translating cognitive neuroscience into actionable, engaging daily lifestyle activities as part of general health prevention strategies. Memorial BrainWorks, a Midwestern hospital based community outreach program offers these types of programs. Program evaluation feedback was solicited from 4467 program participants in 2010. On completed surveys, 88% of individuals reported that “most or all” of the information was new, and 89% indicated that they will “do something different” in their life because of the information they learned. Another 50% of individuals gave consent to contact them in six months for follow-up on personal goals. An opportunity exists to bring research outcomes to community members for their quality of life and intellectual vitality. Program feedback reflects the relevance and novelty of this information, as expressions like “Use it or Lose It” and “Brain Fitness” have an increased presence in the media and commercial product marketing.
DOES FATIGUE PREDICT NON-FATAL ISCHAEMIC HEART DISEASE IN MIDDLE AGED DANISH MEN?
A. Ekmann1,2, M. Osler3, K. Avlund4,5, 1. University of Copenhagen, Copenhagen, Denmark, 2. Danish Aging Research Centre (DARC), University of Aarhus, Odense and Copenhagen, Denmark, Aarhus, Odense, Copenhagen, Denmark, 3. Centre for Healthy Aging (CESA), Faculty of Health Science, University of Copenhagen, Copenhagen, Denmark, 4. Research Centre for Prevention and Health, Glostrup University Hospital, Glostrup, Denmark

Midlife chronic disease may affect the risk of old-age disability. Early signs of chronic disease might serve as screening factors. An early sign may be fatigue. This study aimed at investigating the association between fatigue and ischaemic heart disease (IHD) in middle-aged men. Questionnaire-data were collected in 2004 within a cohort of Danish men born in 1953 (n=5266). Hospitalization with IHD was registered by the Danish National Registry of Patients between 2005 and 2008 (n=133). Fatigue was measured by questions on feeling worn out and energy level during the past four weeks. Analyses were stratified by blood pressure (BP). Among participants with normal BP, men who felt fatigued had HR 2.64 (C195%-1.30-5.34) compared to those not fatigued. Among participants with high BP, we found no association between fatigue and IHD. In conclusion, fatigue among healthy middle-aged men might be a first sign of progressing pathological processes and might serve as a subjective screening factor.

MOBILITY RELATED FATIGUE, WALKING SPEED AND MUSCLE STRENGTH IN OLDER PEOPLE
M. Manty1,2,3, C. Mendes De Leon4, A.N. Pedersen5, A. Ekmann6,7, M. Schroll1, T. Rantanen6,7, P. Era8, K. Avlund2,7, 1. Department of Public Health, University of Copenhagen, Copenhagen, Denmark, 2. Center for Healthy Aging, University of Copenhagen, Copenhagen, Denmark, 3. Gerontology Research Centre, University of Jyvaskyla, Jyvaskyla, Finland, 4. Department of Epidemiology, University of Michigan School of Public Health, Ann Arbor, Michigan, 5. Technical University of Denmark, Copenhagen, Denmark, 6. Research Centre for Prevention and Health, Glostrup University Hospital, Glostrup, Denmark, 7. Danish Aging Research Center, Universities of Odense, Aarhus and Copenhagen, Copenhagen, Denmark

The purpose of the present study was to examine the association between mobility related fatigue and walking speed, and to test the degree to which muscle strength accounts for this association. The study is based on baseline (n=647) and five-year follow-up data (n=351) from a cohort of 75-year-old persons. Standardized assessments include measures of mobility related fatigue, medical history, walking speed and muscle strength. One unit increase in fatigue scores was associated with 0.05 m/s (β = -0.05, p<0.001) and 0.02 m/s (β = -0.02, p = 0.16) lower walking speed in the cross-sectional and prospective analysis, respectively, while adjusting for important covariates. Muscle strength accounted up to 30% for the cross sectional and up to 11% for the prospective association between fatigue and maximum walking speed. Mobility related fatigue is associated with lower walking speed in older adults. The results suggest that muscle strength is one of the underlying factors explaining this association.

LEUKOCYTE TELOMERE LENGTH A BIOLOGICAL MARKER FOR FATIGUE IN AGING DANISH TWINS
L. Bendix1,2,3, M. Thinggaard1, M. Kimura4, A. Avis5, M. Osler2, K. Christensen1, 1. Danish Aging Research Center, Odense, Denmark, 2. Copenhagen University, Copenhagen K, Denmark, 3. University of Southern Denmark, Odense, Denmark, 4. New Jersey Medical School, Newark, New Jersey

Fatigue is a common complaint among elderly. While it is often a symptom of underlying psychiatric or medical illness, for many older persons it is not possible to identify an underlying cause. It has been suggested that oxidative stress (e.g. caused by mitochondrial dysfunction or chronic sub-inflammation) could be an underlying factor. Oxidative stress, as well as inflammation, is known to result in accelerated shortening of leukocyte telomere length. Telomeres are the specialized DNA structures located at the end of chromosomes, believed to work as the cells biological clock. We hypothesized that leukocyte telomere length (TLT) is a biomarker of fatigue. We present data showing a significant association between TLT and fatigue in 274 same-sex twins. We find that within twin-pairs the twin with the shortest telomeres is also significantly more often the twin that is most fatigued. Covariates such as smoking, BMI and depression did not explain the association.

QUALITIES OF FATIGUE AND ASSOCIATED CHRONIC CONDITIONS IN OLDER ADULTS
S.E. Hardy1, S. Studenski2, 1. Geriatrics, University of Pittsburgh School of Medicine, Pittsburgh, Pennsylvania, 2. Pittsburgh VA GRECC, Pittsburgh, Pennsylvania

Different qualities of fatigue may represent different underlying diseases or pathophysiologies. To elucidate the relationship between fatigue quality and disease, we examine their associations with mortality. Among 495 community-dwelling primary care patients aged 65+ years, we identified six different fatigue qualities: general, emotional, cognitive, lack of energy, sleepiness, and weakness. When controlling for age, race, and gender, each individual quality except emotional fatigue was significantly associated with mortality. When controlling for other fatigue qualities, only lack of energy remained a significant predictor of mortality (HR 1.91; 95% CI 1.41-2.59). This association remained highly significant after adjusting for the presence of chronic disease (cardiac, neurological, pulmonary, and diabetes). Fatigue qualities accounted for little of the association of these diseases with mortality. Different qualities of fatigue do not have independent effects on mortality. Fatigue’s effect on mortality is almost completely independent of chronic disease, suggesting differing pathophysiologies of fatigue and chronic disease.

SESSION 2215 (SYMPOSIUM)
INFUSING GERIATRIC BEST PRACTICES IN HOSPITALS: IMPROVING THE WORK ENVIRONMENT AND FOSTERING QUALITY CARE
Chair: M. Boltz, College of Nursing, New York University, New York, New York
Co-Chair: E. Capezuti, College of Nursing, New York University, New York, New York

Hospitalization is inevitable for the majority of older adults; thus the hospital setting will continue to play an essential role in the North American health care delivery system. Older adults are at increased risk for complications, unplanned readmissions, and costly rehabilitation consumption. Given that the hospital event has profound implications for the older adults’ post-acute longevity, functioning, and utilization of services, efforts to improve the quality of care and services during hospitalization are warranted. NICHE (Nurses Improving Care of Health-sytem Elders) is a national geriatric program that supports organizational capacity to provide age-sensitive care. Using the NICHE geriatric acute care framework, member organizations utilize guiding principles, clinical protocols, staff training programs, and benchmarking tools to improve the geriatric care environment. Using this framework, this session will address the urgent need to infuse geriatric best practices from the point of initial contact in the emergency department through post-acute care and in various settings, including rural sites. Presentations describe the geriatric care environment in multiple settings and the pressing issues demonstrated though benchmarked Geriatric Institutional Assessment Profile data, clinical outcomes, staff interviews, and field observations. The findings underscore the importance of geriatric-specific, system-level interventions to promote high quality care.
The significant role of patients and families in guiding implementation is emphasized.

NURSES’ VIEW ON THE CARE ENVIRONMENT FOR OLDER ADULTS IN THE EMERGENCY ROOM
J. Shuluk1, M. Boltz2, E. Capezuti1, V. Vaughan Dickson1, M. Secic3, I. College of Nursing, New York University, New York, New York, 2. Secic Statistical Consulting, Chardon, Ohio

Older adults’ experiences and outcomes in the emergency department (ED) are much less positive than those of younger patients. This secondary analysis utilized mixed methods to examine, in a national sample of ED nurses (N=1,382) from 73 NICHE hospitals, their perception of the geriatric care environment. Linear mixed methods demonstrated that, controlling for other nurse and institutional characteristics, older ED nurses (> age 42) find working with older adults more rewarding than younger nurses (F= 13.4, p <.001). Additionally, ED nurses find academic medical centers less elder friendly than non-teaching hospitals (F= 7.22, p < 0.001). Nurses identified common pressing issues to be addressed to improve the quality of care provided to older adults: improving staff knowledge of the evaluation and treatment of cognitive impairment, identification of the appropriate decision-maker, and prevention of complications in the ED, including skin breakdown, medication adverse events, and catheter-associated urinary tract infections.

A COMPARISON OF THE US AND CANADIAN NICHE GERIATRIC ACUTE CARE ENVIRONMENT

Significant positive relationships between Canadian nurses’ perceptions of their general nursing practice environment (NPE) and their perceived quality of patient care have been found comparable to American hospital nurses; lower care quality is associated with unfavorable quality of nurse-physician collaboration, managerial leadership, resources and staffing. Prior research has not described their views of work environment specific to caring to older adults. This secondary analysis examines perceptions of the geriatric NPE to their perceived quality of older patient care in a sample of 2,022 nurses from 8 Canadian hospitals who completed the Geriatric Assessment Institutional Profile, compared to 22,404 nurses from 209 US hospitals between 2005 and 2009. Canadian nurses perceived less legal vulnerability in their work environment; however, their perceptions of their NPE (55.6 ± 24.6 vs. 68.1 ± 21.04) as well as perceived quality of care (22.1 ± 10 vs. 25.5 ± 9.25) were less positive compared to US nurses.

RURAL HOSPITAL NURSES PERCEPTIONS OF CARING FOR OLDER ADULTS
M. Boltz, E. Capezuti, V. Vaughan Dickson, D. Cline, College of Nursing, New York University, New York, New York

Rural hospitals face a variety of challenges when providing care to hospitalized older adults. This qualitative study analyzes nurses’ responses to the following open-ended question: What are the most pressing issues you face when caring for older adults? Responses were gathered from 290 nurses working in 8 small (150 or less beds) rural hospitals participating in the Nurses Improving Care for Health System Elders (NICHE) program. Emerging themes include: the importance of family when caring for older adults and the continuum of care from home to hospital, and back to home. Study findings may inform organizations to develop more effective quality improvement initiatives aimed at improving care for older adults residing in rural settings.

IMPROVING CARE FOR OLDER ADULTS IN RURAL ACUTE SETTINGS
J. Shuluk, E. Capezuti, M. Boltz, V. Vaughan Dickson, C. Nigolian, College of Nursing, New York University, New York, New York

NICHE is a national leader in improving geriatric hospital care. NYS has the third largest population of older adults in the US with a higher proportion of elders in rural counties than the national average and yet there are no current NICHE sites serving rural areas. A barrier for hospitals in rural areas to join NICHE is that their size and location makes it difficult to employ a Geriatric Nurse Specialist (GNS) to facilitate NICHE implementation. We are utilizing a GNS to facilitate an on-line rural hospital learning community and a rural-urban collaborative via long-distance communication strategies. Findings from GNS logs of NICHE implementation in six hospitals in rural northern New York State indicates strong interest in learning and sharing best practices to meet their current and growing older patient population. Facilitated by recognition of their consumer needs, administrative support is essential for building and sustaining staff enthusiasm.

NICHE BOOST: IMPROVING NURSE AND HOSPITALIST CAPACITY TO DELIVER HIGH QUALITY TRANSITIONAL CARE

Hospitalization in older adults is associated with increased complications, post-acute services, and readmissions. This pilot study examined the feasibility of implementing a blended model of NICHE and BOOST in one large urban teaching hospital to modify hospital operations to support interdisciplinary, elder-friendly care, with systematic carryover of that care to the post-acute home setting. The blended model emphasizes hospitalist and nurse co-management of the discharge process, as well as post-acute evaluation and counseling. The treatment fidelity model guided the feasibility evaluation of study design, training of interventionists, delivery of the intervention, in two medical units. Key elements integral to successful program implementation were identified through the Geriatric Institutional Assessment Profile (GIAP) administered to 45 staff: inclusion of family in decision-making and care delivery, a multi-component delirium protocol, and a discharge planning protocol implemented upon admission that combines seamless integration into the electronic medical record with patient-friendly educational tools.

SESSION 2220 (SYMPOSIUM)

METHODOLOGICAL INNOVATIONS IN THE STUDY OF MEDICAL AND PSYCHIATRIC COMORBIDITY OVER THE LIFESPAN
Chair: B. Mezuk, Epidemiology and Community Health, Virginia Commonwealth University, Richmond, Virginia
Co-Chair: M. Cerda, Columbia University, New York, New York
Discussant: J.J. Gallo, University of Pennsylvania, Philadelphia, Pennsylvania

There is increasing recognition of the need to shift beyond looking at medical and psychiatric health problems in isolation, and to instead, consider the interconnections between physical and psychiatric health problems. However, the bulk of current research on medical-psychiatric disorder comorbidity is limited by the use cross-sectional studies, retrospective measures, and a focus on static pairs, rather than dynamic clusters, of disorders. Additionally, the conceptualization of comorbidity is generally not informed by, nor does it reflect, the underlying behavioral and biological processes that the co-occurrence of psychiatric and medical conditions may indicate. In this symposium, we will present research approaches to the study of comorbidity between medical and psychiatric problems that highlight key methodological innovations to
OBESITY AND DEPRESSION ACROSS THE LIFE COURSE

B. Mezuk, K. Lapane, Epidemiology and Community Health, Virginia Commonwealth University, Richmond, Virginia

Depression often co-occurs with physical health conditions in later life, including osteoporosis and fracture. Frailty, a geriatric syndrome characterized by weakness, slowness, fatigue, and weight loss, is associated with heightened risk of falling, disability, and mortality. It has been suggested that depression and frailty may be overlapping syndromes, however few studies have explicitly investigated this interrelationship. Data come from the Baltimore Epidemiologic Catchment Area Study, a prospective community-based sample and analysis is limited to participants age 50 and older (n=600). Latent class analysis (LCA) was used to examine the relationship between indicators of depression and frailty. The prevalence of depression was 12.9%, and 9% of those with depression had 3+ indicators of frailty, as compared to 3.9% of those without depression (p<0.024). Depression was most strongly associated with the exhaustion and weakness components of frailty. LCA results were consistent with the hypothesis that late-life depression and frailty are overlapping syndromes.

EXPLORING THE INTERRELATIONSHIPS BETWEEN DEPRESSION AND FRAILTY

B.L. Needham, UAB, Birmingham, Alabama

Although the correlation between obesity and depression is well-established, there is little longitudinal research in this area. Using latent growth curve modeling, a recent study examined bi-directionality in the association between obesity and depression in a sample of young adults. Over a fifteen-year period, initial symptoms of depression were associated with a faster rate of change in waist circumference; but initial body mass index (BMI) and waist circumference were not associated with the rate of change in symptoms of depression. The purpose of this session is to present new evidence on the association between trajectories of obesity and depression for a population of adolescents as they transition to adulthood. We will discuss similarities and differences in the obesity-depression relationship during different periods of the life course.

A LATENT CLUSTER ANALYSIS APPROACH TO INVESTIGATE PATTERNS OF POSTTRAUMATIC STRESS SYMPTOMS AND FUNCTIONAL IMPAIRMENT AFTER A MASSIVE DISASTER

M. Cerda1,2, F. Norris2, 3, M. Tracy1, 2, S. Galea1,2, J. Xiang3, 1. Epidemiology, Columbia University, New York, New York, 2. National Center for Disaster Mental Health Research, White River Junction, Vermont, 3. Dartmouth Medical School, Hanover, New Hampshire

Despite evidence that posttraumatic stress symptoms (PTSS) lead to considerable impairment of social and occupational functioning, few studies have examined the links between PTSS and functional impairment. Using repeated measures latent class analysis, we examined co-occurring patterns of adult PTSS and functional impairment after a natural disaster, and investigated how traumatic events and stressors shaped this relationship. We found three long-term patterns: (1) no functional impairment/no PTSS; (2) low functional impairment/moderate PTSS; and (3) high functional impairment/high PTSS. While disaster- and post-disaster traumatic events predicted membership in the high impairment/high PTSS group, exposure to post-disaster and daily stressors were common predictors of membership in both the low impairment/moderate PTSS and the high impairment/high PTSS groups. After this session, participants will understand how to use latent class analysis to examine the nosology of posttraumatic stress disorder, and the role that mass trauma plays in shaping PTSS and impairment.

SESSION 2225 (PAPER)

ISSUES IN CHRONIC CARE — RISK FACTORS AND OUTCOMES

INJURY PATTERNS AMONG OLDER ADULTS: EXPLORING RISK FACTORS AND OUTCOMES

M. Carter1, F.W. Porell2, J. Xiang3, 1. West Virginia University, Morgantown, Massachusetts, 2. University of Massachusetts Boston, Boston, Massachusetts

Estimates suggest that the size of the older adult population increased 142% during the past 50 years, from 16.6 million older adults in 1960 to 40.2 million older adults in 2010. This remarkable increase has in turn contributed to the changing demographics of the typical injury victim, with 2 out of every 5 hospital visits for injury now made by adults aged 65 years and older. In response, this study examined risk factors, patterns and associated long-term outcomes of sentinel injury among older adults. Eight years (1998-2005) of survey and administrative claims data from the Medicare Current Beneficiary Survey and Medicare Non-Response Files were used to estimate both discrete-time survival models and multinomial logistic regression models to identify risk factors of injury over time. Injury categories were identified using the Barell Injury Classification Matrix and multilevel models for change, using a case cross-over design to adjust for selection effects, were used to estimate the long-term consequences associated with each injury category. Findings suggest that risk of sentinel injury is positively associated with advancing age, female gender, poorer health, functional limitations and ADL impairment levels. Fracture represented the most frequently occurring injury category, followed by internal injury. Importantly, more than 45% of all injury episodes were classified as multiple-category injuries. On average, the long-term effects of injury were observed to continue for 22 months without interruption, although patterns varied widely by injury category and level of complexity. Improving long-term outcomes may necessitate reconsidering trauma care designation among older injury victims.

UNDERSTANDING THE LONG TERM CONSEQUENCES OF INJURY: TRANSITIONS TO DISABILITY AFTER A SENTINEL INJURY

F.W. Porell1, M. Carter2, J. Gerontology, University of Massachusetts Boston, Boston, Massachusetts, 2. West Virginia University, Morgantown, West Virginia

Despite a precipitous drop in injury rates over 30 years, little progress has been made in reducing injury rates among older adults. About 40% of injury-related hospital visits are made by adults aged 65 years and older. Relative to younger adults, older adults sustaining a serious injury often experience poorer outcomes that largely reflect the complexities of managing traumatic injury in a population with higher rates of prevalent comorbidities and reduced physiological reserve. Since research to date has focused primarily on event-specific outcomes rather than longer-term consequences of injury, less is known about the impacts of injury on older adults who survive the initial injury episode. To explore the effects of sentinel injury on disability status over time, Markov transition models were estimated with panel data from the Medicare Current Beneficiary Survey (1998-2005). Since transition rates to disability are influenced by age, health behaviors, comorbidities, and other

The Gerontological Society of America
factors, a rich set of covariates were specified as controls to isolate the effects of both incident and prevalent sentinel injuries on these transition rates. Findings suggest that among functionally independent beneficiaries, the odds of functional decline not only increase after an incident sentinel injury, but also remain higher during post-injury periods over a year later. Moreover, beneficiaries who sustained a sentinel injury were much less likely than their non-injured counterparts to experience improvements in functioning in the years that followed an injury-related disability. The results suggest that the risk of permanent disability remains elevated over the long run.

THE EFFECTS OF CHRONIC ILLNESS ON COSTS OF CARE FOR OLDER PERSONS RECEIVING LONG-TERM CARE
T.Y. Lurn1, S. Parashuram1, R. Kane1, P. Homyk1, A. Wysocki1, 1. University of Minnesota, Minneapolis, Minnesota, 2. University of Hong Kong, Hong Kong, Hong Kong

Background: Using Medicaid and Medicaid claims data in 2005, we examined the effects of chronic diseases on the Medicaid and Medicare expenditures associated with persons receiving long-term care (LTC) in seven states. Methods: Participants were elderly beneficiaries in seven states receiving Medicaid paid long term care services. We created our chronic disease variables from the ICD9 codes in the Medicare and Medicaid claims data using on algorithms similar to the CMS Chronic Condition Data Warehouse - Chronic Condition Categories. We classified beneficiaries into community or institution group using state provided enrollment data. We calculated per-person month health care expenditures based on actual Medicare and Medicaid claims for 2005. Results: Medicaid medical care expenditures were low across all chronic illnesses in both community and institution groups and were higher for the community group. The Medicare medical care expenditures were also higher for community care recipients, but were substantial for both groups. Prescription drug expenditures were higher for beneficiaries in institutions. The Medicare medical care, Medicare LTC, and Medicaid medical care and prescription drug expenditures increased substantially as the number of chronic illnesses increased, while there was a very small increase in Medicaid LTC expenditures. Conclusion: Medicare expenditures for both medical care, LTC, and prescription drug were more sensitive to chronic disease than were Medicaid expenditures. The level and extent of Medicaid paid LTC services were more sensitive to functional needs than to medical ones. Once chronic disease was controlled for, older age and being White were associated with lower expenditures.

EVALUATION OF STATEWIDE IMPLEMENTATION OF THE RECLAIMING JOY PEER SUPPORT PROGRAM FOR MEDICAID HCBS/FE WAIVER RECIPIENTS: BARRIERS & SUCCESSFUL STRATEGIES FOR SUSTAINABILITY

The Reclaiming Joy Peer Support Program (PSP) is an innovative, strengths-based program for addressing mental health concerns among older adults. PSP pairs older adult “participants” experiencing mild to moderate depression with trained older adult peer “volunteers.” Over 10 weeks, volunteers help participants identify personal strengths, resources, and goals. We successfully piloted the program in three Area Agencies on Aging (AAAs) in Kansas. Participants had significantly lower levels of depression, improved health/functioning, and lower health care service utilization after the intervention (Chapin et al., 2010). We also identified replication strategies for sustainability to ensure pilot sites and additional AAAs could cost-effectively maintain or implement an AAA-based model. Methods: In 2010, seven AAAs across the state implemented PSP. We worked with AAAs to individualize replication strategies appropriate for their communities. Through regular interviews with staff, we evaluated progress and identified barriers and successful strategies. Results: Maintaining fidelity to PSP’s key components, all AAAs successfully implemented the program, using a variety of strategies for coordination, recruitment/referral, volunteer training, screening/intake, matching/providing support, and documenting outcomes. Barriers included difficulty in discussing the program with potential participants and having sufficient volunteers ready when referrals were made. Successful strategies AAAs used included developing tools for case manager coaching on starting the conversation and partnering with other agencies to recruit volunteers. Implications: The PSP is viable and can be implemented across various settings. This evaluation provides evidence on the sustainability of PSP and the ways agencies are tailoring this peer support program based on their resources and communities.

SESSION 2230 (SYMPOSIUM)

BEFORE AND AFTER: HUMANISTIC INSIGHTS ON MOVING INTO A CONTINUOUS CARE COMMUNITY
Chair: H.Q. Kivnick, School of Social Work, University of Minnesota, St. Paul, Minnesota

What is the experience of a “young-old” wife as a new resident in a CCRC? This woman is a retired gerontologist; how is her current experience related to a lifetime of professional familiarity with concepts of aging, transition, deterioration, adaptation, and wisdom? While social scientists might address these questions in terms of causality and intervention strategies, scholars in humanities and arts disciplines are more likely to delve into meaning, excite thinking, and promote deepening understanding of this particular experience associated with aging. This symposium constitutes a kind of humanists’ grand rounds — focusing on an autobiographical account of a common life transition in aging and drawing on existing scholarship. Four scholars will consider this experience through different domains within the arts and humanities of aging. Wyatt-Brown, retired literature scholar and former editor of the Journal of Aging, Humanities, and the Arts, will reflect on her own recent relocation to a CCRC. de Medeiros will explore the transition in terms of narratives of aging, expressions of selfhood, and social context. Ray will reflect through lenses of feminist gerontology and ethics of care. Kivnick’s contribution will consider themes of vital involvement and the life cycle. What can the humanities offer real people encountering the challenges of aging? In this symposium, scholars with different perspectives will shine multiple lights on a particular personal experience, such that: 1) observers can learn from these diverse insights; 2) the focal person gains new perspective; and 3) ideas sparked by the interaction can push the field forward.

FROM OBSERVER TO PARTICIPANT: A HUMANIST’S JOURNEY
A.M. Wyatt-Brown, Linguistics, University of Florida, Baltimore, Maryland

When my husband and I moved into a continuing care community on May 20, 2010, I discovered that being a humanistically-inclined gerontologist did not eliminate initial negative feelings. Many of the residents are much older than I, and some use walkers or wheelchairs. Fortunately, I have learned to respect the vitality of many of them. Taking part in organized activities, athletics, and a weekly vigil for peace also introduced me to interesting people. The kindness of many residents, who cheerfully eat with those who are in wheelchairs or have spotty memories, has impressed me. It didn’t take too long before I could put a human face on problems that I had read about in novels, memoirs, and gerontological texts. Perhaps over time I will find a way to combine my professional knowledge and insider status to help my friends and me survive some of life’s inevitable losses.
TRANSITIONS INTO RETIREMENT COMMUNITIES: NEGOTIATING TIME, SELF AND IDENTITY
K. de Medeiros, Miami University, Oxford, Ohio

People living in retirement communities often describe their experiences in terms of two concepts of time: free time and the managed time. Free time describes new learning and social opportunities that become available through decreased domestic obligations (upkeep of a home, meal preparation.) Managed time describes the acute awareness of living within a restricted place, where, despite the promise of autonomy, staff ultimately develop and oversee activities within the community. In this paper I draw upon narratives by older adults who have lived in a CCRC for five or more years to inform and guide my reading of Anne Wyatt Brown’s narrative of transition as a new CCRC resident. Overall, I will consider some of the challenges in negotiating identity and self within the context of time.

FROM OUTSIDE TO INSIDE THE EXPERIENCE OF OLD AGE
R.E. Ray, English, Wayne State University, Detroit, Michigan

In “From Observer to Participant,” Wyatt-Brown acknowledges her initial difficulty in letting go of an outsider status within the retirement community. She hopes to one day combine her knowledge as a gerontologist with her growing insider experience as a resident. Her narrative raises two major issues of our time: how to embrace old age without fear and to live well in communities that respect people of all ages and abilities. I will respond from the perspective of a feminist ethic of care that is based on acceptance, rather than avoidance, of human dependence and that argues the importance of interdependence, rather than independence, in our relations with others. This ethic can release us from the unequal social relations that create “insiders” and “outsiders” to human experience of any kind and prompt us to imagine more creative, interesting and socially just ways of living together.

RENEWING LIFELONG THEMES IN ADAPTING TO A TRANSITION OF AGING
H.Q. Kivnick, School of Social Work, University of Minnesota, St. Paul, Minnesota

Erikson, Erikson, and Kivnick (1986) clarified that developing old-age wisdom requires surviving life’s inevitable tragedies, fully experiencing life’s richest satisfactions, and carrying on with daily life - balancing emergent integrity with inescapable despair. Wyatt-Brown has spent a lifetime vitally involved with the scholarly worlds of English literature, women’s writing, and writers’ insights about aging. Following generational norms, she has spent that same lifetime nurturing intimate family relationships, and locating her scholarship around them. About moving into a CCRC, she acknowledges embarrassment that her professional knowledge did little to mitigate her own initial ageist feelings at moving into a building where hallways were dominated by wheelchairs and walkers, and she was a decade and a half younger than the average resident. Nonetheless, the themes of her adaptation draw heavily on both psychosocial themes from her lifelong vital involvement, and also nuggets of content from her scholarly work.

SESSION 2235 (SYMPOSIUM)
BUILDING A COMMUNITY OF AGE FOCUSED RESEARCHERS
Chair: V.W. Marshall, Institute on Aging University of North Carolina, Charlotte, North Carolina

Governments, funders and universities are increasingly undertaking programmes to develop the ageing research community in terms of size, focus and quality. However, there has been little opportunity to share the accumulated knowledge from such initiatives. This symposium, involving speakers from Canada, England, Wales and Ireland, will provide delegates the opportunity to consider different models for successfully building a community of age focused researchers in priority areas. The symposium will cover programmes led by those within academia, government and the non government sector and will include both small scale targeted actions and large scale substantial initiatives. Presenters will draw lessons from: Canada’s Institute of Aging of the Canadian Institutes of Health Research, established in 2000; The UK’s Strategic Promotion of Ageing Research Capacity (SPARC) developed in response to a traditionally dispersed approach by government research funding; The Older People and Ageing Research and Development Network setup to raise the profile and capacity of ageing research in Wales; The Centre for Ageing Research and Development in Ireland, established to build greater cooperation and influence the direction of ageing research across Ireland – north and south. This symposium will provide delegates with an opportunity to consider various techniques such as ‘pump-priming’ newcomers to ageing research, capacity building, promoting collaboration and cooperation across disciplines, sectors and geographies, encouraging researchers to engage with end users, prompting usability and ultimately enhancing the quality and volume of research
research on ageing and older people was taking place across the island of Ireland, but there was little or no connection and co-ordination of this work, limiting its potential. Operating at a strategic level and in an advisory capacity, CARDI has focused on promoting research co-operation across sectors, disciplines and the island of Ireland. It has concentrated on influencing the strategic direction of research into older people and ageing in Ireland – north and south. This presentation, using the CARDI grant programme, will case study a model which has used a modest funding budget, in a focused manner, to support the development of 25 research partnerships, raise the profile of ageing research and helped build a greater sense of community within ageing research across Ireland.

CANADA’S ‘SUMMER PROGRAM IN AGING’: TRAINING FOR EXCELLENCE IN RESEARCH ON AGING, ACROSS DISCIPLINES, BEYOND BOUNDARIES

A. Martin-Matthews, Professor of Sociology, University of British Columbia and former Scientific Director, Institute of Aging, Canadian Institutes of Health Research, Vancouver, British Columbia, Canada

Since 2001, the Institute of Aging of the Canadian Institutes of Health Research has promoted the building of research capacity across all areas of biomedical, clinical, health services and population health research in aging. This has included initiatives targeted toward trainees, as well as researchers in cognate fields who work is of relevance to aging. In this presentation we discuss the outcomes of a variety of capacity development initiatives, including summer institutes (with six held to date, involving over 300 trainees at Masters, Doctoral and post-doctoral levels); and recognition awards and prizes, and publication awards, based on follow-up evaluation of trainee outcomes and perspectives. In addition, capacity-development mechanisms at later career stages, particularly through catalyst funding support to test innovative and high-risk ideas, validate new tools and methods, and test new collaborations, is discussed.

SESSION 2240 (SYMPOSIUM)

CONCEPTUALIZING OLDER PEOPLE’S ‘CONNECTIVITY’ AND CONTRIBUTIONS TO COMMUNITY LIFE

Chair: C. Hennessy, Faculty of Health, University of Plymouth, Plymouth, United Kingdom

Discussant: G.D. Rowles, University of Kentucky, Lexington, Kentucky

Older people’s connections to the life of their communities have been considered from a number of vantage points; their social networks, physical propinquity and access, use of technology, and shared cultural practices and understandings. Until recently, however, most research on these connections has been conducted from a problem-based focus to the comparative neglect of their contributions, skills and participation in relation to wider aspects of community life. This symposium highlights two interrelated research projects on older people’s ‘connectivity’ in their communities. The ‘Grey and Pleasant Land?’ project is a three-year program of interdisciplinary research, investigating the circumstances, experiences, and quality of life impact of older people’s inclusion in rural civic society in England and Wales. A linked Canadian project provides an international comparative dimension, and focuses on older people’s connectivity and well-being in these settings. The objective of this symposium is to provide a perspective on older people as community capital through an examination of the empirical findings and shared conceptual framework on their connectivity developed from these projects. The symposium features four presentations that interrogate existing concepts around the basis for older people’s community connections and portray the diversity of their types of involvement in civic activities across a typology of rural environments. A critical human ecology perspective frames findings on older rural residents’ engagement with and contributions to their communities, and identification of the principal barriers and facilitators to their civic inclusion.

RETHINKING CONNECTIVITIES OF OLDER RURAL ADULTS

N. Keating1, J. Eales1, J.E. Phillips2. 1, Human Ecology, University of Alberta, Edmonton, Alberta, Canada, 2, Swansea University, Swansea, United Kingdom

Despite longstanding interest in interpersonal, community and place connections of older adults, there remains an epistemological tension around their conceptualization. The ‘beneficiary lens’ views connections as essential in compensating for late-life losses; while the ‘contributor lens’ focuses on enhanced well-being of families and communities of older adults resulting from their engagement. We clarify the construct of connectivities, examining the relative importance of types of connectivities from the perspective of older rural adults. Qualitative data are drawn from linked programs of research in rural Canada and the UK. Results indicate systematic differences in connections of community active, marginalized and stoic older adults. The diversity and complexity of connectivity is also highlighted in comparing older respondents’ modes of connectivity such as driving or walking. A critical human ecology lens incorporating constructs of personal agency and person-environment fit is proposed as the basis for a new conceptualization of connectivities in context.

EXPLORING THE ROLE OF PLACE AND INTEREST IN FACILITATING THE DEVELOPMENT OF OLDER PEOPLE’S COMMUNITY CAPITAL AND CONNECTIVITY

S. Evans, R. Means, N. Curry, University of the West of England, Bristol, Bristol, United Kingdom

Traditional views of ‘place’ as a key factor in a sense of community are undermined by emerging evidence for the engagement of older people in communities based on shared interests. This paper explores the meaning of ‘place’ for older people in the context of the ‘Third Age’, globalisation, social mobility and communications technology. A large majority of survey respondents reported living in a close knit community and took part in a wide range of community activities. They also used the internet for a range of participative activities, including online social interaction, pursuing hobbies and finding information. This session offers delegates a grounding in theories of community and an appreciation of the need for a view of ‘place’ and ‘interest’ that avoids false dichotomies between the two and acknowledges the impact of social, economic and cultural change upon the connectivity of older people.

THE VIRTUOUS CIRCLE OF MOBILITY CAPITAL AND SOCIAL CAPITAL IN OLDER PEOPLE’S CONNECTIVITY

G.P. Parkhurst, I. Shergold, C. Musselwhite, Centre for Transport & Society, University of the West of England, Bristol, Bristol, United Kingdom

Mobility activity is an enabler for the accumulation of social capital, whilst mobility is central to its facilitation; therefore a conceptual link is proposed between ‘mobility capital’ and community connectivity. In developed nations older people are of increasing importance to community activity, but their mobility is problematical in a context of rising car dependence in which the car is not, or ceases to be, an option for some older people. The community interactions of a sample of rural elders living in Southwest England and Wales are examined, drawing on a survey and semi-structured interviews. Key findings were the localised nature of most community activities and the wide range of transport modes used. It is concluded that car availability is important, but that to enhance connectivity there needs to be greater emphasis on facilitating walking, cycling, community transport schemes and the use of mobility scooters for short-range travel for social purposes.
CULTURAL CONNECTIVITY AND LEISURE LIVES
C. Hennessey, Y. Staelsens, G. Lankshear, J. Faculty of Health, University of Plymouth, Plymouth, United Kingdom, 2. University of Bournemouth, Bournemouth, United Kingdom

At a time when the importance of leisure activities to social capital formation is increasingly acknowledged in leisure research, gerontological studies on leisure have been criticized for their lack of attention to diversity among older people, especially marginalized populations. Ethnic minorities and rural elders are among those groups comparatively neglected by gerontologists interested in leisure. This paper explores older people’s connections with the cultural life of their communities in rural settings in the south west of England through an exploration of their leisure participation. Data are presented from oral histories of leisure conducted with 70 older rural people, including Gypsy-Travellers, who are members of the area’s largest ethnic minority group. These findings indicate the significance of leisure activities for the maintenance of social capital both within and across cultural groups, and the connection with the rural landscape through leisure as a source of memory and identity for older individuals.

SESSION 2245 (SYMPOSIUM)

HEALTH DISPARITIES AND RESILIENCE AMONG LGBT OLDER ADULTS: FINDINGS FROM A NATIONAL STUDY
Chair: K.I. Fredriksen-Goldsen, University of Washington, Seattle, Washington

As older adults become increasingly diverse in American society, new challenges emerge in gerontological research, services and policies. This symposium provides important new information on aging and health in historically disadvantaged communities. The presentations highlight findings from the first national project addressing the health of lesbian, gay, bisexual and transgender (LGBT) older adults, with the research funded by the National Institute of Health and the National Institute of Aging. Utilizing population-based data, Fredriksen-Goldsen and Kim examine health disparities by sexual orientation among older adults. Based on a separate survey of 2,560 LGBT older adults, both risk and protective factors and subgroup differences are investigated as they relate to physical and mental health. Emlet and colleagues investigate HIV-risk among older sexual minorities and the relationship between stigma, efficacy, social support and HIV risk behaviors. Addressing the well-being of LGBT older adults, Petry and colleagues explore the role of leisure and physical activities as they predict quality of life and positive health outcomes. Williams and colleagues present on the use of respondent driven sampling (RDS) as an innovative sampling methodology to increase capacity to reach hidden populations. Worthington and Kirmisky discuss key policy and service implications to address the aging and health needs of LGBT older adults and their families. This symposium provides critical insights on health disparities in marginalized communities, innovative sampling methodologies for conducting research in hard-to-reach communities, and service and policy implications to promote healthy aging in our increasingly diverse society.

HEALTH DISPARITIES AMONG LGBT OLDER ADULTS: PREVALENCE AND RISK
K.I. Fredriksen-Goldsen, H. Kim, University of Washington, Seattle, Washington

The identification of health disparities by sexual orientation among older adults is a major gap in aging research. This is one of the first studies to comprehensively examine health disparities among sexual minority older adults. By utilizing population-based data from the Washington State Behavioral Risk Factor Surveillance System (N=83,913), findings indicate the prevalence rates of disability, poor physical health and mental distress are higher among specific groups of sexual minority older adults as compared to heterosexual counterparts. Risk and protective factors impacting health are further investigated by analyzing data from a national survey of LGBT older adults (N=2,560). Results indicate that risk factors such as victimization and discrimination significantly predict physical and mental health outcomes as well as risky health behaviors. Health disparities among LGBT older adults are of major concern. Future prevention and interventions efforts need to address the unique health and aging needs of LGBT older adults.

CORRELATES OF HIV RISK BEHAVIOR AMONG OLDER LGBT ADULTS: RESULTS FROM A NATIONAL SURVEY
C.A. Emlet, K.I. Fredriksen-Goldsen, H. Kim, University of Washington, Seattle, Washington

The number of older adults infected with HIV is increasing significantly (CDC, 2011). Utilizing data from a cross-sectional survey of 1,386 sexually active LGBT older adults, this study examines the relationship between self-stigma, self-efficacy, social support and HIV risk behavior. Bivariate analyses show significant correlations between the degree of HIV risk behavior, self-stigma, self-efficacy and social support. Self-efficacy (b=0.04; p<.05) and social support (b=-0.07; p<.01) significantly predicts HIV risk behavior. When self-stigma is added to the models, both self-efficacy and social support no longer significantly predict HIV risk behavior, but self-stigma remains significant for both models (b=0.10; p<.01; b=0.09; p<.01). These results indicate that self-stigma fully mediates the relationship between self-efficacy and HIV risk behavior and between social support and HIV risk. This research yields important information to facilitate the development to age appropriate stigma reduction prevention interventions to reduce HIV-risk behaviors among older adults.

LEISURE ACTIVITIES: EFFECTS ON HEALTH AND QUALITY OF LIFE IN OLDER LGBT ADULTS

Existing research on LGBT aging provides evidence of the positive effect of social support on health and quality of life. Little is known about the effect of non-physical leisure activities on these outcomes among older LGBT adults. Based on a national survey of 2,560 LGBT older adults, this paper examines the relationship between leisure activities and moderate and vigorous physical activities and health outcomes. Older LGBT adults reporting higher degrees of leisure activities and physical activities showed significantly better quality of life and more positive mental health. As interventions are developed to improve the health of older LGBT adults it is imperative to recognize the positive effect of leisure activities on health and quality of life and integrate this knowledge into health promotion efforts.

RESPONDENT-DRIVEN SAMPLING WITH LGBT OLDER ADULTS
M. Williams, K.I. Fredriksen-Goldsen, E. Erosheva, H. Kim, School of Social Work, University of Washington, Seattle, Washington

Respondent-driven sampling has been used increasingly over the past decade to research “hard-to-reach” populations. Relying on peer-to-peer recruitment chains, RDS aims to make population-level inferences from social network data. A sampling feasibility study of RDS with lesbian, gay, bisexual and transgender adults, age 50 and older, was conducted to examine whether this population would participate in peer-to-peer recruitment and whether their recruitment behavior would meet the assumptions on which RDS analysis rests. Sixteen LGBT adults in total were recruited using RDS that started from four diverse seeds. Participants recruited primarily within their own race, age-cohort, and socioeconomic status but across gender and sexual orientation sub-groups.

The Gerontological Society of America
No research participants recruited transgender individuals, and participants reported knowing relatively few bisexual and transgender peers whom they could potentially recruit. Implications for further efforts to utilize RDS and other innovative sampling techniques to obtain representative samples in hidden populations will be discussed.

IMPROVING QUALITY OF LIFE FOR LGBT OLDER ADULTS: POLICY AND SERVICE IMPLICATIONS
S. Worthington¹, L. Krinsky², K.I. Fredriksen-Goldsen¹, 1. University of Washington, Seattle, Washington, 2. SAGE, New York, New York, 3. LGBT Aging Project, Boston, Massachusetts

Public policies and services must be responsive to the changing context of aging in this country and the increasing diversity in our society. To date, there are over 3 million LGBT older adults. Based on a census of LGBT aging agencies, two-thirds of LGBT elders report the need for aging-related programs and services. Markedly, 13% were denied or provided inferior health care because they are LGBT and 15% of LGBT older adults fear receiving health services in the general community while 8% fear receiving health services within the LGBT community. Yet, many federal and state laws and institutional policies that benefit older adults are biased against LGBT elders and their families, such as Medicaid spend-downs, social security benefits, family leave policies and bereavement leave. To meet the needs of LGBT older adults, public policies and programs need to insures responsiveness to differences by sexual orientation, gender identity and cultural diversity.

SESSION 2250 (SYMPOSIUM)

INNOVATIVE LIFE REVIEW AND REMINISCENCE GROUPS IN TAIWAN: HYBRIDS BETWEEN EASTERN AND WESTERN CULTURES
Chair: T. Kuo, Central Taiwan University of Science and Technology, Taichung, Taiwan
Discussant: C.M. Svensson, University of Southern California, Los Angeles, California

The life review and reminiscence groups are frequently used interventions to improve the quality of life and self-integrity of older adults in home- and community-based services or at nursing homes. The older adults participating in such groups are subjected to reflecting past life events, sharing feelings, and expressing thoughts about the meanings associated with their lives. In Taiwan where the aging rate is at the fastest world-wide and an effective psychosocial program is urgently needed, this symposium introduces four innovative models that integrate computer technology, western ideology, horticulture, and self-observed techniques to create culturally and socio-structurally appropriate life review and reminiscence programs. The first symposium examined how a popular American-based Guided Autobiographic model was modified and affected Taiwanese elderly on quality of life and self-esteem. The second symposium combined both audio-visual and computer technology to create a prototyping “Information Recording Management System” that allowed for instant analysis of older adults’ outcomes in reminiscence groups. The third symposium validated the use of horticulture and life review as an effective way for better intergenerational communications. The last symposium used a self-observation technique to find meaningful topics for people when first conversing with an older person. The results showed significant qualitative and quantitative changes on quality of life and self-efficacy and generated implications for practice, research and future disseminating strategies. In conclusion, this symposium documents steps and cultural issues on how life review and reminiscence can be applied as effective interventions for the elderly in diverse Asian communities or Asian countries like Taiwan.

EAST MEETS WEST: AN EVALUATION OF A MODIFIED LIFE REVIEW PROGRAM IN TAIWAN
T. Kuo, A. Lai, Central Taiwan University of Science and Technology, Taichung, Taiwan

This paper examined the applicability and effectiveness of a Guided Auto-Biographic (GAB) Program in Taiwan by modeling after a popular life review program in the U.S. The GAB program was a 10-week professionally led program with the purpose to assist older adults in writing their own life stories. Cultural and structural modifications were made to better suit the spiritual and social dimensions of the elderly in Taiwan. A total of 71 older adults completed the GAB program in 6 groups. The results showed significant improvement in quality of life, self-efficacy, family relations as well as self-actualization in planning for their lives. This paper concluded by discussing important cultural and socio-structural issues when designing life review programs for increasingly ethnically diverse societies in Asia. Future plans for program diseminations, with educational and organizational collaborations, will demonstrate important research and practice contributions in conducting life reviews.

DEVELOPMENT OF AN INFORMATION RECORDING SYSTEM FOR REMINISCENCE GROUPS
S.D. Hsu, Hung Kuang University Affiliated Aging Care Hospital, Taichung City, Taiwan

Based on literature reviews, user’s requirement, expectations from residents’ families, and Information system designer, this study evaluated a prototype model of “activity recording information management system” for recording participants in reminiscence groups at a long-term care facility. The reason for developing the system was that manual method was complicated and not easy to manage. Thus, 8 program leaders were asked to evaluate the system. Results showed in 5 dimensions that: (1) system value: users and families held positive feedback on the system.(2) system interface: users were satisfied with the content, (3) service platform: the recorded information facilitated better understanding of clients by new staff members or students; (4) organizational model: the system helped collect information not only meeting the needs of the service providers but also assisting transitions among group leaders; (5) revenue/cost: users were confident on the saving of labor cost and would recommend the system to other institutions.

REVALIDATING REMINISCENCE-BASED HORTICULTURAL PROGRAMME FOR THE ELDERLY IN AN URBAN COMMUNITY
L. Luhuang¹, Y. Liou¹, 1. Department of Geriatric Health Promotion, Kainan University, Taoyuan County, Taiwan, 2. Department of Geriatric Habitation, Kainan University, Taoyuan, Taiwan

The literature indicated positive impacts of horticultural therapy for the improvement of elderly health as they provide sensory effects. However, less research concern about how the horticulture and plants make sense in the aged informants’ past life and how they are (can be) integrated in their life activities. The aim of this article explores the effects of horticulture or plants (horticultural activities) used as stimulus in reminiscence groups by means of quantitative and qualitative methods. To achieve the above-mentioned goal and to know how they can be used to enrich the reminiscence group programme, a ten-week reminiscence group activity centered on horticulture and plants is conducted in this research. The result shows that applying horticulture and plants in reminiscence group is not only a creative aging program but also an intergenerational program. Based on quantitative analysis, the functions of intimacy maintenance and bitterness revival are significantly revealed.

64th Annual Scientific Meeting
CULTURAL AND STRUCTURAL CONCERNS IN SELECTING LIFE REVIEW AND CONVERSATIONAL TOPICS
S. Tsay1, M. Liu2, 1. Department of Health, Bureau of Nursing and Health Services Development, Nantou County; Taiwan, 2. Central Taiwan University of Science and Technology, Taichung, Taiwan

The paper examines the cultural and structural concerns in selecting life review and conversational topics with the elderly. A detailed daily life observation and a structural interview were performed based on the principle of life review for one-on-one chatting with 30 Taiwan’s older adults. Data were analyzed using content analysis and the results showed that productivity of grandchildren, family care and political discussions were among the most frequently mentioned topics. Depending on gender, socio-economic status, and family status, the elderly also exhibited differences on topics of concerns. These findings not only provided a guideline for people to have better talks with the elderly, when starting a conversation can be difficult, but also form important elements for older adults to reach successful aging. In a society where nuclear families are the norm, the implications allow working professionals and family members to have more meaningful interaction or inter-generational relationships with the elderly.

SESSION 2255 (PAPER)

CARE SUPPORTS, PROGRAMS AND SERVICES

THE SAVVY CAREGIVER PROGRAM: WHAT’S NEXT?
L. Samia1, K. Hepburn2, L. Nichols1, 1. University of Southern Maine, Portland, Maine, 2. Emory University, Atlanta, Georgia

Study Aims The Savvy Caregiver Program (SCP) is a six-week psycho-educational program shown to improve dementia family caregiver knowledge, skills, and attitudes. Caregivers (n=238) from one New England state demonstrated improved confidence in their role following completion of an Administration on Aging-supported provision of the SCP. Seventy-eight percent of these caregivers also expressed the need for additional training to plan and respond to future challenges; enhance problem-solving and decision-making capacity; and manage progressive self-care needs. This IRB-approved qualitative study sought to develop the curriculum content for the SCP–Part 2. Sample A purposive sample of 37 caregivers was drawn from previous SCP participants representing the five Area Agency regions of the state. Twenty-six caregivers participated in one of five 90-minute focus groups. Methods A semi-structured focus group interview reflected draft curriculum content derived from a qualitative analysis of open-ended comments submitted at five months post-program by 250 SCP participants. Focus groups were audio-taped. Data were managed using NVivo 8. Data analysis was guided by open and axial coding methods. Constant comparison was used throughout. Data collection and analysis occurred concurrently. Results Key themes that will serve as the foundation of a four session SCP-Part 2 include: re-establishment of calm; concentrated emphasis on guiding and shaping care recipient behaviors (to promote calm behavior in ADLs and other daily activities, and personal safety); caregiver self-care, including long-range concerns of loss and grief; and resource assessment and planning (including informal resources). A pilot of the SCP-Part 2 is planned for summer, 2011.

PREPAREDNESS, APPRAISAL OF BEHAVIORS AND ROLE STRAIN IN FAMILY CAREGIVERS
D. Zwicker, E.W. Gonzalez, Drexel University, Philadelphia, Pennsylvania

Little attention has been given to preparedness for the caregiver role in dementia research even though prior research has indicated that it is a necessary component of dementia family caregiving. The frameworks used to guide this study were Interactional Role Theory and Lawton’s Appraisal Model. The aim of this study was to examine the relationship between caregiver preparedness, appraisal of behavioral problems and caregiver role strain. Data was collected from a study on enhancing resourceful skills in family caregivers of persons with Alzheimer’s disease. Data were analyzed using descriptive statistics and a multivariate linear regression analysis. The results showed that there was a significant positive relationship, F(2, 74)=16.07, p =.001, between the appraisal of behavior problems and role strain and a negative relationship between caregiver preparedness and role strain, F(2, 74), 16.07, p = .001. The total variance accounted for by preparedness and appraisal of behavior problems was 30%. Although limited in power, there was no observed interaction effect between the two predictors in relation to the outcome variable; thus the final model showed the main effects of the two dependent variables on the outcome variable were significant without the interaction term. This study provides an empirical base for further research to examine interventions to enhance preparedness in family caregivers of persons with Alzheimer’s Dementia.

TELEPHONE-BASED PROBLEM SOLVING THERAPY FOR FAMILY CAREGIVERS OF STROKE SURVIVORS – RESULTS OF A RANDOMIZED CONTROLLED TRIAL
K. Pfeiffer1, D. Beische1, M. Hautzinger2, 1. Robert-Bosch-Krankenhaus, Stuttgart, Germany, 2. University of Tuebingen, Tuebingen, Germany

Background: Each year more than 150,000 Germans experience a stroke. Approximately 25% of them have residual deficits that require assistance with activities of daily living. Approximately 70% of the care receivers in Germany are cared at home. Family members are the predominant providers of long-term care and may have difficulty adapting to the caregiving role. So far there is some evidence that problem-solving therapy (PST) based interventions may be effective for this target group. Methods: The impact of a telephone-based PST for caregivers of at least 60 year old stroke survivors was evaluated in a randomized, controlled study. The intervention consisted of two home-visits and regular telephone calls by a clinical psychologist. The intervention comprised a 3 month lasting main phase and a follow-up period over 9 months. Intervention and control group received monthly letters with stroke-specific topics. Results: The data refer to 101 caregivers (mean age: 66.0 years) who had provided care for their spouses (N=90) or (grand)-parents (N=11) for 6 months to 5 years before inclusion. Depressive symptoms were common in this group (Mean CES-D=21.6). Repeated-measures analyses of variance showed statistically significant changes of the primary outcomes depressive symptoms and burden over time for all participants and group x time interactions in favour of the intervention group for depressive symptoms and subjective physical complaints (secondary outcome). Discussion: The outcomes will be discussed in regard to specific effects on older versus younger caregivers as well as on domains of caregiver burden that were addressed during PST sessions.

CULTURALLY APPROPRIATE ONLINE INTERVENTIONS FOR SPANISH AND CHINESE SPEAKING ALZHEIMER’S FAMILY CAREGIVERS
X. Lu1, H. Chen2, M. Pagan-Ortiz3, D. Cortes4, S. Levkoff5, 1. Environment and Health Group, Inc., Cambridge, Massachusetts, 2. Harvard Medical School, Boston, Massachusetts, 3. University of South Carolina, Columbia, South Carolina, 4. Northeastern University, Boston, Massachusetts, 5. Cambridge Health Alliance, Cambridge, Massachusetts

Despite numerous interventions being developed in the past decades for dementia caregivers, ethnic minority family caregivers do not benefit from this progress, mainly because these interventions are not culturally appropriate, cannot reach the users, and are too costly to be available and sustainable. To overcome these “implementation gaps”, two culturally-sensitive education and support online intervention programs were developed for Spanish or Chinese speaking family caregivers respectively. Analysis of the implementation process provided insight.
CLINICIAN AND CAREGIVER CONCORDANCE FOR DYADIC PERFORMANCE IN ACTIVITIES OF DAILY LIVING TASKS

P.C. Griffiths, L. Kunce, and P. Metoyer, 1. Rehabilitation Research & Development, VA Medical Center, Decatur, Georgia, 2. Emory University Division of Geriatrics & Gerontology, Atlanta, Georgia, 3. Birmingham/Atlanta VA Geriatric Research, Education and Clinical Center (GRECC), Decatur, Georgia, 4. Georgia Tech Center for Assistive Technology & Environmental Access, Atlanta, Georgia

Challenges in providing assistance with activities of daily living (ADLs) is one common and potentially modifiable problem identified by family caregivers (CGs) that is also a direct and indirect risk factor for falls, injury and institutionalization. Unfortunately, without appropriate assistive technology and training many CGs must strategize the most expedient solutions for helping with these fundamental activities each day. The resulting improvisations derived from utilization of personal and environmental resources at hand, while admittedly quite creative and resourceful, can lead to iatrogenic and excess disability in the care receiver and injuries for one or both members of the dyad. We compared caregivers’ subjective self-reports of dyadic performance during ADL task execution with objective, observation-based ratings made by clinical experts (CE) as part of the comprehensive assessments in the CG ASSIST pilot study (N=19). Ratings of ADL performance in 4 domains were examined using percent agreement (P+/-, Cohen’s Kappa and the intra-class correlation coefficient (ICC)). Concordance varied by task and domain for: level of assistance (ICC=.36, NS -.84, p<.005), safety (P+/-=.11 -.53; Kappa = -.07 -.11, NS), satisfaction with skills (P+/-=.42 -.75 Kappa =.11 -.23, NS), reports of environmental features present (ICC =.01, NS -.60, p<.005) and environmental features used (ICC =-.06, NS -.53, p<.05). Results are discussed in terms of dyadic characteristics influencing concordance and AT use and the implications of these findings for the selection or prescription of AT devices and the need for CG dyad training.

SESSION 2260 (PAPER)

DYNAMICS OF SOCIAL TIES IN LATER LIFE

R. Ward, Sociology, SUNY-Albany, Albany, New York

Social relationships are important sources of well-being, but their contributions are not straightforward. Social networks include various types of social tie, and may entail both positive and negative dimensions. Data from Wave 2 of the national Midlife in the United States (MIDUS) survey (N = 1,599) are used to address two questions: 1) Are positive or negative aspects of social relationships more influential on well-being (life satisfaction and affect)? 2) Do these implications vary across different types of social relationships? Parallel measures of relationship quality (positive and negative) with spouse/partner, family, and friends are analyzed, as well as frequency of contact and problems experienced by network members. Positive experiences are more frequent for spouse/partner, whereas negative experiences are less frequent with friends; positive and negative interactions tend to be correlated across relationship types. Patterns of positive and negative experiences within types of social ties vary by gender and age. Problems experienced by network members are associated with fewer positive and more negative interactions. Contact frequency is related generally to more positive interactions, but also to more negative interactions with friends. Both positive and negative relationship dimensions are related to measures of well-being, but positive experiences exhibit generally stronger associations. Quality of relationship with spouse/partner generally appears to be more influential for well-being than relationships with other family or friends. Overall, these patterns show the complexity of social networks and of their influences on well-being.

INTERACTIONS BETWEEN OPTIMISM AND SOCIAL SUPPORT ON WOMEN’S WELL-BEING

A.M. Sherman, Psychology, Oregon State University, Corvallis, Oregon

The impact of social relations on psychosocial functioning across the lifespan is well documented. However, personality may influence both perceptions of social environments and well-being. For example, optimists report more social support and less social strain than pessimists and are often in better psychological health. Thus, testing for interactive effects between optimism and social relations variables is important. We assessed social support, strain, optimism, and well being (depressive symptoms, life satisfaction and self-esteem) for 250 mid-life and older women (Mean age = 57.56, range 41-89, 42% Native American, 34% African American and 24% White) from a rural region of North Carolina. Caucasian women were more likely to be married than African American or Native American women, but no other significant race differences in demographic variables emerged. Hierarchical multiple regression analyses showed that social support, social strain, and optimism all significantly contributed to the variance in well-being (depressive symptoms: $F(12, 209) = 21.44$, $p < .000$, adj. $R^2 = .54$; Life Satisfaction: $F(12, 208) = 10.84$, $p < .000$, adj. $R^2 = .36$; self-esteem: $F(12, 209) = 15.14$, $p < .001$, adj. $R^2 = .45$). Further, there were significant interactions between optimism and support for all three outcomes. These interactions indicate that the combination of low support and low optimism is distinctly negative for well-being in this sample. Implications for the well-being of women at mid-life and older ages are discussed.

THE DAILY SOCIAL CONTEXT OF GOAL PROGRESS: PROCESSES OF SUPPORT, HINDRANCE AND SATISFACTION

S. Mejia, 1, S. Choun, T. Pham, R. Metoyer, K. Hooker, 1. Oregon State University - Department of Human Development and Family Sciences, Corvallis, Oregon, 2. Oregon State University - School of Electrical Engineering and Computer Science, Corvallis, Oregon

Older adults are known to be particularly effective at regulating their social environments to maximize satisfaction, by adjusting their social goal hierarchy. Across the lifespan individuals construct supportive convoys, which after a lifetime of social exchanges, may create distinct patterns of social support, hindrance, and satisfaction later in life. Although social goals are embedded within daily social experiences, little is known about older adults’ daily goal progress within the social environment. This paper examines the social context of older adult’s social goals, with attention to between-person differences in goals and social environment, and intrapersonal daily goal processes. Specifically, we examined social predictors of goal trajectories, and daily processes of social support, hindrance, and satisfaction over 100 consecutive days. We used data from the Personal Understanding of Life and Social Experiences...
THE STRUCTURE OF SUPPORT: EXPLORING THE IMPACT OF SOCIAL CONVOYS ON THE HEALTH OF U.S. WOMEN AND MEN

W.D. Brynildsen, Sociology, Duke University, Durham, North Carolina

A social convoy is a concept that refers to the social structure within which social support is given and received. An individual’s social convoy may consist of individuals (family, friends, others) whom they rely on for support and/or who rely on them for support. Previously, sociologists have measured social convoys through variables measuring marital and parental status, frequency of contact with children, presence of friends/other relatives, and participation in religious and/or formal organizations. I label these measures investigator-determined because inclusion of these variables assumes, on the part of the investigator, what social relations are most relevant to respondents. This paper presents a new way of measuring social convoys using data on close confidants as reported by the respondents. I call these measures of social convoys respondent-determined because using these variables assures that the social relationships fulfill a substantive definition of social support, characterized by affect, affirmation or aid. Using the American Changing Lives Survey, I create a number of social convoy variables (network size, density, and gender homogeneity and relationship type) from data on respondents’ close confidants. I then examine the effect of these respondent-determined social convoys on depression separately for men and women. This paper serves to highlight the importance of friendships and non-kin relationships in the provision of social support, especially for women, African-Americans and older adults. In examining the influence of structural and compositional aspects of social convoys on depression, I find that both structural (such as convoy size) and compositional (such as relationship types) features are important predictors of depression.

POSITIVE AND NEGATIVE MARITAL EXCHANGES AND DEPRESSIVE SYMPTOMS: A LATENT GROWTH CURVE ANALYSIS

H. Ahn, SOCIAL WORK, UNIVERSITY OF WISCONSIN MADISON, Madison, Wisconsin

Research demonstrates that involvement in marital relationships benefits psychological and/or physical well-being. Marital quality is also known to have significant impact on well-being. I conduct a series of latent growth curve analyses using Mplus (6.1). Data are from the Americans’ Changing Lives Survey, I create a number of social convoy variables (network size, density, and gender homogeneity and relationship type) from data on respondents’ close confidants. I then examine the effect of these respondent-determined social convoys on depression separately for men and women. This paper serves to highlight the importance of friendships and non-kin relationships in the provision of social support, especially for women, African-Americans and older adults. In examining the influence of structural and compositional aspects of social convoys on depression, I find that both structural (such as convoy size) and compositional (such as relationship types) features are important predictors of depression.

HEALTH LITERACY AND DECISION-MAKING

Elders’ self health care behaviors are important, yet factors contributing to their use are not well understood. Using structural equation modeling, this study examined factors related to the self care behavior of seeking health information, theorizing that elder’s attitude toward self care would predict this health behavior. In the path model, attitude toward self care was hypothesized to be directly related to health behavior, with self-efficacy, internal health locus of control, and self-rated health directly related to self care attitude and indirectly related to seeking health information. Age and SES were exogenous variables. Participants were 86 Midwestern elders (71% women, 49% married) aged 60-92 (M = 75.4). Measures included seeking health information, self care attitude, self-efficacy, internality, self-rated health, SES, and age. Lisrel 8 estimated the path coefficients in the hypothesized model with satisfactory goodness of fit (chi square test for independence = 93.63, p < .05, RMS = .07; GFI = .93). Path coefficients directly related to seeking health information were .35 for self care attitude and .32 for self-efficacy; while coefficients directly related to self care attitude were .14 for internality and .29 for health; these variables explained 28% of the variance in seeking health information. In secondary analysis, seeking health information was correlated with other health behaviors: exercise (r = .26, p = .02), adhering to a diet (r = .18, p = .10). Results confirm the importance of self care attitude and self-efficacy for seeking health information and its relevance to other health behaviors.

MEASURING THE RELATIONSHIP BETWEEN AGE AND PREFERENCES FOR HEALTH INFORMATION AND DECISION-MAKING

B. Xie, M. Wang, R. Feldman, L. Zhou, University of Maryland, College Park, Maryland

Existing measurements of patient preferences cover only a limited range of information and an even more limited range of decision-making. This study aimed to explore the breadth and variances in patient preferences for information and decision-making, and to understand the relationship between age and each type of preference. The Health Information Wants Questionnaire was administered during May-December 2010 to collect data about desire for seven types of information and corresponding decision-making: diagnosis, treatment, laboratory test, self-care, complementary and alternative medicine, psychosocial factors, and health care providers. A convenience sample of 438 individuals participated in the study. This included 226 undergraduates (mean age=20; SD=2.15) and 212 community-dwelling older adults (mean age=72; SD=9.00). Results: Participants expressed higher levels of preference for information than for decision-making in six of seven areas. However, for psychosocial factors, they expressed stronger desire for decision-making than for information. Age had no predictive effect on the overall preferences or specific preferences for information and deci-
sion-making about standard treatment and complementary and alternative medicine. Older adults preferred more information and decision-making about laboratory test than younger adults. The reverse was true for self-care. For diagnosis, younger adults preferred having more information than older adults, whereas older adults preferred having more decision-making than younger adults. For psychosocial factors and health care providers, older adults preferred having more information than younger adults, whereas younger adults preferred having more decision-making than older adults. Conclusions: Participants had a broad and diverse range of preferences. The predictive effect of age on patient preferences varied.

OUTCOMES ASSOCIATED WITH E-HEALTH LITERACY AMONG OLDER ADULTS

Despite having the highest incidence of health related problems, older adults have the lowest level of health literacy of any age group. The proliferation of health information online along with increasing access to technology among older adults provides a new opportunity to improve the knowledge and health behaviors among this population. Because electronic (“e-”) health literacy requires a skill set and knowledge base distinct from health literacy, it is unclear as to whether improvements in e-health literacy confer the same benefits as do improvements in health literacy. In this study, we used a cross-sectional survey design to examine whether e-health literacy is correlated with three outcomes associated with health literacy: self-efficacy in doctor/patient interactions, self-reported health, and preventive health behaviors. The survey was distributed to a diverse sample of 84 older adults recruited from two Café’s serving older adults and three senior centers. We conducted correlation and regression analysis on the data, controlling for a variety of demographic characteristics and personal traits. We found that E-health had small to moderate correlations with self-efficacy in doctor/patient interactions (r=0.29, p<0.001), self-reported health (r=0.32, p=0.008), and preventive health behaviors (r=0.45, p<0.000). Our study provides preliminary evidence that increases in e-health literacy yield some of the same benefits as increases in health literacy, and suggests that programming to increase e-health literacy may represent a promising strategy to improve the health of older adults.

A COMPARISON OF AFRICAN AMERICAN AND CAUCASIAN KNOWLEDGE AND CONCERNS ABOUT AUTOPSY
E. Souder, L. Mitchell, U Arkansas Medical Sciences, Little Rock, Arkansas

Purpose: To explore and compare factors that influence African Americans (AAs) and Caucasians in their decision whether to consent to a brain autopsy upon death as part of their participation in an NIH-funded Alzheimer’s disease (AD) study. Background: The prevalence of AD has been reported as higher in AAs than in Caucasians, leading the Alzheimer’s Association to declare AD a “silent epidemic” among AAs. Yet, AAs are underrepresented in AD research, and have a low autopsy consent rate. Besides confirming the diagnosis, an autopsy can identify co-morbid conditions in the body and brain. This knowledge promotes understanding of AD and its presentation and expression in varied cultural groups. Methods: Researchers gathered both quantitative and qualitative data from 39 AA and Caucasian participants who served as controls in the Memory Research Center (MRC), and had either consented or remained undecided about an autopsy. Qualitative data were collected through a series of recorded individual and focus group interviews and entered into Ethnograph. We used content analysis and constant comparison techniques to analyze the data. Questionnaires queried demographic factors, knowledge about autopsy, and perceived importance of factors influencing autopsy decisions. These data were summarized using descriptive statistics. Findings: AAs verbalized much more concern about how the body would be treated after death, appearance of the deceased, funeral delays caused by autopsy, and exhibited avoidance in making a decision. There was no difference between groups in autopsy knowledge. There were questions about autopsy, and many reported confusion about how to be an organ donor and arrange for an autopsy. Conclusions: Differences in willingness to discuss autopsy, and barriers to autopsy consent were found between AAs and Caucasian. This knowledge can be used to tailor information to cultural groups.

HEALTH LITERACY, EDUCATION AND HEALTH OUTCOMES IN OLDER POPULATIONS
T. Yamashita, J. Brown, S. Kunkel, Miami University, Oxford, Ohio

The relationship between education and health has been well established over the last several decades. However, traditional education measures such as years of formal education or highest degree earned may not sufficiently capture the knowledge and skills of the older population due to the elapsed time since completion of formal education. Health literacy (HL) abilities necessary to acquire and use information to make health decisions reflects current health-related practical skills. HL therefore, is a theoretically sound mediator of the association between education and health. HL, therefore, is a potential mediator of the association between education and health. HL may reduce health disparities associated with educational attainment since, unlike formal education, it can be more easily altered at the population-level. In this study, data are derived from the Canadian component of International Adult Literacy and Life Skills Survey (IALSS). The IALSS is the only dataset including detailed characteristics about older adults and a measure of HL. Binary logistic regression is used to model self-rated health (good vs. poor health) as a function of total years of education, HL and other covariates. Results show that education is no longer a significant predictor of health after adjusting for HL. Given the fact that older adults are more likely to have limited HL despite their increasing needs for health compared to younger populations, improving older adults’ HL is an important public health concern. Implications for health care professionals and health policy makers, and specific strategies for promoting older adults’ HL are discussed.

SESSION 2270 (PAPER)
INTERGENERATIONAL ATTITUDES AND RELATIONSHIPS
USE OF MEXICAN AMERICAN FAMILY LOYALTY SCALE TOWARD ELDERLY RELATIVES
H.S. Kao, M.L. Lynn, School of Nursing, The University of Texas at El Paso, El Paso, Texas, University of North Carolina at Chapel Hill, Chapel Hill, North Carolina

Purpose of the Study. Hispanics/Latinos (H/Ls) will be the largest aged minority population in the U.S. by 2050. This, together with the key role the Mexican American (MA) families play in giving care to their elders, makes the advancement of MA family eldercare instruments particularly important to both consumers and providers of healthcare. The 16-item Expectations of Family Loyalty of Children Toward Elderly Relatives (EFLOCTER) was derived from the Expectations of Filial Piety Scale- Spanish version (EFPS) and reanalyzed with a small MA sample. The applicability of EFLOCTER was so refined as to improve the psychometric properties of EFPS and make it suitable to the cultural inclination of the largest homogeneous H/L subgroup-MA. Design and Method. A methodological, descriptive, and correlational design was used. A convenience sample of 193 MA family caregivers of elders was interviewed by promotoras in El Paso, Texas in 2007-2008. Results. Principal Axis Factoring with Direct
GENDERED AGING: OLDER WOMEN IN APPALACHIA

M. Diderich¹, V. Manlow², 1. Shawnee State University, Portsmouth, Ohio, 2. Brooklyn College, New York, New York

Our paper focuses on older females – the matriarchs of Appalachian (primarily working class) families. We confine our interviewees to women who are 65 years or older. Who are they and how do they view themselves in relation to men? We conduct oral life histories revolving around questions about their education (or lack thereof), their outlook on gender and gender roles, the division of labor within their household and their views about women in contemporary society (for instance how they see their daughters and granddaughters). Our paper aims to present our findings, based on thirty in-depth interviews with elderly females in the Appalachian region who have been recruited via a convenience sample. In particular we draw our subjects from the Southern Ohio/ Northern Kentucky/West Virginia area – a geographical environment that has been generally economically depressed which deals with the “culture of poverty”. Our research findings expand on a pilot study previously presented at the 63rd Annual Meeting of the Gerontological Society. Additional findings demonstrate that older women advocate a traditional and, at best, a transitional gender role for their daughters and granddaughters as it is believed that their main focus should be on kinship obligations such as taking care of (extended) family members.

AGE AND INTERGENERATIONAL ATTITUDES IN THE FAMILY AND THE WELFARE STATE

S. Daatland, M. Veenstra, K. Herlofson, Norwegian Social Research, Oslo, Norway

Often overlooked in the debate on generational equity is that older and younger age groups in the society at large, interact as generations in the family setting. These personal, micro-level experiences may reduce or prevent conflict on the societal level, but only few have explored these issues empirically. This paper fills in some of the gap by investigating if people tend to hold family and welfare state attitudes that serve their own or other age-groups. More specifically, the article investigates if family and welfare state attitudes are characterised by generational altruism or self-interest, and additionally – to what extent family attitudes and experiences are reflected in attitudes to welfare state priorities. Data from a large-scale Norwegian study (N=9,591, aged 18-79) on life-course, ageing, and generations are used to address the questions empirically. The findings suggest that attitudes are mixed in both areas, but balanced towards altruism in the family, and towards self-interest in the welfare state. Age remains one of the most important determinants for intergenerational attitudes also after controlling for age-related variables such as health and family position. A potential explanation may be that age and life-cycle position function as sources of social identity and as a position from where one perceives the world. The lower support for family obligations and the higher support for the welfare state among women, may be motivated by personal experiences in family care, and an awareness of the need for family support from the welfare state.

THE EDUCATIONAL SUPPORT PROGRAM IN ELEMENTARY SCHOOL FOR THE CHILDREN OFFERED BY THE SENIOR VOLUNTEERS AND ITS INFLUENCE ON CHILDREN’S IMAGES OF THE ELDERLY

H. Uchida¹, Y. Fujiwara², S. Shinkai³, T. Nishigaki¹, S. Matsuura¹, J. Kuroda¹, T. Okamoto¹, 1. University of Hyogo, Himeji, Japan, 2. Tokyo Metropolitan Institute of Gerontology, Tokyo, Japan, 3. Matsuura Clinic, Himeji, Japan, 4. Kinki University, Izuka, Japan, 5. Himeji Dokkyo University, Himeji, Japan

This study was to clarify the educational support program in elementary school given by the senior volunteers for the children and its influence on the children’s images of the elderly. The program served children in grades 2-3 (age 7 to 8) during the school day, and a volunteer was assigned to a classroom. The participants were six seniors (age 66.8±5.8) and 81 children who lived in Himeji, Japan. The program ran for two years from April 2007 to March 2009, and it did not continue after that. We carried out a follow-up survey in March 2011, and asked children about the effects of the program and their images of the elderly. We measured the images using the short version of emotional-like image scale of older adults assessed by the Semantic Differential method. The general images of the elderly and the specific images of these volunteers were compared, using Wilcoxon signed-rank test. We found 80 percent of the children welcomed the program. For example, they mentioned, “I could learn more” and “It was fun to play together”. The images of the volunteers marked significantly higher in the items such as “reliable”, “strong”, “active” and “fast” (P<0.01, respectively). Regarding the differences of the image scores between boys and girls, the score of “reliable” was higher in girls (P<0.05). It was suggested that the children’s satisfaction with the program was high even after two years from the end of the program and also that their images of the volunteers were positive ones.

OLDER ADULTS’ PERCEIVED BENEFITS AND CONCERNS IN AN INTERGENERATIONAL PROGRAM: THE LINC PROJECT

T.L. Young¹, M. Janke², 1. School of Aging Studies, University of South Florida, Tampa, Florida, 2. University of South Florida Polytechnic, Lakeland, Florida

The perceived benefits and concerns of stakeholders such as older adults have important implications for intergenerational program development; however, the area lacks necessary literature to guide future programs. Furthermore, little to no research has examined factors associated with program participation and outcomes. Thus, the goal of this study was to explore older adults’ (n=195) experiences in The Linking Intergenerational Networks in Communities (LINC) Project, a statewide collaborative program offered in seven communities in South Carolina. The majority of the sample was between the ages of 60-79 (59%), female (78%), and white (74%). Data was collected pre and post involvement in the program and was analyzed using t-test and regression analyses. Findings from the paired t-tests suggested that older adults reported significant improvements in perceived physical health, mental health, social life, life satisfaction, community involvement, and knowledge and skills. Regression models predicting social life, energy level, and community involvement were significant. Average number of concerns increased for older adults. However, there were no significant changes in concerns over time. Regression models predicting concerns related to youth responsiveness, transportation, weather, and ability to get along with youth were significant. Specifically, race was associated with gains in social life and problems in working with the youth. Blacks reported greater improvement in social life, but also noted more difficulty getting along with the youth and with youth responsiveness. These findings will be discussed in terms of implications for program implementation and sustainability with a diverse population of older adults.

600
LEISURE AND WELL-BEING

DOES PARTICIPATION IN LEISURE ACTIVITIES PROTECT AGAINST COGNITIVE DECLINE?
G. Hagger-Johnson1, S. Sabal1,2, M. Hamer1, M. Jokela1, M. Marmot1, M. Kivimaki1, A. Singh-Manous1,2. 1. Epidemiology and Public Health, University College London, London, United Kingdom. 2. INSERM, U1018, VILLEJUIF CEDEX, France.

OBJECTIVE: Leisure activities, particularly those thought to be cognitively stimulating, may protect against cognitive decline and dementia. In order to assess this hypothesis we examined the association between 13 leisure activities and cognitive decline over 10 years in a middle-aged cohort. METHODS: Data are drawn from the Whitehall II study (N=5187, 70% men), aged 45-70 at baseline. Leisure activities were first classified as requiring ‘high cognitive’ or ‘low cognitive’ effort, then classified as being principally ‘social’ or ‘individual’. The cognitive test battery, administered 3 times over a 10-year follow-up, consisted of tests of reasoning, memory, semantic/phonemic fluency and vocabulary summarized as a global cognitive score. Latent growth curve models were used to examine the association of participation in leisure activities with global cognition at baseline and cognitive decline over 10 years. RESULTS: Strong associations were observed between cognitive function at baseline and greater engagement in cognitive, social, individual or total activity (B range: .05 - .15, p <.01). Participation in activities requiring high cognitive effort was associated with cognitive decline (B=-.03, 95% CI -.04; -.01), although this effect size was small. The association remained after controlling for socio-demographic variables, health behaviors, health status and non-ignorable drop-out. CONCLUSION: There was no evidence for a robust association between participation in leisure activities and cognitive decline. Our data suggest that associations arise primarily from the high correlation between cognitive function and engagement in leisure activity in midlife, providing those with better cognitive function at baseline with a higher starting point.

CREATIVE HOBBIES AS A PATH TO GENERATIVITY AND WELL-BEING IN MIDDLE AND LATE ADULTHOOD
C. Adams-Price1, L. Morse1, 1. Psychology, Mississippi State University, Mississippi State, Mississippi. 2. Mississippi State University, Mississippi State, Mississippi

Participation in creative activities is often recommended as a path to wellness for individuals suffering from mental or physical diseases (e.g., Evans, 2007; Goff & Torrance, 1991). However, less is known about the benefits of creative activities for healthy middle-aged and older adults. Adams-Price and Steinman (2007) suggested that creative activities provide feelings of mastery and spirituality for middle-aged adults, which in turn increase feelings of generativity. The purpose of this study is to examine the link between active participation in a creative hobby and generativity for middle-aged and older adults. Approximately 150 adults between the ages of 38 and 90 (70% female) answered questions about participation in one or more creative hobbies, using the Creative Meaning Questionnaire (CMQ, Adams-Price & Morse, 2010). The CMQ contains three factors: Spiritual Benefits, Mastery, and Recognition from Others/Identity. Participants also completed the Loyola Generativity Scale, and the Satisfaction with Life Scale. Long-term and frequent participation in a creative hobby were associated with feelings of mastery, and with identity/appreciation from others, and to a lesser extent, with spiritual benefits. In turn, mastery and appreciation of others/identity correlated with generativity scores, and generativity correlated with life satisfaction. The link between generativity and the creative meaning factors of mastery and identity/appreciation was somewhat stronger in middle-aged adults than in older adults. A structural model of creative activities as a path to wellbeing in middle- and later life will be examined. Creative activities as one route to positive development in middle and later life will be discussed.

THE ROLE OF LEISURE SATISFACTION IN DETERMINING OVERALL LIFE SATISFACTION IN NORTHEAST ASIA
J.J. Liang, T. Yamashita, J. Brown. Sociology and Gerontology, Miami University, Oxford, Ohio

Literature suggests that leisure satisfaction is positively correlated with overall life satisfaction. However, cross-cultural research on life satisfaction has been confined to the industrial countries in America and Europe. Given the rapid population aging in Asia, understanding how leisure satisfaction influences life satisfaction over the life course could have significant implications not only for individuals’ quality of life but also for health and aging policies. Considering the diversity across Asia, this study examines the role of leisure satisfaction focusing on Japan, Mainland China and South Korea because of their shared cultural values (e.g., Confucianism) and practices. Data are derived from the 2006 AsiaBarometer, which includes nationally representative information regarding demographic/socio-economic characteristics, satisfaction measures and attitudes toward society among 20 to 69 year-old individuals in seven Asian nations. Ordinal logistic regression is used to model overall life satisfaction as a function of leisure satisfaction and other covariates. Results show that leisure satisfaction has a significantly positive role in predicting overall life satisfaction in these three countries after adjusting for the covariates. However, the associations between leisure satisfaction, demographic characteristics, socio-economic status and other satisfaction measures (e.g., family satisfaction) vary across Northeast Asia. For example, the effects of leisure satisfaction on overall life satisfaction are appreciably larger in South Korean than China or Japan after adjusting for socio-economic status. Possible explanations about cross-national differences and practical implications are discussed.

“I’M FLOATING THROUGH SCHOOL”: IDENTITY CONSTRUCTION IN A LIFELONG LEARNING INSTITUTE
S. McWilliams, Sociology, Florida State University, Tallahassee, Florida

Lifelong learning programs have become widespread among university communities and popular activities for older adults with growing emphasis on successful aging in our society. This paper examines data from ethnographic research in a southeastern lifelong learning institute associated with a state university, including observations over three semesters in various courses and interviews with students, teachers, and administrators. The results reveal three main strategies through which older adults construct a lifelong learner identity. First, they highlight self-direction in coursework as lifelong learners are committed to education without need for constant concern over tests and homework. Secondly, they display self-relevance of subject matter in that particular classes reflect their personal interests and relate to both lifetime and current experiences. Finally, they work together to develop a community characterized by connectedness and involvement of lifelong learners in social and educational aspects of the program outside of the classroom. These strategies simultaneously emphasize lifelong learners’ age and experience in contrasting their program with educational practices of early life and reduce the salience of age in their identities by focusing on the lifelong process of learning. Both actions and talk employed by students, teachers, and administrators construct a lifelong learner identity that highlights the positive value associated with later life learning, while distinguishing the institute from other educational programs and activities for older adults.
RESILIENT ELDER TRAVELERS: EXPERIENCE AND THEORY
E. Kahana1, B. Kahana2, J. Brown3, L. Lovegreen1, 1. Case Western Reserve University; Cleveland, Ohio, 2. Cleveland State University, Cleveland, Ohio

This paper seeks to unpack challenges faced by older travelers who venture outside the familiarity of language, customs and comforts of their homeland. These circumstances are of theoretical interest to gerontologists and health care professionals as they challenge stereotypes of aging and coping in late life. They also help further our understanding of resourcefulness and successful aging to expand life space of disabled elders. In this paper we present a conceptual framework, anchored in the stress paradigm and our prior work on cancer survivors, for understanding targeted adaptations of elders traveling abroad, while facing challenges of frailty (Kahana & Kahana, 2009). The “Resilient Elder Traveler” model presented here differs from prior formulations, as it is focused on dealing with potential stressors framed as challenges, and on meeting those challenges through anticipating them. Successful coping in this framework combines elements of anticipation and careful planning, with flexibility in reframing goals to meet environmental pressures (Kahana, Lovegreen, Kahana, 2010). Stress appraisal, resourcefulness, and marshalling support are discussed in an ecological framework, as they illuminate older adults’ ability to adapt to of environmental stressors. The authors reflect on model components based on participant observations by the senior authors regarding wheelchair assisted travel through four European countries during a month long trip. Distinct differences were observed in policies, practices, and expectations related to disabled travelers in different regions, adding further challenges to adaptation. Informal orientations to assisting wheelchair-bound travelers, were associated with greater responsiveness, while bureaucratized approaches were unresponsive to travelers’ needs.

SESSION 2280 (PAPER)

MORTALITY AND MORTALITY RISK

A MORTALITY INDEX FOR PERSONS IN HOME AND COMMUNITY BASE WAIVER PROGRAMS
C.W. Given1, M. You2, S. Spoolstra3, 1. Family Medicine, Michigan State University, East Lansing, Michigan, 2. Michigan State University, College of Nursing, East Lansing, Michigan

Information on characteristics of describing the life span of persons residing at home and served by Home and Community Based Waiver (HCBW) programs can be used to prepare clients and families, and to guide services. Using a population of 9849 clients enrolled between 01/01/02 and 12/31/07 in a HCBW program a mortality risk index was identified based on variables from the Minimum Data Set-Home Care version. The population was split into a development and confirmation sample. Logistics and proportional Cox models were used to define factors that included: four comorbidities, ADL’s, hospitalizations, age, gender, and falls all significantly related to mortality. Among them, renal disease had the highest hazard ratio. A mortality index was developed based on beta weights in Cox model. Logistic model (death vs. survival) as outcome and risk index as predictor such that 1 unit increase in the index will cause a 2.7 higher risk of death (CI 95% 2.5-3.0). The index was classified into tertiles. Survival curves were generated; each tertile had a significant difference in rate of survival. Data were confirmed on the validation sample. A summary table revealed that patients in the highest tertile mean age of 83 have the greatest number of comorbid conditions, ADL losses, falls, hospitalizations, and more were male. Agencies could address fall prevention and improving ADL’s. Recognizing that the presence of COPD, renal disease, CHF, and cancer each raise the risk of death by 10%, may precipitate the opportunity to discuss transition to hospice care.

SOCIAL SUPPORT AND DISTANCE TO DEATH: A LOOK AT COMMUNITY-DWELLING OLDER ADULTS

Literature regarding predictors of distance to death, or mortality, frequently point to demographic variables and indicators of physical and mental health. Few studies look at the effects of social support variables in addition to indicators of physical and mental health, especially over an extended period of time (25 years). The data for this study came from a sample of 278 community-dwelling adults 65 years of age and older in Iowa. Initial interviews were conducted in 1985 and public records were used to confirm survival status and dates of death up to December 2010. The average age at time of interview was 72 years, while the average age at death was 88 years; 32 individuals were still living. Cox and hierarchical regression analyses determined the significance of social support factors and survival, in addition to indicators of mental and physical health status. Perceived support was measured using the Social Provisions Scale (Cutrona & Russell, 1987), which assesses six relational provision categories (Weiss, 1974). Results indicate that perceived social support is a significant predictor for survival, even after controlling for physical and mental health variables. Additionally, perceived social support is shown to become increasingly important as a predictor of mortality over time. Additional analyses examining subtypes of social support indicated that attachment, opportunity for nurturance, reassurance of worth, and guidance were important for long-term survival. Results from this study are important in understanding the importance of perceived social support in long-term survival for older adults.

POSITIVE AND NEGATIVE MENTAL HEALTH DIMENSIONS REPORT DIFFERENTIAL NON-LINEAR EFFECTS ON MORTALITY
R.A. Burns, K. Anstey, Centre for Mental Health Research, Australian National University, Canberra, Australian Capital Territory, Australia

The well-being literature discriminates between positive and negative dimensions of mental functioning. Using the vitality and mental health scales from the Short Form-36, this presentation will describe the relationship between positive and negative dimensions of mental health with mortality and their association with mortality risk. Participants (n = 35,083) were from the Dynamic Analyses to Optimize Ageing (DYNOPTA) project and aged between 45-98 years at baseline (M = 59.90; SD = 12.10). Cox regression indicated only increased vitality as associated with reduced risk of death (HRR = .896; SE = .023; p < .001) though this effect disappeared when controlling for demographics and physical health. Latent Growth Modelling then modelled well-being change over a distance to death metric of 10 years for those participants (n = 3,501) that reached mortality. A quadratic trend reported best fit to the data in comparison to a linear or piecewise trend with a 3 or 5 year inflection in slope. For both vitality and mental health, increased distance to death was associated with higher intercepts, lower linear decline, but higher quadratic decline. Decline in well-being was not associated with the control variables. Whilst decline in well-being is associated with mortality, baseline vitality and mental health were not significant predictors of hazard risk for mortality when adjusting for other covariates. That vitality was indicated as a significant predictor of mortality risk in unadjusted models, confirms an emerging literature that positive and negative mental health dimensions are independent oblique factors.

OBESITY & MORTALITY IN OLDER ADULTS
M. Stommel, Michigan State University, East Lansing, Michigan

This study focuses on the associations among BMI levels and mortality risks among persons who already survived at least to age 65. Using linked data files from the National Health Interview Survey (NHIS) from 1987-1994 and the National Death Index (NDI) from 1987-2006, the mortality risks of more than 120,000 U.S. residents older than 64
years of age will be examined. While standard recommendations for physical activity and weight loss assume that the benefits of physical activity and weight loss are similar across all adult age groups, this study specifically focuses on three age cohorts of older adults: U.S. residents aged 65-74, 75-84, and 85 and older (the “oldest old”). The analysis relies on Cox-proportional hazard models, with days to mortality as the main outcome (from 2 years after the interview—to avoid reverse causation problems—up to 21 years follow-up) and numerous control variables, including sex, age (within the age categories), race/ethnicity, poverty status, rural/urban, region of the country, residency location, health status at the interview, etc. Using detailed BMI categories, the results show that the BMI range at which mortality risk are lowest tends to increase with age: among U.S. residents older than 74 years, mortality risks are lowest at a BMI range of 28-31.5 and highest at BMI values < 20. In addition, the association between variations in BMI and mortality risks weakens with age. Reasons include the differential survival of relatively healthy obese persons at older ages, as well as changes in the onset of obesity in different generational cohorts.

SMOKING TRAJECTORIES ACROSS THE LIFE COURSE AND PROSPECTS FOR HEALTHY AGING

N. Agahi1, B. Shaw2, M.G. Parker1, 1. Aging Research Center, KI/SU, Stockholm, Sweden, 2. University at Albany, School of Public Health, Rensselaer, New York

Background: We examined how trajectories of smoking observed during a 34-year period were associated with subsequent mortality as well as trajectories of a variety of aging-related health problems, including circulatory problems, mobility problems, musculoskeletal pain and psychological distress, during the same time period. Methods: Data came from the Swedish Level of Living Survey (LNU) and the Swedish Panel Study of the Oldest Old (SWEOLD). When merged, a nationally representative sample of Swedish adults (aged 15-63 at baseline), could be followed across four observation periods, from 1968 through 2002. Mortality status was tracked until 2007. Trajectories of smoking were identified through cluster analysis, and then used as predictors of health trajectories in multilevel regression models. Results: Five smoking-related trajectories were identified: continuous nonsmokers (n=1505); early quitters (n=289); late quitters (n=333); intermittent smokers (n=307); and continuous smokers (n=517). All health problems increased significantly over time for the continuous nonsmokers; a pattern that was no different for the early quitters. For the more persistent smokers (e.g., late quitters and continuous smokers), higher rates of increasing health problems were evident, particularly with respect to mobility problems. Trajectories of psychological distress, however, were mostly unrelated to smoking trajectories. Mortality risk was higher among persistent smokers, while the risk for early quitters was similar to the continuous nonsmokers. Conclusions: Studying the linkages between smoking trajectories and health trajectories as people enter older adulthood is affected by various factors, including socio-cultural, health, actual physical abilities, and personal characteristics. The conceptual model as well as potential applications of the scale will be discussed.

SESSION 2285 (PAPER)

PSYCHOLOGICAL ISSUES IN AGING: MEASUREMENT ISSUES

SELF-EFFICACY, FUNCTIONAL CAPACITY, AND REAL-WORLD FUNCTIONING IN MIDDLE AND LATE-LIFE SCHIZOPHRENIA

S. Abel1,2, V. Cardenas2, D. Tiznado2,2, A. Harmell2, T.L. Patterson2, D. Jeste2, B. Mausbach1, 1. Alliant International University (CSPP), San Diego, California, 2. Psychiatry, University of California, San Diego, La Jolla, California, 3. San Diego State University, San Diego, California

Background: Individuals with schizophrenia often suffer functional impairments. Measures of functional capacity have been shown to predict real-world functioning in this population, yet capacity does not always translate to actual functioning. We examined the moderating effect of self-efficacy on the relations between functional capacity and real-world functioning and hypothesized that functional capacity would be more strongly related to real-world functioning when self-efficacy was high vs low. Methods: Ninety seven community-dwelling individuals with schizophrenia were administered three measures of functioning: the Specific Level of Functioning (SLOF) scale and both the Work and Social Impairment Subscales of the Behavior Activation Scale for Depression (BASD). Participants also completed the Revised Scale for Self-Efficacy in Schizophrenia and the Brief UCSD Performance Based Skills Assessment (UPSA-B), a measure of functional capacity. The moderating effect of self-efficacy on the relations between functional capacity (UPSA-B) and functional outcomes was assessed via linear regression analyses, with emphasis on the UPSA-B-Self-Efficacy interaction. Results: Functional capacity (UPSA-B) scores were significantly related to proxy ratings of real-world functioning (SLOF scores) when self-efficacy was high (p=.02) but not low (p=.73). Higher UPSA-B scores were also significantly related to lower self-reported work impairment when self-efficacy was high (p=.02) but not low (p=.29). Similarly, higher UPSA-B scores were associated with lower social impairment when self-efficacy was high (p=.001) but not low (p=.80). Discussion: Individuals with high functional capacity may still have real-world functional impairments. Clinicians tasked with predicting/enhancing real-world functioning should consider both functional capacity and self-efficacy as determinants.

DEVELOPMENT AND VALIDATION OF THE BODY IMAGE SCALE FOR OLDER ADULTS

L. Baker, E. Gringart, Psychology and Social Science, Edith Cowan University, Joondalup, Western Australia, Australia

Whilst body image satisfaction is significant to well being across the life span, there is no specific measure with which to assess this in older adulthood. A multidimensional model of body image in older adulthood and a quantitative scale for its assessment were developed. The development of the scale involved five stages. Stage 1 comprised three focus groups involving 15 older adults and provided support for the validity of the multidimensional model. In Stage 2, an initial pool of 77 items was developed and scrutinized by 422 older adults in Stage 3. Nineteen items making four sub-scales remained after statistical processing. In Stage 4, the revised measure was piloted along with a social desirability scale with 123 older adults. The 19 item scale was then tested, in Stage 5, for convergent and divergent validities with 243 older adults. Preliminary findings show that, congruent with the model, body image in older adulthood is affected by various factors, including socio-cultural, health, actual physical abilities, and personal characteristics. The concept model as well as potential applications of the scale will be discussed.

NATURALISTIC AND OBJECTIVE MEASURES OF SOCIAL ENGAGEMENT VIA AUTOMATED SPOKEN LANGUAGE PROCESSING

I. Shafraan, A. Stark, N. Larimer, M. Lehr, N.C. Mattek, J. Yeagars, K. Wild, J. Kaye, Oregon Health & Science University, Portland, Oregon

Many studies suggest social engagement (SE) is associated with health. Current self-report assessments of SE are limited in their ability to probe this association further. Augmentation of self-reports of social activities with more nuanced and objective measures of social networks, e.g., their dynamics such as quantifying level of participation in networks can improve assessment. This may be achieved by taking advantage of current advances in automated recording and analysis of spoken language derived from a number of sources (telephone, in-person contact, Internet chat). Within this framework, algorithms not only quantify the social network, but parse the quality of relationships using statistics of language usage and paralinguistic markers such as speaker
states (affect) and vocal behaviors (laughter, hesitations). This framework was tested in a 12-month feasibility study of 10 volunteers (mean age = 82.7 yrs). Telephone calls representing samples of social interactions were recorded securely with encryption and analyzed automatically. Automatic analysis was adapted to capture individual voice and affective speech characteristics using subjects’ spontaneous verbal descriptions of standard probe pictures/videos at baseline. Over 10,000 calls were analyzed (mean 5.1 calls/day/participant; 389.1-3711.9 words/day/participant). Markers related to SE were extracted including the type, number and regularity of telephone contacts and characterization of language use within conversations. Participants showed high variability in frequency, type and duration of calls. Objective measures were not always congruent with self-perception of activity. These results suggest that automated assessment of SE through analysis of everyday speech is feasible and may provide novel measures of engagement in older people.

ACCELEROMETER DATA REDUCTION: IS THERE AN OPTIMAL INTERRUPTION PERIOD FOR OLDER ADULTS?
E.L. Mailey, N. Gothe, R.W. Motl, E. McAuley, Kinesiology & Community Health, University of Illinois at Urbana-Champaign, Urbana, Illinois

The criteria one uses to reduce accelerometer-measured physical activity (PA) data can profoundly influence the interpretation of research outcomes. One criterion is the allowable interruption in wear time based on the number of consecutive zeros recorded within a given hour. In older adults, an important concern is that a short interruption period would incorrectly classify sedentary time as non-wearing time, and thus eliminate useful data. The purpose of the present study was to compare 20, 30 and 60-minute interruption periods in a sample of community dwelling older adults. Participants [N=242, M age=71.20] were instructed to wear an accelerometer for 7 days. Following this period, the data were downloaded and scored using 20, 30, and 60-minute interruption periods. A total PA score was calculated by summing the counts from the valid days (>10h of wear time) for each data file. Results showed the percentage of participants with at least 5 valid days of data increased from 58.6% to 89.3% to 97.2% for 20, 30, and 60 zeros, respectively. Accelerometer-measured PA was significantly correlated with self-reported PA with 20- (r=.27) and 30-minute (r=.27) interruption periods, but not 60 minutes (r=.09). A similar pattern of associations emerged for functional limitations and exercise self-efficacy. To our knowledge, this is the first study to assess the suitability of various interruption periods in objectively-measured PA among older adults. Our findings suggest using a 30-minute interruption period is optimal, as this allows a majority of the data to be retained without compromising the validity of the data.

EXAMINING THE USE OF THE CORNELL SCALE FOR DEPRESSION IN DEMENTIA AS A PROXY MEASURE OF DEPRESSION

Depression is a common problem in nursing homes and often goes unrecognized in residents with dementia. This study evaluated the utility of the Cornell Scale for Depression in Dementia (CSDD) as a proxy report by examining factors associated with the difference between resident self-report and nurse-proxy ratings of the CSDD. Data for this cross-sectional, descriptive study were collected as part of a larger clinical trial in 28 Washington State nursing homes. The CSDD, a widely used, validated, 19-item scale, was administered in a semi-structured interview format to residents and the nurse who managed their care. We calculated a CSDD discrepancy score (nurse-proxy – resident self-report rating) for each resident and nurse-proxy pair (n = 395); negative discrepancy scores indicated that nurse-proxies rated residents as less depressed than residents rated themselves. Descriptive statistics and regression models were evaluated to identify factors associated with discrepancies in resident and nurse-proxy ratings. Of the group of residents (n= 140) who rated themselves as having at least mild depressive symptoms, 78% went undetected by nurse-proxies. Discrepant scores did not vary based on resident cognitive impairment, but pain reliability, pain summary score, and age were associated with discrepant scores. R2 =.05 F(3,373) = 6.86, p<.001. Residents with reliable pain reports had negative discrepancy scores and rated themselves as more depressed compared to nurse proxies. These findings underscore the importance of obtaining resident input when assessing depression in persons with dementia, and suggest that a simple response reliability assessment can aid in interpreting self-reports from such persons.

SESSION 2290 (SYMPOSIUM)

EFFECTS OF COGNITIVE TRAINING: RESULTS FROM THE ACTIVE STUDY AT 5 YEARS
Chair: S.L. Tennstedt, New England Research Institutes, Watertown, Massachusetts
Discussant: J. King, National Institute on Aging, Bethesda, Maryland

Methods to enhance cognitive abilities and maintain daily function are of great public interest. ACTIVE was a multi-site, randomized, controlled clinical trial (n=2,802) of 3 cognitive training programs - reasoning, memory, and processing speed - hypothesized to improve the targeted cognitive ability and transfer to daily function over time. At 5 years, results support the effectiveness of cognitive intervention in maintaining cognitive abilities over the long-term and indicate modest but detectable far transfer to IADL function. This symposium presents data regarding: 1) amount of training and booster training needed to maintain cognitive performance gains and transfer to functional outcomes; and 2) effect of training on incident dementia. Latent growth models for each intervention show that compliance with initial and booster training resulted in greater training effects for reasoning and speed but did not attenuate rates of normal age-related memory decline. Magnitude of booster effects for reasoning and speed were approximately one-half of initial training effect. Predictors of size and maintenance of training gain differed by group but indicated overall that these training interventions were highly effective for many older persons with intact cognitive function. 186 participants met criteria for incident dementia, defined using a combination of interview- and performance-based methods. A multivariable model showed that training was not associated with a lower rate of incident dementia over 5 years of follow-up. Implications of these findings for the value of cognitive training will be discussed.

ACTIVE COGNITIVE TRAINING AND RATES OF INCIDENT DEMENTIA

Systematic cognitive training produces long-term improvement in cognitive function and less difficulty in performing instrumental activities of daily living. We examined whether cognitive training was associated with a reduced rate of incident dementia in ACTIVE study participants (n = 2,802) after 5 years of follow-up. Incident dementia was defined using a combination of interview- and performance-based methods. A total of 186 participants met criteria for incident dementia. A multivariable model with significant predictors of incident dementia and training group revealed that cognitive training was not associated with a lower rate of incident dementia. Cognitive training did not affect rates of incident dementia after 5 years of follow-up. Longer follow-up
MEMORY TRAINING IN THE ACTIVE STUDY: WHO BENEFITS?
G. Rebok1, J. Langbaum2, R. Jones3, A. Gross4, J.M. Parisi1, A.P. Spira1, A.M. Kueider1, J. Brandt2,1. Johns Hopkins University, Baltimore, Maryland, 2. Banner Alzheimer’s Institute, Phoenix, Arizona, 3. Hebrew SeniorLife, Boston, Massachusetts, 4. Johns Hopkins University, Baltimore, Maryland

Data from the memory training arm (n = 629) of the Advanced Cognitive Training for Independent and Vital Elderly (ACTIVE) trial were analyzed to characterize change in memory performance through five years of follow-up as a function of memory training, booster training, adherence to training, normal aging, and demographic and other person characteristics. Latent growth curve analyses revealed that memory training was associated with improved memory performance through year five, and that neither booster training nor adherence to training significantly influenced this effect. Only age was associated with change in memory performance attributable to the passage of time alone (i.e., to aging), and only education and self-rated health were associated with change in memory performance attributable to training. These findings confirm that memory training can aid in maintaining long-term improvements in memory performance. Adherence to training and booster training do not appear to attenuate rates of normal age-related memory decline.

REASONING TRAINING IN ACTIVE TRIAL: FINDINGS AT FIVE-YEAR FOLLOW-UP
S.L. Willis1, G.I. Caskie1,2, J. Psychiatry and Behavioral Sciences, University of Washington, Seattle, Washington, 2. Lehigh University, Bethlehem, Pennsylvania

Reasoning training effects (N = 699) from the ACTIVE trial were examined for trajectories of four reasoning measures, using piecewise growth models. Significant training effects for all outcomes were maintained at 5-year follow-up. Initial training gain was comparable in magnitude to age-related decline expected to occur over 5 years with no training. All outcomes showed a significant 3rd annual booster effect. Magnitude of the booster effect was approximately one-half the size of the initial effect. Training compliance (initial and booster training) resulted in greater training effects. Significant baseline covariates included: higher education, MMSE, better health, and younger age. Higher MMSE (Baseline) was related to larger training effects, larger linear slopes and smaller Booster effects. For primary functional outcomes, a significant training effect occurred for the Complex Reaction Time test (CRT). A significant 1st annual booster effect occurred for the CRT and the Observed Tasks of Daily Living.

SPEED OF PROCESSING TRAINING: IMPACT ACROSS FIVE YEARS ON PROCESSING SPEED AND EVERYDAY FUNCTIONING
K. Ball1,2, L.A. Ross1, J.D. Edwards2, D.L. Roth1, 1. University of Alabama at Birmingham, Birmingham, Alabama, 2. University of South Florida, Tampa, Florida

Targeted training can improve speed of processing (SOP), an important mechanism of cognitive slowing, and can translate to everyday functioning. However, the amount of training and the effect of booster training needed to maintain SOP and transfer effects are unknown. The present analyses focused on 702 older adults randomized to SOP training to address the impact of training and booster training sessions on maintaining SOP (via the Useful Field of View, Ufov) and functional abilities. Latent growth curve models indicated that initial training effects were maintained over five years and further increased by booster sessions. Booster session effects on Ufov performance were large, and a single booster session counteracted 4.92 months of age-related SOP decline. Ufov performance improved by 2.5 standard deviations for compliant participants. Implications and significant training effects on the Road Sign Test and the Timed-Instrumental Activities of Daily Living test will also be discussed.

SESSION 2295 (SYMPOSIUM)

WIDOWHOOD AND LONELINESS: THE INFLUENCE OF LIFESTYLE
Chair: K.M. Bennett, Psychology, University of Liverpool, Liverpool, United Kingdom
Discussant: C. Victor, Brunel University, London, United Kingdom

Many widowed people experience loneliness following their bereavement. However, the experience of loneliness is not universal. Further, the nature of that experience varies from individual to individual, and varies within an individual’s daily life. The papers illustrate the variance within the loneliness experience, and explore the role which lifestyle plays. Utz et al., present data from a longitudinal study of bereavement, exploring differences in social engagement and support. Exciting results demonstrate that whilst loneliness declines with the passage of time, so does social support. However, social support does not predict loneliness. This finding can be explained by the paper by Bennett et al., which explores qualitatively the experiences of widowed women. Their results highlight the finding that it is not the presence of social support that determines loneliness; rather it is the way in which widows interpret their situations, and in particular the loss of their spouse. Richardson et al., examine the role that religion has in buffering the effects of loneliness. They conclude that the nature of this effect is determined by the duration and circumstances of the bereavement. Bringing these findings together will be Victor, an expert on loneliness research. She will highlight the common features of the research and the values of both quantitative and qualitative research in understanding the experience of loneliness for widowed people. In conclusion, this symposium demonstrates that loneliness is more complex than the absence of social support. Intrapersonal, lifestyle and situational factors all influence whether and how a widowed person experiences loneliness.

HOW OLDER WIDOWED PEOPLE EXPERIENCE LONELINESS: THE ROLE OF COGNITION
K.M. Bennett, E.L. Smith, E. Clark, Psychology, University of Liverpool, Liverpool, United Kingdom

Relatively little work has focused on how older widowed people describe their experiences of loneliness and how they make sense of them. In this study interviews with 19 older widowed women explored experiences of loneliness. The role of cognition, was one of the most interesting themes to emerge. Participants experienced tension between their own needs and perceptions of their situation, and the expectations of their family and friends, and wider society. These tensions led to feelings of loneliness. The degree of loneliness was influenced by whether their thoughts were more negative or positive. But it is important to note that these thought patterns vary very not only between individuals but within individuals. Time, both in the context of daily life and in the context of the longer passage of time, had an impact on the relationship between cognition and loneliness. The implications of these intrapersonal experiences for intervention are discussed.

FEELING LONELY VS. BEING ALONE: SOCIAL SUPPORT AND LONELINESS AMONG RECENTLY BEREAVED PERSONS
R. Utz1, K. Bearson1, M. Caserta1, D. Lund1, B. De Vries2, 1. University of Utah, Salt Lake City, Utah, 2. San Francisco State University, San Francisco, California, 3. California State University, San Bernardino, California

Widowed persons often report that loneliness is among the most challenging aspects of bereavement, yet they also commonly report, at least
initially, an outpouring of support from friends and relatives following the death. Using data from the Living After Loss study (n=328), this presentation will explore differences between loneliness and social support during the early months of bereavement. We used structural equation modeling to predict both the level (intercept) and change (slope) in loneliness and social support over time. We found that widowed persons have elevated levels of loneliness (compared to estimates from non-widowed samples), but that loneliness declined over the first year and a half of bereavement. Similarly, social support from friends and family also declined. However, the amount or quality of social support one has did not modify loneliness over time, suggesting that loneliness is not easily impacted by interventions aimed at increasing social support or engagement. NIA-R01-A023090.

LONELINESS AND DEPRESSION DURING WIDOWHOOD: CAN RELIGION HELP?
V.E. Richardson, J. Han, J.H. Kim, Virginia Richardson, The Ohio State University, Columbus, Ohio.

The moderating effect of religious involvement on the association between loneliness and depression was examined among 250 and 195 older widowed persons at 6 and 18 months after bereavement, respectively. Using data from the Changing Lives of Older Couples, we conducted hierarchical regression analyses while controlling for age, gender, income and ethnicity at both times. Social and emotional loneliness were significantly related to depression at the 6- and 18-month periods. While religious involvement moderated the association between depression and social loneliness at six months, this moderating effect was not significant at 18 months. Income was related to depression only at 6 months. The results suggest that widowed adults alternate how they manage loneliness during bereavement, and they underscore why coping strategies should be assessed at different times throughout bereavement. The potential buffering effect of religion on loneliness and depression evidently varies depending on the duration and circumstances of bereavement.

SESSION 2297 (SYMPOSIUM)

COMPLEXITY SCIENCE AND AGING RESEARCH: EARLY FINDINGS AND A PROMISING FUTURE
Chair: H.E. Whitson, Duke University Medical Center, Durham, North Carolina
Discussant: A.L. Goldberger, Harvard Medical School, Beth Israel Deaconess, Boston, Massachusetts

Complex systems typically involve multiple components and their interconnected networks, which are governed by nonlinear and dynamic relationships, feedback loops, and feedforward mechanisms. Although such systems are difficult to model or simulate, they exhibit characteristic patterns and features of organization. Complex systems are abundant in human biology, and in recent years several investigators have applied complexity science, in various ways, to understanding the aging process. In this symposium, we present an overview of complexity science and explore how it relates to developing ideas and promising avenues for future study in aging research. The first presentation will introduce complexity and its computation in biological systems. The second presentation will detail loss of complexity with age across a number of physiologic systems with attention to the clinical implications of these findings. The third presentation will explore new research which conceptualizes frailty as an emergent property of an impaired complex system. The final presentation will highlight a direct application of complexity science in medicine by discussing the use of stochastic resonance devices to enhance balance control in diabetes and stroke patients. In the discussion that follows, participants will be encouraged to consider other potential applications of complexity science within the field of aging.

LOSS OF COMPLEXITY WITH AGING: EXAMPLES AND CLINICAL IMPLICATIONS
L. Lipsitz, 1. Institute for Aging Research, Hebrew SeniorLife, Roslindale, Massachusetts, 2. Beth Israel Deaconess Medical Center, Boston, Massachusetts, 3. Harvard Medical School, Boston, Massachusetts.

Under “steady-state” conditions, healthy physiologic systems demonstrate complex dynamics that represent interacting regulatory processes operating over multiple time scales. Aging and disease are associated with loss of complexity in the dynamics of physiologic systems (e.g. heart rate, respirations, gait variability), leading to impaired adaptive capacity and the onset of functional disability and frailty. For example, the loss of visual and sensory inputs to the balance control system are associated with decreased complexity of center-of-pressure displacement during quiet standing and increased postural sway during a dual task. Further, subjects with falls or frailty have reduced complexity of their postural sway dynamics. By recognizing the complex dynamics that characterize healthy physiologic function, nonlinear mathematical approaches can be used to predict the onset of frailty or other adverse outcomes, and dynamic interventions can be developed to prevent functional decline.

NETWORK MODELS FOR STUDYING FRAILTY AS A DYNAMICAL SYSTEM
R. Varadhan1, H. Zhu2, 1. Geriatric Medicine, Johns Hopkins Center on Aging and Health, Baltimore, Maryland, 2. Ohio State University, Columbus, Ohio.

Frailty is a state of health signified by vulnerability to adverse health outcomes in the face of stressors. We propose Boolean network models for studying frailty as a dynamical system and characterizing the “resilience” of the system, based on stimulus-response experiments. We demonstrate that resilience of a complex system can be quantified and modeled in different ways: (a) the time it takes to achieve equilibrium following stimulus, (b) the structure of correlations in system response at different time scales, and (c) sensitivity (large response to small, but “good” stimuli) and specificity (small response to large, but “bad” stimuli). The properties of regular networks, random networks, and scale-free networks are compared in terms of different measures of resilience, emphasizing the relationship between network entropy and the dynamics of stimulus response. Our work attempts to provide a deeper understanding of multisystem, complex interactions in the physiologic underpinnings and manifestation of frailty.

ENHANCING BALANCE CONTROL USING STOCHASTIC RESONANCE DEVICES
J. Niemi, Wyss Institute at Harvard University, Boston, Massachusetts.

Previous work has demonstrated that physiologic complexity can be lost through aging, injury, and disease. This loss may diminish sensorimotor performance, leading to a loss of balance control as well as instability in gait. One potential solution is through the application of a vibratory stochastic resonance (SR) stimulation. Stochastic resonance is the counterintuitive notion that you can enhance the sensitivity of certain types of systems through the proper application of external noise. Experiments have demonstrated that the application of subsensory vibratory noise to the feet of subjects increases complexity which results in improvements in balance and gait. This effect occurs in young and elderly patients, as well as patients with diabetes and stroke. Although it remains to be seen whether such technology will prevent falls, which are multifactorial events, the results point toward an exciting frontier in the application of complexity science to clinical care.

OVERVIEW OF COMPLEXITY AND ITS COMPUTATION
M. Costa, 1. Beth Israel Deaconess Medical Center, Boston, Massachusetts, 2. Wyss Institute for Biologically Inspired Engineering at Harvard University, Boston, Massachusetts.

Physiologic signals are largely analyzed using traditional time and frequency domain measures. However, such measures fail to account
for important properties related to multiscale organization and non-equilibrium dynamics. The complementary role of conventional signal analysis methods and emerging multiscale techniques is, therefore, an important frontier area of investigation, with particular relevance to assessing aging and the frailty syndrome. This presentation will focus on two recently developed multiscale computational tools—multiscale entropy and multiscale time irreversibility—which are able to extract information from signals, such as heart rate dynamics, not contained in traditional methods based on mean, variance or Fourier spectrum (two-point correlation) techniques. These new “dynamical assays,” with careful attention to their limitations, may be useful in a variety of areas related to quantifying the loss of complexity with aging, in monitoring countermeasures to frailty, and in drug safety testing.

SESSION 2300 (PAPER)

GAIT AND BALANCE

THE DISCREPANCY BETWEEN ACTUAL & PERCEIVED GAIT ABILITIES AMONG NON DEMENTED OLDER ADULTS

M. Brozgol1, M. Dorfman1, T. Herman1, A. Mirelman1, G. Yogev-Seligmann1,2,3, E. Sprecher4, N. Giladi4,5, J. Hausdorff2,3,1, I. Dept of Neurology, Sackler Faculty of Medicine, Tel-Aviv University, Tel Aviv, Israel, 2. Department of Medicine, Harvard Medical School, Boston, USA, Massachusetts, 3. Laboratory for Gait and Neurodynamics, Movement Disorders Unit, Department of Neurology, Tel-Aviv Sourasky Medical Center, Tel Aviv, Israel, 4. Technion-Israel Institute of Technology, Faculty of Medicine, Haifa, Israel, 5. Department of Neurology, Tel-Aviv Sourasky Medical Center, Tel Aviv, Israel

Objective: A mismatch between perceived and actual abilities may increase the risk of falls. We examined: a) the factors that contribute to self-perceptions about gait quality and b) the divergence between actual and perceived performance among non-demented older adults. Methods: 221 community-living healthy older adults (age: 76.3±4.2 yrs; 62% women; MMSE: 28.7±1.3, range: 25-30) were studied. Self-perception of gait quality was determined using a visual analog scale (VAS-gait: 0-worst and 10-best). Other measures included gait speed during usual-walking and dual-tasking, performance-based measures of mobility, cognitive function (e.g., Trails Making Test A and B), and affect (Geriatric Depression Scale, Spielberger anxiety state and trait). The miss-match between perceptions and ability was determined by calculating differences between z-scored VAS-gait and usual-walking gait speed. Results: VAS-gait was 8.2±1.8 and usual-walking gait speed was 127±22 cm/sec. 51% of the subjects reported very good gait (VAS-gait>9). In multivariate analyses, those with VAS-gait>9 had higher dual-tasking gait speed, better DGI scores, and less anxiety (state). Those whose gait speed and VAS-gait scores matched (n=112; abs(delta Z-scores)=0.77) were generally similar to those who under(n=54) or over-estimated their gait quality (n=55), except that over-estimators took longer to complete the TMT B (170±66 sec vs 141±60 sec; p<0.005). Conclusions: Among non-demented community-living older adults, self-perception of walking quality is related to performance-based measures of mobility and anxiety. Most subjects (75%) did not over-estimate their gait quality. However, in the subset that did, deficits in executive function apparently contributed to inappropriate over-estimation, even among these relatively healthy older adults.

EFFECT OF A VOCAL CHOICE REACTION TIME TASK ON STEP KINEMATICS FOLLOWING A SUDDEN UNDERFOOT PERTURBATION DURING GAIT

J.O. Nnodim, H. Kim, J. Ashton-Miller, University of Michigan, Ann Arbor, Michigan

The cognitive processing required during walking is proportional to the level of complexity of the gait task. Non-gait cognitive tasks performed while walking can also place demands on attentional resources. Since central processing capacity is finite, concurrent gait and non-gait tasks could conceivably interfere with each other. The purpose of this study was to explore the nature of that interference. Twenty-one healthy adults (mean±SD age: 23.1±3.3 years) were tested using a dual-task paradigm. Randomly, in one-third of the 24 gait trials, a rigid protrusion concealed in the outer sole of their specially-designed footwear, was deployed late in swing phase to unexpectedly invert or evert the mid-foot 16 degrees during one single-support phase. Step kinematics were recorded using a Optotrak Certus system. In the dual-task trials, subjects used headphones to listen to a randomized sequence of high and low tones, answering “yes” immediately a high tone sounded. The simultaneous administration of the auditory stimulus and underfoot perturbation resulted in a significantly decreased step length (74.6±/5.1 cm vs 71.2±/4.2 cm; p<0.01) and increased step time (0.55±/0.04 s vs 0.57±/0.03 s; p<0.03) relative to the gait-only task. Dual-tasking did not affect step width or gait variability. Vocal recognition reaction time increased significantly by 27.9% during perturbed gait, compared with stance (480 ms vs 375 ms; p<0.01). We conclude that, in young adults, a concurrent cognitive task interferes with gait by significantly altering step kinematics in response to an unpredictable gait perturbation.

THE ROLE OF MUSCLE MASS AND MUSCLE QUALITY IN THE ASSOCIATION BETWEEN DIABETES AND GAIT SPEED

S. Volpato1, L. Bianchi1, C. Maraldi2, F. Laurerat3, F. Lauratn4, G. Zuliani5, J.M. Guralnik1, L. Ferrucci1, 1. University of Ferrara, Ferrara, Italy, 2. Department of Internal Medicine, Hospital of Ferrara, Ferrara, Italy, 3. Department of Geriatric-Rehabilitation, University Hospital of Parma, Parma, Italy, 4. Tuscan Health Regional Agency, Firenze, Italy, 5. Department of Epidemiology and Public Health, University of Maryland School of Medicine, Baltimore, Maryland, 6. Longitudinal Studies Section, Clinical Research Branch, National Institute on Aging, Baltimore, Maryland

To investigate the association of diabetes mellitus with lower-limb muscle mass and muscle quality and to verify whether diabetes-related muscle impairments mediate the association between diabetes and low walking speed. Cross-sectional analysis of 852 participants (65 years and older) enrolled in the InCHIANTI population-based study. Total, muscular, and fat cross-sectional areas of the calf and relative muscle density were measured using peripheral quantitative computerized tomography. Indicators of muscle performance included knee extension torque, ankle plantar flexion and dorsiflexion strength, lower extremity muscle power, and ankle muscle quality (ankle strength/calf muscle area). Gait performance was assessed using 4-m and 400-m walking speed. Diabetes was ascertained by standard criteria. Prevalence of diabetes was 11.7%. After adjustment for age and gender, participants with diabetes, despite having greater calf muscle area (β:2.27±1.07 cm2, p<0.05), had lower muscle density, knee and ankle strength, muscle power and worse muscle quality (all p values< 0.05). Diabetics were also slower on both 4-meter (β:0.12±0.024 m/s, p<0.001) and 400-meter (β:0.051±0.023 m/s, p<0.05) walking task. In multivariable linear regression models, lower-limb muscle characteristics accounted for 27.5% (95% Confidence Interval: 20.5-33.8) and 15.1% (95% C.I. 13.4-28.9) of walking speed difference comparing diabetics and nondiabetics in the 4-meter and 400-meter walks, respectively. After full adjustment for potential confounders and mediators, diabetic participants remained significantly slower in the 4-meter (β:-0.073±0.021, p<0.01), but not in the 400-meter walking task (β:-0.027±0.019, p=0.165). In older persons,
diabetes is associated with reduced muscle strength and worse muscle quality. These impairments are important contributors to the walking limitations related to diabetes.

24/7 ACTIVITY RECORDINGS FROM >1,000 PEOPLE: QUANTITATIVE AND QUALITATIVE GAIT PARAMETERS
R. Feichtinger1, T. Brauner2, T. Hortmann2,3, M. Göverein4, E. Steinhagen5, M. Gietzelt6, M.D. Schulze6, M. Marschollek3, J. Humotion, Tübingen & Münster, Germany, 2. TUM Technische Universität München, Munich, Germany, 3. Medical Park St. Hubertus Bad Wiessee, Bad Wiessee, Germany, 4. Research Group Geriatrics, Charité, Berlin, Germany, 5. Peter L. Reichertz Institute for Medical Informatics, Braunschweig & Hannover, Germany.

Accelerometers for activity monitoring have often been used in recent years. We built a sensor system adding gyroscopes in 3 dimensions. We measured with accelerometers and gyroscopes at the lower lumbar (L3-L5) back. A study on 29 rehabilitation patients who recently received a hip-TEP implant to 30 age- and BMI-matched controls revealed that, while walking speed almost reached control levels at the third week of rehabilitation, gait symmetry was still highly significantly impaired. A striking gender difference was found during the progression of rehabilitation therapy. With the same recording system we measured over a thousand people in Berlin, aged (>65+ years) as well as a young (20-35years) controls for 24/7 during their normal life. We present quantitative data on activity patterns comparing this aged versus young urban population as well as qualitative gait symmetry parameters from the same study group.

THE SHORT- AND LONG-TERM EFFECTS OF PHYSICAL THERAPY ON THE BALANCE OF OLDER ADULTS AS MEASURED BY THE ACTIVITIES-SPECIFIC BALANCE CONFIDENCE SCALE AND TINETTI’S PERFORMANCE ORIENTED MOBILITY ASSESSMENT

Introduction: Physical therapists often administer a battery of outcome measures to quantify the short-term effects of interventions for older adults with impaired balance. Unfortunately, the long-term effects of physical therapy on balance have not been adequately studied. This study evaluated the short- and long-term effects of physical therapy on balance as measured by the (self-reported) Activities-specific Balance Confidence Scale (ABC) and the (performance-based) Tinetti’s Performance Oriented Mobility Assessment (POMA). Methods: Fifty-three consecutive community dwelling older adults (mean age = 78.1 ±6.7 years) referred to physical therapy (PT) participated in this longitudinal study. All participants had diagnoses that impaired their balance (mean duration 8.5 ±9.1 months). PT interventions included balance exercises, gait training, and strength training among others (mean visit = 9.5 ±4.0). Balance was measured at evaluation, discharge, and 6-month follow-up. Results: Thirty-two percent of participants returned for 6-month follow-up testing. There were no significant differences between those that did and did not return for follow-up testing for age, gender, fall history, symptom duration, visits, or measures of balance at evaluation or discharge. For those that did return, there were significant (p < .001) improvements in ABC and POMA subscales and total scores between evaluation and discharge. There was no significant difference in POMA scores between discharge and 6-month follow-up. There was, however, a significant (p < .001) decline in ABC scores between discharge and 6-month follow-up. Conclusion: Physical therapy improved self-reported and performance-based measures of balance in the short-term. The long-term effects on balance were maintained for performance-based but not self-reported measures.

SESSION 2305 (PAPER)

FEASIBILITY OF IMPLEMENTING THE SUPPORTIVE SUPERVISION INTERVENTION IN LONG TERM CARE
K.S. McGilton1,2, J. Poffetto-McGrath3, A. Robinson1, 1. Research, Toronto Rehabilitation Institute, Toronto, Ontario, Canada, 2. Faculty of Nursing, University of Toronto, Toronto, Ontario, Canada, 3. Faculty of Nursing, University of Edmonton, Edmonton, Ontario, Canada.

Providing quality care in nursing homes is dependent on having clinically and interpersonally competent RNs in supervisory roles. The primary purpose of this study was to determine the feasibility of implementing an intervention focused on enhancing the supportive capacity of RNs in nursing homes. The objectives of the study were that supervisors would perceive increased job satisfaction following the intervention. Further, supervised staff whose supervisors were trained in the intervention would perceive (a) increased supportive supervision; (b) enhanced job satisfaction; and (c) increased knowledge utilization. A repeated measures group design was used to address the objectives. The study was conducted in one conveniently selected nursing home in urban location in Canada. 15 RNs, 8 LPNs, and 17 HCAs participated in the study. Following the supervisory intervention which included a workshop, weekly reflections, and on-unit coaching, there was an increasing trend in the supervisors’ work satisfaction scores; however there were no changes perceived by the supervised staff according to their job satisfaction or level of supportive supervision. There were significantly higher scores for supervised staffs’ instrumental knowledge use (t = 2.68, df = 1.13, p = .018), overall knowledge use (t = 2.1, df = 1.13, p = .047), and conceptual knowledge utilization (t = 2.58, df = 1.13 p = .014). The results of the feasibility data study suggests that the intervention requires modification prior to proceeding to a controlled trial but does provide some preliminary evidence that supportive supervisors may enhance knowledge use of their supervised staff.

POSITIONING YOUR TELEHEALTH PROGRAM FOR SUCCESS: BE PREPARED TO MEET THE CHALLENGES
M. O’Connor1, M. Adelsberger2, K.H. Bowles1, 1. School of Nursing, University of Pennsylvania, Philadelphia, Pennsylvania, 2. Penn Care at Home, Bala Cynwyd, Pennsylvania

Many skilled home health providers are seeking new ways of caring for an increasingly complex and costly geriatric patient population, many of whom are suffering from multiple co-morbid conditions. Telehealth is an emerging technological tool where wireless biometric devices and video technology are placed in patient homes, transmitting health data to community based clinicians via the patient’s telephone line, internet or wirelessly through 3G communications. Telehealth is believed to improve patient outcomes by frequent monitoring and timely intervention when patient deterioration is detected, but implementation presents many challenges. With over 10 years of experience in telehealth research and practice, presenters explore common challenges and offer practical advice critical to a successful telehealth implementation. Challenges to successful telehealth implementation include field staff and physician acceptance, leadership support, agency culture, staffing shortages, equipment installation and maintenance, financial resources, patient resistance, generating and maintaining staff enthusiasm and the technological readiness of the individual agency. Practical advice is discussed related to choosing and financing equipment, staffing and logistics of the program, targeting the ideal patient population to service, preparing agency leadership and staff for implementation, physician collaboration and community outreach, and defining and maintaining success.
CLINICAL AND BUSINESS IMPLICATIONS OF A FALL SCREENING AND EXERCISE PROGRAM IN ASSISTED LIVING

G. Sloves, A. Gomez, Fox Rehabilitation, Cherry Hill, New Jersey

Falls are a major health problem in the elderly community, increasing the risk of mortality, morbidity, disability and frailty as well as increasing medical costs. The purpose of this novel evidence-based program is to: provide comprehensive fall risk assessments and progressive group exercise classes to reduce the incidence of falls in assisted living residents; provide independent seniors residing in the community with no-cost progressive exercise classes; provide assisted living corporations with showcase programming to promote facility as community resource center. All residents of 10 assisted living communities (1,000+ residents, ages 55-100 years) participated in a fall risk assessment, upon move into community, quarterly, at functional decline or post fall. Assessment includes fall history, strength testing (30 Sec Chair Stand), gait testing (Timed Up & Go Test) and balance testing (Functional Reach). 900 high fall risk residents received an interdisciplinary improvement plan including physician/nurse systems review, medication review, occupational, physical, or speech therapy, environmental hazards assessment, caregiver education, change in toileting routine, or use of DME. 100 low to moderate fall risk residents participated in customized 12 week therapeutic exercise classes, designed by physical therapists and lead by exercise physiologists, 2x/wk for 60 minutes per session. This innovative collaborative project resulted in fall reductions up to 43% in one year. Resident impairments and function also significantly improved: Sit-Stand by 2.9 repetitions, TUG by 1.2 seconds, and Functional Reach by 1.8 inches. Independent community seniors also attended exercise classes increasing the viability of the facility as a community resource center for seniors.

ACCESS: SATISFACTION WITH TELEHEALTH CANCER CARE RESOURCES BY MATURE ADULTS

V.F. Rempusheski, P. Klemm, J.F. Teixeira, J.R. Perry, C. Jurkovitz, M. Merson, A. Exner, 1. University of Delaware, Newark, Delaware, 2. Cancer Care Connection, Newark, Delaware, 3. Christiana Care Center for Outcomes Research, Newark, Delaware

Cancer is primarily a disease of older adults. By 2050, the cohort of Americans age ≥65 will double and herald a surge in the number of older Americans needing cancer-related information. An aim of the Academic-Community–Clinical Engagement for Support and Successful Outcomes (ACCESS) study is to evaluate outreach to older adults affected by cancer and their family caregivers. To partially address this aim, we assessed satisfaction of callers to Cancer Care Connection (CCC), a non-profit telehealth service offering free professional cancer coaching and personal care resources. Between 1/22/2010 and 2/15/2011, CCC received calls from 462 persons in 33 US states, District of Columbia and Canada. One hundred-twenty callers agreed to be contacted to evaluate the CCC telephone service. A 7-item, 5-step Likert scale (1=not at all, 5=complete) and comment section were completed by 63 callers (51% response rate): 65% were mature adults age 46-64 y/o, 19% were ≥65 y/o, 84% were female, and represented 17 states across the USA. Those who answered the survey did not differ significantly from those who did not by gender, age group, age of older adults, or location. Most reported that they completely understood the information (83%); that coaches listened attentively (95%), completely answered their immediate questions (91%), provided useful information or resources (86%), and helped them make decisions (64%). Four themes about coaches emerged from caller comments: time spent, someone to talk to, compassion, and follow-up. Financial assistance was expressed as a need of most callers. These findings raise further questions about cancer care resource needs. Funded by NIH/NCRR.

SMALL-SCALE LIVING FACILITIES IN DEMENTIA CARE: EXPERIENCES OF FAMILY CAREGIVERS AND NURSING STAFF

H. Verbeek, S.M. Zwakhalen, E. van Rossum, G.I. Kempen, J. Hamers, Health Care and Nursing Science, Maastricht University, Maastricht, Netherlands

Long-term Dementia Care Is Increasingly organized in small-scale and homelike care facilities, reflecting a cultural change movement. In these facilities, residents are encouraged to participate in household activities, emphasizing normalization of daily life with person-centered care. Despite the large increase of such facilities, research into experiences is scarce. This study therefore investigated experiences of family caregiver and nursing staff. The study was part of the process evaluation of a large effect study into small-scale living facilities (SSLFs) in the Netherlands. Questionnaires were sent to family caregivers in SSLFs and traditional nursing homes (TNHs) (n=130) and nursing staff in SSLFs (n=101). In addition, semi-structured interviews (n=20) were held with family caregivers and nursing staff in SSLFs. Family caregivers of older people in SSLFs experienced the facility as significantly more homelike than family caregivers of older people in TNHs. The largest difference was found for the domain ‘having an ordinary household’ (p<.001); the smallest difference was reported for the domain ‘physical resemblance of an archetypical home’ (p<.05). Interviews showed that almost all participants reported positive experiences with SSLFs regarding personal contact, a home for life principle and homelike atmosphere. Nursing staff welcomed the broadening of their tasks, although some experienced working often alone as a disadvantage. They were most positive about the personal contact with residents and the working environment. Experiences with SSLFs for people with dementia are mainly positive. With the changing role of family and nursing staff, more insight is needed into caregiver burden and nursing staff’s skills.

SESSION 2310 (PAPER)

OLDER ADULTS IN THE COMMUNITY

CONJOINT TRAJECTORIES OF DEPRESSION AND SELF-RATED HEALTH IN COMMUNITY DWELLING ELDERLY

M. Kuchibhatla, K. Hayden, G. Fillenbaum, 1. Duke University Medical Center, Department Of Biostatistics and Bioinformatics, Durham, North Carolina, 2. Duke University Medical Center, Department Of Psychiatry, Durham, North Carolina

Correlated trajectories and the reciprocal effects of depressive symptomology and self-rated health were modeled simultaneously using latent growth curve models. The sample comprised 3976 White and African American participants aged 65 years and older (mean 73 years) from the Duke Established Populations for Epidemiologic Studies for the Elderly (EPESE). Participants were evaluated by trained interviewers with a structured questionnaire at baseline, three, six, and ten years later. On each occasion, depressive symptoms were measured using the modified Center for Epidemiologic Studies Depression (CESD) scale (range 0–20) and self-rated health was obtained (excellent = 1, poor = 4). A latent linear growth curve fit both CESD depressive symptomology and self-rated health measured at the four time points. The estimated mean and standard error (SE) of the latent intercept of CESD were 3.08 and 0.05; the latent slope of CESD was 0.05. The latent intercept, (SE), and latent slope of self-rated health were 2.59, (0.02) and 0.03 respectively. Regression of the latent intercepts of self-rated health on the latent slopes of depression symptomology were significant and positively associated (coefficient = 0.05, p-value = 0.005). That is, poor self-rated health status (larger values of self-rated health) at baseline was associated with increase in depression symptomology over the next 10 years. Effects of other covariates on the trajectories, and association of the resulting parameters will be examined. CTSA grant 5UL1 RR024128-04 from

64th Annual Scientific Meeting 609
Depression and chronic pain are related conditions that may share a common pathway leading to falls in older persons. In the population-based MOBILIZE Boston Study, 722 older adults (mean age 78.3y, 63.6% female) completed baseline assessments about chronic pain and depressive symptoms. Chronic pain was measured by number of pain sites (none, single site, or multisite), pain severity, and pain interference with daily activities. Depressive symptomatology was assessed by the CES-D total score and within 2 domains, cognitive or somatic symptom scores. Participants recorded falls on monthly calendar postcards over an 18-month period. Fall rate ratios were derived from negative binomial models adjusted for sociodemographics, chronic conditions, cognitive function and multiple fall risk factors. Older adults with more depressive symptoms had higher fall rates compared to those with fewer/no symptoms for each of the 3 depression measures. Average fall rates from the lowest to the highest total CESD quartiles were: 0.71, 0.89, 0.89, 1.40 per year, respectively. Adjusted fall rate ratios comparing quartiles 2, 3 and 4 of the total depression score to the lowest quartile were 1.11(0.82–1.49), 1.26(0.92–1.73), 1.91(1.39–2.61), respectively. Similar graded associations were observed according to cognitive and somatic CESDR domains. Although pain location and pain interference were mediators (±10% change in estimate) of the depression-falls relationship, the association between depression and falls remained significant after adjustment for chronic pain. Chronic pain was also independently associated with increased fall risk. Both pain and depression are treatable conditions, offering opportunities to reduce falls risk in aging.

PARENTING GRANDPARENTS: PILOT TESTING OF THE GP-PRAISEDDD INTERVENTION TO IMPROVE HEALTH
R.D. Satyshur, B. Resnick, Family and Community Health, Baltimore, Maryland

Aims: The purpose of this study was to utilize a socio-ecological model approach to test the feasibility and effectiveness of a community-based intervention with parenting grandparents (PRAISEDDD-GP). Methods: A single group pre and post test design was used to evaluate the feasibility and preliminary efficacy of this six month intervention. Pilot subjects consisted of 9 grandparents, 40 years or older who had full time responsibility for raising grandchild(ren) in parent absent households. Participants were exposed to 6 monthly, 1 hour classes/discussion groups conducted by a registered nurse. Topics included: Stress Management, Exercise and Barriers, Medication Compliance, Diet, Positive Discipline, and Children’s Emotional and Educational Needs. Measures were completed prior intervention and then 4 weeks post intervention. Stress Measure: Brief Symptom Inventory (BSI); Social Support: Family Support Scale (FSS); Health Behavior: Yale Physical Activity Survey (YPAS); Food Intake measure: Brief Block Questionnaire (BBQ). T-test for paired samples were used to compare pre and post mean scores. Results: The PRAISEDDD-GP intervention resulted in decreased psychological distress scores and increased social support scores. Class discussions facilitated sharing information among grandparents related to diet, exercise, health, well being, childrearing and reducing stress and isolation. Grandparents reported awareness of healthier dietary choices and cooking habits. One subject reported engaging in regular exercise activity. Conclusions: Educational interventions (PRAISEDDD-GP) are a critical first step maybe in changing behavior. Ongoing work, however, is needed to move beyond education and teach and engage parenting grandparents in activities such as exercise, buying, and cooking heart healthy diets. Few policies or programs exist to improve the health outcomes of parenting grandparents.
Correlation Coefficient of the CAM and CAM-FAM was 0.856 (p=0.01).
Conclusion: We have confidence in the CAM-FAM utility in research and potentially in care partnerships.

SESSION 2315 (SYMPOSIUM)

EVALUATING GERONTOLOGICAL OUTCOMES IN THE PRESENCE OF COMPETING RISK OF DEATH

Chair: Q. Xue, Medicine, Johns Hopkins University, Baltimore, Maryland
Discussant: R. Varadhan, Medicine, Johns Hopkins University, Baltimore, Maryland

The symposium introduces novel analytic methods to account for competing risk of death. Many longitudinal and time-to-event studies of non-fatal health outcomes in the geriatric population face challenges of non-ignorable missing data and informative censoring resulting from competing risk of death. Standard methods such as Cox models and random effects models (REM) may lead to biased inference because of their unlikely assumption of independence between death and the outcome of interest. The first talk gives an overview of statistical approaches for modeling trajectories of longitudinal data truncated by death, and illustrates how standard techniques such as REM and Generalized Estimating Equations (GEE) may be applied or extended to address different research aims in this setting. The second talk introduces a competing risk model for survival analysis. Instead of treating death as a censored event, the model estimates the cumulative incidence of the event conditional on event-free survival. The third talk discusses joint modeling of both event and event-free death through a mixed likelihood approach, the mixing parameter being the proportion of subjects who experienced the event (vs. died before event onset). This model aims to assess how interventions modify the mixture in terms of both the mixing parameter and the survival time distributions of the event and death. Real data examples are used to illustrate the methods, with the goal of improving our understanding of competing risk and its implications in the prediction and prevention of poor health outcomes among older adults.

LONGITUDINAL DATA WITH FOLLOW-UP TRUNCATED BY DEATH: MATCHING ANALYSIS METHODS TO RESEARCH AIMS

Diverse analysis approaches for longitudinal data truncated by death are illustrated using cognitive functioning data (MMSE) from the Cardiovascular Health Study. Unconditional models, such as random effects models, average longitudinal responses over the survival distribution and may implicitly impute data beyond the time of death. Fully conditional models stratify by time of death and describe individual trajectories in terms of either aging (age, or years from baseline) or dying (years from death). Modern causal models (principal stratification) describe group differences at one timepoint for a cohort that will survive past a later timepoint. Partly conditional models reflect the average response in survivors at a given timepoint, rather than individual trajectories. Joint models of survival and longitudinal response describe the evolving health status of the entire cohort. Researchers should consider which method of accommodating deaths is consistent with study aims, and analyze data accordingly.

INFERENCIE FOR MUTUALLY EXCLUSIVE COMPETING EVENTS THROUGH A MIXTURE OF GENERALIZED GAMMA DISTRIBUTIONS

W. Checkley, R. Brower, A. Munoz, Johns Hopkins University, Baltimore, Maryland

Time-to-event data with two or more types of endpoints are common in epidemiological settings. Instead of treating the times for one of the endpoints as censored observations for the other, we treat competing events as distinct outcomes in a mixture of survival distributions. The model aims to determine if and how the mixture was modified in response to an intervention. Using data from patients with acute lung injury, we compared the effects of liberal vs. conservative fluid-management strategies (LFM vs. CFM) and low vs. traditional tidal volumes strategies (LTIV vs. TVT) on the frequency and survival times of two competing events: unassisted breathing (UAB) followed by hospital discharge alive and in-hospital death. We found that LTIV lowered the frequency of death (p<0.005), but did not affect time to UAB or death (p=0.1). CFM shortened time to UAB (p=0.001), but did not affect frequency of death or time to death (p>0.2).

COMPETING RISK OF DEATH: AN IMPORTANT CONSIDERATION IN STUDIES OF OLDER ADULTS

S.D. Berry1, L.H. Ngo2, E.J. Samelson3, D.P. Kiel1, 1. Institute for Aging Research, Boston, Massachusetts, 2. Harvard Medical School, Boston, Massachusetts

Clinical studies of elderly persons are often faced with the difficult problem of how to account for participants who die without experiencing the study outcome of interest. Traditional approaches to describe risk of disease include Kaplan-Meier survival analysis and Cox proportional hazards regression. In these methods individuals who die without experiencing the study outcome are censored, yet censored individuals are assumed to still be at risk of disease. Consequently, these methods overestimate risk. We illustrate this concept by comparing a competing risk approach with a Kaplan-Meier approach to estimate risk of second hip fracture in the Framingham Osteoporosis Study. In this example, Kaplan-Meier survival analysis overestimated the five-year risk of second hip fracture by 37% and the ten-year risk by 75% compared with competing risk estimates. We conclude a competing risk approach should be used to determine risk of disease in studies of elderly persons with long follow-up.

SESSION 2320 (SYMPOSIUM)

MATCHING NEEDS TO SERVICES PROVIDED TO ELDERLY PEOPLE

Chair: B. Vrijhoef, TRANZO, Tilburg University, Tilburg, Netherlands
Discussant: B. Vrijhoef, TRANZO, Tilburg University, Tilburg, Netherlands

Given the heightened pressures for careful use of scarce resources, it is imperative that healthcare providers ensure that services are appropriate to the needs of elderly people. In so doing, it is believed that one needs to assess the needs of elderly people and relate these to existing services. In this symposium 4 different examples of such assessments are presented. First, an approach based on aspects of social marketing in which the analysis of the situation of the customer is point of departure and evaluation of the intervention is an essential part will be presented. The second example is a project about assessing the effectiveness of early detection of health problems among community-dwelling older people and their subsequent referral to appropriate care and/or well-being facilities by general practices. The third example presents a novel methodology which involved linking over 300 million care records at the person level, and using risk adjustment to understand where tele-health and telecare technologies might best be targeted. The fourth example discusses to what extent obligatory measurement of clients’ experiences result in improved quality of long term care. Based on these...
examples we will discuss the feasibility and challenges of how to best match needs to services provided to elderly people.

DEMAND-BASED INTERVENTIONS FOR LONELY PEOPLE
K. Luijkx, Tranzo, Tilburg University, Tilburg, Netherlands

Due to the negative impact of loneliness to both the physical and the mental health of elderly people, it is important to intervene in order to reduce these feelings. It seems possible to reduce feelings of loneliness with interventions, of which an overwhelming variety exists. However, the scarce research in this area shows that many interventions are not effective. It is supposed that there is too little attention for the individual situation of lonely elders to provide suitable effective interventions. In a cooperation of science and practice (welfare organizations) a systematic approach has been designed to develop, implement and evaluate interventions aimed to diminish loneliness. This approach was based on aspects of social marketing in which the analysis of the situation of the customer is point of departure and evaluation of the intervention is an essential part.

HOME VISITATION PROGRAM FOR THE EARLY DETECTION OF HEALTH PROBLEMS AMONG OLDER PEOPLE
M.M. Stijnen1, I.G. Duimel-Peeters1,2, M.W. Jansen1, B. Vrijhoef1,2, J. Maastricht University, Department of General Practice, Maastricht, Netherlands, 2. Maastricht University Medical Centre, Department of Integrated Care, Maastricht, Netherlands, 3. Public Health Service South-Limburg, Geleen, Netherlands, 4. University of Tilburg, TRANZO, Tilburg, Netherlands

In the Netherlands, general practices are increasingly held responsible for organizing preventive care for older people. There has been an increased focus on the timely identification of health risks among older people that may ultimately be detrimental for maintaining independent living. For this purpose, a home visitation program has been developed for the early detection of health problems and risk situations among community-dwelling older people (aged ≥ 75 years) by general practices. Practice nurses perform a comprehensive multidimensional assessment of the health and well-being of older people and, if necessary, older people are subsequently referred to additional diagnosis, preventive care or treatment based on their own needs and wishes. A quasi-experimental study is being conducted to examine whether this approach leads to sustained or improved health-related quality of life and reduced disability. Furthermore, the feasibility of the program for general practices is assessed by means of an extensive process evaluation.

IMPACT OF ASSISTIVE TECHNOLOGIES ON SERVICE USE: FINDINGS FROM A LARGE RANDOMISED TRIAL

There has been significant interest in the potential of technology to reduce financial pressures on health care systems and improve the quality of care. In England, the Department of Health sponsored a large randomised control trial of a system of multidisciplinary working, supported by telehealth and telecare technology in the home. This Whole System Demonstrator is believed to be one of the largest randomised trials of these technologies ever conducted, with almost 6,000 participants. We will present findings related to impacts on the use of primary and secondary health care and long-term domiciliary and residential care. Assessing the effects of community-based interventions is challenging. We employed a novel methodology which involved linking over 300 million care records at the person level, and using risk adjustment to understand where these technologies might best be targeted. Objectives: Participants will be describe findings relating and discuss the role of risk adjustment.

SESSION 2325 (SYMPOSIUM)

THE NEW REGULATORY MODEL TO PREPARE ADULT-GERONTOLOGY ADVANCED PRACTICE NURSES: FACULTY RESOURCES TO FACILITATE MODEL IMPLEMENTATION
Chair: J. Stanley, American Association of Colleges of Nursing, Washington, District of Columbia
Co-Chair: C. Auerhahn, Hartford Institute for Geriatric Nursing New York University College of Nursing, New York, New York
Discussant: D.L. Thompkins, American Nurses Credentialing Center, Silver Spring, Maryland

The 2011 IOM report on nursing emphasizes the importance of nurses working to their full scope of practice. Advanced Practice Registered Nurses (APRNs) provide high quality and cost effective care to adults including long-term care. Older adults comprise a large proportion of the patients cared for by APRNs. Yet only a small number of APRNs are prepared specifically in geriatrics. Currently, there are approximately 4,500 geriatric nurse practitioners (NPs) and clinical nurse specialists (CNSSs) as compared with over 30,000 adult NPs and CNSSs. The proposed Consensus Model for APRN regulation (the LACE model), endorsed by 47 national nursing organizations, will markedly expand the APRN work force prepared in geriatrics by combining geriatric and adult APRN preparation into Primary Care Adult-Gerontology NP, Adult-Gerontology CNS, and Acute Care Adult-Gerontology NP programs. In 2007, the John A. Hartford Foundation funded the American Association of Colleges of Nursing (AACN) and the Hartford Institute for Geriatric Nursing at the NYU College of Nursing to prepare resources to help APRN faculty implement these changes, due to be in place by 2012. This Symposium describes resource development for APRN faculty (e.g. competencies, model curricula, evolving case studies, a slide library, teaching strategies) and faculty evaluation from dissemination activities. Specific, measurable outcomes for this symposium are: After attending this Symposium, participants will be able to: 1) describe faculty resources developed to facilitate the transition to the Adult-Gerontology APRN role(s) and 2) discuss strategies for dissemination of these resources.
COMPETENCIES FOR THE NEW ADULT-GERONTOLOGY APRN REGULATORY MODEL

This session describes the newly-developed competencies for Primary Care Adult-Gerontology NP, Adult-Gerontology CNS, and Acute Care Adult-Gerontology NP programs. The consensus-building process used to develop them will be discussed and the competencies will be reviewed. Also discussed will be the findings from a needs assessment conducted by AACN and the Hartford Institute in preparation for the development of faculty resources. Key faculty in existing NP and CNS Adult and Gerontology programs were surveyed and subsequent focus groups were held to determine resources that APRN faculty would view as relevant to implementing the new model.

FACULTY RESOURCES TO HELP IMPLEMENT THE NEW ADULT-GERONTOLOGY APRN REGULATORY MODEL

This session describes the resources that have been developed to assist APRN faculty in the transition to adult-gerontology programs. These resources were developed based on the recommendations of the faculty needs assessment discussed earlier. They include: 1) web-based interactive evolving case studies, for use by students in preparation for classroom and clinical discussions; 2) three learning modules focused on teaching strategies and available print and eLearning resources to help faculty re-direct classroom presentations and clinical seminars to fully integrate both adult and gerontology content, model curricula which allow faculty to explore how APRN nursing programs that have already integrated their adult and gerontology programs have allocated content and clinical experiences, and essential gerontological/geriatric content and its integration into adult-gerontology APRN programs; and 3) a slide library with state of the art content in four areas of geriatric care.

PRE-CONFERENCE WORKSHOPS AS A MEANS OF DISSEMINATION OF FACULTY RESOURCES

This session describes the pre-conference workshops conducted at four APRN professional organization meetings: AACN Masters Conference, National Organization of Nurse Practitioner Faculties, American Association of Critical Care Nurses, and American Academy of Nurse Practitioners. Content presented at the workshops included: an overview of the New Regulatory Model; the new adult-gerontology competencies for NPs and CNSs; and faculty resources including web-based interactive case studies and the slide library. Presentations derived from the three learning modules described earlier were also included. Presenters were all expert APRNs and were chosen from a variety of institutions. There was also an opportunity for participants to apply the content of the workshop in small group discussions facilitated by the presenters.

RESOURCE EVALUATION AND FUTURE PLANS FOR DISSEMINATION

This session describes the evaluation of the APRN resources garnered from attendees from pre-conference workshops, summary of web statistics as to people accessing the on-line materials, and an on-line survey of users. Future plans for dissemination include an ongoing electronic resource to assist faculty who have not attended pre-conference workshops in person to utilize the online resources, and development of an ongoing electronic resource and platform for faculty exchange of ideas and questions. This platform will allow for posting of new curricula models and resources as they are developed, and for exchange of best practices, questions, and solutions as faculty redesign and implement the new curricula.

SESSION 2330 (PAPER)
FAMILY CAREGIVING
POLICY INTERSECTIONS, RECOMMENDATIONS, AND ACTION STEPS FOR SUPPORTING FAMILY CAREGIVERS AND THE DIRECT SERVICE WORKFORCE
A. Hewitt¹, S. Edelstein², C. Blakeway¹, 1. University of Minnesota, Minneapolis, Minnesota, 2. PHI, New York, New York, 3. The Lewin Group, Falls Church, Virginia

Although family and professional caregivers experience similar rewards and challenges, public policies and programs affecting these two groups are typically uncoordinated. In September 2010, CMS convened an invitational summit of leaders in the caregiving field to identify policy intersections, recommendations, and action steps to work together to build capacity and support for all caregivers. Twelve common policy goals emerged, addressing specific goal for family caregivers and direct service workers, coupled with broad systems change goals. Summit participants identified five immediate next steps to follow up on the discussions: 1) continue and expand stakeholder discussions to share information and build consensus; 2) reach out to CMS Center for Innovation and other Affordable Care Act implementation groups; 3) support ongoing compilation and dissemination of information; 4) develop a roadmap of currently available caregiver competencies; and 5) reach consensus among stakeholders on a common set of core competencies to guide the development of training materials. This session will discuss the recommendations and progress on action steps. We will also present additional resources providing background on family caregivers and the direct service workforce. Finally, we provide example programs and initiatives related to caregiver training, stakeholder partnerships, long-term care financing, community based supports models, peer support, and recruitment/selection/retention.

A TEST OF RIVAL THEORIES FOR REDUCING HARDSHIPS IN SANDWICH GENERATION HOUSEHOLDS
G.A. Rainville¹, M. Nguyen², 1. AARP, Washington, District of Columbia, 2. University of Massachusetts, Boston, Massachusetts

The jobless recovery provides an opportunity to assess rival theories about the resiliency of sandwich generation households. Implications from two theoretical orientations are tested with household-level data from AARP gathered during 2010. The economies of scale literature suggests that sandwich generation households may reduce hardships by pooling housing resources within its large network of available kin. Another view of households is that each successive co-residing working-age adult (including spouses) fails to offer sufficient income for these theories is garnered by whether reduced or increased hardships are reported in households with greater than one working-age adult. Household compositions are divided into exhaustive categories and regressed on a SIPP-like (i.e. Survey of Income and Program Participation) hardship index with demographic and income-related controls. Single-stage OLS models found that sole households reported significantly lower scores on the hardship index than those with any other household configuration. Heckman models show consistent, but attenuated, results for the measures of chief theoretical interest. Empirical
support for a theory that suggests limited pooling and exchanges within sandwich generation households implies that family-based solutions for reducing household hardships—such as seeking economies and setting up a system of intra-household exchanges—appear insufficient to offset scarcities imposed by the business cycle. The degree to which older adults may negotiate the configurations of their households is discussed in a consideration of whether such findings could lead to actionable policy or lifestyle choices.

I CANNOT MAKE IT WITHOUT THEM: PATIENT AND CAREGIVER PERSPECTIVE OF HOME BASED PRIMARY CARE

The Centers for Medicare and Medicaid (CMS) Independence at Home demonstration project will test a home based primary care (HBPC) model within the Medicare economic structure. The project targets the 5%-25% of beneficiaries who account for 43% to 85% of Medicare costs. This model is based on success of the Department of Veterans Affairs HBPC program, which decreases health care costs and improves patient outcomes. The increasing interest in HBPC highlights the need to understand the perspective of patient and caregiver about the benefits and most useful services of this intensive model. In-depth interviews were conducted with 15 Veterans and their caregivers at three VA HBPC sites across the country. Analysis of transcripts identified key themes regarding patient and caregiver experiences and value of specific services. Frail elders and caregivers described how not having to go to the clinic reduced physical strain and stress for both. Relying on the HBPC nurse to order medications and fill pill boxes improved compliance and eased caregiver burden. Patients and caregivers identified the visits from the care team as the most important part of the program, and valued their interactions with HBPC clinicians. These data indicate that practices provided by HBPC not only improve chronic disease management, but provide social engagement and develop coping skills for both patient and caregiver, contributing to mutual well-being. For VA and CMS, these findings provide a basis for targeting services and evaluating outcomes from a patient-centered perspective as well as from a system perspective.

SESSION 2335 (SYMPOSIUM)

IMPACT OF ORGANIZATION OF NURSING HOME MEDICAL STAFF ON RESIDENTS’ HOSPITALIZATIONS

Chair: O. Intrator, Center for Gerontology and Health Care Research, Brown University, Providence, Rhode Island, Providence VAMC, Providence, Rhode Island
Co-Chair: T. Wette, Center for Gerontology and Health Care Research, Brown University, Providence, Rhode Island
Discussant: A. Bonner, Centers for Medicare and Medicaid Services (CMS), Baltimore, Maryland

As the severity of illness in nursing home (NH) residents continues to increase, the physician’s (MD) role in their care grows in importance. Yet little is known about how NHs structure or organize the work of medical staff—physicians, nurse practitioners, and physician assistants—-are often limited by NH characteristics of administrative control. Limits in medical staff involvement may affect their knowledge of residents, their oversight of residents’ changing conditions and care transitions such as hospitalizations. Practices of nursing home (NH) medical staff—physicians, nurse practitioners and physician assistants—are often limited by NH characteristics of administrative control. Limits in medical staff involvement may affect their knowledge of residents, their oversight of residents’ changing conditions and care transitions such as hospitalizations.

HOW DO WE THINK ABOUT PHYSICIANS IN NURSING HOMES? DEVELOPING MEASURES OF MEDICAL STAFF ORGANIZATION

R. Shield1, M. Rosenthal2, D. Tyler1, T. Wette1, M. Clark1, O. Intrator1, 1. Brown University, Providence, Rhode Island, 2. Rutgers University, New Brunswick, New Jersey

Practices of nursing home (NH) medical staff—physicians, nurse practitioners and physician assistants—are often limited by NH characteristics of administrative control. Limits in medical staff involvement may affect their knowledge of residents, their oversight of residents’ changing conditions and care transitions such as hospitalizations. Practices of nursing home (NH) medical staff—physicians, nurse practitioners and physician assistants—are often limited by NH characteristics of administrative control. Limits in medical staff involvement may affect their knowledge of residents, their oversight of residents’ changing conditions and care transitions such as hospitalizations.

IS NURSING HOME MEDICAL STAFF ORGANIZATION ASSOCIATED WITH REHOSPITALIZATIONS AMONG RESIDENTS?

Little is known about NH medical staff organization (MSO) and its relationship to quality of care (e.g., rehospitalizations). We merged primary data describing MSO collected from NH medical directors to resident assessment data (MDS), Medicare claims, and the OnLine Survey Certification and Reporting (OSCAR) database to examine the association between MSO and thirty-day rehospitalizations among NH residents. Having a more formal appointment process for physicians was associated with fewer rehospitalizations. A higher proportion of residents seen by a single physician was associated with more rehospitalizations. A higher proportion of residents seen by a single physician was associated with more rehospitalizations. A higher proportion of residents seen by a single physician was associated with more rehospitalizations.

614 The Gerontological Society of America
MEDICAL STAFF ORGANIZATION AND RE-HOSPITALIZATIONS: HOSPITAL-BASED VERSUS FREE-STANDING NURSING HOMES

O. Intrator, E. Minca, J.C. Lima, T. Wette, Center for Gerontology and Health Care Research, Brown University; Providence, Rhode Island

Longitudinal multivariate analyses of rehospitalizations from nursing homes (NHs) using data from www.ltcfocus.org showed that hospital based (HB) NHs were less likely to rehospitalize residents than free-standing (FS) NHs ($b=0.69\%$, $p=0.036$). This may reflect differences between HB and FS NHs’ medical staff organization (MSO) and the degree to which medical staff meet the needs of staff (MD MIA). Using primary data collected from NH administrators and Directors of Nursing (DON), we examined differences in MSO and MD MIA between HB and FS NHs. HB and FS NHs differed significantly on many factors including; how and whether medical directors are paid for their administrative duties, credentialing processes, and physician involvement. Medical directors of HB NHs, for example, were more likely salaried than their FS counterparts. Compared to those in FS NHs, physicians in HB NHs were more likely to attend care plan meetings, talk to pharmacy consultants, and communicate with families.

SESSION 2340 (SYMPOSIUM)

LONG TERM CARE QUALITY INITIATIVES: MEASUREMENT AND EVALUATION

Chair: A. Muma, Abt Associates Inc., Durham, North Carolina
Co-Chair: A.J. White, Abt Associates Inc., Durham, North Carolina
Discussant: N. Castle, University of Pittsburgh, Pittsburgh, Pennsylvania

The Centers for Medicare & Medicaid Services (CMS) oversees the quality of care in our nation’s nursing homes and other long term care settings. This session will provide background on some current CMS initiatives in evaluating long term care quality. These initiatives cover a broad range of topics including: The Nursing Home Compare 5-Star Rating System, The Quality Indicator Survey (QIS), defining the relationship between staffing and quality, and measuring rehospitalizations and nursing home stays resulting in a hospitalization within the Medicare Population.

MEASURING REHOSPITALIZATIONS AND NURSING HOME STAYS RESULTING IN A HOSPITALIZATION IN THE MEDICARE POPULATION

M.R. Plotzke, A.J. White, C. Williams, Domestic Health Division, Abt Associates, Inc., Cambridge, Massachusetts

Reducing hospitalizations is one method of improving quality and minimizing costs. Certain hospitalizations may be avoidable through careful management of specific patient types and discharge planning. This is one of the only studies that calculates provider level trends for nursing homes. Also, identifying providers with high rates of hospitalization may be of interest to agencies that regulate these providers.

NURSING HOME COMPARE FIVE-STAR QUALITY RATING SYSTEM: THE SECOND YEAR

In December 2008, the Centers for Medicare & Medicaid Services enhanced its Nursing Home Compare website to include “star” ratings for each US nursing home, measuring multiple dimensions of quality including performance on selected quality measures, outcomes of health inspections, and staffing levels. The five-star rating system has been in place for two years. After the first year of the rating system, we examined stability and longitudinal changes in the underlying components of the ratings. After the second year of ratings, we again examined rating stability and longitudinal changes among US nursing homes, and compared the results to Year 1 findings, noting significant changes from Year 1 to Year 2. We also noted new and different trends from the second year of the rating system. Finally, we used qualitative information from the five-star Helpline to aid in understanding the quantitative trend data from the second year of the rating system.

THE QUALITY INDICATOR SURVEY FROM 2008-2010 – HOW DO FINDINGS COMPARE TO TRADITIONAL NURSING HOME SURVEYS?

A.J. White, C. Williams, Health Policy, Abt Associates, Durham, North Carolina

CMS designed the Quality Indicator Survey (QIS) with several goals in mind, including improving survey consistency and accuracy by using a more structured process and focusing survey resources on areas within facilities with greater quality concerns. The QIS has been implemented to varying extents in fifteen states. We used survey results (cited deficiencies) from QIS and traditional surveys to examine how survey findings differ between the two processes. Analyses focused on paired analyses for providers that have had both types of surveys and examining trends for facilities with multiple QIS surveys. There is no overall trend towards more or fewer deficiencies being cited by the two types of surveys, but substantial state-to-state variation is observed. For example, in Florida, QIS surveys tend to find fewer deficiencies, while in Kansas, QIS surveys cite more deficiencies. It is clear that these trends are evolving as states gain more experience with the QIS.

RELATIONSHIP BETWEEN NURSE STAFFING LEVELS AND THE QUALITY OF NURSING HOME CARE

A.J. White, C. Williams, M.R. Plotzke, Health Policy, Abt Associates, Durham, North Carolina

The scoring rules for the staffing domain in the 5-star rating system use thresholds identified in the 2001 CMS Staffing Study. We analyzed the relationship between staffing and measures of nursing home quality to assess whether these thresholds still apply. Analyses were conducted at the facility level, using staffing data from OSCAR and quality measures based on health inspection surveys, survey quality measures from the MDS, and potentially avoidable hospitalizations, using methods and models similar to those used in the 2001 staffing study. Analyses focused on identifying specific staffing levels below which quality is lower and above which additional staffing increases are not associated with additional quality improvements. Multivariate models were used to control for facility case-mix. The identified thresholds could be used as the criteria for achieving a 5-star rating for staffing and are also relevant for the question of whether minimum staffing standards should be required in nursing homes.

64th Annual Scientific Meeting
SESSION 2345 (PAPER)

COGNITIVE ASSESSMENTS AND TRAINING EFFECTS

WHAT DOES SELF-REPORTED COGNITION REALLY MEASURE, AND DOES ITS MEANING VARY BY AGE?
M.L. O’Connor, T. Salthouse, Psychology, University of Virginia, Charlottesville, Virginia

Prior research has suggested that among older adults, self-reports of cognitive abilities may exhibit stronger relationships with psychological characteristics than objective cognitive performance (Salthouse, 2010). The present study examined predictors of self-reported cognition at different ages. Data were from 3,782 participants in the Virginia Cognitive Aging Project (age range=18-97 years; median age=52). Our measure of self-reported cognition was based on items from the Memory Functioning Questionnaire and the Views on Thinking and Reasoning Questionnaire that exhibited invariant factor loadings across two participant age groups split by median age. These items were interpreted as representing three factors: general memory functioning, seriousness of memory failures, and perceived changes in cognition. Structural equation models revealed that each factor was positively associated with the Big Five personality dimensions and memory test performance; each factor was negatively associated with depressive symptoms, anxiety, and negative affect. The change factor was negatively associated with age, and the general factor was positively associated with performance on tests of processing speed, reasoning, vocabulary, and spatial cognition (p<0.05 for all). After controlling for mood and personality, all measures of objective cognition except reasoning remained significant predictors of the self-report factors. Associations between predictors and factors were similar in magnitude across individuals older and younger than the median age, as Cohen’s d values were ±0.1 for differences between predictor regression coefficients. These results suggest that self-reported cognition demonstrates convergent validity with objective cognitive performance, and has a similar meaning, among adults of different ages.

THE BCAT: A NEW COGNITIVE TEST EMPHASIZING CONTEXTUAL MEMORY AND EXECUTIVE FUNCTIONS
W. Mansbach1, E.E. MacDougall2, A. Rosenzweig4, 1. MedOptions, Towson, Maryland, 2. Loyola University Maryland, Baltimore, Maryland, 3. Brown University, Providence, Rhode Island

Geriatric health care professionals generally agree that early identification of dementia is critical. However, most screening measures are relatively weak in assessing verbal memory and executive functions, two defining characteristics of this syndrome and predictors of functional decline. We contend that the ideal cognitive screening tool: (1) can be administered by both paraprofessionals and clinicians; (2) can be completed in approximately 15 minutes; (3) can differentiate among MCI, mild dementia, and moderate dementia; (4) contains strong verbal recall components; (5) has a complex executive function component, and (6) correlates with IADL performance. The primary objective of this study was to develop and validate a new cognitive screening test that meets these standards. The Brief Cognitive Assessment Tool (BCAT) is a multi-domain cognitive measure emphasizing verbal memory and executive functions. 103 participants referred for neuropsychological evaluation were recruited from assisted-living facilities (32% with mild cognitive impairment (MCI); 37% with mild dementia; 31% with moderate dementia). The psychometric quality of the BCAT was confirmed with strong evidence for reliability, construct validity, and predictive validity. A cut-score was set to maximize sensitivity (.99), with corresponding specificity (.79), positive predictive value (.90) and negative predictive value (.96). The accuracy of the BCAT total score, as measured by the area under the ROC curve (AUC = .951), was excellent. Executive control items and contextual memory items (i.e., orientation and story memory) were the best predictors of diagnostic category. The strengths and weaknesses of the BCAT in comparison to existing cognitive screening tools are discussed.

616 The Gerontological Society of America

THE EFFECT OF DEPRESSION ON MEMORY AND MEMORY TRAINING INTERVENTION IN OLDER ADULTS: RESULTS FROM THE ADVANCED COGNITIVE TRAINING FOR INDEPENDENT AND VITAL ELDERLY (ACTIVE) STUDY
M. Lohman1, G. Rebok2, A.P. Spira1, J.M. Parisi3, A.L. Gross2, A.M. Kueider2, 1. Virginia Commonwealth University, Richmond, Virginia, 2. Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland

Background: Cognitive training improves cognitive abilities among older adults and has the potential to delay age-related cognitive decline; however, the differential effects of training programs on older adults with and without depressive symptoms has not been examined. Methods: We evaluated the effect of depressive symptomology on verbal episodic memory scores in older (age>65) adults trained in mnemonic strategies as a subset of the ACTIVE study. In the memory-trained group, 146 of 703 participants and in the control group, 164 of 698 participants had elevated depressive symptoms at baseline, as measured by a total score of 9 or higher on a 12-item version the Center for Epidemiological Studies-Depression Scale (CES-D). Longitudinal analysis of memory scores over baseline and five follow-up measurements compared average memory trajectories in the two training conditions. Results: Participants with elevated depressive symptoms scored significantly lower than less depressed participants at baseline on both recall and recognition tasks, and their scores declined faster than those of less depressed participants. Memory score differences among depressive symptom categories did not differ between training conditions. Discussion: Results of the present study suggest depression is associated with lower baseline memory ability in elderly adults. Data also suggest elevated depressive symptoms may predict declining memory ability over time, but
DOES MEMORY TRAINING WORK? A SYSTEMATIC REVIEW AND META-ANALYSIS

1 Hebrew SeniorLife, Harvard Medical School, Boston, Massachusetts; 2 Johns Hopkins University, Baltimore, Maryland; 3 University of Massachusetts Medical School, Worcester, Massachusetts

Maintaining memory and preventing memory decline are important to the preservation of daily functioning and well-being among older adults. A systematic review and meta-analysis of memory training research was conducted to characterize the effect of memory training strategies on memory performance, and to identify characteristics of programs and of individuals associated with improved memory among cognitively intact, community-dwelling older adults. An initial review of memory training studies identified 402 publications between 1967 and 2010. Of these, 35 studies with a treated and control group met criteria for inclusion. These studies provided information about 10 distinct memory strategies (association, categorization, visual imagery, rehearsal, concentration, method of loci, face-name recognition, number mnemonics, story mnemonics, external memory aids). The overall effect size estimate, representing the mean standardized difference in pre-post change between memory-trained and control groups, was 0.31 standard deviations (SD; 95% confidence interval (CI): 0.22, 0.39). The pre-post training effect was 0.43 SD (95% CI: 0.29, 0.57) and the practice, or retest, effect for control groups was 0.06 SD (95% CI: -0.05, 0.16). Meta-analytic methods revealed that training in categorization, rehearsal, and external memory aids improved memory in older adults. The overall number of strategies taught during training also was associated with larger training gains. Treatment gains among memory-trained individuals were not affected by the average age of participants, session length, or type of control condition (active or no-contact). These findings can be used to inform the design of future memory training programs for older adults.

SESSION 2350 (PAPER)

ENVIRONMENTAL AND PERSONAL FACTORS FOR PHYSICAL HEALTH OUTCOMES IN OLD AGE

REGION OF ORIGIN AND MEXICAN AMERICAN CVD RISK ALONG TEXAS MEXICO BORDER

J.J. Salinas 2, B. Abdelbary 1, A.R. Rentfro 1, S.P. Fisher-Hoch 1, J.B. McCormick 1, 1 Epidemiology and Disease Control, UT School of Public Health, Brownsville, Texas; 2 University of Texas at Brownsville, Brownsville, Texas

Objective: To determine whether place of origin has an effect on Mexican American CVD risk on the south Texas border. While many studies have investigated the effect of immigration on Mexican American health, few have considered how region of origin may impact CVD risk. Methods: The Cameron County Hispanic Cohort (CCHC) study is a cohort of community-residing Mexican origin adults 18 years or older. Subjects were divided into 3 groups according to place of origin; Non-border Mexico, Border Mexico, Border US. Descriptive statistics were conducted adjusting for age and sex. Logistic regression was conducted for select CVD biomarkers and self-reported diabetes, disability and elevated blood pressure and adjusting for age, sex, income, and education level. Results: Logistic regression revealed that subjects born in US Border States and Mexico Border States were significantly less likely to have high cholesterol and high triglycerides (P < .05) than those born in Non-border Mexico. Subjects born in Mexico Border states were less likely to be diabetic (p < .05) and to report disability (p < .1). After adjusting for number of years in the US, outcomes for Border Mexico were similar to the first model. However those born in the US Border were less likely to be diabetic (p < .001), report disability (p < .01) or high cholesterol (p < .01) than those born in Non-border Mexico. Discussion: This study illustrates the importance of considering region of origin in studying the effect of immigration on Mexican American health beyond the standard: number of years in the US.

NEIGHBORHOOD EFFECTS ON 10-YEAR CARDIOVASCULAR DISEASE RISK AMONG OLDER ADULTS ATTENDING SENIOR CENTERS IN NEW YORK

H. Shen, W. Gallo, M.C. Fh, Hunter College, School of Public Health, New York, New York

Cardiovascular disease (CVD) is the leading cause of death in America, claiming more lives each year than the four causes of death combined. Neighborhood attributes (e.g. presence of recreation services) play an important role in shaping people’s health behaviors (e.g. physical activity), which are important risk factors for CVD. Little is known, however, about the relationship between neighborhood environment and CVD risk among urban older populations. Using data from the 2008 Health Indicators Project (HIP), a survey of 1870 senior center participants in New York City (NYC), we applied Finite Mixture Model methodology to elucidate factors that mediated the relationships between the presence of recreation services and 10-year CVD risk. The 10-year CVD risk was calculated from the Framingham Heart Study sex-specific simple office-based non-laboratory algorithms. Mediators of primary interest were affordability, accessibility, perceived age acceptability, and participation in recreation services. Health status, limitations of activities of daily livings, depression scores, living in public housing, NYC boroughs, gender, marital status, race and education were controlled in the final model. Findings from a 2-component model suggested that the presence of recreation services was associated with 1.8 times increased risk in 10-year CVD risk among members of a latent class that was predominantly characterized by utilization of recreation services. We conclude that existence of recreation services plays an important role of reducing CVD risk only when older people use such services. Implications of policies and ways to intervention will be discussed.

CHRONIC ILLNESS AND FUNCTIONAL ROLE IMPAIRMENT IN OLDER ADULTS: EXAMINING RACIAL/ETHNIC DIFFERENCES

Background/Significance: Risk of chronic illness increases with age. The public health implications of chronic illness in the aged are substantial. This study was undertaken to better understand differences in role impairment among racially and ethnically diverse older adults with chronic illness. Methods: Secondary data analysis of the Collaborative Psychiatric Epidemiology Surveys (CPES), a compilation of three nationally representative surveys. Hierarchical multiple regression analysis looked at the impact of cardiovascular disease, arthritis, cancer, and diabetes on role impairment and loss of time in role (as measured by the WHODAS) and how this varied with age, sex, race, ethnicity, income, and education. Results: Sample (N = 2626) was diverse (54.4% non Hispanic White, 22% African American, 11.4% Hispanic, 6.6% Asian, and 5.4% Black Caribbean) and 57.6% female. Multivariate analysis showed that cardiovascular disease, arthritis, and diabetes predict time out of role and role impairment. Cancer was not associated with either role impairment or time out of role. When demographic variables are entered into the model, time out of role for cardiovascular
INDIVIDUAL AND ENVIRONMENTAL BARRIERS TO EYE CARE IN AN URBAN NEIGHBORHOOD

Vision represents a health priority that needs to be addressed safely live independently. It has been estimated that 61 million individuals are at serious risk for vision loss due to a problem, diabetes, and older age. Further, Latino and African American seniors are at higher risk of developing vision impairment from diabetic retinopathy and glaucoma. Disparities in access to quality health care remain pervasive, particularly in the area of eye care. Within New York City, the neighborhood of East Harlem represents an area with the highest rates of diabetes morbidity and mortality. Among its residents, little is known about eye care utilization. In partnering with the Communities IMPACT Diabetes Center, an environmental assessment revealed that within a two census track area of East Harlem, there were no eye care facilities; multiple environmental hazards were also present, such as sidewalks that were in disrepair or obstructed. 609 seniors screened, two-thirds needed primary or low vision eye care. Through a survey of these seniors, we identified individual barriers to care, including financial or insurance issues (28%), lack of motivation or education about needing an exam (10%), difficulty finding a doctor that they liked (21%), language barriers (32%), and transportation issues (27%). Given the large number of individuals in need of eye care within East Harlem, the presence of multiple environmental and individual risk factors may preclude an individual from presenting for an eye exam. This may lead to or exacerbate social isolation, falls, health problems, anxiety, and depression.

EFFECTS OF NEIGHBORHOOD ENVIRONMENT ON CARDIOVASCULAR DISEASE RISK: EVIDENCE FROM OLDER ADULTS ATTENDING SENIOR CENTERS IN NEW YORK

H. Shen, W. Gallo, M.C. Fahs, Hunter College, School of Public Health, New York, New York

Recent research has identified the neighborhood’s physical and social environment be relevant to improving health and preventing disease. Cardiovascular disease (CVD) is the leading cause of death in America, however, little is known about the relationship between neighborhood environment and CVD risks among urban older populations. We used data from the 2008 Health Indicators Project (HIP), a survey of 1870 participants (age 60+) of New York City (NYC) senior centers, to examine the cross-sectional association between perceptions of neighborhood social environment (social cohesion and social safety), physical environment (walkability) and 10-year CVD risk. Ten-year CVD risk was calculated from the Framingham Heart Study sex-specific simple office-based non-laboratory algorithms. Neighborhood measures were scale variables that were constructed by summing responses to individual Likert-scaled items. Control variables included health status, limitations of activities of daily living (ADLs), depressive symptoms, living in public housing, NYC boroughs, gender, marital status, race and education. Results from Ordinary Least Squares regression models suggested that 10-year CVD risk reduced by 0.78% for a 1-standard deviation increase in social cohesion; a 1-standard deviation increase in walkability increased the 10-year CVD risk by 0.70%. No effect on CVD risk was found for perceived neighborhood safety. We conclude that perceptions of neighborhood environment may influence urban older adults’ CVD risk. Policy implication and suggestions to future research will be discussed.

SESSION 2355 (PAPER)

HEALTH CARE ASSESSMENT AND PRACTICE

TRANSLATION OF RESEARCH EVIDENCE TO NURSING HOME CARE PRACTICES: RESEARCH FINDINGS

Although ample research evidence exists for the successful treatment of pain and urinary incontinence (UI) in nursing home (NH) residents, evidence-based practice (EBP) interventions are rarely used on a routine basis. A conceptual model that combined the theories of adoption and diffusion and staff empowerment provided the theoretical framework and explicated the proposed relationship between the interventions, organizational processes and structures, individual characteristics, and nursing home and resident outcomes. The innovative MTRAIN intervention addressed the lack of knowledge about EBP by providing education for staff teams, leadership training for RNs, and the use of an “insider” nurse consultant to facilitate practice change. Identified NH and staff barriers to change were also addressed in the study design. A cluster randomized trial with repeated measures was employed in 48 (25 intervention and 23 control) Iowa nursing homes to test the effect and sustainability of an intervention to implement EBPs on resident and NH outcomes. Two measures of EBP adoption were used to rate the adoption of EBPs in each NH. An investigator-developed, criterion-based instrument used data obtained from direct observations of staff; extraction from study facility and resident records; and interviews with staff, residents, and families. Another measure of EBP adoption assessed staff perception of use of evidence before, during and after introduction of EBP into the system. The processes and extent of EBP adoption, the effect on NH quality measures and resident outcomes, and the relationship of facility characteristics to high and low adoption of EBPs will be discussed.

OPTIMIZING DISCHARGE PLANNING WITH EVIDENCE BASED TOOLS

Our previously funded studies resulted in two evidence based discharge planning (DP) decision support tools - the Early Screen for Discharge Planning (ESDP) and the Discharge Decision Support System (D2S2). The ESDP engages discharge planners early in the hospital stay, allowing more time to identify and plan how to meet continuing care needs. The D2S2 guides decision making regarding the need for post acute care. The purpose of this study was to examine the relationship of the tools’ scores and the rates of referrals to post acute services and reported problems and unmet needs after discharge. The tools were administered within 24 hours of admission for 292 medical patients 55 years or older. Patients receiving dialysis or living in a skilled nursing or rehabilitation facility were excluded. Patients were interviewed one week after discharge using the Problems After Discharge Questionnaire. Referrals to post acute care were collected from the hospital administrative database. High ESDP and D2S2 scores were associated with referrals to post acute services (ESDP and D2S2 p<.0001) and more problems after discharge (ESDP p=.0021; D2S2 p<.0001). The D2S2 did a better job at differentiating patients with unmet needs after discharge (p=.0057) than the ESDP (p=.0567). Although hospital DP is a

The Gerontological Society of America
frequently occurring and expensive care process done annually for more than 13 million Medicare beneficiaries, there are no nationally recognized, empirically derived decision support tools to assist in making these important decisions. The ESDP and D2S2 show promise in optimizing DP decision making by identifying at risk patients.

CARE: THE ROLE OF HEALTH CARE SOCIAL WORKERS

BARRIERS AND FACILITATORS TO HEART FAILURE CARE: THE ROLE OF HEALTH CARE SOCIAL WORKERS

Social workers have important and unique competencies that are critical for addressing the needs of older adults with heart failure. However, few existing studies have examined the role of health care social workers in providing services for the growing number of older adults with this condition. The purpose of this study was to obtain an in-depth understanding of the experiences of social workers providing heart failure care. This study is based on data collected from surveys and interviews with eight social workers from the Detroit Metropolitan area who reported working with heart failure patients. The mean age for social workers was 48.57 years of age (SD= 12.92) with a range between 29 and 64 years. Seven participants noted that they were Caucasian American and one participant identified as African American. Respondents had an average of 12.14 years working with heart failure patients (SD= 10.12), with a range of three to 32 years. Thematic analysis of the qualitative interview data revealed several key themes, including 1) the role of the social workers within the health care team 2) the need for awareness of heart failure by heart failure patients, family members, and social workers; and 3) limitations on access to both formal and information care services. Results of this study provide a basis for furthering the development of competencies and suggests the need for ongoing research that outlines the specific roles and responsibilities of health care social workers as providers of care to older adults with heart failure.

SESSION 2360 (PAPER)

HEALTH CARE DELIVERY: EMERGING ISSUES, INNOVATIONS, AND PROGRAM EVALUATION

PRIMARY CARE PROVIDERS’ PERSPECTIVES ON COUNSELING FOR PREVENTION WITH COMPLEX PATIENTS

As medicine advances, individuals are living longer with chronic conditions; the majority of older adults have multiple health conditions. Providing medical care for older adults with multiple health conditions presents a number of challenges, including balancing health promotion and disease prevention efforts with multiple morbidity management. Primary care physicians play a pivotal role in the management and prevention of health conditions. We conducted in-depth semi-structured interviews with 12 primary care physicians about how they care for their complex patients, with a particular emphasis on prevention. Thematic analysis of tape-recorded sessions suggests that existing conditions can serve as either competing content that makes prevention discussions more challenging to fit in, or can serve as triggers for the relevance or value of prevention. Physicians discussed strategies for motivating their patients to engage in preventive health behaviors, including education, personalizing risks and benefits, and developing relationships of trust. Indicating that the existing healthcare system creates challenges for efforts to promote preventive health among complex patients, physicians recommended the development of alternate care delivery and reimbursement models to meet the needs of complex patients. The role of socioeconomic and environmental resources in preventive health behaviors was also recognized. Implications for maximizing the health and quality of life of older adults with multiple health conditions are explored.

EXPLORING THE ADDED BURDEN OF PTSD ON HEALTH AND WELL-BEING IN OLDER ADULTS WITH CHRONIC CONDITIONS

Although posttraumatic stress disorder (PTSD) is a highly prevalent and often chronic condition found in both military and civilian populations, the impact of PTSD on physical activity (PA) and indices of functional and psychological well-being, particularly among individuals with concomitant physical comorbidities, remains unclear. Methods: Analyses were conducted in a random sub-sample of older adults with impaired glucose tolerance participating in an ongoing PA counseling trial. 25 study participants with a PTSD diagnosis (M age=66 years) and 25 participants with no PTSD diagnosis (M age=71 years) were identified at baseline. Self-report PA, health-related quality of life, and functional performance were assessed. Results: Participants with PTSD reported dramatically lower scores (indicative of worse functioning) across all subscales of the SF-36 (between-group difference ranges=6.6-57.4). The greatest between-group differences were observed on those subscales that assessed the impact of both physical and mental health problems on interpersonal functioning and daily activities. Participants with PTSD also reported far fewer minutes of moderate-intensity PA (M=64.0 minutes/week) than participants without PTSD (M=169.1 minutes/week). Although participants with PTSD were younger, the two groups had comparable scores on tests of physical performance: usual gait speeds (1.05 v. 1.13 m/sec), rapid gait speeds (1.70 v. 1.66 m/sec), and scores on the short physical performance battery (10.3 v. 10.3). Conclusions: The differences observed here are highly clinically meaningful and highlight the importance of intervening in this at-risk group.
Influence of Adherence to a Systematic Care Program for Caregivers of Dementia Patients

Objective: To evaluate the influence of adherence to the intervention protocol for patient and caregiver outcomes on the Systematic Care Program for Dementia (SCPd) study. Design: Data were drawn from the SCPd study - a single-blind, multicentre, cluster-randomized, controlled trial. We used multivariate regression analyses to assess the influence of adherence. Setting: Six community mental health services (CMHs) across the Netherlands. Participants: Forty-eight mental health professionals treating 125 patient-caregiver dyads who were referred to the CMH because of suspected patient dementia. Intervention: Training of professionals in the SCPd and its subsequent use. The SCPd consists of a systematic assessment of caregiver problems and consequent interventions. The intensity of the interventions is left to the discretion of the professionals. Measurements: The dependent variables were the sense of competence, caregiver’s depressive symptoms, caregiver’s distress due to patient’s problem behavior and its severity. The main independent variables were adherence to the SCPd intervention protocol and the intensity of the SCPd interventions. The follow-up lasted 12 months. Results: Caregivers treated by professionals who adhered to the SCPd intervention protocol had a better sense of competence than caregivers treated by nonadherent professionals at follow-up. The program was not intense enough, even for dyads treated by professionals who adhered to the intervention protocol. Conclusions: Future controlled trials of daily clinical practice should not overlook the influence of adherence to the intervention protocol on outcomes. Furthermore, the intensity of a program is crucial and should not be left to the discretion of health professionals.

An Evidence-Based Adoption of Technology Model for Remote Monitoring of Elders’ Daily Activities

D.F. Mahoney, School of Nursing, MGH Institute of Health Professions, Boston, Massachusetts.

The purpose of this study was to develop a model to inform technology outcome studies. Gerontechnology research has focused on technical operations using laboratory based studies. Research critics highlight the need to advance theoretical development. Needed are studies conducted with a variety of real endusers that apply theoretical models to increase understanding about the multiple influences on older adults’ and their caregivers’ technology adoption. A secondary data analysis was conducted on four gerontechnology field intervention studies. Each study offered innovative telephone and/or Internet based wireless remote monitoring technologies to community dwelling older adults and their informal and/or formal caregivers. Original de-identified qualitative transcripts and statistically significant quantitative outcomes were reanalyzed in a metasynthesis approach. Factors affecting the acceptance and use of the monitoring technologies by older adults and their caregivers were the focus of this analysis. Model components came from the complex interplay of family-resident-staff dynamics found in real world residential settings that arose as significant factors in two or more of the contributing studies. Findings resulted in the development of an evidence based theoretical model for remote monitoring of elders’ daily activities. The model portrays pre-disposing and mediating variables that lead to a key nexus point and results in adoption or non-adoption with related proximal and distal outcomes. Empirical testing of the model’s predictive capacity is now recommended. As monitoring technologies increase, providers as well as technology developers can benefit from greater understanding of the factors influencing technology adoption and usage by older adults and their caregivers.

Session 2365 (Paper)

Health, Longevity and Well-Being: The Influence of Religion, Emotions, and Psychosocial Factors

Dimensions of Religiousness as Predictors of Well-Being in Congestive Heart Failure Patients

Religiousness has generally been shown to be both important to many people living with congestive heart failure (CHF), and related to better psychological well-being and quality of life. However, although the broader literature has identified multiple distinct aspects of religiousness that may have very different relations with well-being, few studies have examined links between these multiple dimensions and well-being in CHF patients. We assessed multiple dimensions of religion with the BMMR/S and, three months later, physical, mental, and existential well-being in 101 patients with severe CHF (61% men, Mage 69.7, Mlength/dx = 6.5 years). Results revealed different patterns for different aspects of well-being. For example, no aspects of religiousness predicted physical well-being, but religious identity and forgiveness were inversely related to mental health (depressive symptoms), and religious identity, religious social support and daily spiritual experiences predicted subsequent existential well-being (life satisfaction). These findings suggest promising clinical implications and research directions.

Sects and the City: Aging in Place, Place in Aging, and Religious Engagement of Older Urban Adults

J. Garoon, H.N. Gitlin, S.L. Santon, Johns Hopkins School of Public Health, Baltimore, Maryland.

Research on how lower-income urban adults age in place highlights religious engagement as a key determinant of their health and quality of life. Religious belief is typically described as working through two psychosocial pathways: (1) it has direct positive effects on older people’s mental health and well-being; (2) it leads to greater participation in social activities – e.g., through church programs – which in turn, leads to increased social capital and social inclusion, and thus to better mental and physical status. Drawing on extensive qualitative research with 12 Protestant, Catholic, and Jewish low-income older adults aging in place in Baltimore City, this paper argues that these two pathways overlook a critical mediator: how place itself affects religious engagement. Analysis of more than 50 in-depth interviews, as well as direct observations of neighborhood environments and field notes, revealed that participants’ residential contexts – including patterns of racial and economic segregation, prevalent modes of transportation, and building plans – played major roles in their decisions about whether and how to participate in religious activities, and influenced the benefits of such participation. Challenging built environments, for example, made it difficult for participants to reach the location of religious activities – and, just as importantly, often made more mobile participants reluctant to continuing attending their accustomed places of worship. Similarly, neighborhood and congregation demographics hindered participants’ abilities to form and maintain social networks, and limited their social...
LIFE SATISFACTION IN OLDER AGE: THE ASSOCIATION OF RACE AND SPIRITUALITY
K.A. Skarupski, G. Fitchett, D.A. Evans, C. Mendes De Leon, 1. Rush Institute for Healthy Aging, Rush University Medical Center, Chicago, Illinois. 2. The University of Michigan, Ann Arbor, Michigan

Purpose: Social gerontologists have examined a range of factors associated with life satisfaction. Among them is religiosity, which has been shown to be associated with life satisfaction among older African Americans. However, there has been very little examination of race differences in the factors associated with life satisfaction in older age. Design & Methods: The participants were 6,864 community-dwelling persons aged 65+ (66% Black) who participated in the Chicago Health and Aging Project. Life satisfaction was measured using a 5 question composite (range = 1-4) and we used a 5-item version of the Daily Spiritual Experiences scale. Results: Blacks reported slightly lower average life satisfaction scores compared with Whites (2.8 [SD=.5] vs. 2.9 [SD=.5]). In a core model adjusting for age, sex, marital status, education, and income, we found that Black race was associated with lower life satisfaction (estimate = -.07, SE = .02; p-<.001). When we added spirituality (estimate = 0.10, SE = .01) to the core model, the estimate for race increased (estimate = -.10). In an additional model, there was a significant race x spirituality interaction term (estimate = .04, SE = .01, p-value < .01), indicating that spirituality is more positively associated with life satisfaction among Blacks. Based on this model, racial differences in life satisfaction are reduced at higher levels of spirituality. Implications: Although older Blacks report lower life satisfaction than their White counterparts, the data suggest that spirituality enables older Blacks to overcome a substantial part of the disadvantage in life satisfaction.

ASSOCIATIONS OF SUBJECTIVE WELL-BEING AND HEALTH OVER TIME: LIFE SATISFACTION AND POSITIVE EMOTIONS PRESERVE PHYSICAL FUNCTIONING AND SELF-RADED HEALTH
M. Wiest, B. Schüz, O. Huxhold, German Centre of Gerontology, Berlin, Germany

This study investigates the effect of well-being on changes in individual health. Benefits of well-being on health outcomes are well-documented, but underlying mechanisms are poorly understood. Therefore, this study aims at exploring how differences in baseline levels and changes in well-being affect changes in health. Furthermore, this study examines potential differential relations of different facets of well-being (life satisfaction, positive affect, negative affect) and health aspects (physical health, functional health, subjective health). Longitudinal data of community-dwelling participants aged 65 years and older from the German Aging Survey were used (N = 2031). A latent change score model was employed to analyze effects of levels and changes in well-being on changes in health adjusting for age, gender and education. Level and change in life satisfaction (LS) and positive affect (PA) predicted changes in functional health and self-rated health. Higher LS and PA at baseline and less change over time in LS and PA were associated with less declines in functional health and self-rated health. Level and change in negative affect (NA) predicted change in physical health. High NA at baseline and increase in NA over time were related to stronger decline in physical health. NA was not related to functional health or self-rated health. This study underlines that different facets of well-being and health are associated differentially. In order to understand the beneficial effects of well-being on health, a focus on unique mechanisms linking facets of well-being to special health aspects is indispensable.

PSYCHOSOCIAL FACTORS ASSOCIATED WITH LONGEVITY IN THE UNITED STATES: AGE DIFFERENCES BETWEEN THE OLD AND OLDEST-OLD IN THE HEALTH AND RETIREMENT STUDY
J.A. Allshire, E. Crimmins, Andrus Gerontology Center, USC-Earth Sciences, Los Angeles, California

Recent growth in the number of very old adults raises questions about the quality of life associated with increased longevity. Psychosocial factors have received relatively little attention in research on quality of life among the oldest-old. This study uses nationally representative data on older U.S. adults to examine how social relationships, feelings of loneliness, and satisfaction with life and the aging experience differs for the oldest-old, those who have survived to age 90 or older, and older adults in their 70s. We find that the oldest-old are able to maintain social relationships with family and friends and receive more social support than younger elderly adults. Yet the oldest-old are more likely to feel lonely. Satisfaction with life was similar for both age groups, but the oldest-old had more negative perceptions of the aging experience. Psychosocial dimensions of longevity should be considered in research on quality of life among the oldest-old.

SESSION 2370 (PAPER)

PATTERNS AND EXPERIENCES OF FAMILY CAREGIVING
CARINGSCAPES, CARING ROUTES AND THE CARE CONTEXT OF COUPLES GROWING OLD TOGETHER WITH DISABILITIES
C. Törge, National Institute for the Study of Ageing and Later Life, Linköping University, Norrköping, Sweden

This article presents findings from a qualitative interview study of older couples aging with disabilities (55 years and over) that aims to explore mutual care and the care context in an intimate relationship where both partners have had disabilities since youth or middle age. Nine couples with different kinds and levels of physical disabilities were interviewed. The study uses a life course approach and considers the effects of both individuals’ impairments and changing functional abilities over time, as well as the significance of disability reforms, formal care and technical aids in shaping the older disabled couple’s care context. Not all of couples needed extensive help in their daily routines; rather they helped each other as much as they could to live independently. But for those couples who received formal help in the form of escorts or personal assistance, this assistance was indispensable for the possibility of living and aging together as a couple with disabilities. Inspired by the theory of Caringscapes, the author discusses how partners’ care contexts change over time with partners’ changing functional abilities, health status, and availability of other sources of help. Care is defined both as specific activities – how the disabled partners help each other in everyday activities – and as part of a process of assessing, planning and anticipating help, especially when one’s own possibility for helping is / becomes limited. Many of the interviewed couples, already having lived with disabilities for a long time, anticipated increased impairments and illness complications as they grow older.

A JAPANESE NARRATIVE 1992 - 2011: APPLYING A LIFE COURSE PERSPECTIVE ON AGEING, LIFE AND CARE
E. Anbacken, School of Human Welfare Studies, Kwansei Gakuin University, Nishinomiya, Japan

A qualitative longitudinal study evolved as I followed the Suzuki couple for nearly two decades through life turning points and crises, such as the 1995 Hanshin Earthquake which destroyed their house. We discussed the subsequent steps on where and how the parents should live. Would the traditions of filial duty guide the choices of them and their adult children, or would the Suzuki couples’ clearly voiced wish...
to live on their own and take care of themselves be respected? I have followed their temporary move to their daughter’s residence, their permanent move to a condominium, and a couple of years thereafter, the sudden death of Mr Suzuki. Since his death, I meet Ms Suzuki regularly, finding her now at the age of 89, continuing to live on her own. This paper will discuss views on ageing, life and care from a sociocultural point of view in Japan. Moreover it applies a life course perspective. This paper explores what happens with norms and values in transitions and crises throughout individual lives. The discussion continues a survey on societal levels in the process of a “socialization of old age care” initiated by the national long term care insurance of 2000. Though a case study, this paper will draw on previous studies especially in the fields of social and cultural gerontology and Japanology. Participants of this session will be able to discuss the importance of addressing sociocultural aspects of ageing while applying a life course perspective.

TRANSNATIONAL CARE
J.M. Kalavar1, S.H. Zair2, J. Duvalu1, J. Penn State University, New Kensington, Pennsylvania, 1. Penn State University, 2. State College, Pennsylvania, 1. Sri Venkateshwara University, Tirupati, India

Providing care to elderly family members across national borders can be complex as it involves many challenges, including time, money, health, work schedules, marital status, travel costs, visa limitations, and competing familial obligations. This project examined transnational care giving experiences among Asian Indian elderly residing in India whose children resided outside India. A subsample of elders whose children resided exclusively in India also participated. A total of 70 adults participated in this project in the cities of Bangalore and Mumbai. Individuals participated in either a group meeting, completed a survey, or an extended phone interview to capture some of their transnational care giving experiences. Survey data indicated that the sample was primarily male (60%), Hindu (83.3%), married (86.7%), and the average age was 70.10 (SD=5.809) years. Majority of the seniors whose children resided outside India were educated, middle-income category or higher, socially active, enjoyed good health, and were not keen to live in multi-generation households. Survey findings suggest that transnational care is reciprocal in nature. Care provided by seniors involved provision of socio-emotional support, advice when sought by adult children, babysitting grandchildren, occasional financial assistance from parent to adult child. Care rendered by adult children included frequent telephone contact, periodic visits, emergency crisis care, and support during bereavement. Communication technology has enhanced intergenerational contact as evidenced by the use of Skype (56.7%), email (73.3%), Vonage phone set-up (66.7%), and webcams (63.3%). In today’s global economy, transnational care carries implications for the health and well-being of both generations involved.

RELATIONSHIPS BETWEEN APPRAISALS OF CAREGIVER COMMUNICATION STRATEGIES AND BURDEN AMONG SPOUSES AND ADULT CHILDREN

The purpose of this study was to investigate the impact of caregivers’ appraisals of the effectiveness of their own communication strategies on caregiver burden when caring for family members with Alzheimer’s disease (AD). Family caregivers (N = 84) of participants with AD completed questionnaires appraising communication strategies, problem behaviors, and levels of three types of burden. Hierarchical linear regression models revealed that effective strategies and kinship status were significantly linked with stress burden, whereas effective strategies and problem behaviors were significantly related to relationship burden. Cognitive status of participants with AD significantly predicted objective burden. Caregivers who rated effective strategies as helpful were more likely to experience lower levels of stress and relationship burden. Findings provide preliminary support for understanding mechanisms by which the appraisals of communication strategies influence caregiver burden and justify testing empirically derived communication interventions.

The Gerontological Society of America
within the apartment building blocks substantially decreases an individual sense of feeling left out or isolated; marriage and the household structure do not cause the same effect. These results are found for the young old, particularly women of Chinese ethnicity but to a lesser extent for the oldest old.

SOCIAL CAPITAL AS A PREDICTOR FOR DECLINE IN PSYCHOLOGICAL HEALTH AND FUNCTIONAL CAPACITY AMONG COMMUNITY-DWELLING OLDER ADULTS

Y. Fujiwara1, E. Kobayashi1, T. Fukaya1, M. Nishi1, M. Saito1, K. Nonaka1, F. Fukushima2, S. Shinkai1, 1. Research Team for Social Participation and Community Health, Tokyo Metropolitan Institute of Gerontology, Tokyo, Japan, 2. Nihon Fukushi University, Research promotion center for community care, Ohbu, Japan, 3. National Institute of Public Health, Wako, Japan

Background & purpose: Recently a number of studies have accumulated suggesting that social capital (SC) independently predicts health outcome in older populations. However, few studies thus far have been conducted in Asian countries, including Japan. The purpose of this study is to provide new evidence for the relationship between social capital and subsequent psychological health and functional capacity. Methods: We examined a prospective cohort of 2,275 community-dwelling persons, aged 65 years and older who responded to the baseline mail survey in Wako City, a suburb of Tokyo, in 2008. Participants were asked about six-item SC index : your neighborhood is safe; your neighbors help one another; your neighbors are willing to take care of one another; you are relieved due to neighboring medical facilities; your neighbors cheerfully exchange greetings; you want to live in your neighborhood in the future (scored 1-30), age, gender, years of schooling, annual income, mobility, functional capacity (Tokyo Metropolitan Institute of Gerontology Index of Competence, TMIG-IC), and psychological variables such as 15-item Geriatric Depression Scale (GDS15), index of anxiety about the future, and self-rated health. Multiple logistic regression models were used to examine independent association between SC and subsequent decline in psychological variables and functional capacity, controlling for important confounders. Results: Of 2,275 subjects who participated in the baseline survey, 1,782 persons (78.3%) responded to the follow-up survey in 2010. Poor SC score had increased risks of ‘depressive mood (GDS≥6)’ [Odds ratio(OR): 1.22, 95% CI: 1.10-1.36], more anxiety about the future [OR: 1.25, 95% CI: 1.12-1.40], and poor functional capacity (TMIG-IC<13) [OR: 1.14, 95% CI: 1.01-1.29] Conclusion: Poor SC might predict decline in psychological health and functional capacity among community-dwelling older adults.

THE MODERATING EFFECTS OF SELF-EFFICACY, SOCIAL SUPPORT, AND NEIGHBORHOOD CHARACTERISTICS ON THE RELATIONSHIP BETWEEN POVERTY AND DEPRESSION IN LATE LIFE

J. Kim1, J. Han2, V.E. Richardson1, 1. Social Work, The Ohio State University, Columbus, Ohio, 2. The Ohio State University, Columbus, Ohio, 3. The Ohio State University, Columbus, Ohio

Although the relationships between depression, poverty, and poor health are well documented, we lack adequate evidence on whether social and community supports, including neighborhood characteristics, buffer the effects of poverty on older persons’ well-being. We tested the potentially moderating effects of multiple levels of social support on the association between poverty and depression among 2,615 older persons 65-years of age and older using data from the Health and Retirement Survey. We focused on possible interaction effects of support influences - ranging from support from friends, spouse, and children to physical and social characteristics of the community - that might mitigate the effects of poverty on depression. We controlled for background factors as well as selected psychological influences. Hierarchical regression analyses were used to systematically identify the best fitting model. The findings confirmed previous research showing that poverty, health, gender, and education are significantly related to depression. We uncovered important interaction effects indicating that selected support variables moderate the impact of poverty on older persons’ depression. Impoverished older persons who reported support from a spouse evidenced less depression than those who lacked this support. Ethnic variations emerged, but became nonsignificant when possible interaction effects were taken into account. In addition, although neighborhood characteristics had no influence on depression, support from children and higher levels of self-efficacy were related to less depression. The results have important implications for practitioners and policy-makers committed to improving the well-being of our most impoverished older persons.

SOCIAL SUPPORT AND PHYSICAL ACTIVITY: THE MODERATING ROLE OF LIFE SATISFACTION

B.J. Ayotte1, Y. Aviv2, J. Margrett1, J.H. Patrick1, 1. Psychology, University of Massachusetts Dartmouth, North Dartmouth, Massachusetts, 2. Iowa State University, Ames, Iowa, 3. West Virginia University, Morgantown, West Virginia

Social support is consistently related to physical activity. However, research has not extensively investigated potential moderators of the associations of positive and negative social support with physical activity. We investigated whether life satisfaction moderated the associations of positive and negative social support with physical activity in middle aged and older adults. Participants included 232 middle aged and older adults between the ages of 50 and 75. Information regarding demographics (age, education, sex, and number of health conditions), perceived positive and negative family support for physical activity, and physical activity were collected. Data were analyzed using hierarchical multiple regression with three steps: (1) demographics, (2) social support and life satisfaction, (3) interaction terms of life satisfaction by positive social support and life satisfaction by negative social support. Demographics accounted for 4% (p<.05) of the variance, with life satisfaction and positive and negative social support accounting for an additional 29% (p<.05) of the variance. The interaction terms accounted for an additional 4% (p<.05) of the variance. Overall, the model accounted for 37% of the variance (p<.05). Follow-up analyses indicated that positive social support was more positively related to physical activity in people with high life satisfaction compared to low life satisfaction, and that negative social support was more negatively related to physical activity in those with low life satisfaction compared to those with high life satisfaction. These results suggest that efforts to increase physical activity by focusing on social support should consider both positive and negative support, as well as life satisfaction.

SESSION 2380 (SYMPOSIUM)

ADVANCES IN THE CONCEPTUALIZATION AND MEASUREMENT OF NEIGHBORHOODS

Chair: J. Norstrand, Social Work, Boston College, Newton, Massachusetts
Co-Chair: G. Luhr, Portland State University, Portland, Oregon
Discussant: I. Yen, University of California, San Francisco, California

This year’s Annual Scientific Meeting of the Gerontological Society of America focuses on lifestyles across the lifespan. An important aspect of lifestyle for older adults is the neighborhood, that is, places were adults live and conduct their daily lives. How neighborhoods are perceived may impact our physical and emotional health. However, in order to fully understand this relationship, we must first better understand how older adults define neighborhoods. While much research has focused on the geographical constructs of place, it is important to acknowledge that neighborhoods capture many dimensions including cognitive, behavioral, cultural and temporal. The study by Katagiri provides an understanding of the how length and type of experience of
neighborhood shapes the definition of neighborhood. Weinstein and colleagues' study provides a qualitative analysis of the meaning of neighborhood through use of interviews, Photovoice and GIS mapping. Rvivcker and colleagues' study provides insight into how barriers in neighborhoods may determine accessibility of neighborhood in terms of physician care. Finally, the study by Gallagher and colleagues examines the impact of neighborhood environment along with mobility limitations, self-efficacy and outcome expectations on neighborhood walking. These studies may foster opportunity to further the conversation on different ways of conceptualizing neighborhoods among older adults. Further important questions that may be explored in this symposium include what measurement technologies are best suited to capturing the multi-dimensional aspects of neighborhoods as seen through the eyes of older adults? And how can multi-disciplinary research, focused on conceptualization and measurement of neighborhoods, best contribute to this topic?

FACTORS RELATED TO NEIGHBORHOOD WALKING FOR TRANSPORTATION AND RECREATION IN OLDER, URBAN ADULTS

Factors influencing walking in older adults (OA) may differ by reason for walking. This cross-sectional study examined the association of mobility limitations, self-efficacy, outcome expectations and neighborhood environment (density, design and destinations) on neighborhood walking in OA walking for recreation or transportation (n=326, age 60-99 years, M=76.1,SD=8.34). Measures included the Neighborhood Physical Activity Questionnaire, Pepper Assessment Tool for Disability, Multidimensional Outcome Expectations for Exercise Scale, Neighborhood Environment Walkability Scale, and self-efficacy scales. Multiple regression revealed that the variables explained 22.4% (p<.05) of the variance in neighborhood recreational walking; only gender (β=0.15, p=0.01) and self-efficacy (β=0.49, p<0.001) were significant. In contrast, for neighborhood transportation walking, the variables explained 19.8% of the variance (p<0.001); only neighborhood density (β=0.17, p<0.01) and destinations (β=0.31, p<0.001) were significant. Although walking interventions are unlikely to impact density, they should incorporate local destinations popular with older adults to increase transportation walking, and target self-efficacy to increase recreational walking in OA.

THE EFFECTS OF PHYSICIAN SUPPLY AND NEIGHBORHOOD FACTORS ON PRIMARY CARE USE AMONG URBAN ELDERS

This study examined the relationships between local primary care physician (PCP) supply, perceived neighborhood characteristics, and primary care use among older adults in New York City. Using geographic data on PCP supply and survey data from 1,260 senior center attendees, we analyzed factors that facilitate and hinder primary care access for individuals living in service areas with different supply levels. Supply quartiles varied significantly in their racial and socio-economic composition, perceived neighborhood social cohesion and safety, and PCP use. Stratified multivariate models showed that, within the lowest and second-lowest quartiles, individuals who used public transit were 81% and 85% more likely than those who did not to have seen a PCP in the past 12 months (p<0.01). This suggests that elder-friendliness of public transit may facilitate primary care access in low-supply areas. This work highlights the role of environmental barriers in disparities in health care access among urban older adults.

CAPTURING “NEIGHBORHOOD” THROUGH A NEW LENS: USING PHOTOVoice AND GIS TO UNDERSTAND HOW OLDER ADULTS PERCEIVE THEIR URBAN SURroundINGS

J. Weinstein, P. Carder, J. Kohon, Institute on Aging, Portland State University, Portland, Oregon

Researchers who study the relationship between older persons and neighborhoods have to confront the imprecise nature of neighborhood boundaries. While some researchers rely on U.S. Census tracts or other arbitrarily imposed boundaries, others attempt to categorize neighborhoods based on local and subjective understandings. This study took a more personalized look at the meaning of neighborhood for 43 older adults (55+) who live in subsidized housing in Portland, Oregon. Through qualitative interviews and the use of Photovoice, study participants provided vivid descriptions and shared rich stories about the geographic constructs, social relationships and daily uses that shaped their unique perceptions, positive and negative, of their neighborhoods. Combining individual case studies with Geographic Information Systems (GIS) mapping, we portray both fluid and fixed neighborhood boundaries as defined through the lived experience of older adults in urban areas.

DIRECT EXPERIENCE SHAPES THE NOTION OF “THE AREA OF RESIDENCE” IN JAPANESE SENIORS

K. Katagiri, 1. Sugawara, 1. Institute for Social Gerontology, Nipponkoa Welfare Foundation, Tokyo, Japan, 2. Institute of Gerontology, the University of Tokyo, Tokyo, Japan

“Aging in place” is an important subject in aging societies. However, how do people define the “place”? A random-sampling survey on 50–60-year-old Japanese was conducted in urban and local cities in 2008. The question “How large is the area you imagine when you hear the phrase ‘your area of residence’?” was asked. Seven choices were provided, from “1. around your home” to “7: larger than your prefecture,” with the areas stretching farther as the number increased. 33.2% answered “around your home” and 36.4%, “in your town.” The main results of ANOVAs showed that people who lived in the area in their younger days, participated in social activities, or lived in small cities chose a wider range for their areas of residence. This suggested that people with more knowledge and direct experiences in the areas broaden their notions of “areas of residence.”

SESSION 2385 (SYMPOSIUM)

ENGAGEMENT AND DISENGAGEMENT AMONG OLDER ADULTS FACING ADAPTATION CHALLENGES

Chair: J. Heckhausen, Psychology, UC Irvine, Irvine, California Co-Chair: C. Wrosch, Psychology, UC Irvine, Irvine, California Discussant: J. Heckhausen, Psychology, UC Irvine, Irvine, California

This symposium will introduce the topic of motivation and self-regulation in older adults. The Motivational Theory of Life-Span Development proposes that engagement with goals and disengagement from goals should match with available opportunities for control and goal attainment. When confronted with controllable challenges such as in temporary and reversible health problems, goal engagement and primary control striving are adaptive. In contrast, when facing irreversible loss and disability, goal adjustments and goal disengagement lead to better outcomes. This set of presentations shows that it is not a particular strategy of motivational self-regulation, but instead the matching of motivational behavior with contextual opportunities and constraints, that makes or brakes successful aging. Wrosch and Rueggeberg examine the effectiveness of health-related control striving among older adults over a span of 6 years, and show that among those who are lonely self-
protection and goal engagement lead to reductions in perceived stress and cortisol volume and ultimately to less systemic inflammation. John and Lang used a video vignette technique to elicit control strategies with progressive illness and disability. They show that older but not younger adults benefit from generating opportunity-congruent control strategies. Heyl and Wahl show that sensory unimpaired older adults benefit from tenacious goal pursuit in terms of subjective well-being, while visually or hearing impaired older adults benefit particularly from flexible goal adjustment. Finally, Morse introduces a newly developed scale for assessing control strategies and examines among older adults with depressive symptoms how control strategies are related to physical functioning and severity of depression.

PURSUING HEALTH GOALS: STRATEGIES AND THEIR RELATION TO DEPRESSIVE SYMPTOMS
1.Q. Morse, Western Psychiatric Institute & Clinic, University of Pittsburgh, Pittsburgh, Pennsylvania

The downward spiral resulting from a combination of depressive symptoms and functional impairment impedes intervention, especially for older adults. First-line interventions for depression and medical illnesses associated with impairment are hampered by loss of motivation and poor treatment adherence. Primary and secondary control strategies may help us conceptualize these motivational issues. The goal was to develop a scale assessing control strategies while attending to the literacy demands of new items. Qualitative interviews were conducted and coded to write new items and a pilot scale has been tested in a large national sample (n=500) of community adults aged 40 to 80+, half reporting difficulties with an ADL and half not. The psychometric properties of the new scale will be examined in this community sample and in a small sample of older adults reporting some symptoms of depression. The relations between the new scale, physical functioning, and depression will be examined.

HEALTH-RELATED CONTROL STRATEGIES PREDICT PSYCHOLOGICAL AND BIOLOGICAL BENEFITS AMONG LONELY OLDER ADULTS
C. Wrosch, R. Rueggeberg, Concordia University, Montreal, Quebec, Canada

This 6-yr longitudinal study (N = 122) examined the effects of loneliness and health-related self-protection (i.e., compensatory secondary control, CSC) on older adults’ psychological stress, cortisol volume, and systemic inflammation (C-RP). We reasoned that with the onset of psychological decline in older adulthood lonely older adults would be particularly likely to exhibit stress-related psychological and biological problems, unless they use CSC in response to emerging health threats. The results showed that baseline CSC was association with a 2-yr reduction of psychological stress and cortisol volume, and predicted lower C-RP after 6 years, but only among lonely participants. In addition, mediation analyses showed that the buffering effect of CSC on 6-year levels of C-RP among lonely older adults was mediated by 2-yr changes in cortisol volume. These findings suggest that lonely older adults can avoid stress-related psychological and biological problems if they engage in CSC to manage their health threats.

ADAPTATION TO UNAVOIDABLE LOSS ACROSS ADULTHOOD: A THINKING-ALOUD STUDY WITH VIDEO VIGNETTES
D. John, F.R. Lang, Institute of Psychogerontology, Erlangen, Germany

Confrontation with unavoidable loss across adulthood enforces adaptation that may either be resource-neutral (e.g., reorientation of goals) or involve investment of resources (e.g., striving for maintenance, improvement). We examined whether age-differential effects of resource investments on affect can be found in a mere simulation task of unavoidable loss-management. In an experimental study, we confronted 83 healthy young, middle-aged, and old adults with fictitious video vignettes of a person suffering from Multiple Sclerosis. Participants engaged in a thinking-aloud task on managing life changes of the fictitious person after learning about the diagnosis. Consistent with expectations, the video-vignette task led to greater salience of loss among older adults than among young adults. Only the older participants’ striving for improvement was associated with an increase of negative affect after the thinking-aloud task, whereas their resource-neutral reorientation strategies led to enhanced affective well-being. Findings show age-differential effects of simulating adaptational resource-allocation across adulthood.

GOAL ENGAGEMENT AND DISENGAGEMENT AND GENERAL WELL-BEING IN ADVANCED OLD AGE: DOES SENSORY IMPAIRMENT MATTER?
V. Heyl¹, H. Wahl², 1. Institute of Special Needs Education, University of Education, Heidelberg, Germany, 2. University of Heidelberg, Heidelberg, Germany

This study investigates the role of goal engagement and disengagement in general well-being, comparing visually impaired, hearing impaired, and sensory unimpaired older adults. According to arguments that flexible goal adjustment increases in importance with age and disability, we hypothesized differential relationships between modes of self-regulation and general well-being when comparing sensory impaired and sensory unimpaired older adults. Structural equation modeling based findings rely on samples of 121 visually impaired, 116 hearing impaired and 150 sensory impaired adults in advanced old age (M = 82 years). While flexible goal adjustment seems to be of great importance for general well-being in all samples, presumably due to the advanced old age of participants, sensory unimpaired older adults benefit more from tenacious goal pursuit than sensory impaired individuals. It is concluded that the ability to adjust goals to reduced capacities is crucial when it comes to a constraining condition such as sensory impairment.

SESSION 2390 (SYMPOSIUM)

HEALTH AND AGING IN ASIA: LIVED EXPERIENCES OF OLDER ADULTS IN CHINA, TAIWAN, AND JAPAN
Chair: K. Chee, Department of Sociology, Texas State University–San Marcos, San Marcos, Texas
Co-Chair: F. Ejaz, Benjamin Rose Institute on Aging, Cleveland, Ohio
Discussant: F. Ejaz, Benjamin Rose Institute on Aging, Cleveland, Ohio

This symposium addresses the diverse experiences of older adults in Asia who live in different environments. Findings from three research projects conducted in China, Taiwan, and Japan reveal several themes: a) the lifestyles of older adults in Asian countries vary greatly, depending on the environment in which they live or receive care; b) older adults’ experiences with formal or informal care vary by the region within which they live, the level of their health or disability status, and the level of their socioeconomic status; and c) older adults may negotiate how they meet their care needs through social relations that they maintain with their adult children or care providers. Lydia Li will first discuss her qualitative study of older adults with chronic illness in Shandong, China. Her findings include differences between rural and urban residents in terms of how they deal with barriers to health care access. Next, Liou and Jarrott will report on their ethnographic research in two adult day care environments in Taiwan. Their findings reveal how staff members and elders interacted in these environments. Finally, Lum will explain findings from qualitative research on healthy middle-class older adults in Tokyo, Japan, centering on gender and age differences in their adaptation to aging. The chair and co-chair will discuss how findings from these studies contribute to an understanding of environment-based differences in the lifestyles of older adults and diverse paths to healthy aging. Discussion will also include suggestions for future research in the Asian context.
ADULTS IN THE GREATER TOKYO AREA
L. Li, Y. Suí, L. Gao, Y. Long, J. School of Social Work, University of Michigan, Ann Arbor, Michigan, 2. Renmin University of China, Beijing, China, 3. University of Jinan of China, Jinan, Shandong, China

This qualitative study, based on semi-structured interviews with 24 elders with chronic illness from Shandong, China, examines and compares the health care experience of older adults in rural and urban China. The results indicate that rural elderly Chinese received lower quality of primary care, experienced more barriers to access secondary and tertiary care than their urban counterparts, and relied on children for medical care payment. To reduce medical spending, rural elders ignored symptoms, delayed treatment, rationed health care and self-medicated. Both rural and urban elders found hospital in-patient care to be too costly and unaffordable. The findings provide a contextual understanding of the disparity between rural and urban elders in health care access and quality, and have implications for health reforms in China and other emerging economies experiencing population aging and variance in rural vs. urban health delivery systems.

EXPERIENCES OF TAIWANESE ELDERS IN TWO DIFFERENT ADULT DAY CARE ENVIRONMENTS
C. Liu, S.E. Jarrott, Virginia Tech, Blacksburg, Virginia

Adult day services (ADS) have demonstrated benefits to elders’ and caregivers’ well-being but also reveal infantilization and disrespect for elders. Many ADS environments are socially constructed as places for cognitively impaired elders: here, ADS clients are labeled as child-like dependents. We utilized environmental theory to examine two ADS environments in Taiwan. We collected ethnographic data with 270 hours of observations; and also conducted qualitative interviews with fifteen staff members and eight elders. Findings revealed that treatment of elders took on a teacher-to-student orientation. Elders referred to staff as “teachers” as they were directed to their “classrooms.” Elders with more limited cognitive and physical abilities face more teacher-to-student interaction. However, more independent elders expressed a sense of powerlessness to exert change with this orientation. Findings suggest that changing such practices may result in generating greater respect for impaired elderly, while acknowledging the feelings of those with enhanced cognitive abilities.

LIFESTYLES OF MIDDLE-CLASS JAPANESE OLDER ADULTS IN THE GREATER TOKYO AREA
S. Lum, Waseda University, Tokyo, Japan

In-depth, qualitative studies on the lifestyles of older adults in Japan are scarce. The purpose of this research was to gain an in-depth understanding of the daily lives of healthy, retired older adults who did not need formal care. The sample consisted of 35 older adults, living in the Greater Tokyo area in Japan and whose age ranged from 60 to 85 years. The in-depth interviews explored areas in the older adults’ lives, including daily activities, and family and social contacts. Data were analyzed from two perspectives – gender and age group. Results: Significant gender differences were observed, where continuity featured in the female older adults’ lives, while most male older adults tended to make new social contacts after retirement. Differences were also observed across age groups. The sixties were observed to be a time of upheaval, the seventies, a time of adjustment and the eighties as a time of acceptance.

SESSION 2395 (PAPER)
COMPLEMENTARY THERAPIES
USE OF COMPLEMENTARY/ALTERNATIVE THERAPIES IN COMMUNITY OLDER WOMEN WITH ARTHRITIS
C. Cheung, Nursing, St. Catherine University, St. Paul, Minnesota

Arthritis is a common chronic disease among older women with no effective cure. The aims of this study were to: 1) understand the impact of arthritis on the lives of older women; 2) describe older women’s experience of complementary/alternative therapies (C/AT) use; 3) identify types of C/AT use and factors that influence older women’s decisions to use C/AT; and 4) evaluate the level of knowledge related to benefits and risks associated with C/AT use. A qualitative research design using focus groups was used. A purposive sample of 27 community-dwelling older female C/AT users ages 65 – 93 were recruited to participate in four focus groups (5-9 participants/group). A semi-structured interview guide was based on the Health Belief Model. Interviews were audio-taped and transcripts were analyzed using thematic approach. Most of the participants were Caucasian (81%) and educated (mean level of education: 13 years, range 8 – 18). Common themes included: arthritis is debilitating. Nutritional supplements, hot/cold therapy, and plant-based ointments were commonly used. Use of C/AT was motivated by the desire to regain physical mobility/function and limited treatment options in conventional care. Cost and unaccessability were the main barriers to C/AT use. Most C/AT were perceived as effective but C/AT knowledge was limited among users. Most participants did not discuss their C/AT use to their primary care physician. Older women are motivated to use different C/AT to manage arthritis without evidence based knowledge. Strategies are needed to improve communication between health care providers and older patients on C/AT use.

USE OF COMPLEMENTARY/ALTERNATIVE THERAPIES FOR ARTHRITIS AMONG OLDER WOMEN OF URBAN, SUBURBAN AND RURAL COMMUNITIES
C. Cheung, C. Geisler, Nursing, St. Catherine University, St. Paul, Minnesota

Arthritis is a chronic and painful disease that affects primarily older women. Many arthritis sufferers use complementary/alternative therapies (C/AT) to help manage arthritis symptoms. The purposes of this study were to explore the: 1) prevalence and types of C/AT use for arthritis management by older women residing in urban, suburban, and rural geographical settings; 2) factors that influence community-dwelling older women’s decisions to use C/AT; 3) sources of C/AT information used for arthritis management; and 4) extent to which older women disclose their C/AT use to their health care providers. A qualitative research design using focus groups was used. Fifty community-dwelling women (ages 66 – 101) who manage arthritis with C/AT participated in eight focus groups. A semi-structured interview guide was based on the Health Belief Model. Thematic approach using codes and links were employed for data analysis. The majority of study participants were Caucasian (90%), widowed (42%) and educated (mean educational level was 14, range 8-22 years). Nutritional supplements were the most commonly reported type of C/AT across all locations. Rural participants reported the greatest variety of C/AT use. Dissatisfaction with conventional medicine and perceived safety and convenience of C/AT motivated C/AT use. Most participants obtained information on C/AT from friends, family, and media advertisements, and do not fully disclose their C/AT use to their primary health care provider. Findings suggest the need for health care professionals to better communicate with and understand the health care needs of this client group when designing, organizing and delivering appropriate arthritis care.

ADAPTED TANGO: FEASIBILITY AND EFFICACY IN OLDEST-OLD ADULTS WITH VISUAL IMPAIRMENT
M.E. Hackney1,2, C. Hall1,2, K. Echt1,2, S. Wolf1,2, 1. Rehab R&D, Atlanta VAMC, Decatur, Georgia, 2. Emory University School of Medicine, Atlanta, Georgia

Fall risk increases with age and visual impairment; yet, the oldest-old (> 85 years) are rarely studied. Because partnered dance improves mobility, balance and quality of life in older individuals with movement disorders and balance impairment, the present investigation was designed to determine the feasibility and efficacy of an adapted tango program targeting balance, gait, and participant satisfaction amongst these older-
est-old adults with visual impairment. Fourteen older adults with mild-to-severe visual impairment (11 females, mean age 84.9±9.2 years; best eye acuity: 0.64±0.5 logMAR; level of visual impairment, mild: n=5, moderate: n=5, severe: n=4), participated in an adapted tango program of 20, 1.5 hours lessons, completed within 11 weeks. Participants were evaluated for balance, gait, lower body strength, and cognition, in two baseline observations before the program, immediately after, and one month later. Aspects of feasibility examined were safety, facility access, retention and training of volunteers, and retention and satisfaction of participants. Twelve participants completed the program. Participants improved from pre- to post-training scores for: dynamic gait index (p<0.001), lower body strength (p=0.045), and spatial working memory span (p=0.012). Forward, backward and fast gait did not decline. The study was feasible in that no injuries were sustained, the facility was adequate and volunteers and participants were retained throughout. Participants reported enjoyment and improvements in aspects of their physical well-being. These older individuals with visual impairment benefitted from 30 hours of tango instruction adapted for their capabilities. Larger samples are needed to verify the efficacy of adapted tango.

DAILY BLUEBERRY CONSUMPTION CAN IMPROVE DECISION-SPEED AND SELF-REPORTED HEALTH INDICATORS

BACKGROUND: In laboratory experiments blueberry extracts have been reported to increase hippocampal neurogenesis and plasticity, improve survival of transplanted nerve cells, improve rotarod and maze performance, reduce Alzheimer’s-like changes, and decrease tumorigenesis. A critical question is whether blueberries provide similar benefits to humans. METHODS: To help answer this question, we conducted a sixteen-week randomized, non-blinded, multi-center, crossover trial involving 97 participants aged 60 plus were recruited at the New Fairfield and Mansfield Senior Centers in Connecticut. The protocol included four 4-week phases: baseline measurement, treatment periods 1 and 2, and post-treatment follow-up. Treatment 1 was either one cup daily of wild Maine blueberries or an antioxidant supplement selected by participants from coenzyme Q10 (30 mg/day), alpha lipoic acid (25 mg/day) or vitamin E (500 IU/day) in consultation with their physicians. Participants crossed over to the other treatment after four weeks. Single-choice decision speed measurements were conducted each week from the study web site at Blueberrystudy.com. Errors and decision speed predictions were obtained during and after each measurement session to quantify participant expectations and motivation. Results: Among those receiving blueberries, significant improvement occurred in all measured indicators including decision speed (t-test p=0.024), self-reported aches and pains (p=0.017), energy level (p=0.002), sharpness (p=0.001), sleep quality (p=0.017), mood (p=0.010), peacefulness (p=0.005) and overall health (p=0.001). Blueberry group response times improved by 4.2% compared to baseline, more than twice the improvement in the antioxidant control group. Conclusions: This study indicates that regular blueberry consumption can improve decision speed and a number of self-reported health indicators.

EFFECTS OF TAI CHI ON PHYSICAL AND COGNITIVE FUNCTIONING IN ELDERS WITH MILD COGNITIVE IMPAIRMENT AND OSTEOARTHRITIC KNEE

P. Tsai1, J.C. Chang1, C. Beck1, Y. Kuo1, J. University of Arkansas for Medical Sciences, Little Rock, Arkansas, 2. The University of Texas Medical Branch, Galveston, Texas

This study was a cluster-randomized clinical trial with two arms to test the efficacy of a 20-week Sun-style Tai Chi (TC) program in improving physical and cognitive functioning in community-dwelling elders with knee osteoarthritis (OA) and mild cognitive impairment (CI). Eight sites (55 participants) were randomly assigned to a TC group (4 sites, 28 participants) or an attention control group (4 sites, 27 participants). Outcome measures included the Western Ontario and McMaster (WOMAC) OA pain, physical functions and stiffness subscales, the “Get up and Go” test, the “Sit and Stand” test and the Mini Mental State Exam measuring at baseline and at the end of the 4th, 8th, 12th, 16th and 20th week. The intent to treat principle was used to analyze the results. The main effect showed improvement in every outcome in the TC group (p=0.0455-0.0000) while there were no significant changes in the attention control group (p=0.0596-0.4171). The interaction effect showed the trajectory of the WOMAC pain score (p=0.033) and WOMAC stiffness score (p=0.000) over the 5-month study period was significantly different between the two groups. The study results indicate that practicing Tai Chi can significantly reduce elders’ pain and stiffness in a time-dependent manner.

SESSION 2400 (PAPER)

FALLS

FALLS ARE A POWERFUL DETERMINANT OF ER USE BY NURSING HOME RESIDENTS

C. Stephens1, J.Y. Chang1, K. Covinsky2, M.A. Blegen1, S. Lee2, J. University of California, San Francisco, San Francisco, California, 2. San Francisco VA Medical Center, San Francisco, California

Background: Falls in nursing home (NH) residents lead to disability, reduced quality of life, higher healthcare costs & increased morbidity. Almost 25% of falls in this population result in fracture, laceration or need for hospital care, however the relationship between falls and transfer to the ER has not been well described. Methods: We examined the association between falls and ER use in a 5% random sample of Medicare beneficiaries residing in NHs in the US (n=132,753) in 2006. Federally-mandated Minimum Data Set (MDS) data were linked to CMS inpatient claims, outpatient claims, and Beneficiary Summary File data to determine the presence of a fall in the past 30 days and associated ER use with and without hospitalization. Multinomial logistic regression was used, controlling for case-mix severity, sociodemographic/health-related factors. Results: Of the 35,735 residents with a fall in the past 30 days, 76% (n=28,403) went to the ER and were more likely to be hospitalized (62.8% vs. 44.1%, p<0.0001) or seen in the ED without hospitalization (42.0% vs. 31.8%, p<0.0001). After adjusting for other factors, residents with a fall in the past 30 days had a 2.5 times greater odds of any ER visit (95% CI, 2.4-2.5) than those without a fall in the past 30 days. Conclusions/Implications: Falls are common & identify a subgroup of NH residents at high risk for decline and high acute care utilization. Although it is not possible to prevent all falls in the NH, further interdisciplinary interventions to prevent/decrease falls may improve patient outcomes & decrease costs.

DOES KYPHOSIS CONTRIBUTE TO FALLS?

Background: Hyperkyphosis is common among older adults; its association with falls is controversial. Objective: We aim to determine the association between hyperkyphosis, falls and injurious falls in a population of community-living older adults. Design: The MOBILIZE Boston Study, a population-based study of adults aged ≥65 years old living in the community, performed kyphosis measurements (n = 615) at 18-month follow-up visits. Falls were assessed by monthly fall calendar postcards for up to two years thereafter; injurious falls were ascertained...
ORTHOSTATIC HYPOTENSION IN ELDERLY NURSING HOME FALLERS: WERE THEY DIZZY?

Orthostatic hypotension (OH) is a common cause of older adult falls. It is well known across many age-groups that OH is often heralded by symptom experiences of lightheadedness and/or dizziness, serving as a marker for its occurrence and management. However, little is known if elderly nursing home fallers who meet the standard diagnostic criteria of OH are indeed symptomatic [with dizziness] at the time of their fall. A secondary analysis was conducted on data from a prospective, quasi-experimental 3-year study using the 30-item validated Post-Fall Index as an intervention to comprehensively assess older adults post-fall. Of the 77 fallers with 195 explained falls by nurses, 46% (n=89) failed to meet the diagnostic criteria of OH whereas only 13.3% of the sample (n=26) clearly met, or nearly met the OH criteria. For another 39% of the sample (n=76) we could not confirm the presence or absence of OH due to omission of data. Of the 26 fallers with OH only one experienced dizziness. An empirically derived explanatory model is presented along with clinical implications relevant to practice in order for health care professionals to detect and manage OH in the absence of premonitory or antecedent symptoms.

STEADI—A FALL PREVENTION TOOLKIT FOR PRIMARY CARE PROVIDERS

J. Stevens,1 E. Phelan*, 1. Centers for Disease Control & Prevention, Atlanta, Georgia, 2. University of Washington, Seattle, Washington

Falls and their associated injuries are a growing public health concern, responsible for nearly 20,000 deaths nationwide and costing over $26 billion (in 2008 dollars) annually. In 2009 alone, 2.2 million older adults were treated in emergency departments for fall injuries and nearly 600,000 of these patients were hospitalized. Clinical assessment and individualized risk factor reduction is effective in reducing falls and fall injuries, and the American Geriatrics Society (AGS) has published practice guidelines to promote fall risk assessment and management. However, guideline awareness among health care providers is low; primary care providers report they do not know how to assess fall risk or do not have adequate knowledge about fall prevention. To address these concerns and fill this identified knowledge gap, the Injury Center at the CDC is developing STEADI (Stopping Elderly Accidents, Deaths, and Injuries), a comprehensive fall prevention toolkit. This toolkit incorporates findings from formative research with physicians. It follows a simplified version of the AGS guidelines and includes a pocket guide, fact sheets, “how-to” pages on focused falls physical exams, and other training materials designed to help primary care providers incorporate fall risk assessment and individualized fall interventions into their clinical practice. This presentation will provide background information about fall risk screening and management, describe the developmental process of the STEADI toolkit, and share current versions of toolkit materials.

MEDIATING EFFECT OF PHYSICAL ACTIVITY IN KNEE OSTEOARTHRITIS (OA) AND RISK OF FALLS IN OLDER ADULTS

U.D. Nguyen1, Y. Zhang1, J. Niu1, D.P. Kiel2,3, S.G. Leveille1, R.H. Shmerling1, C.A. Oatis1, M.T. Hamre3, 1. Medicine, Boston University School of Medicine, Boston, Massachusetts, 2. Hebrew SeniorLife Institute for Aging Research, Boston, Massachusetts, 3. Harvard Medical School, Boston, Massachusetts, 4. University of Massachusetts, Boston, Boston, Massachusetts, 5. Beth Israel Deaconess Medical Center, Boston, Massachusetts, 6. Arcadia University, Glenside, Pennsylvania

Physical activity may mediate the effect of knee OA on the risk of indoor and outdoor falls differently for men and women. In the MOBILIZE Boston Study, a population-based cohort of community-dwelling older adults, we used ACR criteria to assess knee OA. Falls were assessed using monthly calendars and phone interviews. Physical activity was assessed using PASE. Separate negative binomial regressions were performed for men and women, to estimate the mediating effect of physical activity on the risk ratio (RR) of knee OA with risk of indoor and outdoor falls separately, adjusting for confounders. Of 764 people (mean age; 78 years; mean BMI:27.3), 25% had knee OA. Over 2.3 years of follow-up, 318(42%) had ≥1 indoor fall, and 300(39%) had ≥1 outdoor fall. In 276 men, mean PASE scores were 97(SD67) and 118(SD83) among those with and without knee OA, and in 488 women, 111(SD64) and 102(SD66), respectively. The adjusted RR for knee OA compared with no knee OA on risk of indoor falls was 1.19(95%CI:1.0,1.1) for women, and 1.69(95%CI:1.0,2.5) for men. The corresponding RR for outdoor falls was 1.79(95%CI:1.2,2.4) for women, and 0.9(95%CI:0.6,1.4) for men. Further controlling for PASE, the RR for indoor falls was 1.1(95%CI:0.8,1.5) for women, and 1.5(95%CI:0.9,2.4) for men. The RR for outdoor falls was 1.6(95%CI:1.2,2.3) for women and 0.9(95%CI:0.6,1.4) for men. Knee OA was associated with increased risk of indoor falls in men, and outdoor falls in women. Such associations were not explained by differences in physical activity levels in either men or women.

SESSION 2405 (PAPER)

MEDICATIONS IN OLDER ADULTS

ANTIPSYCHOTIC (APM) INITIATION AND LONG-TERM USE FOLLOWING LIFESTYLE CHANGE WITH LONG-TERM CARE (LTC) ADMISSION

J.A. Lucas1, S. Chakravarty1, J.R. Bowblis1, T. Gerhard1, E. Kalay1, M.J. Siegel1, S. Crystal1, 1. Rutgers University, New Brunswick, New Jersey, 2. Miami University, Oxford, Ohio

Background: Dementia-related neuropsychiatric symptoms are distressing to patients and caregivers, often triggering major lifestyle changes with NH placement. APM is widely used to manage behavioral disturbances despite safety concerns and only moderate effectiveness. There is limited information on APM initiation, duration, and on whether these follow CMS guidelines. Objectives: Identify resident and facility characteristics associated with APM initiation; examine by class, agent, dosage, and time to discontinuation. Methods: Retrospective analysis using 2001-2004 Medicaid, MDS and OSCAR data for 6 states. From 89,528 dual eligible 65+ LTC residents without prior use (6 mos.) and without conditions considered appropriate for APM under CMS guide-
lines, we identified 8,724 residents who initiated APM after LTC admission. Cox proportional hazards models estimated adjusted hazard ratios of resident and facility characteristics for APM initiation. Results: APM was initiated by 20% within 30 days and 48% within 90 days of LTC admission. Those at higher risk of initiation were: male, African American, with dementia, wandering and resisting care behaviors; residing in facilities that were large, for-profit, highly reliant on Medicaid funding, and with high numbers of deficiencies. Staffing (nursing, mental health and physician-extender teams) was not significant. 90% initiated on atypicals; doses were above CMS thresholds for 23% of conventional and 2% atypical. Median time to discontinuation was 95 days; 34% discontinued after 180 days. Conclusions: Initiation occurs early in LTC stays among residents without CMS-approved indications; over 34% discontinued after 180 days. Conclusions: Initiation occurs early in LTC stays among residents without CMS-approved indications; over 34% discontinued after 180 days. Conclusions: Initiation occurs early in LTC stays among residents without CMS-approved indications; over 34% discontinued after 180 days. Conclusions: Initiation occurs early in LTC stays among residents without CMS-approved indications; over 34% discontinued after 180 days. Conclusions: Initiation occurs early in LTC stays among residents without CMS-approved indications; over 34% discontinued after 180 days. Conclusions: Initiation occurs early in LTC stays among residents without CMS-approved indications; over 34% discontinued after 180 days. Conclusions: Initiation occurs early in LTC stays among residents without CMS-approved indications; over 34% discontinued after 180 days. Conclusions: Initiation occurs early in LTC stays among residents without CMS-approved indications; over 34% discontinued after 180 days. Conclusions: Initiation occurs early in LTC stays among residents without CMS-approved indications; over 34% discontinued after 180 days. Conclusions: Initiation occurs early in LTC stays among residents without CMS-approved indications; over 34% discontinued after 180 days. Conclusions: Initiation occurs early in LTC stays among residents without CMS-approved indications; over 34% discontinued after 180 days.

Objective: To investigate whether institutionalization was associated with use of antiepileptic drugs (AEDs) and to compare the association between use of AEDs and psychotropics in community-dwelling and institutionalized elderly, after adjustment for age, sex and co-morbidity (i.e. number of other drugs). Methods: We analyzed data on age, sex and dispensed drugs for individuals aged >65 years registered in the Swedish Prescribed Drug Register from July to September 2008, record-linked to the Swedish Social Services Register (n=1 345 273; 1 258 565 community-dwelling and 86 708 institutionalized elderly). Multivariate logistic regression analysis was used to analyze whether institutionalization and use of psychotropics (i.e. antipsychotics, anxiolytics, hypnotics/sedatives and antiedeppressants) were associated with use of AEDs. Results: AEDs were used by 2% of the community-dwelling and 9% of the institutionalized elderly. The most commonly used AEDs were carbamazepine, gabapentin, pregabalin, valproic acid and lamotrigine. Institutionalization was strongly associated with AED use (OR adjusted=3.98 (95% CI 3.86-4.10)). In community-dwelling elderly, AED use was associated with an increased probability of use of all of the types of psychotropics. However, among institutionalized elderly, the associations between use of AEDs and psychotropics showed a mixed pattern. Conclusions: AED use seems common in institutionalized elderly and institutionalization is a strong determinant of AED use. Moreover, our results might indicate an off-label prescribing of AEDs as an alternative to psychotropics in the institutional setting. This finding needs to be confirmed by others and evaluated with respect to outcomes of this treatment in institutionalized elderly.

Objective: To investigate whether institutionalization was associated with use of antiepileptic drugs (AEDs) and to compare the association between use of AEDs and psychotropics in community-dwelling and institutionalized elderly, after adjustment for age, sex and co-morbidity (i.e. number of other drugs). Methods: We analyzed data on age, sex and dispensed drugs for individuals aged >65 years registered in the Swedish Prescribed Drug Register from July to September 2008, record-linked to the Swedish Social Services Register (n=1 345 273; 1 258 565 community-dwelling and 86 708 institutionalized elderly). Institutionalization was strongly associated with AED use (OR adjusted=3.98 (95% CI 3.86-4.10)). In community-dwelling elderly, AED use was associated with an increased probability of use of all of the types of psychotropics. However, among institutionalized elderly, the associations between use of AEDs and psychotropics showed a mixed pattern. Conclusions: AED use seems common in institutionalized elderly and institutionalization is a strong determinant of AED use. Moreover, our results might indicate an off-label prescribing of AEDs as an alternative to psychotropics in the institutional setting. This finding needs to be confirmed by others and evaluated with respect to outcomes of this treatment in institutionalized elderly.

Cytomegalovirus Infection and Responsiveness to Influenza Vaccination in Elderly Residents of Long-Term Care Facilities

W. den Elzen, A. Vossen, H. Cools, R. Westendorp, A. Kros, J. Gussekloo, 1. Public Health and Primary Care, Leiden University Medical Center, Leiden, Netherlands, 2. Netherlands Consortium for Health Ageing, Leiden, Netherlands

Ample evidence suggests that infection with cytomegalovirus (CMV) leads to accelerated aging of the immune system and may contribute to poor responsiveness to influenza vaccination in older persons. The objective of this study was to investigate whether CMV infection, acquired earlier in life, affects the response to influenza vaccination in a randomized controlled trial (RCT) among older persons in long-term care facilities. During the 1997-1998 influenza season, 731 residents (median age 83 [interquartile range 78-88], 75.4% female) in 14 long-term care facilities in the Netherlands were randomly assigned to receive 15 or 30 μg of inactivated influenza vaccine, followed by a 15 μg booster vaccine or a placebo vaccine at day 84. Blood samples were collected at day 0, day 25, day 84 and day 109. Seroresponses to influenza vaccination were measured by hemagglutination-inhibition tests to the A/H3N2 strain at all time points. Subsequently, baseline levels of IgG anti-CMV antibodies were measured using an automated chemiluminescent microparticle immunoassay. Participants with CMV antibody level ≥6 AU/mL were considered to harbor CMV infection. At baseline, no differences in pre-vaccination geometric mean antibody titers (GMT) were observed between participants with (n=571, 78.1%) or without CMV infection (n=160, 21.9%). During follow-up, participants with and without CMV infection had similar responses to influenza vaccination as measured with changes in GMT (linear mixed model, adjusted for gender, age, pre-vaccination GMT and vaccination strategy, p=0.46). Analogously, no association was found between CMV infection and a more than 4-fold increase in antibody titer (Generalized Estimating Equations, adjusted OR 1.14 [95%CI 0.80;1.64]) or an antibody titer ≥40 (adjusted OR 1.24 [95%CI 0.86;1.80]). In conclusion, CMV infection did not explain poor responsiveness to influenza vaccination in residents of long-term care facilities.

Predictors of Non-Pharmacological and Pharmacological Treatments Stopped and New Treatments Started Among Nursing Home Residents with Dementia

M.R. Simpson, C.R. Kovach, College of Nursing, University of Wisconsin-Milwaukee, Milwaukee, Wisconsin

The purpose of this study was to: a) describe the pharmacological and non-pharmacological treatments stopped and new treatments started over 6 weeks among a sample of nursing home residents with moderate-to-severe dementia and b) identify the nurse and resident factors associated with starting new and stopping ineffective/unnecessary non-pharmacological and pharmacological treatments. One hundred and thirty-four nursing home residents with dementia and 39 nurses from 12 nursing homes in the Midwest participated in this study. Resident and nurse process data were collected on daily tracking forms completed by the primary nurse over a six week period. Of the 134 study participants, 56 (41.8%) had non-pharmacological and pharmacological treatments stopped and 93 (69.4%) residents had between 1 and 12 treatments started. More pharmacological treatments were stopped (n = 50) than non-pharmacological treatments (n = 37). Of the new treatments started/added to the care of these residents, 172 were non-pharmacological and 129 were pharmacological. Among the individual resident characteristics of age, Mini-Mental Status Examination score, length of stay, and total comorbid conditions, the only significant association was between resident total comorbid conditions and new treatments started (r = -.176, p <.05). After accounting for the random effect of nurse and exposure effect for days of resident study participation, two nursing processes (assessment-driven treatment and evaluation-driven follow through) were significantly associated with both treatments stopped and new treatments started. The nurse serves an essential role in maintaining resident physiological and psychological homeostasis by vigilantly responding to residents’ physical problems and behaviors with assessment-driven treatment and evaluation-driven follow through.

Accelerometer-Based Physical Activity in a Large Observational Cohort (ACTIFE-ULM) – Associations with Polypharmacy

M.D. Denkinger, K. Rapp, R. Peter, T. Nikolaus, J. Agapie, Bethesda Hospital, Ulm, Germany, 2. Institute of Epidemiology, Ulm, Germany, 3. Robert Bosch Krankenhaus, Stuttgart, Germany

Background: Physical activity (PA) is an important predictor of healthy ageing, while polypharmacy may be a problem in older people.
The association of PA with certain medication groups and polypharmacy has rarely been studied. Methods: We have set up a population-based observational study in 1502 community dwelling older persons (65 to 90 years) stratified for age and sex. The study has a cross-sectional part (1) which focuses on PA and disability and two longitudinal parts (2) and (3). The primary information for part (2) is a prospective 1 year falls calendar including the assessment of medication change. Primary variables of interest include disability, PA, falls and others. All major geriatric domains have been considered at baseline including a detailed assessment of medication and novel measures such as accelerometer-based PA sensors, carried continuously over a one week period and accompanied by a prospective activity diary (Denkinger et al. 2010, BMC Geriatrics, 10(1), 50) Results: Preliminary analyses of n=995 participants show a well functioning population. Mean age was 75.5 years (SD 6.7), 46% were female, mean MMSE was 28.1 points (SD 1.91; 5.2% below 24 points), mean handgrip strength was 34.1 kg (SD 11.9), mean gait speed was 0.97 m/s (SD 0.28). Active time walking was 107 minutes (females 106 min., males 108 min), active time standing was 278 min. (females 307 min., males 255 min.). As the study is ongoing, analyses of certain medication patterns and association with PA are currently conducted and will be available at the conference.

Discussion: The assessment of PA using a high standard accelerometer-based device is feasible in a large population-based study. Preliminary analyses show differences in physical activity according to gender. The design of the study and above mentioned associations will be demonstrated at the conference.

SESSION 2410 (PAPER)

DEALING WITH DIFFICULT DECISIONS

ATTITUDES AND BELIEFS THAT AFFECT ASSENT TO BRAIN DONATION AMONG FOUR ETHNIC GROUPS

If we could prevent Alzheimer’s disease, we would dramatically enhance the quality of life for many older adults. In many Alzheimer’s disease longitudinal studies, brain autopsy provides critical clinical and neuropathological comparisons. People from minority ethnic groups have been under-represented in this research, especially in their agreement to donate their brain. This presentation will report on a study of attitudes and beliefs about brain donation of research subjects from four NIH-funded Alzheimer’s Research Centers. Focus groups were conducted with Caucasian, African American, Hispanic and Chinese subjects who have assented and those who have not assented to donate their brain. We also interviewed their family members. The interviews were tape-recorded, translated (as necessary), transcribed, and entered into NVIVO qualitative software for analysis. The focus groups explored perspectives about brain donation, including their reasons for agreeing and reasons for not agreeing to donate their brain. Factors included participants’ experiences in being asked to donate their brain; religious beliefs; concerns about how the body is treated during the autopsy process; and how people feel about health providers, researchers and healthcare institutions. The results of the focus groups will be used to construct a survey instrument to compare differences among ethnic groups in assent to brain donation. Ideas about effective ways to approach potential study volunteers from different ethnic groups will be discussed.

ALZHEIMERS ORGANISATIONS AND PREVENTING SOCIAL DEATH

A. Kirkman, Social and Cultural Studies, Victoria University of Wellington, Wellington, New Zealand

This paper examines the concept of social death as it is applied to people with dementia and examines the role of Alzheimer’s organisations in reducing this practice. Social death has been described by sociologists as the situation where people are treated as corpses while still alive. Characteristics that lead people to become socially dead as those such as a lengthy terminal illness, becoming very old and those suffering from loss of their essential personhood. The paper demonstrates that while examples of social death persist, the increased exposure to, and awareness of dementia, brought about through the work of advocacy organisations like Alzheimers New Zealand has helped reduce this conception of people with Alzheimer’s disease as bodies without selves. The paper draws on qualitative data gathered from a range of sources over a five year period including a survey of paid community workers for Alzheimers New Zealand, along with in-depth interviews of quantity of the respondents to this survey; analysis of newsletters and websites from Alzheimer’s organisations; and media coverage of dementia. The paper illustrates the role that advocacy organisations have in enabling people with dementia through the ideal of person-centred care and the more recent ideal of full citizenship rights for people with dementia. Problems resulting from associating dementia with the ageing process are also identified.

THE INFLUENCE OF GENDER ON DECISION-MAKING BY COUPLES LIVING WITH DEMENTIA

L. Warren, 1. G.M. Boyle, 2. Sociological Studies, University of Sheffield, Sheffield, United Kingdom, 3. University of Bradford, Bradford, United Kingdom

Recent changes in mental capacity policy and law in the UK and internationally have highlighted the importance of facilitating decision-making by people with dementia. However, whilst there is a better awareness of their decisional capacity, there has been little recognition of the role played by social factors - particularly gender - in influencing their involvement in, and control over, decision-making in their everyday lives. This paper will report initial findings from a 2-year qualitative study being undertaken in England which explores the extent to which decision-making by people with dementia (and their partners) is not simply a cognitive process, but is also a social process, influenced by social and economic factors. The study was funded by the UK Economic and Social Research Council. Ethnographic methods (participant observation and interviews) were used to examine in-depth the types of decisions that couples living with dementia make on a daily basis and the processes by which these decisions were made. The paper highlights the important influence of gender on their decision-making and the dynamic and interactive processes by which everyday decisions are negotiated or made, and the tensions and conflicts which can arise. The authors highlight how both partners (with or without dementia) seek to exercise agency within the relationship and the key role of gender in facilitating or constraining personal agency. The authors draw parallels between decision-making in couples living with dementia and decision-making in intimate relationships more generally.

ADDRESSING THE CONTINUUM OF CANCER CONTROL IN DIVERSE COMMUNITIES: TASKS OF LAY PATIENT NAVIGATORS

Cancer affects many older people, but the US cancer care system is complex and difficult to navigate. Cancer Patient Navigation (PN) programs train and sponsor individuals to help cancer patients navigate the cancer care system, and programs show good outcomes. Some PN programs use lay navigators (i.e. those without a clinical license); how-
however, there is limited literature on the key tasks that lay navigators can be trained to perform. We employed two conceptual frameworks to guide data collection from five PN programs across the US. These served Native Hawaiians in Hawaii, African Americans in North Carolina, Native Americans in the Western US, and Hispanics in 6 US sites. The frameworks helped us organize tasks by phases of the cancer care continuum (education and outreach, screening, diagnosis and staging, treatment, survivorship, and end-of-life) and intent to make cancer services understandable, available, accessible, affordable, appropriate, and accountable. We also gathered case studies. The similarities and differences of the five PN programs are described. Tasks are presented by phase of the cancer care continuum. Variation in approaches used for different ethnic groups are illustrated through case studies. Findings show that lay navigators performed similar tasks but that their specific approaches reflect differences in community context, program setting, and funding. Detailed task lists can inform the development of programs, job descriptions, training, and evaluation. They also may be useful in the move to certify navigators and establish mechanisms for the reimbursement of navigation services.

SESSION 2415 (SYMPOSIUM)

NEW PERSPECTIVES ON CARE WORKER-RESIDENT RELATIONSHIPS IN NURSING HOMES
Chair: T.J. Roberts, School of Nursing, University of Wisconsin - Madison, Madison, Wisconsin
Co-Chair: J. Meyer, City University, London, England, United Kingdom
Discussant: B. Mc Cormack, University of Ulster, Jordanstown, Northern Ireland, United Kingdom

Current culture change efforts in the nursing home industry are inspiring transformations in care philosophies to support and value the development of care worker-resident interpersonal relationships. Evidence indicates that these changes can improve quality of life and create person-centered cultures. Whilst resources are being devoted to these efforts, there is a dearth of literature about the strategies that are successful for care workers to develop relationships with residents. In addition, strategies for evaluating the effectiveness of relationships, as well as the outcomes arising are poorly articulated. The purpose of this symposium is to present international and interdisciplinary perspectives on relationships, presenting studies that will extend existing knowledge of care worker-resident relationships. The first will demonstrate the application of interdependence theory to explain relationship development. The second will illustrate strategies for successful relationship development, with the testing of a relationship skill-based intervention. The third, drawing from Humanistic theories, will describe the development of humanistic relationship instruments to measure care worker-resident relationships. The last presentation will be a grounded exploration of resident definitions of relationships and subsequent outcomes. Our discussion will be guided towards generating new understandings of person-centered cultures in nursing homes and the place of care worker-resident relationships in these cultures.

NICE AIDES AND AIDES RESIDENTS REALLY CONNECT WITH: NURSING HOME RESIDENTS DEFINE RELATIONSHIPS
T.J. Roberts, B. Bowers, School of Nursing, University of Wisconsin - Madison, Madison, Wisconsin

Relationships between aides and residents in nursing homes are being given greater precedence in long term care. However, what is meant by “relationship” is not often defined, nor is there a clear understanding of how relationships influence outcomes for residents. A grounded theory study was conducted to explore how residents define and benefit from relationships with aides. Residents were theoretically sampled from several nursing homes and data were analyzed using dimensional analysis. Residents described existence of several different types of relationships. Only in some relationships did they describe deep interpersonal connections with aides. However, deep connections were not always desired or necessary. Residents felt closest to aides who made them feel a part of their lives and did “little things” for them beyond that required by their jobs. Interpersonal connections were important to residents for improving their overall experience of care and quality of life in a nursing home.

MEASURING NURSE-PATIENT RELATIONSHIP SCALES IN CHRONIC CARE
V. Boscart, D. Pringle, K.S. McGilton, E. Peter, F. Wynn, Faculty of Nursing, University of Toronto, Toronto, Ontario, Canada

Quality of life of residents in residential settings is determined largely by the relationships they have with nurses. Given the importance of these relationships, there is an absence of valid and reliable scales to evaluate the effectiveness of these relationships. The purpose of the research reported here was to understand how residents experienced their relationships with nurses and to develop measures to determine what qualities of relationships between residents and nurses were most important. Humanistic Nursing Theory served as a foundation to develop the ‘Humanistic Relationship Importance Scale’ and the ‘Humanistic Relationship Experience Scale’. Relational availability was rated as the most important factor in the nurse-patient relationship although all factors were important to residents. Mean scores indicated that residents’ experience a moderate level of humanistic connection in terms of nurses who generally care for them. Findings from this study contribute to a better understanding of the nurse-patient relationship, and the development of knowledge about relationships in these environments.

APPLYING INTERDEPENDENCE THEORY TO GERIATRIC NURSE ASSISTANT/RESIDENT RELATIONSHIPS
L.J. Medvane, C.K. Coleman, Psychology, Wichita State University, Wichita, Kansas

The present study was concerned with the applicability of interdependence theory for understanding the quality of certified nursing assistant (CNA)/resident relationships in long term care facilities. Interdependence theory, a social psychological theory, has been applied to a variety of relationships. It provides an account of how trust, commitment, closeness and cognitive interdependence (feelings of “we” and “family”) develop in relationships. Seventeen socially skilled CNAs from nine facilities participated in structured interviews. All of the CNAs said they had developed close relationships with some residents. Structured content analysis indicated that CNAs’ thought “relationality” about their interactions with residents. CNAs made reference to commitment and behaviors which promoted relationships, and their responses supported the applicability of interdependence theory. Future research should explore CNAs’ experiences of boundary issues – e.g. being both friends and caregivers. Implications for training are that CNAs should be encouraged to think relationally, as well as dispositionally.

AN INTERPERSONAL PERSON-CENTERED CARE INTERVENTION FOR GERIATRIC NURSE AIDES
C.K. Coleman1, L.J. Medvane2, 1. University of Kansas School of Nursing, Kansas City, Kansas, 2. Wichita State University Department of Psychology, Wichita, Kansas

The goal of this study was to further define interpersonal person-centered care by developing and pilot testing a training intervention for geriatric nurse aides. The training was developed to incorporate content regarding person-centered behaviors, knowing the residents, and understanding relationships. The pilot testing of this intervention was implemented by using a quasi-experimental, waitlist control design in two

64th Annual Scientific Meeting 631
SESSION 2420 (SYMPOSIUM)

SOCIAL RELATIONSHIPS AND RESIDENT HEALTH IN ASSISTED LIVING

Chair: C.L. Kemp, The Gerontology Institute, Georgia State University, Atlanta, Georgia
Co-Chair: M.M. Perkins, The Gerontology Institute, Georgia State University, Atlanta, Georgia
Discussant: T. Antonucci, University of Michigan, Ann Arbor, Michigan

Assisted living (AL) is an increasingly popular long-term care setting for the growing population of frail elders in the United States, and available research indicates that residents' social ties, especially coresident ties, are important to their overall well-being. Yet, few studies, have examined social relationships in AL in depth, and none has focused specifically on how these relationships impact residents' health. This symposium presents key findings from two NIA-funded projects that investigate the impact that social relationships have on residents' health. We define health broadly to include physical, mental, and sexual health, as well as social well-being. One project (1R01 AG030486-01) is a 3-year study that incorporates both qualitative and quantitative methods, and includes social network mapping. Data includes 3,600 hours of observation and interviews with 244 residents and 32 providers from 9 facilities in metro Atlanta. A second project (R21 AG03017-01), also conducted in metro Atlanta, involves 6 homes and focuses on sexual relationships. Data from this 2-year study include 173 hours of observation and 67 interviews with residents, providers, and family members. The symposium consists of four papers in addition to an overview of study methods and a discussion by a leading scholar in the area of social relations and health. Papers address: (1) how couplehood shapes residents' social lives and well-being; (2) challenges of intergenerational communication about sex; (3) the impact of death and decline on residents and the AL social environment; and (4) a test of Antonucci's (1985) Convoy of Social Support model.

"MY DAY REVOLVES AROUND WHAT SHE'S GOING TO DO": COUPLEHOOD AND SOCIAL LIFE IN ASSISTED LIVING

C.L. Kemp, M. Ball, M.M. Perkins, N.K. Sandhu, A. Meadows, The Gerontology Institute, Georgia State University, Atlanta, Georgia

Although a minority, married and unmarried couples frequently reside in assisted living (AL) communities. Yet little is known about how couplehood influences social experiences in these settings where most residents are uncoupled. This paper presents an analysis of ethnographic data from our study on social relationships involving eight AL communities. We consider how couplehood affects residents' social lives and coresident relationships. Findings suggest that being coupled sets residents apart from others in terms of daily routines, social behaviors, and relationships. Couples have "built-in-partners", but interdependence or one partner’s dependence on or concern for the other typically limits coresident relationships, especially in the context of health decline. Marriage and dating often meet with different social receptions. While marriage is admired, certain residents, particularly widows, tend to express disapproval and gossip about unmarried couples. Based on our findings, we discuss strategies for promoting positive relationships for coupled and uncoupled AL residents alike.

"THIS IS OUR LAST STOP.“: DEATH AND DYING IN ASSISTED LIVING

M. Ball, M.M. Perkins, C.L. Kemp, C. Hollingsworth, V. Stanley, Y. Paye, Gerontology Institute, Georgia State University, Atlanta, Georgia

Increasingly residents with greater physical and cognitive impairments are being admitted to assisted living (AL), and recent estimates show that from 14-22% of residents die in AL each year. This paper investigates the experience of residents who are dying and the impact that the changing landscape of AL and the death experience is having on other residents, staff, and family members in eight diverse AL settings where from 0%-25% of residents died over a one-year period. Although acknowledgement of death varied across sites and responses of residents and staff typically depended on prior relationships, the presence of decline and death was a pervasive influence on residents' social networks and the social milieu. Hospice care, available in all facilities and used by the majority of residents who died, enhanced residents’ quality of care and life and ability to die in AL and relieved the burden of families and AL staff.

"NOT MY MOTHER:" CHALLENGES OF INTERGENERATIONAL COMMUNICATION ABOUT SEX AND INTIMACY IN ASSISTED LIVING

E.O. Burgess, A.A. Bender, C.E. Barmon, M. Xavier-Brier, Gerontology Institute, Georgia State University, Atlanta, Georgia, 2. Georgia State University - Sociology, Atlanta, Georgia

In assisted living facilities (ALFs) administrators, staff, and family members are often significantly younger than the older residents. This age gap leads to different approaches to care, health and well-being. Using observational and interview data from six ALFs, this grounded theory project analyzes how generational norms and values about sexuality, intimacy and aging influence how families and providers communicate with and about older adult residents’ sexuality. We found that younger generations had more difficulty with intergenerational dialogue about sex than older residents and the majority of communication about older adult sexuality relies on stereotypes. As a result of the discomfort and ageism in intergenerational communication about sex, older residents are infantilized and patronized. This can reinforce residents’ loss of independence and reduce well-being. Intergenerational communication about sex is further constrained by racial, ethnic, religious, and class differences. We conclude by discussing the importance of education and training about sexuality.

AN EXAMINATION OF THE CONVOY MODEL OF SOCIAL RELATIONS IN ASSISTED LIVING

M.M. Perkins, M. Sweatman, M.M. Ball, C.L. Kemp, Gerontology Institute, Georgia State University, Atlanta, Georgia, 2. Emory University, Atlanta, Georgia

We use a modified version of Antonucci’s (1985, 2001) Convoy Model of Social Relations to analyze the relationship between AL residents’ overall life satisfaction and five types of predictors: (1) personal characteristics, (2) situational characteristics, (3) network structure, (4) network function, and (5) network adequacy. Data for this study come from an NIA-funded project (1R01 AG030486-01) that investigates social relationships in AL and is the first study in this setting to use Antonucci’s (1986) social network mapping tool. The study sample includes 193 residents from 9 AL facilities in metro Atlanta. Results of hierarchical multiple regression analysis largely support the relationships proposed in our conceptual model. Findings show that age, perceived health, network size, and perceived availability and adequacy of emotional support are important determinants of overall life satisfaction. The final model predicts 29% of the variance in this outcome. Findings have important implications for resident health and well-being.
The symposium opens with a global view of elder justice summits and coalitions. The lead investigator in the first national study of these collaboratives will summarize data on their origins, accomplishments and predictors of success. The next presentation will describe the California Elder Justice Work Group start-up year, with a lens on organizing, mobilizing, focusing, and funding. Following that, the Coordinator of Minnesota’s Vulnerable Adult Justice Project will describe issues confronted in a maturing coalition, such as maintaining purpose and focus, committing to inclusion and compromise. New York State’s sustained elder justice work has reached its second summit. The following presentation by its Coordinator will examine the similarities and differences over time. To conclude, the discussant will offer perspectives on the implications of the Elder Justice Act and the Reauthorization of the Older Americans Act for the future of elder justice summits and coalitions.

State-Level Elder Abuse Summits or Task Forces: A National Overview
G. Anetzberger, Health Care Administration Program, Cleveland State University, South Euclid, Ohio

Using results from a national survey, this presentation will describe the formation, structure, and impact of state-level elder abuse summits and task forces. Forty percent of states have convened summits, with an addition 13% holding regional or local events to address elder abuse issues. Typical summit activities will be discussed, including tasks undertaken to implement recommendations. Ohio will be used to illustrate such efforts.

Forging the California Elder Justice Workgroup
A.E. Navarro, University of Southern California, Los Angeles, California

The California Elder Justice Workgroup (CEJW) was launched in October 2009 to protect the rights, independence, security, and well-being of vulnerable elders in California by improving the response of legal, long-term care, and protective service systems. Efforts escalated with an Elder Abuse Summit April 2010, which convened delegates from across the elder abuse and aging and adult services spectrum to discuss and collaborate on California’s Elder Abuse Blueprint. The finalized blueprint informs local, state, and national program developers, policy makers, foundations, and other stakeholders in planning future policy, program, and research initiatives. February 2011 marked the launch of the blueprint at the hearing of the Aging & Long-Term Care and Public Safety Committee; addressing Assembly members and stakeholders from law enforcement, District Attorneys, APS, Ombudsman, Bureau of Medi-Cal Fraud and Elder Abuse, and Advocacy Organizations. Selection of a home agency for the work of CEJW is now underway.

Minnesota's Vulnerable Adult Justice Project
I.C. Freeman, William Mitchell College of Law, Minneapolis, Minnesota

The Vulnerable Adult Justice Project (VAJP) began in late 2007 as a diverse stakeholder group organized to revise the state’s Vulnerable Adult Act and related laws. Its initial legislative effort, the product of months of consensus building, resulted in Chapter 119, Laws of Minnesota, 2009. The legislation tackled the growing problem of financial exploitation, expanded community notification when vulnerable adults are missing, and established the model for a streamlined reporting and response system. The VAJP has since become a regular forum where diverse professionals meet to identify service gaps in the protection of vulnerable adults, identify flaws in the underlying public policies, and actively promote policy changes. This presentation addresses elder justice coalition issues in the process of taking root: maintaining purpose and focus, the stresses of inclusion and the work of compromise.

The Sum of Their Parts (NY, Second Summit)
A. Mason, Elder Abuse Prevention Program (EAPP), Lifespan, Rochester, New York

New York State’s second Elder Abuse Summit in November 2010 was a follow up and update of the 2004 Summit. The 2004 Summit set 10 priorities, including creating a state Prevalence & Incidence Study and and forming a statewide Coalition. The 2010 event updated and reviewed those priorities and created new areas of focus, based on the results of the Prevalence and Incidence Studies.
