SESSION 5 (SYMPOSIUM)

“I WANT TO CONTINUE TO CARE FOR HER AS LONG AS I CAN”: LESSONS LEARNED FROM AFRICAN AMERICAN AND WHITE CAREGIVERS IN THE SOUTH CAROLINA ALZHEIMER’S DISEASE REGISTRY

Chair: S. Spencer, University of South Carolina, Columbia, South Carolina
Discussant: T. McCallum, Case Western Reserve University, Cleveland, Ohio

In 2012, the Alzheimer’s Association estimated that caring for the 5.4 million people in the U.S. who are living with Alzheimer’s disease (AD) totaled $200 billion in direct costs alone. It is unclear how the long-term care system is going to cope in 2050 when the number of individuals with AD is expected to increase to 16 million. What is certain is that there is a critical need to support family caregivers who provide supervision and personal care to their loved ones at home, and research is needed to better understand the factors which can delay or prevent the transition of persons with AD from the community into long-term care facilities. The purpose of this symposium is to explore the factors which contribute to caregiver distress and affect the long-term care decisions of African American and White caregivers. The South Carolina Alzheimer’s Disease Registry is a population-based, statewide registry of residents diagnosed with AD or related disorders. Each of the presentations in this symposium used data from this registry, which is the most comprehensive registry of its kind in the U.S. These data presented the unique opportunity to explore issues of caregiver health and decision-making using a sample of African American and White caregivers who either placed their family members with AD in a long-term care facility or continued providing care at home. Understanding the factors which play into long-term care transitions can be used to support caregivers and the vital role that they play in the long-term care system.

CAREGIVERS’ PERSPECTIVES ON THE ROLE OF BEHAVIOR DISTURBANCES ON NURSING HOME ADMISSION OF PERSONS WITH ALZHEIMER’S DISEASE

C.N. Porter, M.C. Miller, S. Spencer, University of South Carolina, Columbia, South Carolina

Objective: To evaluate use of the Neuropsychiatric Inventory (NPI) to identify behavioral disturbances associated with nursing home (NH) admissions of persons with Alzheimer’s disease (AD), while accounting for caregiver factors. Methods: Study participants included 705 older adults from the SC AD Registry who were eligible for NH care and had a caregiver. Cases entered a NH within 6 months of study initiation; controls resided in the community. Registry data combined with prospective data collected via survey of caregivers was analyzed using conditional logistic regression. Results: A 10% increase in NPI score implied a 30% increase in odds of NH admission. Key individual behavior disturbances were predictive of NH admission, along with having married and male caregivers. Discussion: Few studies have characterized and quantified symptom severity in relation to actual NH admission for persons with AD. Results indicate behavioral disturbances are predictive of NH admission, but key caregiver factors are influential.

THE INFLUENCE OF SUBJECTIVE U.S. AND COMMUNITY SOCIAL STATUS ON DEPRESSIVE SYMPTOMATOLOGY AMONG AFRICAN AMERICAN AND WHITE CAREGIVERS

S. Spencer*, C.N. Porter*, M.C. Miller*, 1. University of South Carolina, Columbia, South Carolina, 2. Office for the Study of Aging, Columbia, South Carolina

Subjective social status (SSS) has been associated with psychological functioning and health-related outcomes, yet little is known about how different measures of SSS might operate in the caregiving context. Data from 271 African American and 283 White caregivers (M age = 59.5 years) were analyzed to determine whether racial variations exist in the association between SSS and depressive symptomatology. SSS was measured using both the U.S. and Community SSS ladders, and depressive symptomatology was measured using the Center for Epidemiologic Studies Depression Scale (CES-D). Results of a linear regression indicated that racial differences emerged for specific caregiver-related factors. Higher caregiver competency and higher Community-SSS were significantly associated with depressive symptomatology among African American caregivers, while among White caregivers, higher U.S.-SSS was associated with depressive symptomatology. These findings suggest that different measures of SSS might be more relevant to the psychological health of African American compared with White caregivers.

CARING FOR INDIVIDUALS WITH ALZHEIMER’S DISEASE AT HOME: A MIXED METHODS STUDY OF CAREGIVERS AND CARE RECIPIENTS

M.C. Miller, C.N. Porter, S. Spencer, Epidemiology and Biostatistics, University of South Carolina, Columbia, South Carolina

A mixed methods study was conducted to examine reasons why caregivers of individuals with Alzheimer’s disease (AD), enrolled in the South Carolina AD Registry, decide to care for their loved one at home (n=316) rather than place them in a nursing home (n=389). A quantitative analysis using logistic regression indicated that the strongest predictors of providing care at home were: caregiver education (odds ratio [OR] = 1.84; 95% confidence interval [CI], 1.14–2.95), employment (OR = 0.56; CI, 0.36–0.87), spousal relationship (OR = 2.29; CI, 1.45–3.63), care recipient’s bowel continence (OR = 2.89; CI, 1.77–4.69) and household size (OR = 1.36; CI, 1.10–1.69). The main qualitative themes identified were: sense of obligation (n=161), belief of better care at home (n=53), and opportunity to provide care (n=27). These results provide both quantitative and qualitative insight into the decision-making process of caregivers of persons with AD.
SESSION 10 (SYMPOSIUM)

A PRIMER ON THE WISCONSIN LONGITUDINAL STUDY: OVER 50 YEARS OF SOCIAL DATA COMBINED WITH GENETIC DATA

Chair: C. Roan, Sociology, University of Wisconsin, Madison, Wisconsin
Co-Chair: P. Herd, Sociology, University of Wisconsin, Madison, Wisconsin

The Wisconsin Longitudinal Study is an important data source for understanding optimal aging. The study is a sample of one in three Wisconsin high school graduates, and a selected sibling, from the class of 1957. WLS is unique among major social scientific resources for the length with which it has followed a large population-based cohort sample and that it includes siblings. We recently released the latest round of data collected between March of 2010 and December of 2012. The new data include anthropometric and functioning measures which add yet a new dimension to the many types of WLS data. The data cover nearly every aspect of the participants’ lives from early life socioeconomic background, schooling, family and work to health, social participation, civic engagement, well-being, and cognition. The study also has a wealth of unique data including examples such as administrative IQ scores from high school, information collected from high school yearbooks that include measures of attractiveness, proxy measures for obesity, and complete lists of student activities for all respondents. Examples of administrative data include Medicare records, Social Security records, and resource data on primary and secondary schools attended by participants. Additionally, the DNA data can be merged with fifty-five years of social data. This session will introduce the study to researchers who are not familiar with the data by providing an overview of the study as well as practical information on the structure of the data. Attendees will be provided with a USB containing documentation and the data.

AN OVERVIEW OF THE WISCONSIN LONGITUDINAL STUDY

P. Herd, UW-Madison, Madison, Connecticut

The WLS provides a unique and central source of data for scholars of aging, across multiple disciplines. WLS is based on a 1/3 sample of all 1957 Wisconsin high school graduates (N=10,317) and a sibling of these graduates. The graduate respondents were originally empaneled with an in-person questionnaire at age 18 (1957), which was followed with data collection at ages 25, 54, and 65, as well as a spouse telephone survey at age 65. An in-person survey exited the field in late 2012. A central advantage to these data is their 55 year (1957-2012) longitudinal nature, the breadth of measures, and subsamples focused on special populations. The content of WLS surveys has changed to reflect the life course of participants: education provided the impetus for the initial data collection (1957), familial and career outcomes received greater attention from respondents in young adulthood (1975/1977) and midlife (1993), and later rounds have given increased attention to respondent’s health, cognitive status, psychological well-being, non-work activities, caregiving, bereavement, social support, and end-of-life preparations (2003, 2011). The study also now includes genetic data.

HOW TO ACCESS AND USE DATA FROM THE WISCONSIN LONGITUDINAL STUDY

C. Roan, H.V. Chang, Sociology, University of Wisconsin, Madison, Wisconsin

With over 27,000 analysis variables covering more than 55 years of data, new users of the WLS data may find themselves overwhelmed when looking for the measures they need to answer their research questions. We will give detailed instructions on how to use the tools and reference materials developed by WLS staff. Attendees will learn how to search for analysis variables, where to find copies of the survey instrument online, and how to download the public data. We will also explain the organizational structure of the data, variable naming conventions, and offer recommendations on how to break the data into smaller pieces if your computing resources are limited. Participants in this symposium will also learn about the differences between publically available data and data available only by application. Finally we will explain how to apply to use the genetic data and other non-public data.

SESSION 15 (SYMPOSIUM)

ACTIVITY ENGAGEMENT IN MIDLIFE AND OLD AGE: TOWARD NEW CONCEPTS, MEASURES, AND INTERPRETATIONS

Chair: J. Smith, Institute for Social Research, University of Michigan, Ann Arbor, Michigan
Discussant: E. Stine-Morrow, Institute for Social Research, University of Michigan, Ann Arbor, Michigan

Research highlights the importance of activity engagement for the maintenance of cognitive functioning, physical health, and successful aging. However, there is little consensus about definition and measurement of this concept. Typically, engagement is operationalized as frequency, intensity, or duration but because most studies are cross-sectional these indicators often reflect memory biases. Popular methods for quantifying activities in large-scale studies include diaries and multiple-item checklists but the representation of activities in these methods is not uniform. Efforts to form generic activity categories such as physical, cognitive, social, productive, or leisure highlight the inherent multi-dimensionality of most activities. Attempts to specify mechanisms for activity-related effects point to dynamic associations with social-environmental contexts and outcomes. Speakers in this session describe innovative approaches. Three presenters analyze longitudinal data from the Health and Retirement Study. Queen and colleagues focus on the associations of arthritis with time-related changes in the composition of leisure activities. Kim and colleagues point to the joint effects of life circumstances, economic background, schooling, family and work to health, social participation, civic engagement, well-being, and cognition. The study also now includes genetic data.
THE IMPACT OF ARTHRITIS ON LONGITUDINAL CHANGES IN ACTIVITY ENGAGEMENT IN OLDER ADULTHOOD
T. Queen, R. Gonzalez, K. Langa, *Institute for Social Research, University of Michigan, Ann Arbor, Michigan*

Maintaining an actively engaged lifestyle is considered an important component of successful aging. Changes in health that are common in older adulthood may constrain the activities in which older adults can participate. Using six waves of time-use data collected in the Health and Retirement Study, a nationally representative sample of adults 51 and older, we compare longitudinal trajectories of activity engagement in response to arthritis. We compare change in participation in different domains of activities including physical, social, and sedentary leisure activities and cognitive activities varying in demand. Over time, the proportion of physical leisure activities declines for those with arthritis whereas the proportion of sedentary leisure activities increases over time. Interestingly, having arthritis also influences long-term participation in cognitively demanding activities, suggesting that those with arthritis reallocate time from less physically demanding to more cognitively enriching activities. The influence of severity of symptoms will also be discussed.

INTERACTIONS BETWEEN LIFE SATISFACTION AND HEALTH BEHAVIORS ON THE FREQUENCY OF DOCTOR VISITS
E.S. Kim, N. Park, J.K. Sun, C. Peterson, *Psychology, University of Michigan, Ann Arbor, Michigan*

Concerns about sustainable, high-quality healthcare have led to a search for new ways of alleviating our burdened healthcare system. Life satisfaction has been linked with good health, but its association with healthcare use has not been investigated. Using data from the Health and Retirement Study, we examined whether higher life satisfaction was associated with fewer doctor visits over a four-year follow-up period (n=6,379). Analyses adjusted for a large array of covariates. We also examined potential interactions between life satisfaction and health behaviors. After adjusting for age, gender, race/ethnicity, marital status, education level, and total wealth, respondents reporting the highest life satisfaction made 43% fewer doctor visits than those reporting the lowest life satisfaction. Furthermore, an interesting interaction emerged among adults who did not exercise and drank the most. Life satisfaction may reduce the frequency of doctors visits, and consequently play an important role in alleviating our burdened healthcare system.

TRAJECTORIES OF PHYSICAL ACTIVITY AND MEMORY: THE ROLE OF PAIN
L.H. Ryan, J. Smith, *Institute for Social Research, University of Michigan, Ann Arbor, Michigan*

The experience of pain is highly prevalent from midlife to old age, and has been associated with lower levels of physical activity. However, its associations with cognitive performance are mixed. The current study extends prior work by simultaneously examining associations of pain with trajectories of memory and frequency of physical activity over 6 years. Data from the Health and Retirement Study were used, selected if respondents were aged 50+ in 2004 and included data from 4 waves (2004 to 2010). The sample (N=12431) was 61% women with an average age of 65.4 (SD=9.4; Range=50–102). Multivariate multilevel models found that individuals aged 70+ had lower levels of both memory and physical activity. Overtime, both memory and physical engagement declined. Over and above age, time-in-study, gender, education, and self-rated health, pain severity was associated with less physical activity, but higher levels of memory in the 70+

ACTIVITY IN COMMUNITY SPACES IS ASSOCIATED WITH BETTER COGNITIVE HEALTH THAN ACTIVITY IN HOME AND IN TRANSIT
M. Carlson, V.R. Varma, A. Adam, *Center on Aging and Health, Johns Hopkins University, Baltimore, Maryland*

We report on the results of a pilot study of daily activity conducted in 18 neurocognitively and functionally well-characterized older, community-dwelling adults using small, wearable accelerometer and GPS devices to continuously collect up to 5 days of activity. After data collection, ArcGIS was used to identify community locations visited (e.g. church, mall, grocery store) in order to develop mobility provides for participants by daily amount of time and activity spent 1) in home; 2) transit outside home; 3) in well defined community spaces outside the home. We correlated these metrics with measures of neurocognitive health and observed the strongest positive correlations for activity in community spaces vs in home as well as community spaces vs total daily activity independent of location. Our results indicate that obtaining real-time information about where and when daily activity occurs in one’s social environment will provide vital information to help promote activities that are beneficial to cognitive and functional health.

SESSION 20 (SYMPOSIUM)

AGE AND CUMULATIVE DIS/ADVANTAGE: NEW ISSUES, NEW QUESTIONS, NEW FINDINGS
Chair: D. Dannefer, Department of Sociology, Case Western Reserve University, Cleveland, Ohio
Co-Chair: S. Crystal, Rutgers University, New Brunswick, New Jersey
Discussant: P. Uhlenberg, University of North Carolina, Chapel Hill, North Carolina

The past several years have seen a rapid increase in interest in the cumulative dis/advantage perspective developed in gerontology in the 1980s and 1990s. This perspective is based on research demonstrating how the effects of initial advantages can cumulate over the life course, producing increased levels of economic inequality in the retirement years, and the role of specific social policies and practices in producing such cumulative effects. Research has also shown that health inequality increases in the later years; and that the effects of early educational advantages increase into the retirement years. While the general idea of cumulative dis/advantage as a cohort-based, life-course process is now quite well established, many important empirical and theoretical questions remain unresolved. Papers in this symposium respond to calls from leading gerontological scholars studying cumulative dis/advantage by presenting work that extends understanding in several significant new directions. These include 1) providing analyses of recent changes and current trends, which in the USA is especially relevant given recent dramatic societal increases in inequality which have occurred despite the somewhat leveling effect of Social Security policies; 2) examining recent data and trends in the relation of health and resources, 3) providing cross-national comparisons using HRS and ELSA (English Longitudinal Study of Ageing) data; 3) examining broader methodological developments with implications for the analysis and interpretation of data related to cumulative dis/advantage.

THE AGE PATTERNING OF INTRAINDIVIDUAL VARIABILITY IN LATE-LIFE HEALTH AND ITS RELEVANCE TO CUMULATIVE DIS/ADVANTAGE THEORY
J. Lin, J. Kelley-Moore, *Case Western Reserve University, Cleveland, Ohio*

Cumulative dis/advantage (CDA) theory predicts systematic interindividual divergence in a given characteristic over time as a result of accumulative mechanisms. In contrast, increasing intraindividual variability (IV) with age may also result in greater heterogeneity in later life in absence of CDA processes (Baltes 1979). IV and its potential age patterning have been obscured by standard modeling procedures.
that tend to smooth wave-specific responses into an average trajectory, indicating a missed opportunity to test Baltes’s counter argument to CDA theory. Using panel data from the Health and Retirement Study, we examine if age is associated with IIV over time in functional limitations, depressive symptoms and cognition. Results indicate that IIV increases with age for functional limitations and for cognition whereas decrease with age for depressive symptoms. Our findings contribute to our knowledge regarding the source of heterogeneity in late-life health and highlight the limitations imposed by comparing average trajectories between subgroups.

CUMULATIVE DIS/ADVANTAGE IN WEALTH TRAJECTORIES: COMPARATIVE DATA FROM THE UNITED STATES AND ENGLAND
J. Kelley-Moore1, J. Nazroo2, D. Dannerf2, T. Bhatta1, J. Sociology, Case Western Reserve University, Cleveland, Ohio, 2. University of Manchester, Manchester, United Kingdom

Cumulative dis/advantage perspective refers to the systematic tendency for inequality to increase as a cohort ages. Since the circumstances that allow for such inequality to accumulate are embedded in the social structure, rather than in properties of individuals, it compels us to consider how differing social structures may lead to differential patterning of inequality. To date, much of the empirical work testing cumulative dis/advantage has been country-centric, precluding comparison across nations. In this study, we undertake a cross-national comparison between the United States and England to document how and to what degree socioeconomic inequality increases among adults ages 50 and older. Using data from the Health and Retirement Study and English Longitudinal Study of Ageing, we calculate intra-cohort differentiation in wealth trajectories. In both nations, wealth inequality increases with age but the predictors of within-cohort patterns of wealth concentration differ across nations.

CUMULATIVE ADVANTAGE IN AN AGE OF INCREASED INEQUALITY: IMPLICATIONS FOR ENTITLEMENT REFORM
S. Crystal1, D. Shea2, J. Sociology, Case Western Reserve University, New Brunswick, New Jersey, 2. The Pennsylvania State University, University Park, Pennsylvania

Studies in the cumulative advantage tradition have shown that effects of initial advantages cumulate over the life course, producing increased economic and health inequality in the retirement years. During the last decade, fundamental economic shifts in the United States have led to an overall increase in income inequality of considerable magnitude. While this trend has received considerable attention in policy debates, there has been little attention to its specific implications for economic well-being for the current and future elderly population. Understanding this phenomenon is critically important at a time when cutbacks to old-age “entitlements” are being proposed. To address this issue, this presentation will review evidence from multiple U.S. and cross-national sources to trends in income inequality and health disparity. Results suggest that disparities are likely to increase in the coming years. We will discuss implications of proposed changes in Medicare, Medicaid and Social Security in light of these trends.

S. Crystal, A. Akincigil, E. Kalay, K.A. Zurlo, Rutgers University, New Brunswick, New Jersey

This paper examines trends in income inequality and the association of income and health disadvantage using data on U.S. elderly from the Medicare Current Beneficiary Survey, a large, nationally representative continuous rotating panel survey. Results indicate an increasing association of income and health disadvantage over this period, with the ratio of median income for individuals with good/excellent versus fair/poor health status increasing from 142% to 146%. The association between educational and income disadvantage also increased over this period, with the income ratio for those with some college education versus high school graduates increasing from 212% to 240%. The Gini coefficient of overall income inequality increased over this period from .43 to .45. Previous research in the cumulative advantage tradition has highlighted the high level of income inequality and strong associations among health, educational, and income disadvantage among the U.S. elderly; this study suggests exacerbation of these patterns in recent years.

SESSION 25 (SYMPOSIUM)

AGING IN MULTIPLE ENVIRONMENTAL SETTINGS: WHAT FACTORS CONTRIBUTE TO OPTIMAL AGING?
Chair: J. Norstr, Boston College, Chestnut Hill, Massachusetts
Co-Chair: M.L. Kaup, Kansas State University, Manhattan, Kansas
Discussant: S. Golant, University of Florida, Gainsville, Florida

The symposium, hosted by the Environmental Gerontology Interest Group, examines factors within diverse environmental settings important for optimal health and well-being of older adults. The diverse settings include elder co-housing communities, urban and suburban neighborhoods, Village Movement settlements, and transportation systems. Four papers addressing research projects which investigated various aspects of well-being will present a holistic picture of aging and various environmental contexts encountered by older adults. First, a study of elderly co-housing communities in the US which promote social contact to enhance optimal aging will discuss models that enhance quality of life. Next, the role of transportation services will be explored from findings associated with optimizing out-of-home mobility and differential effects of race/ethnicity and residency site. A study on physical structures within neighborhoods associated with BMI will present findings and provide an ecological model whereby neighborhoods may be advantageous environments for interventions to maximize health and well-being. And finally, features of Village Movement settlements which encourages walking and shopping, and promote aging-in-place will highlight the testing of an environmental checklist administered by occupational therapists to encourage environmental improvements that support well-being for older citizens. These studies will provide a forum to discuss those factors critical to optimal aging across settings and diverse aging populations, with the goal of developing a more comprehensive environmental framework for promoting optimal aging.

DEVELOPING A WALKING AND SHOPPING CHECKLIST FOR OLDER ADULTS
M.H. Teaford, The Ohio State University, Columbus, Ohio

Safe and pleasant walking areas are important for promoting not only physical activity and fitness, but such areas also can assist older shoppers and shopping is key to maintaining independence. Few environmental scans of urban areas have focused on the needs of older adults who are walking for exercise, shopping, visiting, or to reach mass transit. An environmental checklist is being developed and tested by occupational therapy and other health sciences students with residents in an older historic neighborhood. This neighborhood is part of the Village Movement to encourage aging in place. The purpose of the project is to identify retail hubs where city and private improvements need to be made to support older shoppers and visitors. Items include ability to cross streets safely, traffic and parking, adequate lighting, condition of sidewalks, places to rest, and signage. Presentation of case study will be included.
ROLE OF TRANSPORTATION IN OPTIMAL AGING: EFFECTS OF RACE/ETHNICITY AND SITE OF RESIDENCE
R. Marottoli1, A.P. Herrera2, 1. Internal Medicine, Yale University School of Medicine, New Haven, Connecticut, 2. VA Connecticut Healthcare System, West Haven, Connecticut, 3. University of Maryland, Baltimore, Maryland

Objective/Methods: Data from the fifth National Survey of the Older Americans Act (OAA) transportation module (N=824) were used to explore the effects of race/ethnicity and residence site on transportation service use and perceived benefit to independent living. Results: Hispanic and African American seniors using OAA transportation services were more disabled, less educated, and had fewer financial resources than their White counterparts. Whites used transportation services primarily for medical reasons, whereas Hispanics and African Americans used them more for social and recreational purposes. Suburban residents and individuals with positive interactions with transportation personnel attributed their ability to live independently to transportation availability. Conclusions: Perceived benefits of transportation differed by race/ethnicity and residence site. To best meet all older residents’ needs, metropolitan planners and transportation service providers should incorporate staff training, account for difficulties in non-urban areas, and consider the needs/preferences of culturally diverse elder populations.

ELDER COHOUSING: AN ENVIRONMENT THAT FACILITATES OPTIMAL AGING THROUGH AGING TOGETHER
A.P. Glass, University of Georgia Institute of Gerontology, Athens, Georgia

The first elder cohousing communities in the United States have recently emerged, using a design to promote social contact. A longitudinal mixed-methods study with one of the first of these self-managed intentional communities indicates that, despite challenges, the residents report many benefits. This study demonstrates how this process can occur. Identified from the interviews, better communication about aging-related issues, learning from role models, and mutual support were among the specific ways in which living in an interdependent community helps elders have a better experience with aging. A new model will be shared that illuminates the necessary foundation, as well as the process and the outcomes that can be gained through experiencing aging “in solidarity.” This model could serve as a basis for interventions that could be applied to other settings to provide a supportive new way for people to age together with an enhanced quality of life.

AREA FOOD SOURCES AND OBESITY IN COMMUNITY DWELLING OLDER ADULTS INDIVIDUAL AND NEIGHBORHOOD EFFECTS
M. Wilson Genderson1, R.A. Pruchno2, A. Gupta2, 1. VCU, Henrico, Virginia, 2. UMDNJ, Stratford, New Jersey

Obesity in older adults has been linked to the areas in which they live. Nesting of individual and neighborhood characteristics has limited understanding of the influence attributable to neighborhood. We tested hypotheses about the relationship between neighborhood-level food sources and obesity, controlling for individual level characteristics. Data derived from a random-digit-dial sample of 5,688 community-dwelling adults aged 50-74 residing in 1,644 census tracts in New Jersey. Multilevel structural equation models included latent constructs representing density of fast food establishments and storefronts and an observed indicator for supermarkets (neighborhood) while simultaneously modeling obesity and demographic characteristics (individual). Density of fast food and storefronts were both positively associated with obesity after controlling for individual characteristics; the association of obesity and supermarkets was not significant. Because people living in neighborhoods with a higher density of fast food and storefronts are more likely to be obese, these neighborhoods may be advantageous environments for interventions.

SESSION 30 (SYMPOSIUM)

EMOTIONAL UPS AND DOWNS: AFFECTIVE, PHYSIOLOGICAL, AND BEHAVIORAL RESPONSES TO UPLIFTS AND STRESSORS
Chair: G. Luong, Affect Across the Life Span Research Group, Max Planck Institute for Human Development, Berlin, Germany
Co-Chair: A. Rauers, Affect Across the Life Span Research Group, Max Planck Institute for Human Development, Berlin, Germany

Previous research suggests that responses to emotional events differ with age. This symposium will illustrate the multidimensionality of emotional responses across the life-span. The presented studies will address subjective, physiological, and behavioral responses to emotional events, using a broad variety of methodological approaches such as experimental paradigms, daily diaries, experience-sampling longitudinal measurement bursts, and dyadic experience-sampling. Using various time scales ranging from minutes to years, the presented studies will highlight qualifying factors for responses to emotional events and explore short- and long-term developmental implications of different facets of emotional responding. Cannon and Isaacowitz will present experimental data investigating adult-age differences in physiological reactivity to emotional and informational videos about skin cancer. Bergeman and colleagues will present associations of stress-regulation with primary (e.g., inflammatory markers), secondary (e.g., glucose tolerance, circulating cholesterol) and tertiary health outcomes (e.g., diabetes, cardiovascular disease) in a daily diary study. Schilling and Diel will highlight the differential role of beliefs of control and self-concept incoherence for emotional reactivity to acute and accumulated daily stress in a daily-dairy study. Luong and colleagues will discuss age differences in emotional reactivity to everyday positive events (i.e., uplifts) and longitudinal changes in these associations. Rauers and Riediger will present data from a dyadic experience-sampling study showing that younger and older couples’ communication about daily uplifts and hassles prospectively predicts partnership development.

PHYSIOLOGY-ATTENTION LINKS IN YOUNGER AND OLDER ADULTS VIEWING NEGATIVE HEALTH INFORMATION
M.S. Cannon1, J. Harris1, Y. Cho1, D. Isaacowitz1, 1. Northeastern University, Boston, Massachusetts, 2. Brandeis University, Waltham, Massachusetts

Skin cancer is a particularly relevant health concern for both older and younger adults, with the highest rate of death from this preventable disease occurring in people over the age of 65 and the most risky behavior taking place in individuals 18-29 years of age. In the present study we examined the physiological responses of younger (N=78) and older (N=77) adults to emotional and informational videos about skin cancer. In response to both videos we found greater increases in heart rate reactivity in older adults than younger adults. In addition we assessed fixation patterns, skin cancer related knowledge and a variety of behavioral measures. Increased visual attention to negative portions of the videos was positively correlated with heart rate reactivity for older adults, but unrelated in their younger counterparts. This suggests an important age difference in the relationship between physiological arousal and attention in response to relevant health information.

66th Annual Scientific Meeting 5
THE ABILITY TO DISSIPATE DAILY STRESS ON HEALTH OUTCOMES IN LATER LIFE
C. Bergeman1, P.R. Deboeck2, 1. Psychology, University of Notre Dame, Notre Dame, Indiana, 2. University of Kansas, Lawrence, Kansas

One’s level of perceived stress depends on how many stressors are experienced (input) and the ability to dissipate the emotional arousal associated with them. Daily burst data from the Notre Dame Study of Health & Well-being, analyzed using the Reservoir Model, indicated that there were significant input and dissipation parameters. Dissipation (β = .50), dispositional resilience (β = -.07) and the interaction (β = -.012) were significantly related to immune functioning and inflammatory markers assessed five years later. The ability to dissipate stress and resilience were most strongly associated with Interleukin-6, accounting for 25% of the variance beyond the base model. In contrast, the input variable from the model was not a significant predictor of primary health outcomes. This provides support for the theory that it is not just the amount of stress that one has that is important, but rather the ability to manage it.

DO RISK AND RESILIENCE FACTORS HAVE THE SAME EFFECTS FOR ACUTE STRESSORS VS. STRESSOR ACCUMULATION?
O.K. Schilling1, M.K. Diehl1, 1. Department of Psychological Ageing Research, University of Heidelberg, Heidelberg, Germany, 2. Colorado State University, Fort Collins, Colorado

In our previous work on individuals’ reactivity to daily stress we showed that beliefs of control (BOC) are a resilience factor, whereas self-concept incoherence (SCI) is a risk factor of negative affect (NA) reactivity to daily stress. Using data from a 30-day study with 289 adults, the present study examined the role of these risk and resilience factors in the context of stressor accumulation. We hypothesized that BOC would be associated with decreased, and SCI with increased NA-reactivity to stress accumulated across a 7-day period. Generalized Linear Mixed Models revealed a significant interaction effect of SCI with stressor accumulation, but not with acute daily stress. BOC interacted weakly with stressor accumulation, but stronger with concurrent daily stress. The findings suggest that SCI is particularly important with respect to reactivity to stressor accumulation. Conversely, BOC dampen the NA-reactivity to acute stress, but are less important for coping with stressor accumulations.

CROSS-SECTIONAL AGE DIFFERENCES AND LONGITUDINAL CHANGE IN EMOTIONAL REACTIVITY TO UPLIFTS
G. Luong1, M. Riediger2, C. Wrzus1, G.G. Wagner1,2,3, 1. Affect Across the Life Span Research Group, Max Planck Institute for Human Development, Berlin, Germany, 2. Berlin University of Technology, Berlin, Germany, 3. German Institute for Economic Research, Berlin, Germany

Life-span research on emotional reactivity has focused primarily on negative events (e.g., stressors). Fewer studies have examined age differences and longitudinal change in emotional responses to positive events, such as uplifts. In the current study, participants (12-88 years old) completed two experience sampling assessments approximately two years apart (Wave 1 N = 378; Wave 2 N = 400). Higher ratings of uplift importance were associated with positive affect, and this effect grew stronger over the two years for older, relative to younger, individuals. Additionally, following the occurrence of an uplift, older age was related to greater positive affect at the subsequent assessment, and this effect became more pronounced across the two years. These findings show that for older adults, uplifts are more strongly associated with positive affect, and these effects may persist for hours. The study suggests that uplift reactivity may contribute to changes in emotional well-being across the life-span.

SESSION 35 (SYMPOSIUM)
RURAL AGING AND DIVERSITY: HEALTH AND WELL-BEING ACROSS CULTURAL CONTEXTS
Chair: C. Adams-Price, Psychology, Mississippi State University, Mississippi State, Mississippi
Discussant: C. Adams-Price, Psychology, Mississippi State University, Mississippi State, Mississippi

With high poverty rates and low access to medical care, optimal aging may be difficult to achieve for older adults living in rural and remote areas. Designing interventions to improve the health and well-being of rural older people can be difficult without understanding of diverse cultural contexts. This symposium will address the physical and mental health of rural older adults in different cultural contexts, and how those contexts provide different obstacles and opportunities for physical and mental well-being. Phil St. John will be presenting research on heterogeneity of the elderly in Manitoba, and factors that increase the risk of depression. Bette Ide will speak on health self-efficacy, stress, and social support as moderators of self-perceived health among Native Americans from the Standing Rock Reservation. She will also discuss possible health interventions for older Native Americans living on reservations. Keiko Kitagawa will discuss planning for natural disasters in rural sections of Japan where older adults make up more than 50% of the populations. Carolyn Adams-Price will be the discussant, and will discuss the similarities and differences associated with rural aging in the disparate cultures included in this symposium.

RESEARCH WITH RURAL ELDERS IN ALASKA: BENEFITS AND CHALLENGES OF CONDUCTING TRIBAL PARTICIPATORY RESEARCH
J.P. Lewis, Psychiatry& Behavioral Sciences, University of Washington, Seattle, Washington

Many of the rural villages in Alaska have little to no access to routine health care services let alone a long-term care facility. This presentation will highlight an Elder Needs Assessment that was conducted in the spirit of tribal participatory research (TPR), enabling the communities and elders to drive the project. The results provides support for a much needed paradigm shift in the way services are delivered, from the medical model to more home-based, culturally responsive services that allow Elders to live their remaining years in the community they call home. This presentation will discuss methodological challenges of conducting culturally relevant research with tribal communities. The author discusses the benefits and challenges associated with conducting research with tribal communities in rural Alaska. Recommendations for future researchers on how to work effectively with tribal communities, from entry into the community through dissemination and publication of information will be discussed.

SELF-EFFICACY AS A MODERATOR FOR SELF-PERCEIVED HEALTH OF AMERICAN INDIAN ELDERS
B.A. Ide, B.K. Dahlen, Walden University, Minneapolis, Minnesota

This paper addresses the issue of self-efficacy as a moderator for self-perceived health of American Indian elders. The importance of the relationship between self-efficacy and health or health behaviors for American Indians has recently emerged in the literature. A secondary analysis of needs assessment data from interviews with 178 elders on the Standing Rock Reservation was conducted. A 5-step hierarchical linear regression addressed the following predictors of self-perceived health: demographics, measures of stress, measures of social support, general perceived self-efficacy, and functional health as measured by the Iowa Functional Inventory. In the final step, the remaining significant predictors of self-perceived health were education level, distance to emergency care, and general perceived self-efficacy, which moderated the relationship between functional health and self-perceived health.
Objective: To describe heterogeneity in communities and individuals in rural areas. Setting: the Canadian province of Manitoba. Design: A population-based cohort study conducted in 1991-1997. Individual-level data were gathered and linked to community-level data (census subdivision) from the census of the same year. Results: 690 individuals residing in 141 rural communities were included. Population density varied from 0.06 to 1056 persons/km2. The percent of the population aged 65+ varied from 4% to 42%. The mean household income varied from $17,452 to $65,111CN, and the percent of the population with less than grade 9 education varied from 0.7% to 49.0%. There was also variation in the health of older adults. Conclusions: Even within one province, there is substantial diversity in rural communities and people. This diversity may be even more marked within and between countries and should be considered in the design and interpretation of epidemiologic studies.

**BEHAVIORAL INDICATORS OF QUALITY OF LIFE OF THE ELDERLY**

M.E. Delacruz, D.C. dela Cruz, psychology, centro escolar university, Manila, Philippines

The quality of life of 292 elderly respondents was explored through behavioral indicators of mental health using a Mental Health Status Checklist (Delacruz, 2006), objective and subjective indicators of life satisfaction (Seligman, 2002; Diener, 2007) and their relationship to selected demographic factors. The group responses did not indicate serious psychological disturbance. The responses on objective and subjective indicators of life satisfaction showed a favorable regard of life. None of the demographic factors relate significantly to either mental health or life satisfaction. The over-all quality of life of the elderly respondents is favorable.

**COGNITION**

(CNS) PREVALENCE AND PREDICTORS OF DRIVING AMONG COGNITIVELY IMPAIRED OLDER ADULTS: THE WOMEN’S HEALTH INITIATIVE MEMORY STUDY-Epidemiology of Cognitive Health Outcomes (WHIMS-ECHO)

K.M. Sink1, M. Corbett1, E. Dugan2, M.A. Espeland1, P. Hogan1, S. Rapp1, L. Vaughan1, S.A. Shumaker1, I. Geriatrics, Wake Forest School of Medicine, Winston Salem, North Carolina, 2. University of Massachusetts Boston, Boston, Massachusetts

Driving safely requires the rapid processing of stimuli and good decision-making. Cognitively impaired drivers are at increased risk of driving accidents. We examined driving among participants in WHIMS-ECHO (N=2901) who completed at least one annual phone-based cognitive assessment and were adjudicated as having mild cognitive impairment (MCI) or dementia (N=305). Among ever drivers with cognitive impairment, 52% are current drivers. Compared to current drivers, those who have stopped driving (N=147) are older (mean 84.8 vs 83.1 years; p<0.001), more likely to be Caucasian (p=0.04), and have lower performance on most cognitive tests administered. Mean(SD) Telephone Interview for Cognitive Status (TICS) score (0-50) was 26.6(3.0) vs 24.5(4.6) for current vs former drivers; p<0.001. Among current drivers (N=158), proxies reported problems with driving in 23% (compared with 99% of former drivers). Getting lost and bad coordination were the most commonly reported problems in those still driving. In addition, proxies reported that among current drivers: 21% had trouble finding their way on familiar streets, 38% had difficulty handling money, and 41% had difficulty grasping situations or explanations. Factors associated with continued driving among those with dementia specifically (63 of 156) are: non-white race; ability to find way on familiar streets and recognize faces; and better performance on TICS (all p<0.05; adjusted for age, race, education and TICS score using logistic regression). Despite proxy reports of problems, cognitive impairment does not lead to immediate driving cessation in this cohort. Greater understanding of the process of navigating driving transitions is needed.

DEPRESSIVE SYMPTOMS PRECEDE MEMORY DECLINE, BUT NOT VICE VERSA, IN NON-DEMENTED OLDER ADULTS

L.B. Zahodne, Y. Stern, J.I. Manly, Columbia University, New York, New York

Objective. Numerous studies support an association between depression and increased risk of dementia. Because few studies have directly examined the temporal ordering of depression and memory decline in late life, it is not clear whether depressive symptoms typically precede and/or follow memory declines. Method. The present study used the autoregressive latent trajectory framework to examine the direction of the relationship between depressive symptoms and memory decline. The sample included 2,425 initially non-demented older adults followed up to 12 years by the Washington/Hamilton Heights Inwood Columbia Aging Project, a community-based longitudinal study of aging and dementia in Northern Manhattan. Memory composite scores were computed from three subscores of the Selective Reminding Test. Depressive symptoms were assessed with a 10-item version of the Center for Epidemiological Studies Depression Scale. Analyses controlled for age, sex, recruitment wave, education, Black race and Hispanic ethnicity measured at baseline, and chronic disease burden measured at each study visit. Results. Initial depressive symptoms predicted worse memory scores at the second study visit as well as accelerated memory decline over the entire study period. Memory scores did not predict subsequent depressive symptoms. Conclusion. These findings suggest that depressive symptoms precede memory decline, but not vice versa, in late life. This pattern of results is in line with hypotheses that depression is a prodrome of dementia and/or a causal contributor to cognitive decline. Clinicians should be aware that depressive symptoms may represent an early indicator not only of dementia, as reported previously, but also of memory decline more generally.

EXECUTIVE FUNCTION PROCESSES PREDICT MOBILITY IN OLDER ADULTS

Background. There is growing evidence suggesting an association between cognitive function and physical performance in late life. This study examines the relationship between performance on executive function measures and subsequent mobility outcomes across community dwelling older adults across a 12-month randomized controlled exercise trial. Methods. Community dwelling older adults (N = 179; Mage=66.4) completed measures of executive function including the flanker task, task switching and dual task paradigm, and the Wisconsin card sort test at baseline of the trial. Mobility was assessed using the times to climb up and down a flight of stairs and timed 8-foot up and go test. Participants completed the mobility measures at baseline and after 12 months. Multiple regression analyses were conducted to determine whether baseline executive function predicted post-intervention functional performance after controlling for age, sex, education, cardiorespiratory fitness and baseline mobility levels. Results. Multiple

66th Annual Scientific Meeting
MEMORY SELF-EFFICACY IN COGNITIVELY NORMAL OLDER ADULTS AND ADULTS WITH MILD COGNITIVE IMPAIRMENT

M. Stolder, Nursing, Viterbo University, La Crosse, Wisconsin

Although there are ample studies confirming that memory self-efficacy (MSE) declines with age, less is known about what factors account for the variation in MSE among older adults. The purpose of this study was to examine the relationship between MSE, diagnostic and clinical characteristics, and subsequent episodic memory performance in older adults. A nonprobability sample of 200 cognitively normal and older adults with mild cognitive impairment (MCI) participating in a longitudinal population-based study investigating the incidence, prevalence and risk factors for MCI completed a questionnaire about self-referent beliefs of MSE. Bandura’s (1989) self-efficacy theory informed the descriptive study. Pearson product-moment correlations, a general linear model and a multiple linear regression analysis were conducted. The difference in MSE ratings between the cognitively normal group and the MCI group tested as a whole was significant when adjusting for age, gender and educational attainment (p < .001; ES = 0.585). The overall regression model explained 17% of the variance of MSE (p < .001) and included age, gender, educational attainment, APOE 4 genotype, family history of dementia, cognitive diagnosis and depressive symptoms. After controlling for age and the other variables of interest, adjudicated consensus cognitive classification and depressive symptoms were significant predictors of MSE. Higher MSE ratings were correlated with better episodic memory performance for both groups (r = .273, p < .001). Memory training that capitalizes on the benefits accruing from higher MSE is needed for cognitively normal older adults and older adults with MCI.

AGE, COGNITION, FUNCTIONAL ASSESSMENT AND RESPONSE TO REACTIVE OXYGEN SPECIES

J.W. Elias¹, J. Stafford-Son², C. Pritsos³, S. Omaye³, M. Read³, J. Office of Research, UC Davis School of Medicine, Sacramento, California, 2. University of Idaho, Boise, Idaho, 3. University of Nevada Reno, Reno, Nevada

Age, Cognition, Functional Assessment and Response to Reactive Oxygen Species. Assessing the physiological effects of reactive oxygen species (ROS) is often targeted as a means to better understand disease processes and age-related decline. Few such studies have tied enzymatic and serum measures of oxidative stress to such common cognitive variables as memory and reaction time, or measures of functional aging such as peg board dexterity, hand grip strength, and chair stands. Data from a University of Nevada Reno cognition/nutrition study are presented here to show that for 61 adults (23 males) across the age range of young (19-31) and older adults (58-86) serum and enzyme responses to antioxidants (total antioxidant power (TAP), 8-OH-2-deoxyguanosine (DEOX), glutathione oxidase (GPOX), and super oxide dismutase (SOD)) correlate with the age-related measures of memory, reaction time, and functional aging. TAP was the most consistent correlate with memory (r range = -.34 to .42 pegboard, grip, chair stands), and simple reaction time (RT r = -.35). DEOXY correlated r = .29 with delayed list memory, SOD correlated r = .26 with RT. The behavioral measures correlated with age (r range = -.29 to .62), TAP and DEOXY correlated with age r = -.47 and r = -.37 respectively). With age or TAP partialled from the correlations the values were significantly reduced. However, age and TAP were also shown to be suppressing oxidative correlations with GPOX and DEOX.

SESSION 45 (PAPER)

DEMENTIA: PREDICTORS AND OUTCOMES

QUALITY OF LIFE IN EARLY-STAGE DEMENTIA: LONGITUDINAL TRAJECTORIES AND PREDICTORS OF CHANGE

L. Clare¹, S. Nelis¹, A. Martyr², I.S. Markova³, I. Roth³, R.T. Woods¹, C.J. Whitaker¹, R.G. Morris². 1. School of Psychology, Bangor University, Gwynedd, United Kingdom, 2. University of Hull, Hull, United Kingdom, 3. Open University, Milton Keynes, United Kingdom, 4. Kings College London Institute of Psychiatry, London, United Kingdom

Background. Little evidence is available about how quality of life (QoL) may change as dementia progresses or what factors influence such changes. This study aimed to explore QoL trajectories over a 20-month period and identify which baseline factors predicted changes in QoL. Method. Fifty-one individuals with a diagnosis of Alzheimer’s, vascular or mixed dementia participating in the MIDAS study rated their QoL using the QoL-AD scale at baseline and at 12- and 20-month follow-up assessments. PwD also rated their own mood and quality of relationship with the carer. In each case the carer rated his/her level of stress and perceived quality of relationship with the PwD. Results: There was no change in mean QoL score but nearly one-third of PwD rated QoL more positively at 20-month follow up and nearly one-third rated QoL more negatively. There were no significant differences between those whose scores increased, decreased or stayed the same on any demographic or disease-related variables, or in mood or perceived quality of relationship with the carer. However, regression analysis indicated that while baseline QoL score was the strongest predictor of QoL at 20 months, the PwD rating of perceived quality of relationship with the carer was also independently a significant predictor. Conclusions: Among people with early-stage dementia, more positive ratings of perceived quality of relationship with the carer are predictive of more positive self-ratings of QoL 20 months later. Relationship factors play an important role in maintaining QoL in early-stage dementia.

FALLS AMONG COGNITIVELY IMPAIRED RESIDENTS IN ASSISTED LIVING AND SIMILAR RESIDENTIAL CARE COMMUNITIES: FINDINGS FROM THE 2010 NATIONAL SURVEY OF RESIDENTIAL CARE FACILITIES

E. Park-Lee, M. Sengupta, CDC/NCHS, Hyattsville, Maryland

Cognitive impairment (CI) is a well-recognized risk factor for falls. Assisted living and similar residential care communities (RCCs) provide alternatives to nursing homes for individuals with CI. RCC residents with CI may live in communities where all or some of the units are dementia-specific, or in settings where they cohabit with other residents without CI. Using data from the 2010 National Survey of Residential Care Facilities (n=4,992), we examined if residents with CI in a dementia-specific unit or community (DSU) were more or less likely to have a fall that caused an injury than those in non-DSUs. Of residents in RCCs, 59% were cognitively impaired. About 24% of residents with CI resided in DSUs. A higher proportion of residents with CI in DSUs (22%) had falls that caused injuries than those in non-DSUs (17%). Compared to residents with CI in non-DSUs, more residents with CI in DSUs were older, received assistance with more activities of daily liv-

The Gerontological Society of America
ing (ADLs), wandered, were visually impaired, and had been prescribed medications to control behavior/agitation. Preliminary multivariate analyses showed that the risk of having a fall that caused an injury for residents with CI did not differ significantly by DSU status after controlling for resident demographics and health status. Being older, female, in poor health, having been prescribed medications to control behavior/agitation, and having higher ADL increased risks for injury-causing falls. Implications of findings and study limitations will be discussed.

**CUMULATIVE PSYCHOSOCIAL STRESSORS PREDICT ALZHEIMER’S DISEASE IN CHILDREN OF THE GREAT DEPRESSION**

M.C. Norton1, R. Pfister1, C. Clark1, J. Tschanz1, K. Smith2, J. Family Consumer & Human Development, Utah State University, Logan, Utah, 2. University of Utah, Salt Lake City, Utah

Individual psychosocial stressors (PSS; e.g. early parental death) are associated with cognitive impairment and higher risk for Alzheimer’s disease (AD). However, the lifespan cumulative effect of PSS on AD risk has not been assessed. Most studies of PSS rely on retrospective self-reports, introducing recall bias. In a Utah population-based dementia study, a subsample of 3,785 initially non-demented participants (57% female; age M=74.9/SD=6.9 years) was linked to the Utah Population Database to objectively ascertain total number of PSS spanning birth to baseline interview, including: hospitalization(s) or death(s) of mother, father, sibling(s), spouse(s), offspring; never marrying, divorce(s), remarriage; nulliparity, 8+ offspring, stillborn/premature offspring, out-of-wedlock birth; high school or less education, low SES, and “blue collar” career. Code was aged: 65-69, 70-74, 75-79, and 80+ years. APOE genotype was coded: 0 vs. 1+ e4 alleles. Cox regression modeled survival time from baseline to AD onset, as a function of PSS, age group, gender, and e4 allele. The PSS*agegroup interaction was significant (p=0.007), prompting separate models by agegroup. Among 65-69 year-olds, each additional PSS was associated with a 20% higher risk (p=0.002) for AD, however, PSS was not significantly associated with AD in the second (p=0.98), third (p=0.702) or fourth (p=0.836) age strata suggesting mortality selection. Further, each additional PSS was associated with 36% higher AD risk (p<0.001) among e4 positives, but non-significant among e4 negatives (p=0.707). Cumulative psychosocial stress burden is significantly associated with higher AD risk among individuals who were children during the Great Depression, an effect moderated by APOE.

**ACTIVITY INVOLVEMENT AMONG RESIDENTIAL CARE RESIDENTS WITH DEMENTIA AND OTHER COGNITIVE IMPAIRMENTS**

M. Sengupta, E. Park-Lee, S. Zimmerman, CDC/NCHS, Hyattsville, Maryland

Residential care is becoming an important source of long-term care for elders with dementia. According to the 2010 National Survey of Residential Care Facilities (NSRPF), 42% of residents in residential care communities (RCCs) had dementia. Involvement in meaningful activities may help residents with dementia maintain their functional abilities, improve self-esteem, and enhance their quality of life. While there is evidence that RCC staff and residents’ families may promote activity engagement, little is known regarding activity involvement among residents with dementia in RCCs. Using data from the NSRPF, the first nationally representative survey of RCCs with four or more beds, this study aims to: (a) describe and compare activity involvement between residents with (n=4,992) and those without (n=3,903) dementia and other cognitive impairment; and (b) for residents with dementia and other cognitive impairment, examine which resident and RCC characteristics are related to involvement in a variety of activities. Bivariate analyses show that fewer residents with dementia and other cognitive impairment than other residents participate in selected activities, including reading (42% versus 57%), going out (34% versus 47%), and taking trips (32% versus 52%). There were no differences by dementia status in prevalence of participation in religious activities, craft, and listening to music. Multivariate results will be presented on characteristics that are associated with participation in activities among residents with dementia and other cognitive impairment. These findings may be due to resident physical limitations or facility practices.

**BODY MASS INDEX, BLOOD GLUCOSE, AND RISK OF DEMENTIA**

A.K. Dahl1,2, R. Andel1, W. Xu1, M. Gatz1, 1. Department of Medical Epidemiology and Biostatistics, Karolinska Institutet, Stockholm, Sweden, 2. Joenkoeping University, Joenkoeping, Sweden, 3. University of South Florida, Tampa, Florida, 4. University of Southern California, Los Angeles, California

Background: Higher midlife body mass index (BMI) has been associated with a greater risk of dementia, but the causal pathways are poorly understood. In the current study we examined if higher BMI is associated with a greater risk of dementia when blood glucose is taken into account. Methods: BMI (kg/m2) and blood glucose were available from 769 individuals free of dementia (mean age 62.8 years) at baseline of the longitudinal Swedish Adoption/Twin Study of Aging (SATSA). Dementia was continually screened for and diagnosed adhering to DSM criteria across the study spanning over 21 years. Results: In Cox proportional hazard regression models adjusted for dependency within twin pairs as well as age, sex, and education, BMI (Hazard Ratio [HR]=1.52, p=0.015) and blood glucose (HR=3.12, p=0.006) were independently associated with greater risk of dementia. The risks were attenuated when controlling for prevalence of diabetes at baseline, but still significant (BMI, HR=1.22, p=0.034, and blood glucose HR=2.93, p=0.019). There was also an interaction between BMI or blood glucose and age, whereby higher BMI and higher blood glucose levels were more highly associated at younger ages, with the risk becoming significantly attenuated with increasing age (HR=0.99, p=0.045, and HR=0.99, p=0.028, respectively). Conclusions: Higher BMI and blood glucose measured at midlife were independently associated with higher dementia risk, which suggest that they partly tap different aspects of risk. The associations between high BMI or blood glucose and dementia weaken with age. Preventive actions need to address these risk factors in midlife.

**SESSION 50 (PAPER)**

**FAMILY AND INTERGENERATIONAL RELATIONS: GRANDPARENTING AND PARENTING**

**PROVIDING SUPPORT TO MIDDLE-AGED OFFSPRING: IMPLICATIONS FOR OLDER PARENTS’ WELL-BEING**

L.R. Bangerter1, K. Kim1, K. Fingerman1, S.H. Zarl1, 1. The Pennsylvania State University, State College, Pennsylvania, 2. The University of Texas at Austin, Austin, Texas

BACKGROUND: Family support directly benefits those receiving help, but the ability for older adults to make contributions to their children’s lives may also have implications for their well-being. The current study examines the relationship between older adults’ well-being and the support they give to one of their middle-aged offspring and whether older adults view giving support as rewarding or stressful.

METHODS: The sample was drawn from the Family Exchanges Study and consisted of 337 aging adults (mean age 76) who had at least one living adult offspring. Participants reported tangible or non-tangible forms of support given to one of their adult children and their perceptions of support given as being stressful and/or rewarding. Well-being was assessed by two measures, depressive symptoms and life satisfaction. Regressions were examined for these well-being measures.

RESULTS: For depressive symptoms, significant interactions were found between tangible support and reward as well as between non-tangible support and stress. People who found giving highly rewarding had
lower depression when giving high tangible support. Conversely, people who found giving highly stressful had lower depression when giving more non-tangible support. Similar effects were found for life satisfaction. People who saw giving as highly rewarding had greater life satisfaction when giving high amounts of tangible support, and people who perceived giving as highly stressful had greater life satisfaction when they gave high amounts of tangible support. DISCUSSION: These findings indicate how older people perceive support to offspring conditions how giving affects their well-being.

HOW COPING RESOURCES IMPACT THE PSYCHOLOGICAL WELL-BEING OF CUSTODIAL GRANDMOTHERS AND GRANDCHILDREN IN BLACK AND WHITE FAMILIES

G.C. Smith1, K.E. Cichy1, J. Montoro Rodriguez2, J. Kent State University, Kent, Ohio, 2. California State University, San Bernardino, California

Although past studies reveal that the coping mechanisms used by custodial grandmothers are related to their psychological well-being, the impact of their coping resources on custodial grandchildren’s well-being is unknown. Using SEM, we tested an adaptation of the Family Stress Model (FSM) whereby coping mechanisms (active strategies; passive strategies; and social support) were hypothesized to affect custodial grandmothers’ (n = 733) psychological well-being directly. We further hypothesized that grandmother coping mechanisms would impact grandchildren’s well-being indirectly given the FSM postulate that a caregiver’s psychological state influences parenting practices which, in turn, affects children’s behavioral outcomes (internalizing and externalizing symptoms). The data fit the baseline model well (CFI = .955; RMSEA = .040) revealing that active coping and social support enhanced both grandmother and grandchild well-being; whereas passive coping had the opposite effects. We also tested the model separately for Black (n = 366) and White (n = 367) grandmothers. Although the measurement model was invariant by race, the following structural differences were found (X2 dif = 8.7): For Blacks, education level was negatively associated with passive coping (β = -.19, p < .05), whereas this effect was not significant for Whites. The effect of active coping on dysfunctional parenting was not significant for Blacks, but was significant for Whites (β = -.26, p < .05). Based on the FSM, we conclude that grandmothers’ coping resources affect the psychological well-being of both them and their grandchildren. The implications of observed racial differences will be discussed. [ Funded by NIH R01 066851-02 ]

GRANDMOTHER CAREGIVERS, INTRA-FAMILY STRAIN AND APPRAISALS OF STRESS OVER TIME

C. Musil1, A. Jeanblanc1, C.J. Burant1, J. Case Western Reserve University, Cleveland, Ohio, 2. Jeanblanc & Rosser, Cleveland, Ohio

Grandmothers raising grandchildren typically face greater strains associated with family problems than grandmothers who are not living with grandchildren. These external strains affect grandmothers’ appraisals of their own stress, but little is known about the relationship between such strains and appraised stress, either concurrently or over time. This analysis examines the contemporaneous and longitudinal relationships between intra-family strain and appraised stress in 238 grandmothers (mean age 60) who participated in a study on caregiving to grandchildren. Grandmothers were classified as primary/custodial caregivers to grandchildren, grandmothers living in multigenerational homes, or non-caregivers to grandchildren; all maintained stable caregiving status across waves. Participants completed the Intra-family Strain Subscale of the FILE (McCubbin et al.) and a visual analog stress measure, using mailed questionnaires every 2.5 years over 3 waves. Data were analyzed using a cross-lagged, longitudinal structural equation model in AMOS. Grandmother caregiving group was included using two dichotomous variables. Our final model, with all paths significant at p<.05, yielded fit indices of χ2=24.13, df=12, p = .02, CFI = .98, TLI=.96, and RMSEA =.065, indicating good model fit. Intra-family strain and appraised stress showed high autocorrelations across waves. Intra-family strain had a direct effect on appraised stress, with higher strain contributing to greater appraised stress at each wave. There were significant cross-lagged effects between stress and strain at all waves, with higher stress associated with greater subsequent wave strain. The model suggests that interventions focused on modulating the interpretation of family strains as stressful could potentially reduce the negative effects of stress over time.

PERCEIVED BURDEN OF CARING FOR GRANDCHILDREN: FINDINGS FROM A CROSS-SECTIONAL STUDY OF OLDER CHINESE IMMIGRANTS IN CHICAGO

E. Chang1, R. Chen1, Y. Li1, Y. Zhen1, M.A. Simon1, X. Dong2, J. Rush Institute for Healthy Aging, Rush University Medical Center, Chicago, Illinois, 2. Northwestern University, Chicago, Illinois

Background: Grandparenting in Chinese families is perceived as a continuity of cultural practice. Interaction with grandchildren is associated with general life satisfaction. However, the care burdens resulting from grandparenthood could also pose negative influences on older adults’ well-being. Little is known regarding the experience of grandparenting in the Chinese immigrant community. Methods: The cross-sectional study sampled a population of 3,018 Chinese older adults over 60 years in great Chicago area. Questions regarding older adults’ grandparenting experiences were asked in a in-home interview survey format. Community-based participatory research approach was utilized to partner with Chinese Chicago community. Results: Among surveyed participants (N=3,018), the mean age was 73. Sixty percent was women. The average number of grandchildren was 4.6. Our findings show 10% of the participants reported that taking care of grandchildren in the U.S. was a primary reason for immigration. On a weekly basis, 33% of the participants spent time caring for their grandchildren. Among this subset, 19% of participants considered caregiving as a burden, 10% felt that their health is negatively affected as a result of taking care of grandchildren, and 10% felt pressured by their son/daughters to take care of their grandchildren. Conclusion: Our findings suggest that support to Chinese immigrant grandparents is needed at both family and community levels to ensure their health and well-being. Rigorous research is needed to further examine the effect of caring for grandchildren on health among Chinese older immigrants.

DEVELOPING SERVICES FOR GRANDFAMILIES: ENHANCING STRENGTHS

A.L. Smith, College of Education and Human Development, Western Michigan University, Grand Rapids, Michigan

The session will emphasize the importance of capitalizing on the inherent strengths common in grandparent-headed homes. Lessons learned from the Grandparent-Resource Site project, a 10 state initiative focusing on assisting local agencies to develop programming sensitive to grandfamilies’ strengths, community needs, and existing resources will be shared. Recognition that there is no one “best” way to provide effective services will be emphasized. Strategies for evaluating and adapting programs to increase long-term sustainability will be shared. Participants will increase awareness about kinship care families in the U.S., enhance knowledge related to developing and evaluating services for kinship care family members and community-based professionals, develop understanding about current and future trends in programming for kinship care families and enlarge knowledge about existing resources for professionals working with kinship care family members.
ADAPTIVE LEADERSHIP TO IMPROVE GERIATRIC NURSING CARE: APPLICATION OF MIXED METHODS

Chair: R.A. Anderson, School of Nursing, Duke University, Durham, North Carolina
Co-Chair: K. Corazzini, School of Nursing, Duke University, Durham, North Carolina
Discussant: M. Toles, School of Nursing, Duke University, Durham, North Carolina

Many care issues of older adults are complex and have no readily identifiable solution. The Adaptive Leadership (AL) framework (Bailey et al. 2012) is ideally suited to addressing difficult problems by differentiating between ‘technical challenges’ (i.e., problems with known solutions using technical expertise, e.g., what medication to prescribe) and ‘adaptive challenges’, (i.e., problems with no known solution, requiring shifting norms and belief sets, e.g., how an older adult will self-manage a complex medication regimen or how to create culture change to meet patient preferences). Such differentiation will facilitate nurses in any healthcare setting to recognize when it is necessary to move beyond known technical approaches and employ adaptive approaches. Mixed methods research designs comprise an ideal research method for conducting studies that will advance our understanding, and application, of this theoretical framework, generating knowledge of why and how adaptive approaches are necessary in geriatric nursing care. Mixed method studies have a qualitative “strand,” (for example, description of the patients’ challenges from their own perspective) that is ‘mixed’ with a quantitative ‘strand’ (for example measures of patient symptoms such as pain, fatigue, depression, or cognitive impairment) and may be explored in relation to nursing care interventions. Mixed method designs facilitate understanding of how patient or provider perceptions of challenges correspond with symptoms or care delivery informing development and evaluation of nursing care. This symposium describes the application of mixed methods research in residential, outpatient, and community-based geriatric nursing care settings to advance nursing care designed to address complex geriatric care problems.

OVERVIEW OF ADAPTIVE LEADERSHIP AND MIXED METHOD RESEARCH APPROACHES

R.A. Anderson, K. Corazzini, School of Nursing, Duke University, Durham, North Carolina

About 80 percent of older adults have chronic illnesses that contribute to cognitive and affective changes and disability, which create challenges. The Adaptive Leadership (AL) framework classifies challenges as those that the provider can address (i.e., technical) and those that only the patient/family caregiver can address (i.e., adaptive), thus an understanding of these challenges is needed to provide effective care. Evidence is available for assessing and intervening for technical challenges (e.g., medications for anxiety) but it is sparse for assessing and intervening for adaptive challenges. Understanding geriatric chronic conditions requires measurements (amenable to quantitative methods) as well as describing challenges (amenable to qualitative methods). Thus deliberately “mixing” both types of data using mixed methods research to understand how these two domains inter-relate is essential. This overview describes how mixed methods will advance science for developing adaptive interventions for older adults with challenges of chronic illness and functional decline.

AN ADAPTIVE LEADERSHIP ORAL HEALTH INTERVENTION FOR CAREGIVERS AND INDIVIDUALS WITH MILD DEMENTIA

B. Wu, B.L. Plassman, R.A. Anderson, 1. School of Nursing, Duke University, Durham, North Carolina, 2. Duke University Medical Center, Durham, North Carolina

Maintaining oral hygiene is critical for individuals with mild dementia (IMD), but is often neglected. Using Adaptive Leadership, our intervention protocol uses a mixed method, embedded-design, to improve the IMD’s ability to engage in effective oral care. In the qualitative strand, we will interview IMDs and caregivers monthly during a 6-month implementation to identify unmet technical challenges (e.g., skill, technique, and equipment) and adaptive challenges (e.g., forgetting, poor concentration, misplacing supplies, and uncooperativeness) in oral care; we will incorporate tailored interventions to address these. In the quantitative strand, we will measure monthly, the frequency, duration, and adequacy of toothbrushing using a special electronic toothbrush and measure variables such as oral-health knowledge and self-efficacy. Standard approaches to oral care in this population are primarily technical interventions. By addressing the adaptive challenges we expect to improve IMDs’ ability to engage in effective oral hygiene that will have long term health benefits.

ADAPTIVE APPROACHES AND SELF-MANAGEMENT: THE IMPORTANCE OF PATIENT/PROVIDER INTERACTIONS

D. Bailey, R.A. Anderson, Duke University School of Nursing, Durham, North Carolina

New protease inhibitors and a new genetic blood-test have dramatically improved cure rates for specific patient groups with Chronic Hepatitis C but these new treatments worsen symptoms requiring adaptive work from patients. We used a sequential parallel mixed method design in this longitudinal (9 data-collection points) case study of 4 older adults. In the qualitative strand, patients and providers were interviewed after the index encounter followed by patient telephone-interviews and medical-record review over 24-weeks of treatment. In the quantitative strand, we measured illness perceptions, symptoms, viral load, and self-management. We “mixed” the data using trajectory lines showing changes in scores, challenges, and patient-provider approaches. Adaptive challenges (e.g., fatigue, irritability, and GL problems) were overwhelming. Providers relied heavily on technical approaches, using few adaptive leadership strategies such as raising awareness of potential challenges and supporting patients’ adaptive work. We identified areas where adaptive interventions would facilitate self-management by these patients.

ADAPTIVE CHALLENGES FOR MANAGING DEMENTIA RELATED TO MEALTIME DIFFICULTIES IN THE NURSING HOME

M.B. Aselage, 1. School of Nursing, Duke University, Durham, North Carolina, 2. NHCGNE Claire M. Fagin Fellow, Washington, District of Columbia

Persons with dementia (PWD) are likely to experience difficulty with mealtimes and lose weight. In the nursing home (NH), PWD weight loss triggers technical interventions (e.g., high density protein supplement, appetite stimulants, modifying meal textures) to maintain weight. When a PWD exhibits aversive feeding behaviors (e.g., pushing away, turning away), caregivers may interpret these as “resistive” and cease feeding attempts; however, these behaviors may signal adaptive challenges that would be amenable to adaptive interventions. We will present an intervention study protocol using a longitudinal, embedded, mixed method design that aims to explore the adaptive and technical challenges due to dementia related symptoms PWD exhibit during mealtimes through focus groups. This data will be used to refine and pilot test an adaptive-focused dementia feeding skills training program for NH staff.

DIRECTORS OF NURSING ADAPTIVE LEADERSHIP THROUGH ASSESSMENT AND CARE PLANNING: A MIXED METHODS STUDY

K. Corazzini1, R.A. Anderson1, C. Mueller2, L. Day2, K.A. Porter1, 1. Duke University School of Nursing. Durham, North Carolina, 2. University of Minnesota School of Nursing. Minneapolis, Minnesota

In nursing homes, licensed practical nurses (LPNs) and nursing assistants (NAs) provide the majority of direct resident care, facing multiple adaptive challenges to provide resident-directed care. Registered nurses have a unique leadership role to ensure quality care. However, the sheer diversity of responses to challenges in person-directed care can make academic preparation or quantitative data collection challenging. An adaptive leadership framework can provide a practical approach to assess and address these nursing home challenges. This paper will discuss the use of mixed methods to describe and measure nurses’ perceptions of adaptive and technical challenges and how these perceptions interact with care.
Nurse Directors of Nursing (DONs) are the professional nurse managers in nursing homes, and are therefore in the position to ensure that assessment and care planning facilitates LPN and NA adaptive work, through adaptive leadership (AL). The purpose of this study was to describe DON AL strategies in assessment and care planning in nursing homes, using an exploratory, mixed methods study (Creswell and Plano Clark 2011). Qualitative case study data of nursing practice (N=10 homes) was followed by a quantitative survey (N=101 DONs) of AL strategies identified through the qualitative strand. Results indicate multiple strategies DONs use to ensure that the assessment and care planning process facilitates LPN and NA adaptive work; however, this differs by staffing ratios (p<.01).

SESSION 60 (SYMPOSIUM)

DISSEMINATION OF INNOVATION IN NURSING HOME ORAL HYGIENE CARE: IS FEASIBLE?
Chair: P.D. Sloane, Family Medicine, Univ North Carolina Chapel Hill, Chapel Hill, NC, North Carolina
Discussant: L. Teri, University of Washington, Seattle, Washington

Recent research has identified strong connections between the poor oral hygiene and pneumonia, chronic inflammation, problems controlling diabetes, chronic pain, and reduced quality of life. However, other research has demonstrated that the quality of mouth care provided to cognitively and physically impaired nursing home residents continues to be far less than would be desired. Furthermore, recent advances in products, techniques, and staff allocation methods have not been disseminated into long-term care practice. This symposium, led by investigators from three of the most prominent research programs on improving mouth care for nursing home residents, will explore the issues and challenges related to making real, sustained improvement in this difficult area of personal care practice. The initial presentation by Sheryl Zimmerman, PhD will briefly review the evidence behind the move to improve mouth care in nursing homes. Next, Philip Sloane, MD, MPH will discuss some of the challenges to implementing and sustaining improved mouth care by nursing assistants, based on research and dissemination efforts at the University of North Carolina at Chapel Hill. Subsequently, Rita Jablonski, PhD, CRNP, will discuss her NINR-funded work to develop and disseminate person-centered approaches to successfully provide mouth care to persons with dementia. Next, Pamela Stein, DMD, MPH will discuss a statewide program in Kentucky aimed at improving oral hygiene care by developing effective partnerships between dental professionals and nursing homes. Finally, discussant Linda Teri, PhD will provide a perspective on the policy implications and research opportunities offered by this work.

WHY MOUTH CARE IN NURSING HOMES NEEDS IMPROVEMENT
S. Zimmerman, P. Sloane, L.W. Cohen, Univ North Carolina Chapel Hill, Chapel Hill, North Carolina

Scientific evidence is mounting that oral hygiene is associated with a variety of adverse health outcomes, including aspiration pneumonia, poor diabetes control, heart disease, pain, and reduced nutritional intake. In addition, numerous studies have documented that nursing home care of persons with dementia and/or physical impairments rarely includes adequate oral hygiene care. This overview will review the scientific evidence underlying the need for improvement in oral hygiene care, thereby setting the stage for the remainder of this symposium.

CHALLENGES TO IMPROVING MOUTH CARE OF PERSONS WITH DEMENTIA WHO REFUSE OR RESIST CARE

Care-resistant behavior is one of the primary reasons why person with dementia resist mouth care. We are currently testing interventions to address care-resistant behavior during oral hygiene procedures. These interventions are based on the neurobiology of threat perception: that is, persons with dementia experience alterations in their ability to assess threat level, and as a result, see mouth care as an invasive assault. We were able to provide mouth care to 93% of residents in the experimental group with moderate to severe dementia (n=37, 81% female, mean age 83). The techniques that we use have been disseminated passively via publications, presentations, and internet postings. We are now exploring more active approaches to dissemination and implementation. Barriers to implementation include time constraints by direct care staff and perceived costs by administration. This intervention may have applicability to the current CMS initiative to reduce antipsychotic medication use in the nursing home population.

CHALLENGES TO CHANGING NURSING HOME ROUTINES TO MEANINGFULLY IMPROVE ORAL HYGIENE CARE

A variety of innovations have resulted in best practice for oral hygiene care being far different that what is traditionally taught and practiced in long-term care settings. Among the innovations in products and techniques incorporated into UNC’s Mouth Care Without a Battle program are antimicrobial rinses (to reduce gingivitis and aspiration risk), end-tuft and interdental brushes (to improve plaque removal), and fluoride pastes (to reduce tooth decay). In addition, person-centered techniques minimize pain and anxiety, thereby reducing resistant behaviors and improving quality of life. However, a variety of barriers exist to changing nursing home practice; these include lack of training, lack of supervision, lack of inclusion in quality assurance and nursing home surveys, lack of administrative support, and inadequate funding to support specialized services for mouth care. This presentation will discuss these barriers and suggest solutions by which individual care settings and health policy makers.

DISSEMINATION OF INNOVATION IN NURSING HOME ORAL HYGIENE CARE: IS FEASIBLE?
P. Stein, J. Aalboe, Oral Health Science, University of Kentucky College of Dentistry, Lexington, Kentucky

The oral health of long term care residents is very poor. Provision of oral care was mandated in 1987 by the Omnibus Reconciliation Act but is still woefully inadequate. A new program in Kentucky was developed to improve the daily oral hygiene care provided for residents in nursing homes. The pilot for this program began in one facility with one nursing assistant designated as the facility’s “oral health specialist”. This nursing assistant was trained by a dental team using powerpoints, videos and ongoing bedside coaching. After training, the nursing assistant was responsible for providing the daily oral hygiene care for residents. The pilot program served as a template for Kentucky House Bill 510 which passed into law in April 2012 and approved funding for similar training programs in other regions of Kentucky. Training resources created through

SESSION 65 (SYMPOSIUM)

OPTIMIZING CARE OF THE COMMUNITY-DWELLING OLDER ADULT THROUGH TRANSLATIONAL RESEARCH
Chair: C. Plummer, School of Nursing, Vanderbilt University, Nashville, Tennessee
Discussant: R. Roiland, William S. Middleton Memorial Veterans Hospital GRECC, Madison, Wisconsin

For the community-dwelling older adult, maximizing health provides the opportunity to age in place. This often includes the management of multiple chronic diseases and the maintenance of functional status. Optimizing care for this individual necessitates a partnership between the older adult and his/her health care team. Sherry Goldberg, Perry Gee, and Korey Kennelty will present the results of their translational research studies and address how their findings can be incorporated into optimizing care of the community-dwelling older adult. Sherry Goldberg addresses the need to assess the community-dwelling older adult for “fear of falling”, its impact on his/her daily activities, and its influence on the adult’s interaction with the built environment. Perry Gee examines the question of how and why older adults use electronic personal health record for self-management of chronic illnesses and communication with their health care provider. Finally, Korey Kennelty provides insight into the barriers and facilitators of community pharmacists’ work on medication reconciliation for the older adult transitioning from the hospital back to the home environment.

FEAR OF FALLING AMONG HIGH-RISK, URBAN, COMMUNITY-DWELLING OLDER ADULTS
S.A. Greenberg, School of Nursing, University of Pennsylvania, Scotch Plains, New Jersey

Many older adults develop fear of falling in response to a fall leading to functional decline, curtailment of activities, and immobility, thereby increasing risk of future falls. The cyclical pattern of fear of falling is addressed as a major health issue because it affects older adults’ decisions about which activities to engage in and their level of activity, as well as the significant negative sequelae. Clinically, there is a lack of understanding of how fear of falling translates to older adults’ participation in activities and its relationship to the neighborhood built environment. Even less is known about urban, community-dwelling, nursing-home and dually eligible older adults, who are known to experience transitional care issues and higher health care costs. This presentation will focus on fear of falling and its relationship to the neighborhood built environment and participation in activities using Bronfenbrenner’s Social Ecology Model in a dually eligible population.

USING PERSONAL HEALTH RECORDS FOR SELF-MANAGEMENT SUPPORT: PERCEPTIONS OF THE CRONICALLY ILL ADULT
P.M. Gee, University of California, Davis, Davis, California

Having a diagnosis of chronic illness is costly to older adults and society. One tool that has been promoted to facilitate self-management support of chronic illness by policy makers, health advocates, providers, and consumers is the electronic personal health record (PHR). While adoption and use is strongly encouraged, little is known about the PHR’s efficacy and utilization in self-management support. Chronically ill patients are already using PHR’s at a higher rate than the general population. The question whether patients and providers know the most effective way to use PHR’s for self-management support and productive patient-provider interactions, has led to this descriptive study. Using a grounded theory approach this study analyzes the perceptions of chronically adults and their use of PHR’s for self-management support and effective patient-provider communication. Findings of this study will demonstrate how and why the chronically ill adults are currently using PHR’s and set direction for future research.

COMMUNITY PHARMACISTS PERSPECTIVES ON MEDICATION RECONCILIATION PROCESSES FOR RECENTLY DISCHARGED PATIENTS

Objective: To examine the barriers and facilitators community pharmacists face when reconciling medications for recently discharged patients. Methods: Community pharmacists were interviewed face-to-face, and transcriptions from audio-recordings were analyzed using thematic analysis. The Theory of Planned Behavior guided the development of questions for the semi-structured interviews. Results: All community pharmacists (N=8) described the medication reconciliation process to be difficult and time-consuming for recently discharged patients. Major system-level themes included: prescriber availability for prescription clarification, the time availability for medication reconciliation with pharmacy’s business model focus on prescription volume, hospital formulary changes, and timely accessibility of patient labs and discharge medications list. Major patient-level themes included: caregiver familiarity with patient’s medications and complexity of patient medication regimen. Conclusions: System and patient-level factors influence the medication reconciliation process for community pharmacists. By addressing these factors, community pharmacists may be able to enhance their contributions to care transitions by ensuring medication continuity.

SESSION 70 (PAPER)

ACUTE CARE

EFFECTS OF THE HOSPITAL ELDER LIFE PROGRAM WHEN INTEGRATED IN DUTCH HOSPITAL CARE
F.C. Bakker, A. Persoon, Y. Schoon, M. Olde Rikkert, Geriatrics, Radboud University Nijmegen Medical Center, Nijmegen, Netherlands

Background: In order to improve quality of Dutch hospital care for older persons, an adapted Hospital Elder Life Program is implemented (the CareWell in Hospital program (CWH)). Main goal is to prevent delirium and functional decline among patients aged ≥70 years. Methods: CWH was evaluated in a before–after study (1 January 2011–1 May 2011 and 1 March 2012–1 July 2012). CWH was implemented since April 2011 and comprises screening, a care plan, medication review, follow-up, updated care plan at discharge, medical history by proxy, comprehensive geriatric assessment, trained volunteers, and multidisciplinary meeting. Primary outcome measures are incidence of delirium (CAM), cognitive decline (≥2 points MMSE) and physical decline (≥3 points GARS–ADL) during hospital stay. Secondary outcome measures include physical functioning three months after discharge, readmissions and burden of care among informal caregivers (VAS 0–10). Results: 191 patients pre–CWH and 195 post–CWH were included. Mean age was 77.3 vs 76.7 years. Mean LOS was 8.5 vs 8.7 days. Delirium incidence was 10.5% vs 10.3%, p=0.945; MMSE decline 10.4% vs 7.2%, p=0.329; ADL decline was 37.3% vs 47.3%, p=0.088. Mean ADL change between discharge and three months after discharge was 3.2 vs 5.7, p=0.058. Readmission rate was 11.2% vs 15.3%, p=0.240. Caregivers rated their burden of care lower at three months after discharge: 0.5 vs −0.6, p=0.049. Conclusion: CWH is implemented successfully. This study found no reduction of delirium incidence, and three months
THE EFFECT OF POLICY CHANGE AND EDUCATION ON PHYSICAL RESTRAINT USE IN A GENERAL COMMUNITY HOSPITAL

N. Pearce1,2, S. Edgar1, V. Johnston-Warren1. 1. Grand River Hospital, Kitchener, Ontario, Canada; 2. University of Waterloo, Waterloo, Ontario, Canada

Introduction: A 500-bed general community hospital instituted a new ‘“Least Restraints” policy and education initiative to decrease use of physical restraints. Objectives: To evaluate the impact of the implementation of a “Least Restraining” policy and education on physical restraint use in a general community hospital. Method: Two general medical, 4 rehabilitation, and two mental health units were audited for physical restraint use (lap belts, trunk and limb restraints, full bed rails, and geri chairs) pre and 3-months post policy implementation and education using the Restraint Prevalence Tool (Edwards et al., 2006). The audit consisted of observations of patients and reviewing documentation practices. Results: A total of 420 patients were observed (225 pre and 195 post). Patients had a variety of primary diagnoses including stroke (4.3%), fracture (3.8%), cognitive impairment (2.9%), and mental health disorders (11.0%), were primarily female (57.3%) and ranged in age from 20 – 97 years (mean 73.8 ± 14.3). Post implementation restraint use decreased significantly (p < 0.001) from 28% of observed patients to 5.1%. Documentation requirements improved with a significant increase in documentation of reason for restraint (p <0.001) and presence of a physician’s order for the restraint (p <0.001). Conclusions: Policy change and education decreased restraint use and improved documentation practices. Further research is needed to determine if the change has been sustained.

PREDICTORS OF INPATIENT HOSPITALIZATION AMONG OLDER VETERANS WITH DEMENTIA

K.M. Godwin1,2, R.O. Morgan1, A. Walder2, D.M. Bass4, K. Judge4,5, N.L. Wilson1,2, A. Snow3, M.E. Kunik1,2. 1. Baylor College of Medicine, Houston, Texas; 2. Houston VA Health Services Research and Development Center of Excellence, Houston, Texas, 3. University of Texas Health Science Center at Houston School of Public Health, Houston, Texas, 4. Margaret Blenken Research Institute of Benjamint Rose, Cleveland, Ohio, 5. Cleveland State University, Cleveland, Ohio. 6. The University of Alabama, Tuscaloosa, Alabama

Despite the prevalence of and high costs associated with dementia, few studies have examined the predictors of inpatient utilization among persons with dementia (PWD). This study sought to determine the predictors of inpatient hospitalization, based on the Behavioral Model of Health Service Utilization, by examining a population of veterans with dementia recruited from 5 Veterans Affairs hospitals throughout the United States. Logistic and negative binomial regressions were used to assess whether individual predisposing, enabling, and need factors predicted inpatient hospital utilization and the frequency of inpatient hospital utilization, respectively. Variables significant at the p<0.15 level in the logistic and negative binomial regressions were then analyzed in a multivariate regression. This study of 296 veterans with a diagnosis of dementia and their caregivers (average age 78.6 and 68.8 years, respectively) found marital status (a predisposing variable) to be significant in both the logistic and negative binomial models (B=0.493, p=0.029) and personal care dependency (a need variable) to be significant in both models (B=1.048, p=0.007 and B=0.040, p=0.035, respectively). Thus, being married and having increased personal care dependency predicted having an inpatient hospital admission. Personal care dependency was also predictive of readmission to inpatient care. The findings that personal care dependency leads to initial admission and readmission and that PWD with spousal caregivers have more inpatient admissions are encompassed in the theory of Person-Environment fit. As such, special care should be given to the appropriate envi...
SESSION 75 (PAPER)

BODY COMPOSITION

PHYSICAL PERFORMANCE DECLINE IN A MOUSE MODEL OF CHRONIC VITAMIN D INSUFFICIENCY

K. Selden1,2, M. Pang1,2, M. Hernandez1,2, M. Rodriguez-Gonzalez1,2, B. Troen1,2, I. University of Miami Miller School of Medicine, Miami, Florida, 2. Miami VA GRECC, Miami, Florida

Vitamin D insufficiency (serum 25-OH vitamin D < 30 ng/ml) affects 70-80% of the general population, yet little is known of the long-term impacts on health. Clinical studies suggest linkage between vitamin D insufficiency and declining physical performance in elderly individuals. To elucidate mechanisms underlying the impacts of vitamin D insufficiency, where genetic and environmental factors are controlled, we undertook a longitudinal study of vitamin D insufficiency in mice. For one year, beginning at the age of 6 months, we fed male C57BL/6J mice diets containing either 1000 IU (sufficient) or 125 IU (insufficient) vitamin D3 / kg chow and assessed performance through various physical challenges. After two weeks 25-OH-D levels were 35.1 ± 2.5 ng/ml (1000IU) and 16.6 ± 0.6 ng/ml (125IU), revealing an unexpectedly swift decline. In chronically insufficient mice (9.9 ± 0.2 ng/ml), repletion also occurred rapidly after only two weeks (32.0 ± 2.8 ng/ml). We observed no differences in rotarod, grip strength, and treadmill performance between groups. However, after 12 months of vitamin D insufficiency, mice exhibited worse grip wire endurance (18.6 ± 6.7 versus 65.8 ± 31.8 seconds, p=0.0103), uphill sprint speed (16.0 ± 1.0 versus 21.8 ± 2.4 meters/min, p=0.0007), and stride length (8.2 ± 0.3 versus 8.6 ± 0.2 cm, p=0.0318). Insufficient mice also exhibited greater body fat percentage at 8 months (42.5 ± 5.2 versus 35.4 ± 4.0 %, p=0.0243) but not at 12 months. Therefore chronic vitamin D insufficiency may diminish anaerobic endurance and contribute ultimately to sarcopenia in aging mice.

THE IMPACT OF DIETARY FACTORS AND INFLAMMATION ON COGNITIVE FUNCTION AMONG OLDER ADULTS

E. Handing, B. Small, S.L. Reynolds. Aging Studies, University of South Florida, Tampa, Florida

Evidence is growing that the foods we consume may have an impact on cognitive performance and brain functioning among older adults. Several aspects of diet have been studied previously including antioxidant intake, wine consumption, and fruit and vegetable intake. Inflammatory processes, measured by elevated levels of C-Reactive protein (CRP), fibrinogen, and ferritin, have been linked to cognitive impairment; however few studies have analyzed the association between these inflammatory markers, cognitive function, and dietary factors. This study examines the influence of macronutrients (fat, protein, carbohydrates), and select micronutrients, on the association between inflammatory biomarkers and cognitive performance in adults 60 and older. Subjects included 1,055 adults from the National Health and Nutrition Examination Survey (2001-2002 wave). Using hierarchical regression models, our findings indicated that levels of serum homocysteine, serum folate, and fat intake were significantly associated with better Digit Symbol performance, while carbohydrate intake and protein intake were not associated with cognitive performance on a digit symbol task. High CRP was significantly associated with poorer cognitive function, but did not remain statistically significant after controlling for dietary factors. This study provides evidence that cognitive performance among older adults is impacted by nutritional factors and biological inflammation, therefore diet and nutrition can be a beneficial approach to promote healthy aging.

THE IMPACT OF DISTRIBUTION OF PROTEIN AND ENERGY INTAKE ON THE MUSCLE MASS OF ELDERLY PEOPLE. AN INVESTIGATION WITHIN THE BERLIN AGING STUDY II (BASE-II)

J. Nikolov1, K. Norman1, I. Demuth1,2, E. Steinhagen-Thiessen1, R. Eckardt1, 1. Charité - Universitätsmedizin Berlin, Berlin, Germany, 2. Institute of Medical and Human Genetics, Charité-Universitätsmedizin, Berlin, Germany

Introduction: Equal distribution of energy and protein intake has been suggested as a preventive measure to preserve appendicular muscle mass (ASM) in elderly people. (25-30 g of high quality protein per meal) (Paddon-Jones 2009). Objective: To determine the distribution of energy and protein intake of independently living elderly aged between 60-80. Furthermore the relation between distribution and appendicular muscle mass was investigated. Methods: The appendicular muscle mass was determined by dual-energy X-ray absorptiometry. A 5-day dietary protocol was used to investigate the intake of energy and protein. Results: A sample of 133 subjects (96m; 37w; 60-80y) was included in the analysis. The mean daily energy and protein intake was 24.5 kcal/kg or 0.97g/kg in men and 28.2 kcal/kg or 1.08g/kg in women. The average BMI of all subjects was 27 kg/m2 (SD4.4). 1.5% was overweight, 35.3% normal, 44.4% overweight and 18.8% obese. The energy and protein uptake was distributed as follows: breakfast (6.2 kcal/kg; 0.24g/kg), lunch (11 kcal/kg; 0.44g/kg), and dinner (14 kcal/kg; 0.5g/kg). The energy and protein intake differed significantly between main meals (p<0.001). The total amount of protein of the single meals was 20g (SD13) (breakfast), 33g (SD11) (lunch), and 39g (SD15) (dinner). There were no significant differences between the sexes. The average appendicular muscle mass was 23.7kg (SMI=7.6kg/m2) in males and 15.8kg (SMI=6kg/m2) in females. There were no significant difference in regard of ASM, for subjects (male and female) whose protein intake was less than 30g per meal (breakfast 22 vs. 21, lunch 20 vs. 21, dinner 20 vs. 22 kg). Conclusion: Energy and protein intake was unevenly distributed between the main meals which indicates that an equal distribution might not be necessary to preserve the muscle mass of elderly people, provided that sufficient protein intake is available.

ALLOSTATIC LOAD AND BONE STRENGTH: FINDINGS FROM THE MIDLIFE IN THE U.S. STUDY

T. Mori1,2, T. Seeman1, C.J. Crandall1, S. Merkin1, N. Binkley2, G.A. Greendale2, A.S. Karlamangla2, J. Geriatric Research Education and Clinical Center, VA Greater Los Angeles Healthcare System, Los Angeles, California, 2. Division of Geriatrics, David Geffen School of Medicine at University of California, Los Angeles, Los Angeles, California, 3. Division of General Internal Medicine, David Geffen School of Medicine at University of California, Los Angeles, Los Angeles, California, 4. University of Wisconsin-Madison Osteoporosis Clinical Center and Research Program, Madison, Wisconsin

Accumulated dysregulation across multiple physiological systems, or allostatic load (AL), has been proposed as a biological pathway from psychosocial adversity to poor health. The goal of this study was to examine whether higher levels of AL are associated with lower bone strength in a national sample. Data came from 734 participants in the Biomarker Substudy of the Midlife in the U.S. Study. An AL score (range, 0 to 7) was constructed using biomarkers from 7 different physiological systems (sympathetic and parasympathetic nervous systems, hypothalamic-pituitary-adrenal axis, cardiovascular regulation, lipid metabolism, glucose metabolism, inflammatory system). Bone mineral density (BMD) in the femoral neck, and femoral neck width and length (FNW and FNAL, respectively) were combined with body size to create composite indices of femoral neck strength relative to load in different failure modes: BMD*FNW/weight for compression, BMD*FNW/FNAL*height*weight for bending, and BMD*FNW*FNAL/(height*weight) for impact. These indices are
Inversely associated with incident fracture risk. In mixed effects linear regression controlling for clustering within families, and adjusted for race, gender, age, menopause transition stage, body mass index, education, childhood socioeconomic status, adult finances, and study site, each standard deviation (SD) increment in AL score was associated with between 0.07 and 0.08 SD decrements in each of the three indices (all \( p < 0.05 \)). There was no interaction between AL and gender. Accumulation of dysregulation across multiple physiological systems is modestly associated with lower bone strength relative to load. Future research will determine if AL mediates associations between life course psychosocial adversity and bone strength.

COMBINED EFFECT OF ADIPOSETY MEASURES ON PHYSICAL PERFORMANCE IN OLDER ADULTS

N. de Rekeneire, A. Botoseneanu, H. Allore, T.M. Gill, Section of Geriatrics, Yale University School of Medicine, New Haven, Connecticut

Measures of adiposity, such as body-mass index (BMI) and waist circumference (WC), have shown both independent and additive associations with self-reported disability. However, the combined effect of BMI and WC on objectively-measured physical performance has not been studied. We analyzed baseline data from 5,698 participants in the National Health and Aging Trends Study (NHATS), a nationally representative sample of Medicare beneficiaries aged 65 or older, to evaluate the combined effect of BMI and WC on upper- and lower-extremity performance. Lower-extremity performance was measured using the Short-Physical Performance Battery (SPPB) and upper-extremity performance by grip strength. BMI was calculated using self-reported weight and height, while WC was objectively measured. A 4-level variable combining BMI (normal: 18.5 \( \leq \) BMI < 25, high \( \geq \) 25) and WC (normal: NWC \( \leq \) 88cm in women, \( \leq \) 102 cm in men; high: HWC > 88cm in women, > 102cm in men) was created. The distribution of the adiposity indicators was: 23.2% normal BMI-NWC, 55.5% high BMI-HWC, 11.2% normal-BMI/HWC, and 10.1% high-BMI/NWC. In multivariable linear regression stratified by gender, participants in the normal-BMI/HWC and high-BMI/HWC groups had significantly lower SPPB score—respectively, 8.0 and 8.5 in men, 7.6 and 7.5 in women (p<.001) compared with those in the normal-BMI/NWC group (9.1 in men, 8.4 in women). High-BMI/NWC participants had comparable SPPB score as those in the normal-BMI/NWC group. Abdominal obesity, with either normal or high BMI, is associated with decreased lower-extremity performance in older adults. WC may be a better indicator of obesity-related disability risk than BMI.

SESSION 80 (SYMPOSIUM)

CARE CONSULTATION IMPLEMENTATION, SERVICE DELIVERY, AND OUTCOMES: THE GEORGIA EXPERIENCE

Chair: B. Primetica, Benjamin Rose Institute on Aging, Cleveland, Ohio
Co-Chair: D.M. Bass, Benjamin Rose Institute on Aging, Cleveland, Ohio

This symposium will feature results of a major implementation of BRI Care Consultation, an evidence-based program for older adults with physical or mental health challenges and their family caregivers funded by the U.S. Administration on Aging. BRI Care Consultation is a telephone-based program that provides health- and care-related information, supports family and friend involvement in care, increases awareness and use of community services, and gives emotional support and coaching. It is guided by a comprehensive manual and computerized information system. This symposium will discuss results of the Georgia implementation in three Area Agencies on Aging: Atlanta Regional Commission, Legacy Link, and Heart of Altamaha. With leadership and oversight from the Rosalynn Carter Institute for Caregiving, three Care Consultants and one Care Consultant Assistant served nearly 700 families over two and a half years. Qualitative data from implementation experiences, quantitative data from the computerized information system that guides service delivery; and quantitative data from structured outcome interviews with caregivers are combined to assess program feasibility and effectiveness. Results showed improvement in a variety of outcomes (e.g., caregiver depression, strain, and unmet needs) from enrollment (baseline) to six months post-baseline. Additionally, BRI Care Consultation was found to be feasible for large-scale community implementation based on achieving several important process-outcomes. A number of implementation successes and challenges also were revealed including difficulties integrating this evidence-based program into existing service structures, marketing and recruitment, and sustainability.

DESCRIPTION AND OVERVIEW OF CARE CONSULTATION

C. Holloway, Rosalynn Carter Institute for Caregiving, Americus, Georgia

This presentation will provide an overview of the evidence-based program BRI Care Consultation, history of the program, key features and targeted population. The telephonic program provides four areas of service: Health and Care Related Information, Family and Friend Involvement in Care, Awareness and Use of Community Services, and Coaching and Support. This presentation will present a comparison of BRI Care Consultation service model to an Information & Referral service model, and a Case Management service model. The aim of Georgia Care Consultation is to implement the program in three Area Agencies on Aging in the state of Georgia to provide services for persons living with Alzheimer’s disease or a related dementia and their caregivers. The target population within the agencies includes clients on a growing waiting list for services, underserved clients and clients underutilizing the formal services available.

CARE CONSULTATION SUCCESS AND CHALLENGES: MARKETING, RECRUITMENT, SUSTAINABILITY

L. Eason, Rosalynn Carter Institute for Caregiving, Americus, Georgia

This presentation will discuss the successful translational activities utilized within the current infrastructure within each of the three existing service organizations in the implementation of an evidence-based program. Discussion will target recruitment and marketing challenges and the steps taken to address them. Other barriers overcome involved the dementia educational needs of staff, the written consent process, and the referral flow within the agencies. Brainstorming with each of the three agencies revealed new and creative strategies to sustain the program beyond the grant funding period. Lessons learned in this implementation and sustainability planning process will be shared.

CARE CONSULTATION INFORMATION SYSTEM (CCIS): GUIDED SERVICE DELIVERY AND OUTCOME REPORTS

B. Primetica, J.H. Rentsch, D.M. Bass, Benjamin Rose Institute on Aging, Cleveland, Ohio

This presentation will demonstrate key features of the Care Consultation Information System (CCIS) implemented and utilized by three Area Agencies on Aging in the state of Georgia. The population served included caregivers of older adults with Alzheimer’s Disease and related dementias. The CCIS guided Care Consultants in the delivery of BRI Care Consultation through an Initial Assessment, Action Plan, and Ongoing Maintenance and Support. In addition, the CCIS includes built-in reports to measure process outcomes, such as initial assessment and reassessment. Preliminary results indicate that the highest percentage of areas that were triggered for caregivers include Emotional and Physical Health Strain, Quality of Informal Support, and Arranging Services. For care receivers, the most commonly triggered areas include...
COMMON SENSE PRACTICES FOR NURSE AIDES IN
retention based on their findings. will discuss the implications for practice and policy for improving DSW
between nursing homes and HHAs will also be made. All presenters

tation describes each theme along with illustrative quotations and prac
tice “tips” from facility leaders. The discussion will focus on prac
tice and policy implications regarding implementing good practices with
frontline nursing home workers.

OUTCOMES OF BRI CARE CONSULTATION FOR
CAREGIVERS OF PERSONS WITH DEMENTIA IN
GEORGIA
D.M. Bass, B. Primetica, J.H. Rentsch, Benjamin Rose Institute,
Cleveland, Ohio

The impact of BRI Care Consultation on family caregivers was eval-
uated by examining changes in diverse self-reported outcomes over an12-
month enrollment period. Reliable and valid caregiver outcomes rep-
resented: four types of care-related strain; depression; unmet needs; and
care receivers’ use of healthcare services. Change in outcomes was tested
for over 300 caregivers from three communities who completed two
structured research interviews conducted at baseline and 12 months post
baseline. Results of t-tests and repeated measures ANOVAs showed sig-
nificant decreases in emotional strain, isolation, dyadic relationship
strain, and unmet needs. Significant decreases in depression were
observed for caregivers who initially reported more depressive symp-
toms. There were few changes in care receivers’ healthcare utilization.
Results suggested a large-scale community implementation of BRI Care
Consultation was related to improvements in several caregiver outcomes,
which was similar to conclusions from more controlled studies. Results
are being used to leverage sustained implementation after grant fund-
ing.

SESSION 85 (SYMPOSIUM)

DIRECT SERVICE STAFF IN LONG-TERM CARE
SETTINGS: ADDRESSING CHALLENGES AND
EMPLOYING BEST PRACTICES
Chair: F.K. Ejaz, Benjamin Rose Institute, Cleveland, Ohio

This symposium addresses challenges and best practices related to
employing direct service workers (DSWs) in various long-term care
(LTC) settings. DSWs are commonly referred to as nurse assistants,
home health aids and personal care assistants and generally provide
frontline/hands-on care to clients. In mental health agencies, the most
equivalent frontline worker is the Community Psychiatric Supportive
Treatment Worker (CPST) and generally they provide case management
services. This symposium presents findings from four researchers who
collected data from staff in various LTC settings across Ohio. The
methodologies used to collect data varied and include quantitative and
qualitative methods. Dr. Ejaz will present data from 97 nursing homes
(NHs), home health agencies (HHAs) and providers of services to the
developmentally disabled. She will focus on the similarities and dif-
f erences in services provided by DSWs across settings, rate of DSW
turnover and predictors of turnover. Ms. Bukach & Dawson will focus
on CPST workers in 42 mental health agencies. They will discuss how
services provided by these workers differ from other settings, and sim-
ilarities/differences in the rate and causes of turnover. Dr. Straker will
discuss findings related to DSW workforce best practices in 11 high per-
forming NHs and will discuss the major themes across all facilities. Mr.
Nelson will discuss findings related to workforce best practices in 10
HHAs including major themes emerging across agencies. Comparisons
between nursing homes and HHAs will also be made. All presenters
will discuss the implications for practice and policy for improving DSW
retention based on their findings.

COMMON SENSE PRACTICES FOR NURSE AIDES IN
HIGH-PERFORMING NURSING HOMES
J. Straker, Scripps Gerontology Center, Oxford, Ohio

This paper will share findings from a qualitative interview study in
11 high-performing Ohio nursing homes (NHs). The NHs were selected
based on high performance scores/data from NH Compare, Medicaid
Cost Report, and Ohio NH Resident and Family Satisfaction Surveys.
The NHs varied in size, ownership, and geographic location. Qualita-
tive interviews were conducted with 85 staff members, from adminis-
trators to nurse aides. All interviews were recorded, transcribed verba-
tim, and coded. Analyses found seven most prevalent themes— some
of which the staff referred to as “common sense”. These included choos-
ing and developing good staff, providing individualized treatment of
staff, and being person-centered for both residents and staff. This presen-
tation describes each theme along with illustrative quotations and prac
tice “tips” from facility leaders. The discussion will focus on prac
tice and policy implications regarding implementing good practices with
frontline nursing home workers.

TURNOVER AMONG COMMUNITY PSYCHIATRIC
SUPPORTIVE TREATMENT (CPST) WORKERS IN OHIO
A. Bukach1, F.K. Ejaz1, N. Dawson2. 1. Benjamin Rose Institute on
Aging, Cleveland, Ohio, 2. Cleveland State University, Cleveland,
Ohio

There is increasing need for community mental health services; how-
ever, there is high turnover among workers providing such services.
This study examined turnover among community psychiatric support-
tive treatment (CPST) workers at 42 mental health agencies in Ohio. The
sample was drawn using stratified random sampling by five Ohio regions
based on a list of agencies maintained by the Ohio Department of Men-
tal Health. Administrative staff members were surveyed as part of a
larger study on direct service worker turnover. Mental health agencies
employed a median of 12 CPST workers. The majority were Caucasian,
full-time workers who provided case management and positive behav-
ior support. The average hourly wage was $14.83. For 2011, the reported
CPST turnover percentage was 27% (median), ranging from 0-100%. No
significant regional differences in turnover were identified. Rec
commendations to improve CPST worker retention include offering bet-
ter wages, educational opportunities, and career ladders for advance-
ment within the agency.

EXAMINING DIRECT SERVICE WORKER TURNOVER IN
THREE LONG-TERM CARE (LTC) SETTINGS
F.K. Ejaz, A. Bukach, N.T. Dawson, K. Judge, Benjamin Rose Institute,
Cleveland, Ohio

This study examined turnover among direct service workers (DSWs)
in three LTC settings: nursing homes, home health agencies and
providers of services to developmentally disabled populations. The sites
were selected using stratified random sampling procedures by the three
types of LTC settings and five geographic regions across Ohio. A cross-
sectional study design was used to survey administrative staff in these
sites. A total of 97 provider organizations participated. Findings revealed
that DSWs in these settings primarily provided hands-on care like help-
ing clients with activities of daily living (ADLs) and instrumental ADLs,
although tasks varied by setting type. Turnover was around 33% in 2011
and did not differ significantly by LTC type. However, geographic/regional differences were evident with metropolitan regions
having significantly higher turnover (57%) compared to other regions.
Predictors of turnover included negative social interactions at work and
job burnout. Recommendations for practice and policy will focus on
these findings.

PRACTICE STRATEGIES FOR HIGH-PERFORMING HOME
HEALTH AGENCIES
I.M. Nelson1, B.G. Sarah2. 1. Scripps Gerontology Center, Oxford,
Ohio, 2. Department of Sociology and Gerontology, Miami
University, Oxford, Ohio

This paper will provide results from 50 interviews conducted with 10 high-performing Home Health Agencies (HHAs) in Ohio. The high-
performing HHAs were selected by provider relations staff at each of

Memory Problems and Difficult Behaviors and Arranging Services. A
number of other outcomes will be discussed during this presentation,
including action step assignment and status, contact types, indirect and
direct time.

66th Annual Scientific Meeting
Ohio’s 13 Area Agencies on Aging, HHAAs were chosen based on responsiveness to problems, well-trained staff, and usage of consistent assignment. Staff members such as owners, coordinators, and direct care workers provided details on organizational best practices. Administrators focused on ensuring that direct care workers knew the mission of the organization. Administrators also emphasized the importance of knowing and being responsive to the needs of direct care workers. Home health workers highlighted respect, flexibility, and autonomy as key themes. A good match between home health workers and clients was important. The presentation will discuss implications for practice and policy as well as provide comparisons in practice between nursing home and home health care organizations.

SESSION 90 (SYMPOSIUM)

INTERGENERATIONAL RELATIONS AND THE WELL-BEING OF OLDER ADULTS IN CHINESE IMMIGRANT FAMILIES: A COMPARISON OF IMMIGRANT Sending AND RECEIVING AREAS

Chair: M. Guo, School of Social Work, University of Iowa, Iowa City, Iowa
Co-Chair: I. Chi, University of Southern California, Los Angeles, California

Increasing global population mobility greatly affects the family system and older adults in both immigrant sending and receiving areas. Using data from two recent research projects conducted in Beijing and Los Angeles (LA), this symposium examines the implications of immigration on aging families and late-life well-being in various perspectives. Using the Beijing sample, Guo and Chi found that elders in immigrant families (i.e., at least one child moved abroad) had significantly more monetary support and less instrumental support from children, had more worries about lack of care in sickness but less worries about insufficient financial resources than elders in families without immigrant children. Liu, Guo, and Chi found that elders in immigrant families in LA had a significantly higher level of depression than elders in immigrant families in Beijing. Positive family relations and better functional ability were associated with lower level of depression in both groups. Having more friends was related to lower level of depression in the LA sample only. Xu and Chi examined factors that drive Chinese elders to immigrate. They found that lack of pension, more active social participations, and driving abroad were the major determinants of being immigrants among Chinese elders. Mao and Chi focused on the LA immigrant sample and found that living alone was correlated with poor functional health whereas support from children was positively associated with functional health. Together, the four papers illustrate how individual resources and family contexts shape the family relations and aging experience of elders in immigrant families.

INTERGENERATIONAL RELATIONS AND THE WELL-BEING OF OLDER ADULTS IN CHINESE IMMIGRANT FAMILIES: A COMPARISON OF IMMIGRANT SENDING AND RECEIVING AREAS

M. Guo1, I. Chi2, 1. School of Social Work, University of Iowa, Iowa City, Iowa, 2. University of Southern California, Los Angeles, California

Comparing 293 elders in immigrant families (at least one child moved abroad) and 257 elders in nonimmigrant families (all children remained in China) in Beijing, this study examined the influence of children’s immigration on family relations and well-being of older parents. Regression analyses showed that older adults in immigrant families received significantly more monetary support from children, but were less likely to receive instrumental support from children than elders in nonimmigrant families. The two groups did not differ in levels of depression and life satisfaction, but elders in immigrant families had more worries about lack of care in sickness and elders in nonimmigrant families worried more about insufficient financial resources in later life. Such differences disappeared when health status, number of children remaining in China, and parent-child relationships were taken into account. The findings illustrate how individual resource and family contexts shape the aging experience of elders in immigrant families.

OLDER ADULTS AS IMMIGRANTS VERSUS FAMILY MEMBERS AS IMMIGRANTS: IMPLICATIONS FOR THE MENTAL HEALTH OF OLDER PERSONS

J. Liu1, M. Guo1, I. Chi2, 1. School of Social Work, University of Iowa, Iowa City, Iowa, 2. University of Southern California, Los Angeles, California

Global immigration greatly affects social support and well-being of older persons, but in different ways. This study compares levels of depression among Chinese older adults who are immigrants themselves (n = 237, living in Los Angeles (LA)) and who live in Beijing but have immigrant children (n = 293). Regression analyses showed that even after controlling for demographic, functional health, family and social interaction factors, older immigrants in LA still had a significantly higher level of depression than elders in immigrant families in Beijing. In both groups, positive relationship with immigrant children and better functional ability are associated with lower level of depression. Having more friends was related to lower level of depression in the LA sample only. The finding suggests being an immigrant seems to be a more stressful event for older adults than having immigrant children. Developing supportive networks in the receiving community seems to benefit older immigrants.

WHO STAYS? WHO GOES? SELECTIVE EMIGRATION AMONG THE CHINESE OLDER ADULTS

L. Xu1,2, I. Chi1, 1. School of Social Work, USC, Monterey Park, California, 2. School of Social Work, UT-Arlington, Arlington, Texas

Few studies compared the characteristics of Chinese older adults who stay in China or immigrate to another country when one or more of their children have already migrated abroad. Using a sample of 293 elders that stayed in Beijing who has at least one child migrated abroad and 237 elders that immigrated to Los Angeles, this study examined the differences between these two groups and factors that drives Chinese elders to immigrate. Study found that compared to elders stayed in Beijing, immigrant elders had lower education or less health condition, were less likely being married or have pension, but had more local friends and social participation as well as higher level of English proficiency and higher percentage of driving abroad. Logistic regression indicated that not having pension, more social participation, and driving abroad were the major determinants of being immigrants. The findings illustrated how social contexts drove elders’ immigration choices.

CORESIDENCE WITH OFFSPRING AND FUNCTIONAL HEALTH AMONG OLDER CHINESE IMMIGRANTS

W. Mao, I. Chi, Univ Southern California, Los Angeles, California

Functional health, that is, the ability to fulfill basic physiological functions, has been shown to be a key indicator of health and well-being among older adults. Few studies were conducted explicitly to examine the relationship between living arrangements and functional health among older immigrants with diverse cultural backgrounds. This paper aimed to explore how coresidence with offspring influence functional health among older Chinese immigrants in Los Angeles, accounting for sociodemographic factors. Multiple regression was conducted using SPSS 19. Coresidence with children and/or grandchildren was significantly correlated with poor functional health. Being older, female, having more chronic conditions, poor self-rated health was shown to be significantly associated with poor functional health. Having depressive symptoms and providing tangible support (e.g., money, food, gifts) to children was marginally related with poor functional health while receiv-
ing household chore help and personal care from children was not significantly correlated with functional health.

SESSION 95 (SYMPOSIUM)

NARRATIVITY, AGING AND MEANING
Chair: J. Dohmen, University for Humanistics, Utrecht, Netherlands
Discussant: T.R. Cole, University of Texas, Houston, Texas

The narrative turn in philosophy as well as gerontology is deeply concerned with how identities are constituted in and through narratives.Narrativity is a basic concept which defines aging as a development through time, negotiating between personal aspirations and the expectations of the cultural narratives our lives are embedded in. Our concern in this symposium is with the value of the narrative discourse for thinking about aging and meaning. A common assumption shared by all presenters reads that narrative engagement with our existence potentially generates important conditions for experiencing later life as meaningful. Moral and existential questions focusing on issues of meaning tend to be undervalued in societal, cultural and scientific discourses about aging. Our aim is to present a framework enabling critical reflection on issues of meaning in later life, with the help of the narrative paradigm as developed in philosophical, psychological and gerontological debates in recent decades. Gerben Westerhof and Ernst Bohlmeijer focus on the relation between narrative interventions and the experience of meaning and aging in a care context. They discuss the promising and problematic elements of the narrative approach in this respect. Next, Joseph Dohmen provides a philosophical reflection on the value of metaphor, an important narrative instrument, in the search for meaning and motivation in later life. He focuses on the metaphor of life as a journey, and illustrates his argument with examples from classical and modern literature. Finally, Hanne Laceulle explores the value of a narrative perspective in the critical rethinking of self-realization as a moral ideal that can contribute to meaning. The aim of her paper is to assess the possible contribution of the philosophical concept of self-realization to the creation of inspirational cultural narratives about later life.

NARRATIVITY IN CARE FOR OLDER PERSONS
G.J. Westerhof, E. Bohlmeijer, University of Twente, Enschede, Netherlands

Several demographic, medical, and societal changes ask for an approach that considers the question of what makes a good life, ever and beyond the quality of care. Although longevity increases, people grow older with more chronic diseases. Given improvements in medical technologies, end-of-life care issues become ever more virulent. Last, care for older persons is under economic strain, e.g., concerning lives in nursing homes. Since stories provide a means to provide life with purpose and meaning, we argue that narrativity plays an important role in understanding what makes a good life to older individuals. Using examples from everyday care interactions as well as from narrative interventions we demonstrate how listening to and supporting older people in telling their stories can meaningfully contribute to care. We discuss the promises and pitfalls of narrative approaches.

NARRATIVITY, AGING AND THE METAPHOR OF THE JOURNEY
J. Dohmen, University for Humanistics, Utrecht, Netherlands

Metaphors allow a powerful, linguistic representation of human life. They steer our observation, thought and actions (Lakoff & Johnson 2003). They sketch a certain image of the nature of human activities, elucidate some aspects of our life and hide others. They enable certain orientations and bring coherence in what, without them, would remain a meaningless chaos. The journey is a famous, classical metaphor. The power of this metaphor is tempting and treacherous at the same time. In his book The journey of life. A cultural history of aging in America (1992), the historian Tom Cole has shown how in early modern times under the influence of Protestantism a certain kind of individualization of the human course of life developed. Coles used the metaphor of the journey to write a complete history of aging. In my paper I take the journey in a more philosophical systematic way as a metaphor for the late modern human condition (McIntyre (1981), Taylor (1989)). I start with a short discussion of what is known as a classical story, Homer’s Ulysses. Next I address the rich analogy between life and traveling. My contention is that this analogy offers valuable insights on aging and motivation, which I will explore in my paper. From here I go on to a critical view on the journey-metaphor of the feminist philosopher Margaret Walker. She attacks what she calls ‘whole life ethics’, and considers life as a journey a misleading metaphor of aging. To conclude I will evaluate the power and the weakness of the travel metaphor in classic and modern narratives.

SESSION 105 (SYMPOSIUM)

SELF-REALIZATION AND CULTURAL NARRATIVES ABOUT LATER LIFE
H. Laceulle, University for Humanistics, Utrecht, Netherlands

Several authors have addressed the problematic absence of inspirational cultural narratives that can help us in our search for meaning in later life. Dominant constellations of stories and images about aging are often problematically one-sided, de-individualizing and stereotypical. The absence of individuating, meaning-generating and inspirational cultural narratives about later life will have a profound influence upon the individual existential experience of aging and the individual quest for moral and spiritual meaning in later life. Challenging existing problematic cultural narratives and suggesting alternatives requires the development of a vital identity as aging individuals in late modern culture. The realization of such an identity can be seen as one of the main goals of self-realization, or the moral ideal to shape one’s life according to one’s own appropriate goals and values, applied to the context of late modern aging. My research explores the possibilities of the philosophical concept of self-realization for rethinking existing narratives about aging and contributing to a new moral culture of aging. Narrative discourses offer a fruitful approach for the necessary substantiation of the principles underlying the concept of self-realization. In this paper, I will offer a philosophical exploration on the relation between the premises underlying discourses on narrative and the concept of self-realization, and reflect on the possible value of these combined discourses for the stimulation of new meaningful cultural narratives on aging and later life.

A Glimmer of Home: Transitions in Continuing Care Settings in Nova Scotia, Canada
Chair: E. Roberts, Human Environmental Sciences, University of Missouri-Columbia, Columbia, Missouri
Discussant: B. Schwarz, Human Environmental Sciences, University of Missouri-Columbia, Columbia, Missouri

This symposium explores the outcomes of a government funded expansion of the continuing care sector in the province of Nova Scotia, Canada. In 2009, the Nova Scotia Department of Health and Wellness implemented a 10 year Continuing Care Strategy, one element of which is the funding of 11 new long term care facilities in the small house model. Changes include innovative physical designs, an emphasis on resident-centered care and an emphasis on staff scope of practice. There are few other international opportunities to study the impact of such a large government expenditure on new models of long term care and this symposium is a reminder of the universality of struggle in organizational change, serving as a reference point for any provider, designer, or government entity contemplating wide-spread transitional change in the way that care is provided for vulnerable older populations. The

THE ROAD (AND ROADBLOCKS) TO CHANGE: ASSESSING PROVIDER OUTCOMES IN ORGANIZATIONAL TRANSFORMATION IN LONG TERM CARE IN NOVA SCOTIA, CANADA
E. Roberts, Human Environmental Sciences, University of Missouri-Columbia, Columbia, Missouri

Working within the framework of Environmental Psychology, this study chronologically assesses one provider’s pathways in the Long Term Care transitions brought forth by the Continuing Care Strategy in Nova Scotia, Canada. Concurrently studying the impact of the new regulations on staff, residents, family members, the research focuses on the organizational transitions that the provider went through in adopting the new model based on the government guidelines. Detailed observations and interviews took place with multiple stakeholders in the two facilities owned by this provider. The voices of care staff tell of empowerment in the new settings, while family members speak of caregiver burden, loss and guilt as they relinquish care for their loved one. Most importantly the residents in both the older as well as new facility spoke candidly of their need for and the meaning of care and the significance of remembrances of their life prior to their move into LTC.

CARE AND CONSTRUCTION: WHAT IS THE EFFECT ON RESIDENT’S QUALITY OF LIFE
J. Keefe, Family Studies and Gerontology, Mount Saint Vincent University, Halifax, Nova Scotia, Canada

Nova Scotia legislation requires all nursing home that deliver care to three or more residents to be licensed and admission is contingent upon meeting assessment criteria. The perspectives of residents, family member, and staff of resident quality of life (QoL) were measured using an interRAI assessment tool. Nursing homes (N=23) were recruited to represent different staffing approaches and physical design. Results identify key considerations in the use of this tool to understand resident’s QoL from multiple perspectives. In particular, analysis of the family survey (N=397) revealed traditional homes generally received lower scores on perceptions of resident’s QoL compared to recently built neighborhood designs where staff perform multiple tasks. Significant factors contributing to resident’s QoL are analyzed by characteristics of the family and the resident, philosophy of care, the physical design and home characteristics to ascertain which factors governments may want to include in future request for proposals.

SESSION 110 (SYMPOSIUM)

ALIGNING THE CONCEPT OF SUCCESSFUL AGING WITH CHANGING REALITIES AND MODELS OF DISABILITY AND HEALTH
Chair: M. Campbell, U.S. Department of Education, National Institute on Disability and Rehabilitation Research, Washington, District of Columbia

This symposium will feature three presentations on aging with and aging into disability from both disability and gerontology perspectives. The purpose is to expand our thinking of “successful aging” to integrate the changing demographic realities of disability and new, more inclusive, models of health and participation that focus more on social and environmental factors that support quality of life than on individual attributes. Presenters will argue that restrictive concepts of successful aging based on the avoidance of disability and chronic health conditions have long divided the fields of disability and aging; thus limiting understanding of the needs of these overlapping populations and contributing to silos of empirical knowledge, policy and practice. The first presenter will document the changing demographics of individuals aging with and into disability in the U.S., and discuss the need for bridging concepts of “successful” and “healthy” across disciplines to improve understanding of these overlapping populations. The second presenter will provide a critique of the “successful aging” concept from the social model of disability perspective and summarize alternative views of healthy aging with disability, focused on environmental supports and prevention. The third presenter will summarize recent policy efforts in the U.S that illustrate the role environmental supports and health promotion/disease prevention strategies play in promoting successful aging for middle-aged and older individuals. The discussant will place these findings within a larger context of global policy initiatives that cut across aging and disability lines, and identify high priority opportunities for collaboration to reduce silos and advance knowledge.

THE CHANGING DEMOGRAPHICS OF AGING AND DISABILITY AND IMPLICATIONS FOR THE “SUCCESSFUL AGING” CONCEPT
M. Putnam, School of Social Work, Simmons College, Boston, Massachusetts

This presentation will provide an overview of what is known about demographic trends related to growing older with long-term impairment and disability first incurred before later life and compare it to trends of aging into disability, or experiencing disability for the first time in later life. The concepts of successful and healthy aging will be defined and examples of individual, social, and institutional factors that have potential to differently influence the experience of aging with and aging into disability will be presented. A rationale for expanding the concept of successful aging will be provided. Pathways for bridging knowledge between the fields of gerontology and disability research, policy, and practice will be discussed as a means of improving understanding of how to increase the potential for successful aging for persons growing older with long-term impairment and disability. Specific challenges and opportunities for bridging will be outlined.

NEW MODELS TO ENHANCE OUR UNDERSTANDING OF THE SOCIAL AND ENVIRONMENTAL FACTORS THAT CONTRIBUTE TO SUCCESSFUL AGING WITH AND AGING INTO DISABILITY
M. Campbell, U.S. Department of Education, National Institute on Disability and Rehabilitation Research, Washington, District of Columbia

This presentation critiques the concept of “successful aging” from the perspectives of the social model of disability and the World Health Organization’s International Classification of Health, Disability and Functioning (ICF), Social Determinants of Health and Active Aging Frameworks. Viewed from the social perspective, disability is a complex interaction of bodily functions and structures, personal factors, and social environmental factors, rather than an individual attribute. Informed by this view, the ICF ’mainstreams’ disability by acknowledging that every human being can experience a decrement in health and thereby experience some degree of disability. Similarly, the social determinants and active aging frameworks emphasize ‘good health’ as a ‘successful response to aging’ rather than as the absence of disease or disability. Together, these models shift our focus to the factors than enable successful aging, and better prepare us to meet the challenges of a growing population of people aging with and aging into disability.

The Gerontological Society of America
FEDERAL RESEARCH, PRACTICE, AND POLICY INITIATIVES: DRIVERS FOR NEW MODELS OF SUCCESSFUL AGING AND DISABILITY
M. Washko, US Department of Health and Human Services, Washington, District of Columbia

Increased longevity and a rapidly changing federal policy landscape are helping increasing numbers of individuals with disabilities to remain at home in their communities, with the supports they need. There are several recent initiatives at the federal level which are focused on and will impact the role environmental supports and health promotion/disease prevention activities play in encouraging successful aging for individuals who are aging with or into disabilities. These activities run along the entire spectrum of research to practice and policy; efforts range from investments in data collection (e.g. The National Health and Aging Trends Study) to federal government strategic plans (e.g. the US Department of Health and Human Services’ Multiple Chronic Conditions Strategic Framework; the National Prevention Strategy) to policy & awareness campaigns (e.g. Million Hearts) and new governmental entities (e.g. the Administration for Community Living). These investments encourage an expansion of thinking and new dialogue around “successful aging.”

SESSION 115 (SYMPOSIUM)

ARE SOCIOECONOMIC DIFFERENCES IN HEALTH-RELATED OUTCOMES STILL IMPORTANT IN THE OLDEST OLD?
Chair: M. Jylhä, University of Tampere, Tampere, Finland
Co-Chair: E. Crimmins, University of Southern California, Los Angeles, California

Socioeconomic factors are strong determinants of health and mortality at middle and younger old ages but less is known about their role among the oldest old, the fastest growing population group in many countries. At advanced old age, selection through mortality is high and age-related health problems may seem inevitable. Yet cumulating evidence shows that the role of social status is important even at advanced old ages. In this symposium we will present findings from four population-based studies in the oldest-old in three European countries and the US. The presentations analyze the role of social status from different perspectives, (1) health and functioning, (2) biomarkers and biological risk factors such as telomeres and inflammation, (3) emotional well-being, and (4) utilization of care services. Data come from three representative population studies, the Newcastle 85+ Study in the UK, the Vitality 90+ Study in Finland, and the Health and Retirement Study in the US, and a community-based trial among Alzheimer patients, the Up-Tech Study in Italy.

DOES SOCIOECONOMIC STATUS STILL MATTER AT VERY OLD AGES? EVIDENCE FROM THE HEALTH AND RETIREMENT STUDY
E. Crimmins, J.A. Ailshire, University of Southern California, Los Angeles, California

The U.S. population is experiencing unprecedented growth in the number of adults reaching advanced old age. Although age-related declines in health and functional ability may seem inevitable in oldest-old, research suggests that the aging process is not uniform and that some individuals are able to remain in good physical, mental, and emotional health even as they advance through very old age. There is strong evidence that the likelihood of becoming old is linked to socioeconomic status (SES) in the U.S. This paper examines whether the likelihood of retaining good health at the oldest ages differs by SES in a national sample of older Americans over the age of 80. We find that at these oldest ages those with the highest levels of education, i.e., those with a college education, have better physical functioning, biological risk, and emotional well-being. Differences in the effect of SES within gender and race/ethnic groups are noted.

SOCIOECONOMIC DIFFERENCES IN TELOMERE LENGTH IN THE VERY OLD: RESULTS FROM THE NEWCASTLE 85+ STUDY
C. Jagger1, C. Chiatti2, A. Kingston1, J. Collerton1, K. Davies1, C. Martin-Ruiz1, T. von Zglinicki1, T. Kirkwood1, 1. Newcastle University, Newcastle-upon-Tyne, United Kingdom, 2. INRCA - National Institute of Health & Science on Ageing, Ancona, Italy

A recent review suggests that the relationship between measures of socioeconomic status (SES) and telomere length (TL) is present only for education and weakest after adjustment for confounders. However, this evidence base is lacking in three key areas: multiple SES measures over the lifecourse; variation of TL over time; numbers of the very old. We explore the association between multiple SES measures (education, occupation-based, area-level deprivation) and TL in an unselected cohort of 845 85-year olds (1921 birth cohort) assessed at baseline, 18 and 36 months. First we explore SES differences in the availability of TL data (83.6% had baseline TL). Then we investigate whether those with greater disadvantage in SES had shorter TL at baseline and whether this persisted after adjustment for potential confounders (derived from review of previously published literature). Finally we explore whether change in TL over time differed between various defined SES groups.

SOCIOECONOMIC DIFFERENCES IN HEALTHINESS, BIOMARKERS AND MORTALITY AMONG NONAGENARIANS: RESULTS FROM THE VITALITY 90+ STUDY
L. Enroth1, J. Raitanen1,2, A. Hervonen1, M. Hurme3, M. Jylhä1, J. School of Health Sciences and Gerontology Research Center, University of Tampere, Tampere, Finland, 2. The UKK Institute for Health Promotion Research, Tampere, Finland, 3. Medical School and Gerontology Research Center, University of Tampere, Tampere, Finland

Socioeconomic status (SES) is associated with health and mortality in middle-aged and older people but the situation of the oldest old is poorly known. We utilized a data from a mailed survey in the Vitality 90+ Study, wave 2010, to investigate SES-related health and mortality differences in a cohort of 1283 nonagenarians, including both community-dwelling and institutionalized individuals. In cross-sectional analyses, a social gradient according to education and former occupation was found in health and functioning for both genders. In a three-year follow-up, mortality was lower in upper non-manuals and high-educated compared with manual workers and low-educated, respectively. An analysis in a subsample of 90-year-old individuals suggests that SES is also associated with several biomarkers, and we will analyze the possible role of these indicators as mediators between SES and mortality.

SOCIOECONOMIC DIFFERENCES IN CARE SERVICES UTILIZATION IN THE OLDEST OLD WITH DEMENTIA: THE INFLUENCE OF FAMILY AND CAREGIVING FACTORS IN THE UP-TECH STUDY

Published evidence suggests that, in addition to individual characteristics, families play an important role in determining the level of care utilization of older people. It is especially when older individuals become dependent, e.g., as consequences of dementia, that the factors influencing the access to care may be subject to changes. The presentation draws on baseline data of the Up-Tech study, an Italian community-based trial evaluating the effectiveness of a multi-component intervention for Alzheimer patients, which enrolled 450 dyads of patients and their caregivers, of which about 50% aged over 80 years. We will test whether
individual and/or family-level socioeconomic variables determine the amount of support services usage, and the degree of interaction between these two groups of factors. Finally, we will evaluate whether the effect of socioeconomic variables is stable across the different cohort groups or whether it changes among the oldest old patients.

SESSION 120 (SYMPOSIUM)

COMPUTER USE AND LONELINESS AMONG OLDER PERSONS ACROSS SETTINGS
Chair: L.J. Medvene, Psychology, Wichita State University, Wichita, Kansas
Discussant: J. Smith, University of Michigan, Ann Arbor, Michigan

As we age we are at increased risk for social isolation – whether we age in community settings, or in congregate care settings. Computers are a tool which can enable us to maintain communication with family members and friends at a time in our lives when we have the greatest need for close relationships. The present symposium contributes to the growing body of research on older persons’ use of computers. Noah Webster will present data from a nationally representative sample of older adults (aged ≥ 70, N=629) reporting that half used a computer and that computer users were less lonely across all contexts. Distance from place of worship and stores influenced impact of use. Lindsay Ryan will present data from the 2010 wave of the Health and Retirement Study selected from those aged 50+ (N=6,181), which averaged 70 years-of-age. Results show that daily computer use was associated with lower levels of loneliness, controlling for demographic variables. Samuel Ofie-Dodoo will present findings from a pilot study (N=40) of HCBS customers from a mid-western city. Twenty-five percent of customers were using computers and users had larger social networks and were less lonely. Katy Abbott will present findings from focus groups of 13 residents from an AL facility. Residents talked about barriers to computer use including preferences for traditional communication channels. Jacqui Smith, as discussant, will review these findings and their implications. The potential of computers as a tool for relationship maintenance will be reviewed, along with contextual factors which influence usability and impact.

THE ROLE OF SOCIAL CONTEXT IN THE LINK BETWEEN COMPUTER USE AND WELL-BEING AMONG OLDER ADULTS
N.J. Webster, T.C. Antonucci, Institute for Social Research, University of Michigan, Ann Arbor, Michigan

Previous research has been inconsistent in identifying a link between computer use and well-being among older adults. We explore how the availability (or lack of) social and community resources enhances or diminishes the effect of computer use on older adult well-being. Data are from a nationally representative sample of older adults (aged >70) from the monthly Reuters/Michigan Surveys of Consumers collected over the course of 10 months in 2010 and 2011 (N=629). Just over half (52%) of the sample reported using a computer. Computer use was related to less loneliness in all contexts and to better self-rated health when one’s home was less conveniently located to their place of worship. It was also related to less worry about lack of independence when home was less conveniently located to stores. Results highlight vulnerable populations and unique contexts in which computer use can be most effective in helping to optimize aging.

COMPUTER USE IN ADULTHOOD: IMPLICATIONS FOR LONELINESS
L.H. Ryan, Institute for Social Research, University of Michigan, Ann Arbor, Michigan

Research finds that loneliness is a prevalent experience in old age and that loneliness is linked with greater risk for depression and poor physical health. Given increased access to social contact via technology, the current project examined whether frequency of computer use for email and the Internet was associated with solitude. A subsample from the 2010 wave of the Health and Retirement Study was selected from those aged 50+ who completed a questionnaire on daily activities and wellbeing. The sample (N = 6,181) had a mean age of 70.4 (SD = 9.6), was 58% women, and 63% were currently married. The results indicate that over and above age, gender, education, marital status, extra-version, and physical functional limitations, individuals who used the computer daily had significantly lower levels of loneliness compared to all others. However, daily computer use was associated with greater loneliness in those with poor physical functioning.

ELDERLY HOME AND COMMUNITY-BASED SERVICE CUSTOMERS: COMPUTERS, SOCIAL NETWORKS AND QUALITY OF LIFE
S. Ofie-Dodoo, R. Smith, K. Nilsen, L.J. Medvene, Wichita State University, Wichita, Kansas

The paradigm of providing care for “frail” older persons in nursing homes is shifting and increasing numbers of persons are receiving care in home and community-based (HCBS) settings. Social isolation is a risk for this population and computer mediated communication (CMC) is a technology which could reduce this risk. The present study involved 90-minute interviews with 40 elderly HCBS customers in a moderate sized mid-western city. The interview included questions about customers’ social convoys, loneliness, quality of life, subjective health status, and their interest in and use of computers. At the time of the study 25% of customers were using computers and these customers had significantly larger social networks and were significantly less lonely than non-users (p’s < .05). After seeing a 3-minute video illustrating a CMC system which accommodated visual and manual disabilities, 85% of customers said they would use such a system if it were available to them.

“IF YOU’VE NEVER HAD IT, YOU DON’T MISS IT”: COMPUTER USE AMONG ASSISTED LIVING RESIDENTS
K. Abbott1, 2, J.S. Sefcik1, 1. Polisher Research Institute, North Wales, Pennsylvania, 2. School of Nursing, University of Pennsylvania, Philadelphia, Pennsylvania

It has become the norm for many people to use technology, such as email and Skype to stay connected with friends and family. However, there is a lack of knowledge regarding how older adults use technology to maintain their social connections. The purpose of this study is to describe the use of technology to communicate with friends and family and for looking up health information among cognitively capable AL residents. Four focus groups with 13 participants were held with residents from one AL. Directed content analysis was used to determine facilitators and barriers to technology use. While access is provided by the AL, visual deficits and a lack of knowledge currently deters residents from using computers. Residents prefer to communicate in traditional ways, such as talking in person/phone and seek assistance from younger family members (children and grandchildren) with looking up health information. Implications of these findings will be discussed.

SESSION 125 (SYMPOSIUM)

EMBODIING AGE AND AGEING
Chair: W. Martin, School Of Health Sciences and Social Care, Brunel University, Uxbridge, United Kingdom
Co-Chair: J. Twigg, University of Kent, Canterbury, United Kingdom
Discussant: C. Phillips, University of Manchester, Manchester, United Kingdom

In recent years there has been an increasing interest in the social, biological and cultural dimensions of our bodies as we grow older. Despite a concern within social gerontology that a focus on the bodies of older people could be seen as a return to biological determinism and an overly medical approach, research on ageing bodies has instead pro-
vided a novel lens to examine a range of existing sociological and theoretical concerns, including, the nature of the body, self and ageing; social identities and inequalities; lived experiences and everyday life; health and illness; and ageing across the lifecourse from midlife to deep old age. An analysis of ageing bodies further engages with both biological (medical) and social constructionist (cultural) approaches. The aim of this symposium is to bring together social gerontologists whose work focuses on ageing, bodies and embodiment to explore different theoretical perspectives, methodological approaches and empirical findings. The papers will include perspectives on personhood, clothes and the body (Twigg and Buse); the conflation of ageing, health and appearance concerns in relation to the body (Calasanti and King); embodied identities and ageing (Gilleard and Higgs); the body in everyday life (Martin and Pilcher); and masculinity, ageism and the body (Hurd Clarke). In particular, this symposium aims to: (a) highlight and debate interconnections between the corporeality of ageing bodies and the sociocultural context in which we live; and (b) promote collaborations and networks between members of the GSA and the British Sociological Association (BSA) Ageing, Body and Society study group.

EMBODIED IDENTITIES AND AGEING

P. Higgs, C.J. Gilleard, University College London, London, United Kingdom

The notion of ‘embodied identities’ refers to the selective use of corporeal aspects of the body, or certain corporeal functions, to define an individual’s distinct social position. The rise of identity politics in the 1960s gave added impetus to social identities that privileged key distinctions concerning abled-bodiedness, gender, race or sexuality. This paper explores how the corporeal processes of ageing have been affected by, as well as affecting the construction of later life identities in what has been termed ‘second’ modernity. Drawing upon critical race and queer theory, we suggest that just as the binary categories of male/female, able bodied/disabled, black/white or straight/gay have been challenged, queer theory, we suggest that just as the binary categories of male/female, able bodied/disabled, black/white or straight/gay have been challenged, so the binary of youth/age can also be made problematic, leading increasingly to positions of contingency in individual narratives and performances of age and ageing.

RATIONALES FOR ENGAGING IN ANTI-AGING ACTIVITIES: WHAT MIDDLE-AGED ADULTS SAY

T. Calasanti, N. King, Virginia Tech, Blacksburg, Virginia

Who uses anti-aging products and services? Overt use requires admitting concern about ageing, which also means acknowledging movement toward membership in a stigmatized group. It could also signify concern about how one looks to others, especially when products and services are geared at transforming outward appearance. By contrast, some have treated health as a more acceptable reason for bodily concern (e.g., Hurd Clarke, 2002). And gender might also shape the expression of each of these motivations. Recognizing the possible conflation of reasons given for using anti-aging products and services, this presentation analyzes interviews conducted among middle-aged respondents, to examine the extent to which they cite age, health, and appearance. Results suggest that respondents may engage in a fair amount of anti-aging activities, but are unlikely to label them as such.

VISUALLY REPRESENTING THE BODY IN EVERYDAY LIFE

W. Martin, K. Pilcher, School Of Health Sciences and Social Care, Brunel University, Uxbridge, United Kingdom

Drawing on findings from an ESRC empirical study ‘Photographing Everyday Life: Ageing, Bodies, Time and Space’, this paper explores the significance of the body in the daily lives of 62 women and men aged 50 years and over in the UK. Participants photographed their different daily routines to create a weekly visual diary, which was explored through in-depth interviews, to make visible the rhythms, patterns and meanings that underlie their everyday worlds. This paper focuses on how participants represented their bodies through the visual, including representing the healthy/‘active’ body; the gendered body; and how visual representations indicate that the body is a process of becoming, a continual bodily ‘project’ (Gill et al., 2005), both socially and physically constructed through participants’ bodily maintenance, discipline, and work on and with their bodies. We conclude by exploring the significance of these bodily representations and practices to the ways that age and ageing are understood and represented.

MASCULINITY AND AGING: MEDIA DEPICATIONS IN MAGAZINE ADVERTISEMENTS

L.C. Hurd Clarke, E.V. Bennett, University of British Columbia, Vancouver, British Columbia, Canada

This paper considers how aging masculinity and older men’s bodies are portrayed in men’s magazines. Examining the texts and images of advertisements in six widely read North American, male-oriented magazines (namely, Esquire, GQ, Maxim, Men’s Health, Men’s Journal, and Zoomer), we used critical discourse analysis methods (Fairclough, 2010). Our findings reveal that media depictions of older men are underscored by dominant cultural norms of masculinity and ageist stereotypes. Older men while present are largely invisible and those who are portrayed adhere to the masculine ideal of the distinguished, rich, sexually dominant older individual. The majority of the advertisements market clothing, accessories, vacations, cars, supplements, and alcohol with White, young male models. We consider our findings in relation to West and Zimmerman’s (1987) concept of doing gender and Connell’s (1995; 2005) multiple masculinities, as well as with respect to the existing literature concerning ageism, the body, and masculinity in later life.

DRESS AND THE CONSTITUTION OF AGE

J. Twigg, C.E. Buse, Sociology and Social Policy, University of Kent, Canterbury, United Kingdom

Dress and the Constitution of Age Clothes lie at the interface of the body and its social presentation. They thus play a central part in how identities – including aged identities - are expressed and performed. The paper explores these connections through two qualitative studies, both conducted in the UK. The first addresses the role of dress in the lives and experiences of older women, placing this in the wider cultural and commercial context of the media and the fashion industry. The second examines dress in the lives of people with dementia, exploring how clothes are interwoven with their life-narratives, and how their materiality can both facilitate the retelling of broader life-histories, and support personhood at an embodied level. The implications of these findings for conceptualising ageing, embodiment and identity - as well as for practice and policy – will be discussed.

SESSION 130 (SYMPOSIUM)

LIVING WELL WITH CHRONIC ILLNESS: COMPARING RESEARCH AND POLICY DEVELOPMENTS IN AUSTRALIA, CANADA, UNITED STATES AND CHINA

Chair: A.V. Wister, Gerontology, Simon Fraser University, Vancouver, British Columbia, Canada
Co-Chair: H. Kendig, Australian National University, Canberra, Australian Capital Territory, Australia
Discussant: M.G. Ory, Texas A&M, College Station, Texas

Chronic diseases are a major contributor to disability, deaths, and health care costs in more developed countries undergoing population aging. Indeed, most persons aged 65 and over have at least one chronic illness, and the majority have multiple chronic illnesses. The National Academy of Sciences has identified ‘living well with chronic disease’ as an urgent public and community health goal. However, experiences of diverse societies have not been investigated to better understand how
LIVING WELL WITH CHRONIC DISEASE IN AUSTRALIA: TRAJECTORIES TO DEATH

H. Kendig1, C. Browning2, R.A. Burns2, 1. Centre for Ageing, Health and Wellbeing, Monash University, Melbourne, Australia.

The natural history of chronic diseases and impacts on quality of life need to be better understood as a basis for evidence-based policies. Findings from the Melbourne Longitudinal Surveys of Healthy Ageing (MELSHA) are reported on 1000 people aged 65 years or older in 1994 to their death through 2012. At baseline 72% reported having at least one chronic disease: heart conditions (11%), stroke (6%) cancer (14%), diabetes (6%), arthritis (56%), or chronic obstructive pulmonary disease (COPD) (14%); Yet fully 89% at baseline were ageing well in terms of IADL independence, self-rated health and psychological wellbeing. Those with more chronic diseases at baseline were more likely to have depression and subsequently to not be ageing well and to die earlier. After attending this session participants will better understand the influence of resilience and other predictors on trajectories and wellbeing consequences of chronic disease and implications for Australian policies.

A DEMOGRAPHIC, SOCIAL, PSYCHOLOGICAL AND HEALTH PROFILE OF CANADIAN BOOMERS AND OLDER ADULTS WITH MULTIPLE CHRONIC ILLNESSES, CCHS 2009

A.V. Wister, B.A. Mitchell, Simon Fraser University, Vancouver, British Columbia, Canada

Research examining causes and consequences of multiple chronic illnesses has proliferated in recent years, especially among older populations. Drawing from a resilience model of living well with chronic illness, this paper uses the 2009 Canadian Community Health, Health Aging Survey (n=30,865) to profile demographic, social, psychological and health domains for baby boomer and older Australians living with multiple chronic illnesses. This will provide a basis for comparison with the Canadian profile presented in this symposium. The findings will be discussed within the context of a resources and resilience model of living well with chronic illness.

THE HAPPY LIFE CLUB: CHRONIC DISEASE SELF-MANAGEMENT IN CHINA

C. Browning1, H. Yang3, T. Zhang2, S. Thomas2, Z. Zhao4, A. Chapman1, S. Liu1, 1. Monash University, Notting Hill, Victoria, Australia, 2. Peking University, Beijing, China

China is undergoing rapid health system reforms in response to an ageing population and rapid increases in the numbers of people with chronic diseases. Reforms include establishing a stronger primary health care system that incorporates patient centred care and chronic disease self-management (CDSM) principles. This presentation will provide an evaluation of a CDSM RCT conducted in Beijing, China. The presentation will discuss the primary health care context in China, the translation of Western CDSM principles into the Chinese context, and 6 and 12-month quantiative and qualitative outcomes from the trial. An analysis of the challenges of implementing CDSM in an ageing population in China and the implications for practice and the training of health care practitioners will be discussed.
SESSION 135 (SYMPOSIUM)
TOWARD A CLEARER CONCEPTUALIZATION OF THE RELATIONS OF WISDOM TO OTHER CONSTRUCTS: DISTINGUISHING RESOURCES, CORRELATES, AND OUTCOMES

Chair: J. Glueck, Alpen-Adria-Universität Klagenfurt, Klagenfurt, Austria
Discussant: C.M. Aldwin, Oregon State University, Corvallis, Oregon

As wisdom is generally considered an ideal outcome of psychological development, we tend to expect it to be related to any other positive construct. Indeed, wisdom is correlated to well-being, openness, maturity, gratitude, spirituality, and many others. However, these correlations do not necessarily contribute much to our understanding of wisdom. Is a construct a predecessor, outcome, or byproduct of wisdom? Are there positive constructs that wisdom is not, or not linearly, related to? To study such questions, we need stronger theoretical frameworks – especially as measurement issues are crucial and complex. This symposium presents theoretical ideas and empirical findings on relationships that go beyond correlations. The symposium covers a broad range of measures of wisdom and of related constructs, ranging from intelligence to affect. Igor Grossmann discusses the relationship between wise reasoning and different forms of intelligence. Ursula Staudinger shows that first-order correlations of wisdom-related performance to positive constructs can be explained by one underlying relation. Ute Kunzmann discusses the relationship of emotional reactivity to wisdom-related knowledge. Monika Ardelt shows that relations between wisdom and well-being may be particularly strong in special situations, and that mediation analyses can explain such relationships. Judith Glück uses the simple example of age to illustrate the complexity and measurement-specificity of relationships when it comes to wisdom.

SMART, BUT NOT WISE? RELATIONSHIP BETWEEN WISE REASONING AND INTELLIGENCE
I. Grossmann, University of Waterloo, Waterloo, Ontario, Canada

Scholars since at least the time of Aristotle have speculated that superior reasoning contributes to well-being. However, recent evidence indicated that only wise reasoning, and not intelligence, is positively related to well-being and predicts longevity. What is the relationship between wisdom and intelligence at large, and how does this relationship differ across age groups? In the present talk I review evidence from a series of experimental and cross-sectional probability samples suggesting that fluid cognitive abilities and executive functioning are largely unrelated to wise reasoning, whereas crystallized abilities are weakly positively related to wise reasoning. Implications of this work for the theoretical construct of wisdom are discussed.

THE BERLIN WISDOM PARADIGM IN THE U.S.: RELATIONS WITH PERSONALITY ADJUSTMENT, GROWTH, AND GENERATIVITY
U.M. Staudinger1, P.M. Wink2, I. Jacobs Center on Lifelong Learning, Jacobs University Bremen, Bremen, Germany, 2. Wellesley College, Boston, Massachusetts

In this study the Berlin Wisdom Paradigm was used with an American sample for the first time. Our aims were to (a) test the basic applicability of the BWP in a non-German context, and (b) confirm cross-culturally and further extend the understanding of its convergent validity. We were interested to locate wisdom in the nexus of personality adjustment and growth as well as generativity. Our sample consisted of 163 men and women participants (65-75 yrs.). The zero-order level associations between wisdom-related performance (WRP) and indicators of personality growth as well as adjustment confirmed the hypotheses. Latent path analysis indicated that the bivariate associations between adjustment and wisdom and between generativity and wisdom were both accounted for by the respective relationships between adjustment and generativity with growth. The implications for a broader understanding of the association between WRP and different indicators of positive psychosocial functioning are discussed.

WISDOM AND EMOTIONAL REACTIVITY
U. Kunzmann, S. Thomas, University of Leipzig, Leipzig, Germany

This laboratory study (N = 240 adults between age 20 and 70) investigated the effects of wisdom, defined as expert knowledge about the meaning and conduct of life, on emotional reactivity (i.e., the intensity of emotional reactions to existential life-problems). Participants came into the laboratory for two individual sessions. In the first, wisdom-related knowledge was assessed via the Berlin Wisdom Paradigm. In the second session, emotional reactions to film clips of death and dying and personal growth were assessed via an emotional adjective list that was completed shortly after each film clip. Our analyses suggest that individuals with high wisdom-related knowledge spontaneously experienced greater sadness in reaction to films about loss and greater joy in reaction to films about personal growth than individuals with low wisdom-related knowledge. This evidence corroborates the theoretical notion that wisdom involves emotional sensitivity rather than affective distance and modulation.

WISDOM AT THE END OF LIFE: AN ANALYSIS OF MEDIATING AND MODERATING EFFECTS ON SUBJECTIVE WELL-BEING
M. Ardelt. Sociology and Criminology & Law, University of Florida, Gainesville, Florida

Several studies have shown that wisdom, measured as an integration of cognitive, reflective, and compassionate dimensions, is a positive related to subjective well-being in old age. Yet, we only have begun to study the underlying mechanisms of this relation. Using samples of 156 older community residents (M = 71 years) and 41 older hospice patients and nursing home residents (M = 77 years), this study investigated whether wisdom might be particularly beneficial for people at the end of life, when hedonistic means to increase well-being largely disappear, and whether the association between wisdom and well-being is mediated by mastery and purpose in life. Results of structural equation models showed that, as expected, (1) wisdom had a significantly stronger effect on well-being in the nursing home and hospice sample than in the community sample and (2) those relations were partially mediated by purpose in life, both directly and via a sense of mastery.

THE COMPLEX RELATION OF WISDOM TO AGE
J. Glueck, Alpen-Adria-Universität Klagenfurt, Klagenfurt, Austria

Neither laypeople nor wisdom researchers believe that wisdom comes automatically with age – in fact, age is probably neither a necessary nor a sufficient condition for wisdom (e.g., Staudinger, 1999). While most wisdom researchers seem to agree with this assumption, we are still pleased with positive correlations of our measures to age and disappointed with negative ones. In this talk, I use data from 170 adults, including 47 wisdom nominees, who filled out three different wisdom scales, to analyze linear and nonlinear relations between facets of wisdom and age. Three facets that seem to regularly increase with age are non-wisdom (alienation and simple-mindedness), perspective-taking, and concern for others. Other facets, such as self-reflection, tend to decrease with age but are maintained in a small group of older adults. Wisdom may be a composite of facets with different typical developmental trajectories.
DEPRESSION AND ANXIETY

LIVING WITH DEPRESSION: A CROSS-ETHNIC COMPARISON OF MEANING MAKING AMONG DEPRESSED OLDER WOMEN
E. Apeso-Varano, Betty Irene Moore School of Nursing, UC Davis, Sacramento, California

Background: It is estimated that depression will be the second leading cause of disability worldwide by 2020 and disparities prevail in depression care. Women are twice more likely than men to suffer from depression and improving depression care is of public health significance. With the unprecedented aging of the US population and its increasing ethnic diversity, questions emerge regarding how older women from diverse backgrounds experience depression. Objective: To explain the relation of socio-cultural factors and depression experience to older women’s help-seeking behaviors. Methods: This is a cross-sectional, qualitative study of older women (65+) with clinical depression identified in primary care (15 white, 15 Latinas, 15 Black) in central California. Women meeting criteria completed an in-depth, semi-structured interview covering topics such as their background, health, depression, family, aging, and access to health services. In-depth interviews ranging from 2 to 3 hours in duration were fully transcribed verbatim and thematic analyses in the qualitative tradition were conducted. Results: Women across groups express their depression in similar idioms of distress (i.e. feeling down) and provide similar causal explanations of their depression (i.e., aging, family, economic hardship). Important cross-ethnic/racial differences have emerged, particularly with respect to how Latinas and African American women cope with their symptoms (i.e., African American rely on religion while Latinas draw on family support; whites ask for medical help and medication treatment). Analyses indicate that women across groups embed their depression in a narrative of lifelong suffering due to adverse social conditions such as chronic poverty, discrimination, and abuse.

RECOVERY FROM DEPRESSION AMONG OLDER ADULTS: FINDINGS FROM A 12-YEAR PANEL STUDY OF A REPRESENTATIVE COMMUNITY SAMPLE
E. Fuller-Thomson, M. Battiston, T. Gadalla, S. Brennenstuhl, University of Toronto, Toronto, Ontario, Canada

Depression is a disabling mental disorder common among older adults. Most studies of remission from depression have used clinical samples and relatively short follow-up periods. To investigate time to remission, and the factors associated with it, we followed a representative sample of 188 community-dwelling depressed Canadian women (n=134) and men (n=54), aged 55 and over, from the National Population Health Survey. Individuals were interviewed every two years over a 12-year period. Depression was assessed each wave using the Composite International Diagnostic Interview Short Form (CIDI-SF). Mean time until remission was established using the Kaplan–Meier procedure. Remission rates were very high, with 84% of the sample in remission by 2 years and 91% in remission by 4 years. Several baseline characteristics were associated with significantly lower time to remission, including being physically active (p=.048) and having a confidant (p=.006). Growing up with parents who were addicted to drugs or alcohol was associated with a longer time to remission (p=.02). In contrast to previous research, neither education level nor presence of chronic pain nor chronic health conditions, such as arthritis or migraines, were associated with time to remission. This study suggests that the vast majority of those 55 years or older living in the community recover from depression (at least temporarily), and they do so within a relatively short period of time.

THE IMPACT OF ADULT CHILDREN’S OUT-MIGRATION ON THE ELDERS’ PSYCHOLOGICAL WELL-BEING IN RURAL CHINA
L. Song1, M. Silverstein2, S. Li3, 1. Soochow University, Suzhou, Jiangsu Province, China, 2. Syracuse University, Syracuse, New York, 3. Xi’an Jiaotong University, Xi’an, Shanxi Province, China

This study examined the impact of adult children’s out-migration on the psychological well-being of older Chinese parents left behind in their rural villages. Using data from two waves of the “Longitudinal Study of Older Adults in Anhui Province, China”, analyses showed that, controlling for personal characteristics and resources, the out-migration of children reduced the psychological well-being of their parents, particularly among older fathers. However, the transition to coresidence with an adult child buffered the negative impact of daughters’ out-migration on the psychological well-being of older mothers. These results suggest ambivalent feelings on the part of older parents when their adult children migrate out of their home villages for work or marriage. We also found that there is an important gender division in the adaptation to the out-migration of children. Mothers benefited from entering into a traditional multi-generational living arrangement when their daughters migrated; comparable fathers suffered from worse psychological well-being following entry into such an arrangement, presumably because living with children increased their dependence. It is concluded that a complex gender interaction needs to be considered when examining the consequences of dynamic intergenerational family processes in China.

ASSESSING THE PSYCHOMETRIC PROPERTIES OF THE GERIATRIC ANXIETY INVENTORY (GAI) AMONG COMMUNITY-RESIDING OLDER ADULTS

Anxiety symptoms are prevalent among mood-disordered older adults and may confer risk for suicide (Waern et al., 2002). Pachana and colleagues (2007) developed the Geriatric Anxiety Inventory (GAI), a 20-item dichotomously-scored (Agree/Disagree) measure of anxiety symptoms among older adults to overcome the limitations of existing scales. The purpose of the present study was to investigate the psychometric properties of the GAI among 173 community-residing older adults recruited into a 2-year longitudinal study of risk and resiliency to later-life suicide ideation. Findings supported the internal consistency (KR20=.90) and 2-4 week test-retest reliability (r=.88, ICC=.88; p<.0001) of the GAI. Positive associations between the GAI and the Beck Anxiety Inventory (r=.62, p<.0001) and measures of depression (r=.75; p<.0001), social hopelessness (r=.43; p<.0001), and suicide ideation (r=.37; p<.0001) and negative associations with psychological well-being (r=−.46; p<.0001) and life satisfaction (r=−.35; p<.0001) attested to its construct validity, and non-association with cognitive functioning (r=−.08; p=.29) and social desirability (r=−.12; p=.11) supported its discriminant validity. GAI scores further differentiated between older adults with or without a history of suicidal behavior (t(134)=−4.00, p<.0001). Study findings thus indicate strong psychometric properties for the GAI among community-residing older adults and further suggest value in assessing anxiety symptoms in the context of late-life suicide risk assessment.
MAJOR LIFE EVENTS AND TWO-YEAR CHANGES IN DAILY STRESS, ANXIETY, AND DEPRESSIVE SYMPTOMS IN THE AFRICAN AMERICAN HEALTH COHORT

E.M. Andresen1, D.K. Miller1,2, T.K. Malmstrom2, M. Schootman6, P. Miller6, F.D. Wolinsky1, 1. College of Public Health, University of Iowa, Iowa City, Iowa, 2. Saint Louis University, St. Louis, Missouri, 3. Oregon Health and Science University, Portland, Oregon, 4. Indiana University, Indianapolis, Indiana, 5. Regenstrief Institute for Health Care, Indianapolis, Indiana, 6. Washington University in St. Louis, St. Louis, Missouri

Objective: Major life events are stressful and affect changes in a variety of psychosocial outcomes. In this study we examined the effect of experiencing a major life event on two-year changes in daily stress, anxiety, and depressive symptoms among participants in the African American Health (AAH) cohort. Method: Data on 542 older AAH men and women were used to estimate the crude and adjusted effects of experiencing a major life event (yes vs. no) between 2008 and 2010 on changes in daily stress, anxiety, and depressive symptoms during the same period. Daily stress and anxiety were each measured in 2008 and 2010 by reliable and valid two-item scales. Depressive symptoms were measured in 2008 and 2010 by the reliable and valid 11-item version of the Center for Epidemiologic Studies Depression (CES-D-11) scale. Covariates included age, gender, marital status, education, income, employment status, and self-rated health. Multiple linear regression analysis with propensity score re-weighting to adjust for potential attrition bias was used to predict each psychosocial outcome by its value in 2008, whether a major life event was experienced, and the covariates. Results: Half (49.7%) of the participants experienced a major life event between 2008 and 2010 and that experience increased their everyday stress (Cohen’s d = 0.407, p < 0.001), anxiety (Cohen’s d = 0.437, p < 0.001), and depressive symptoms (Cohen’s d = 0.209, p = 0.002), even after adjustment for all covariates. Conclusion: Major life events increased everyday stress, anxiety, and depressive symptoms among AAH cohort participants.

SESSION 145 (PAPER)

LIFE COURSE AND DEVELOPMENTAL CHANGE

INTERRELATED TRAJECTORIES OF DIFFERENT HEALTH DIMENSIONS IN LATER LIFE ACCORDING TO EDUCATION

S.M. Spuling, M. Wiest, O. Huxhold, S. Wurm, German Centre of Gerontology, Berlin, Germany

It is well known that age and education by themselves but especially in combination have strong effects on health up to and in old age. But previous research rarely considered the multidimensionality of health when examining the age-related health gap between individuals with different educational backgrounds. Thus, the aim of the present study was to examine trajectories of different health dimensions in later life and their interrelation as a function of education. Longitudinal data of community-dwelling adults aged 65 years and older from four measurement occasions of the German Aging Survey was used (N=3,111). A dual change score model was employed to analyze age-related trajectories (linear and non-linear) of physical, functional and self-rated health and their interrelation according to different educational backgrounds. All health dimensions worsened with advancing age: Self-rated health showed the least decline and functional health declined the most. Furthermore, in all health dimensions educational differences were observed. Individuals with higher education consistently reported better physical, functional and self-rated health at age 65. However, educational differences decreased in physical and self-rated health while they increased in functional health with advancing age. Interestingly, trajectories of physical and functional and those of physical and self-rated health were only coupled in individuals with lower educational backgrounds. These findings suggest that individuals with higher educational background are better able to prevent the adverse effects of age-relate decline in physical health on other health dimensions. We discuss possible underlying mechanisms, for instance how higher education is related to psychosocial resources and healthier lifestyle.

GENDER DIFFERENCES IN THE LIFE COURSE ORIGINS OF PHYSICAL FUNCTIONING AMONG U.S. ADULTS

J.K. Montez, Center for Population & Development Studies, Harvard University, Cambridge, Massachusetts

Mounting evidence finds that adult physical functioning reflects socioeconomic circumstances from across the life course. However, it is unclear how the health effects of these circumstances accumulate—for example, additively or synergistically. This study tests four hypotheses about how the health effects of early-life conditions (measured by parents’ education levels) and adult conditions (measured by own education level) accumulate to shape functional limitations, whether the accumulation differs between men and women, and the extent to which key social, behavioral, and biological mechanisms explain the accumulation. It uses data from the 1994-2010 Health and Retirement Study on adults 50-100 years of age (N=24,026). Among men, the benefits of parents’ and own education accumulated additively to shape functional limitations. Among women, the benefits of parents’ and own education generally accumulated, but they tapered-off among women with low-educated mothers. The tapering partly reflected a strong tie between mother’s education level and women’s obesity risk. Taken together, the study reveals subtle differences between men and women in the life course origins of physical functioning. It also sheds light on potential mechanisms underlying a growing number of studies finding that early-life conditions are especially important for women’s health.

FACILITATING SELF-TRANSCENDENCE: DEVELOPING AN INTERVENTION TO ENHANCE OPTIMAL AGING

V.L. McCarthy1, S. Bowland1, G.D. Rowles2, K.J. Linfield2, J.M. Thibault1, J. Wilson1, A. Bockweg1, A. Hoogland1, 1. University of Louisville, Louisville, Kentucky, 2. University of Kentucky, Lexington, Kentucky, 3. Spalding University, Louisville, Kentucky

Self-transcendence, an inherent developmental process, shows promise as a mechanism to increase optimal aging by helping older adults envision, prepare for, and cope with the challenges and the opportunities of late life. In prior research self-transcendence has consistently been associated with well-being, life satisfaction, mood, coping, and acceptance of life situation; however, no intervention has yet been developed to increase self-transcendence and these related factors. Self-transcendence is a dynamic process that expands personal boundaries beyond everyday realities and limitations, changing how older adults view themselves, relationships with others, and their experience of aging. This presentation will describe the development of an intervention rooted in life span development theory that is designed to increase self-transcendence. The concept is informed by Reed (1989, 2003) and McCarthy & Bockweg, (2012). These theories underpin the structure and contents of the intervention. The intervention consists of a series of eight weekly group sessions that increase activity in the five domains of self-transcendence: 1) relationships, 2) creativity, 3) introspection, 4) contemplation, and 5) spirituality. Sessions include training in mindfulness techniques such as meditation, guided imagery and journaling to be practiced independently during – and potentially after – the intervention. The intervention is being pilot tested and revised based on participant feedback. Further testing and revision of the intervention may lead to its dissemination as a comprehensive module which can be implemented by trained staff or volunteers at retirement communities, nursing homes, senior centers, church groups, and other settings where older adults gather.
VULNERABILITY TO FALL AND TRAJECTORIES OF SOCIAL PARTICIPATION AND SOCIAL SUPPORT IN THE ELDERLY

S. Pin1,2, D. Spini2, C. Cogordan1, P. Arwidson1, I. INPES, Saint-Denis, Ile-de-France, France, 2. University of Lausanne, Lausanne, Vaud, Switzerland

According to the theory of the proliferation of stress, consequences resulting from events or chronic strains can spread to other dimensions of life than health. This paper aims to identify the impact of the fall on the trajectories of social participation and social support of older people in Europe. Our sample consists of 13 328 people aged 50 and over from 11 European countries who responded to the first three waves of the Survey of Health, Ageing and Retirement in Europe. A logistic regression was performed to characterize the people who fell at the beginning of the survey. The impact of the fall on the trajectories of participation and social support was examined using GEE models. In wave 1, 3.6% reported having fallen during the last 6 months and 4.0% in wave 2. In the beginning of the survey, being a female, chronic diseases, symptoms, frailty, fracture, hospitalization, fear of falling, and subjective health are associated with a higher likelihood of having fallen. The fall was moreover negatively associated with social participation (OR = 0.83, p < 0.05) and positively with social support (OR = 1.70, p < 0.001). In both cases, the effect was indirect and disappeared with frailty. The link between the fall and social participation is often discussed in terms of activity restrictions. The life course perspective allows understanding the fall as a stressful event with implications beyond the health sphere. Avenues for analysis to examine how psychosocial variables moderate the negative impact of the fall will be discussed.

SOCIOECONOMIC STATUS, MARITAL DURATION, AND MARITAL QUALITY

H. Choi, Penn State Altoona, Altoona, Pennsylvania

Research has suggested that individuals of higher socioeconomic status (SES) may be happier in their marital relationships compared to their lower SES counterparts. However, existing studies tend to be based on cross-sectional data, providing us with only a limited understanding of their associations over time. The present study extended the literature by examining whether the socioeconomic disparities in marital quality might be exacerbated or attenuated by marital duration. Data came from the last 4 waves of the Health and Retirement Study (2004 - 2010), a biennial survey of a U.S. representative sample of men and women aged 50+ and their spouses. The analytic sample consisted of individuals or couples who stayed married to the same spouse over the 6-year period. With regard to study variables, both positive and negative marital quality were examined in relation to education and income. For statistical analyses, a series of multi-level models were estimated using SAS PROC MIXED. Results indicated that SES differentials in marital quality might become exacerbated or attenuated by marital duration. Individuals with higher levels of education reported greater declines in negative marital quality the longer they stayed married. No such trend was found among persons with lower education. Higher levels of income also were linked to better marital quality; however, marital duration did not moderate the income-marital quality linkage. Given that the sample consisted of midlife and older adults who stayed married for an average of 30+ years, the findings suggest that long-term marriages may work in favor of the socioeconomically advantaged.

SESSION 150 (SYMPOSIUM)

ACCESS TO AND UTILIZATION OF PALLIATIVE CARE SERVICES

Chair: E. Kozlov, Psychology, Washington Univ, St. Louis, Missouri

Palliative care can improve quality of life for people with life-limiting illness, but only if this multidisciplinary specialty service is accessible and utilized effectively. Within many settings, palliative care is relatively new, and little evidence exists about its utilization and effectiveness. This symposium presents 1) research that documents how palliative care is currently used and 2) practice initiatives designed to enhance access to palliative care and hospice services. In the first paper, Kozlov and Carpenter describe results from a VA chart review study of the trajectory of palliative care consultation recommendations. In the second paper, Waters and Google identify patient factors that predict access to specialist palliative care services in a community hospital. Next, Sorocco presents research on the mental health needs of palliative care patients and describes levels of interventions that interdisciplinary palliative care teams could provide. Finally, Chung and Burke discuss the results of a study aimed to improve hospice use among Latino elders through an educational video. Together, these presentations summarize data on palliative care utilization patterns in a variety of settings and discuss strategies to improve access to palliative care for patients who could benefit from this multidisciplinary approach to end-of-life care.

CHARTING THE TRAJECTORY OF PALLIATIVE CARE RECOMMENDATIONS

E. Kozlov, Psychology, Washington Univ, St. Louis, Missouri

Since 2008, Veterans Affairs hospitals have used palliative care consultation teams (PCCTs) to provide services to veterans with life-limiting illness. PCCTs within the VA are new, so little is known about their utilization. This study documents types and rates of PCCT consultation recommendations, determined implementation rates, and identified factors related to whether recommendations are made and implemented. This medical records review examined 198 palliative care consultations in one VA hospital between 2009 and 2010. The PCCT made recommendations for 111 patients (55.5%). The mean number of recommendations per patient was 1.44 (SD = 1.81). Fifty-seven percent of recommendations were implemented. Discharge and goals of care recommendations were more likely to be implemented than recommendations for pain and symptom management. χ² (5, N = 287) = 19.681 p < .001. In this medical center, the PCCT offers a range of recommendations to patients, though these recommendations are implemented at differential rates.

PREDICTORS OF ACCESS TO A PALLIATIVE CARE CONSULT AND ADMISSION TO A PALLIATIVE CARE UNIT

L. Waters, C.L. Google, Virginia Center on Aging, Virginia Commonwealth University, Richmond, Virginia

The diffusion of specialist hospital-based palliative care services requires an understanding of utilization patterns. This study examined the population characteristics of decedents (n = 9037) over an eleven-year period (May 2000 – April 2011) in a large public urban teaching hospital. Direct logistic regression was performed to investigate predicting factors that influence whether decedents would receive a palliative care consult or be admitted to a palliative care unit. Although age (85+) was a significant predictor in both instances (OR = 2.0; p = .001), the strongest predictors were secondary diagnosis of a solid cancer for both consult (OR = 2.2; p = .001) and admission (OR = 4.9; p = .001). Solid cancer as a primary diagnosis is not a predictor of a consult and hematologic malignancy as a primary diagnosis is not a predictor for either. Conclusions drawn from these and other comparisons provide insights into improved transitions at end-of-life.

PREVALENCE AND TREATMENT OF MENTAL HEALTH ISSUES AMONG VETERANS RECEIVING END-OF-LIFE CARE

K.H. Sorocco1,2, J. Nelson3, K. Bratkovich1,2, J. University of Oklahoma Health Sciences Center, Oklahoma City, Oklahoma, 2. OKC VAMC, Oklahoma City, Oklahoma

Research indicates higher prevalence rates of psychiatric symptoms at the end of life, but less is known about the mental health needs.
of veterans receiving palliative care. Original data on the prevalence of mental health needs of Veterans who received a palliative care consult will be presented. Prevalence data suggested a high rate of previous mental health issues (58%), highlighting the importance of mental health treatment in end of life care. Depression, substance use disorders, and post traumatic stress disorder were identified to be the most prevalent diagnoses. Different levels of mental health interventions at end of life from an interdisciplinary perspective will be outlined. Attendees will be able to discuss the prevalence of mental health issues among veterans receiving palliative care and levels of mental health interventions at end of life.

IMPROVING THE HOSPICE USE AMONG LATINOS: USE OF A VIDEO
K. Chung, S.C. Burke, J. Jahng, Health Sciences, California State University, Northridge, Northridge, California

Empowering patients/family caregivers to initiate end-of-life care discussions is important, particularly for Latino elders who may have language barriers and be less informed than the general population. The researchers produced a video featuring a Mexican American patient in the end stage of Alzheimer’s. The film highlights the patient by showing how an Alzheimer’s patient who is very close to the end of life suffers not only mentally but also physically. Furthermore, the film contains interviews in Spanish with the patient’s husband, clinical caregivers (RN and LVN), a volunteer, and an expert from American Alzheimer’s Association. Interviewers emphasize the benefits of early hospice enrollment, particularly for caregivers of Alzheimer’s patients. The authors will share preliminary findings in the effectiveness of the film in enhancing the awareness of hospice benefits and increasing the rates of self-referral to hospice in Mexican communities in Southern California.

SESSION 155 (SYMPOSIUM)

ALCOHOL AND DRUG MISUSE IN OLDER ADULTS: AN INTERDISCIPLINARY PERSPECTIVE
Chair: J. Culberson, Baylor College of Medicine, Houston, Texas
Discussant: J. Culberson, Baylor College of Medicine, Houston, Texas

The use and misuse of alcohol and substances in older adults is an emerging public health problem. Heterogeneous medical, psychological and social characteristics of this population provide a unique challenge to researchers and clinicians. This symposium will include presentations from a diverse group of interdisciplinary researchers representing the Health Sciences, Behavioral and Social Sciences, and the Social Research, Policy, and Practice Research Sections. The first presentation will highlight the results of an online prescription drug safety survey distributed to 85 pharmacists in the Kentucky Pharmacy Registry indicating that stigmatization is a major barrier to programs designed to reduce the risk of alcohol and medication interactions (AMI). A second presentation will review the results of the National Epidemiologic Survey on Alcohol and Related Conditions (NESARC), demonstrating that a clinical diagnosis of bipolar disorder predicts alcohol or drug use disorders in older adults. A third presenter will use differential item functioning (DIF) to analyze data derived from the Pathways Study (Scott & Dennis, 2011) comparing measures of substance use disorders across younger and older subjects to demonstrate that all but two measures function commonly. Finally, a fourth presentation will review data collected from a large sample of older adults enrolled in 22 outpatient addiction treatment programs in New York State Office of Alcoholism and Substance Abuse Services to show that programs providing age-tailored services have significantly improved odds of discontinued use. Alcohol and substance use disorders in older adults will be summarized from a clinical and health services perspective.

PREVENTING ALCOHOL AND MEDICATION INTERACTIONS: PHARMACIST VIEWPOINT
F. Zanjani¹, R. Smith⁵, R. Clayton⁷, C. Martin⁷, N.E. Schoenberg¹, 1. Gerontology, University of Kentucky, Lexington, Kentucky, 2. University of Kentucky, Lexington, Kentucky

Prescription overdoses in older adults are commonly associated with alcohol. In combination, alcohol and prescription medication use can seriously undermine and exacerbate health problems, lead to serious alcohol/medication interactions, increase substance misuse risk, and increase health costs. This research aims to reduce alcohol and medication interactions (AMI) among rural older adults. An online prescription drug safety survey was created and distributed through the Kentucky Pharmacist Association and the Kentucky Pharmacy Registry. Preliminary results from 85 pharmacists indicate that 77% of the sample considers that the most important AMI messages are that AMI can be potentially dangerous and even life threatening and 75% indicated the importance of visiting emergency care immediately if experiencing an AMI. Pharmacists also reported that a major barrier to programs preventing AMI is stigmatization, while “financial incentive” is a major motivator. These data will be used to create, test, and implement effective intervention(s) to prevent AMI.

EXAMINING THE TEMPORAL ASSOCIATION BETWEEN SUBSTANCE ABUSE/DEPENDENCE AND MANIA IN OLDER ADULTS
S. Canham¹, C. Kaufmann¹, C. Ramsey¹, A.P. Spira¹, N. O’Rourke². 1. Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland, 2. Simon Fraser University, Vancouver, British Columbia, Canada

Comorbid mania and substance abuse/dependence is an increasing public health concern among older adults, though the temporal relationship between them is unclear. We studied 13,489 participants aged ≥50 years at Wave 1 (W1: 2001-2002) and Wave 2 (W2: 2004-2005) of the National Epidemiologic Survey on Alcohol and Related Conditions. We examined whether lifetime mania at W1 predicted incident alcohol or drug abuse/dependence by W2; and whether lifetime alcohol or drug abuse/dependence at W1 predicted incident manic episode by W2. At W1, 276 adults had mania; at W2, 132 adults had an incident manic episode. Older adults with lifetime alcohol abuse/dependence at W1 had an elevated risk of incident manic episodes (adjusted odds ratio=2.11, 95% confidence interval=1.19-3.75, p=0.011); there was no association between lifetime mania at W1 and incident substance abuse/dependence at W2. Because substance abuse complicates remission from mania, attention to older adults with substance abuse/dependence histories is needed.

AGE AND SUBSTANCE DIFFERENCES IN SUBSTANCE USE DISORDERS (SUD) ITEMS: FOR AN OLDER ADULT SUD SCALE
K.J. Conrad¹, K.M. Conrad², C. Scott¹, R. Funk¹, M.L. Dennis¹, 1. Chestnut Health Systems, Normal, Illinois, 2. Program Metrics, Oak Park, Illinois

The number of older adults in need of substance abuse treatment is estimated to increase greatly. However, the field lacks measures of older adult SUD across the substances of abuse. From the literature, we crosswalked a list of items from the Pathways Study (Scott & Dennis, 2011) with a sample of 1043 persons ranging from 32 to 77 years. Rasch item response theory criteria tested the Pathways items focusing on differential item functioning (DIF) by age and primary substance of abuse. For age DIF, the sample was split into thirds: 32-44, 45-50 and 51-77 as comparison groups. All items were also tested for primary substance. The resulting 28 items formed a unidimensional measure with Rasch reliability .82 and alpha .92. Regarding age DIF, all but two items functioned commonly across the younger and older thirds. The substance
DIF analysis resulted in much more DIF principally from amphetamines and cannabis users.

OUTPATIENT TREATMENT APPROACHES, SERVICES AND OUTCOMES FOR OLDER ADDICTED ADULTS
N.S. MacFarland, University at Albany, SUNY, Albany, New York

In order to determine the effectiveness of age-tailored substance abuse services, this study incorporated a secondary examination of data testing the effectiveness of various treatment approaches for the addicted senior population. Utilizing a sample of 1,415 adults ages 50 and over within 22 outpatient programs licensed by the New York State Office of Alcoholism and Substance Abuse Services, program survey data was matched to client level data, and accounting for pertinent control and interaction variables, a binary logistic regression analysis was conducted. The main findings were that programs that provided age-tailored services had better odds of discontinued use by a factor of 3 (p<.001), and for each increase in the number of age-tailored services provided, programs improved their odds of discontinued use by 15% (p<.01). In addition, programs that provided age-tailored services improved overall odds of goal achievement by 2.1 times (p<.01).

SESSION 160 (SYMPOSIUM)

ANSWERING CAUSAL QUESTIONS IN AGING: CAUSAL INFERENCE IN PRACTICE
Chair: M. Shardell, University of Maryland School of Medicine, Baltimore, Maryland
Discussant: H. Allore, Yale University, New Haven, Connecticut

Researchers in gerontology often want to answer causal questions, but may be limited by research design or analytic conventions. For example, most conventional statistical methods for observational studies estimate associations, and many researchers, cautioned by the saying “association does not imply causation,” abandon the notion of cause altogether in their investigations. A critical mass of accessible modern statistical methods now exists that target causal effects. These methods are beneficial for aging research because they emphasize the crucial role of scientific background knowledge in analysis; explicitly encode necessary assumptions to infer causality; and can be performed using standard statistical software. In this symposium, we exemplify the use of modern causal inference methods in aging research, and we discuss the strengths, limitations, and barriers of using such methods. Presentations include an application of marginal structural models to address time-dependent confounding in an observational study relating sleep quality to frailty and a contrast of intention-to-treat estimates with complier average causal effects in the Resources for Enhancing Alzheimer’s Caregiver Health (REACH II) project, a randomized trial with some intervention non-compliance. We will also address methodological challenges to performing causal inference such as selective attrition due to participant dropout or death, as exemplified by an observational study of vitamin D and gait speed, and measurement error of important confounders in propensity-score analysis.

CAUSAL INFERENCE IN OBSERVATIONAL STUDIES: IS IT A FAKE?
Q. Xue1,2, J. Tian1, I. Johns Hopkins Center on Aging and Health, Baltimore, Maryland, 2. Johns Hopkins School of Medicine, Baltimore, Maryland

RCTs have been the gold standard for making causal inference. However, not all scientific questions can be translated into randomized experiments for ethical and logistical reasons. Inferring causal effects from observational data is complicated by time-independent and time-dependent confounding. To address this, Marginal Structural Model (MSM) was developed to approximate randomization to exposure groups using inverse probability weighting such that factors potentially related to sample selection are “balanced” across the groups. We illustrate this methodology by studying the causal effect of poor sleep quality by self-report on the development of frailty in 252 community-dwelling older women. We found that poor sleep quality was associated with almost three-fold increase in the risk of pre-frailty or frailty onset (hazard ratio=2.70, p<0.001) after adjusting for demographics and time-dependent confounders including pain, depressive symptoms, body mass index, and physical activity. We will conclude this talk with a discussion of strengths and limitations of MSM.

IMPLEMENTING COMPLIER-AVERAGE CAUSAL EFFECT (CACE) MODELS IN ANALYSES OF INTERVENTIONS FOR CAREGIVERS
D.L. Roth, L.N. Gitlin, Johns Hopkins University, Baltimore, Maryland

Analyses of interventions for caregivers and other older adult groups rarely consider the impact of non-compliance on outcomes. The CACE model offers an alternative to the intention-to-treat (ITT) approach for analyzing data from randomized trials. It allows a direct comparison of observed compliers from an intervention condition with a latent class of presumed compliers from the control condition. Data from the Resources for Enhancing Alzheimer’s Caregiver Health (REACH II) project will be used to illustrate its application. An ITT analysis indicated an intervention effect on caregiver depressive symptoms that only approached statistical significance (p = .07). Although compliance was high, 11% of intervention caregivers failed to complete at least ½ of the home-based sessions. The CACE model that took this non-compliance into account revealed a significant intervention effect on depressive symptoms (p = .039). CACE is a useful but underutilized method for testing intervention effects when some non-compliance is evident.

CAUSAL INFERENCE IN STUDIES OF OLDER ADULTS WITH DROPOUT AND DEATH: VITAMIN D AND GAIT SPEED IN INCHIANTI
M. Shardell1, G. Hicks2, L. Ferrucci3, 1. University of Maryland School of Medicine, Baltimore, Maryland, 2. University of Delaware, Newark, Delaware, 3. National Institute on Aging, Baltimore, Maryland

Dropouts and deaths are perpetual complications of causal inference in aging research. Although death and dropout both lead to missing data, death has proven to be the more vexing problem, because dropout renders endpoints unobserved whereas death renders them undefined. To address this problem, we propose inverse-probability weighted estimation using three weights: one to adjust for confounding, another to account for selection bias from missing data, and a third to account for selection bias from death. We also compare the proposed approach to principal stratification and other techniques for handling truncation by death. We apply the method to an observational study to assess the effect of 25-hydroxyvitamin D [25(OH)D] concentrations on four-meter gait speed. Analysis included N=905 participants, among whom 454 completed the study (163 died, 288 dropped out). We estimated a difference in gait speed of 0.07 (SE=0.03) meters/second comparing 25(OH)D >= 20 ng/mL to 25(OH)D < 20 ng/mL.

CROSS-PAYER EFFECTS OF MEDICAID LTSS ON MEDICARE RESOURCE USE USING PROPENSITY SCORE RISK PROFILING
Y. Huang, Dept. of Mathematics and Statistics, Joint Doctoral Program in Gerontology at UMB and UMBC, University of Maryland, Baltimore County (UMBC) and UMB, Baltimore, Maryland

Medicaid administrators look to establish a better balance between long-term services and supports (LTSS) provided in the community and in institutions, and to better integrate acute and long-
term care for recipients who are dually eligible for Medicare. Programs of integrated care will require the solid understanding on the interactive effects that are masked in the separation of Medicare and Medicaid. This paper aims to evaluate the causal effect of Maryland’s Older Adult Waiver (OAW) program on the outcomes of Medicare spending using propensity score based health risk profiling technique. Specifically, dually eligible recipients enrolled for Maryland’s OAW program were identified as the treatment group and matched “control” groups were drawn from comparable population who did not receive those services. The broader impact for this study is that statistical approaches can be developed by any state to facilitate the improvement of quality and cost effectiveness of LTSS for dually eligible recipients who are dually eligible for Medicare.

SESSION 165 (SYMPOSIUM)

CARING FOR PERSONS WITH DEMENTIA IN THE COMMUNITY - AN INTERNATIONAL PERSPECTIVE

Chair: K. Wolf-Ostermann, Alice Salomon University, Berlin, Germany
Co-Chair: M. Boltz, New York University College of Nursing, New York, New York
Discussant: E. Capezuti, New York University College of Nursing, New York, New York

The number of older care-dependent adults with dementia is increasing rapidly all over the world. A high proportion of people with dementia (PwD) are living at home in the community, which places a great demand on developing and evaluating effective and high quality care strategies providing formal as well as informal care. Meeting the demands of PwD and their relatives requires multifaceted networks incorporating different stakeholders (medical doctors, nursing personnel, therapists, hospital facilities, community care services, self-help organizations, local authorities, etc.) for care and support to provide best practice person-centered care. Bringing together academic researchers from multiple disciplines in the US, the Netherlands and Germany, this symposium will examine example of tailored care for PwD in the community.

POST-ACUTE NEEDS OF THE PERSON WITH DEMENTIA AND THEIR FAMILY CAREGIVERS

M. Boltz, J. Galvin, College of Nursing, New York University, New York, New York

The purpose of this study was to consider the post-acute outcomes of dyads of acutely ill older adults and their family caregivers who consented to participate in a study that examined a nurse-family partnership to improve functional outcomes in hospitalized older adults. Using a stepwise multiple regression and controlling for physical function (Barthel Index), and dementia occurrence and severity at discharge, persistent delirium two weeks after discharge was associated with caregiver depression (t= 2.40, p=0.002). Interviews with family caregivers described the following factors as issues influencing their coping: 1) their own health; 2) someone to confide in; 3) opportunities for recreation; and 4) interventions that support physical and cognitive recovery for the person with cognitive impairment. Future research should focus on interventions to improve both the quality of life of both the person with dementia as well as the family caregiver.

LOCAL DEMENTIA CARE NETWORKS IN GERMANY - TYPES AND GOVERNANCE STRUCTURES

S. Schäfer-Walkmann1, A. Peitz1, F. Traub2, W. Hoffmann2, B. Holle1, J. Thyrian3, K. Wolf-Ostermann1, 1. Alice Salomon University, Berlin, Germany, 2. Baden-Wuerttemberg Cooperative State University Stuttgart, Stuttgart, Germany, 3. DZNE Rostock/ Greifswald - German Center for Neurodegenerative Diseases, Greifswald, Germany, 4. DZNE Witten - German Center for Neurodegenerative Diseases, Witten, Germany

The constitution of local networks is an effective policy to reduce complexity and getting over the traditional borders of the segmented and fragmented German health care system. For such complex care arrangements, a welfare-mix is characteristically: you’ll find market elements and players of the Third Sector as well as public organisations and private engagement (e.g. private caregivers, self-help). Like any other organisation, dementia care networks (DCN) operate in a multiple stress field of needs of PwD, their caregivers, legal and economic frame conditions and the civil society. Responsible persons must have creative solutions for positioning the DCN in the local field and ensuring a long life cycle. Successful DCN are responsive to this pressure with hybridizing respectively with special organisational governance. In this case, they are able to claim their position in welfare-mix arrangements as well as they can serve as an intermediate authority and emancipated stakeholder.

WHO ARE USERS OF LOCAL DEMENTIA CARE NETWORKS? – FIRST RESULTS FROM THE GERMAN DEMNET-D STUDY

K. Wolf-Ostermann1, J. Gräske1, S. Meyer1, W. Hoffmann2, B. Holle1, S. Schäfer-Walkmann1, J. Thyrian3, 1. Alice Salomon University, Berlin, Germany, 2. DZNE Rostock/ Greifswald - German Center for Neurodegenerative Diseases, Greifswald, Germany, 3. DZNE Witten - German Center for Neurodegenerative Diseases, Witten, Germany

In our study we evaluate characteristics and health outcomes of people with dementia (PwD) and their relatives being served by 13 local dementia care networks (DCN) in Germany. The DCN differ regionally and include different stakeholders, covering urban as well as rural areas in Germany. Using a sample of up to 750 PwD and family caregivers we assess health-related outcomes, e.g. quality of life, depression, social participation, use and costs of health care supply and burden of care. Results of the assessments will be presented in order to raise knowledge about users of DCN and to improve individually tailored support for PwD. Our results will shed some light on the question which is reached by DCN already implemented in the community. It will deliver hints who they serve as local solutions to improve care and support of PwD.

CASE-MANAGEMENT IN DEMENTIA: AN EVALUATION IN THE NETHERLANDS

A. Pol1, J.M. Peeters2, J. de Lange3, A. Francke2, 1. Trimbos Institute, Utrecht, Netherlands, 2. NIVEL - Netherlands institute for health services research, Utrecht, Netherlands

In the Netherlands, case-management for people with dementia (PwD) and informal caregivers has been set up. Case-managers are assigned to PWD to provide support to the caregivers and to address their needs. In a national survey carried out by Trimbos-institute and NIVEL, >500 caregivers from thirteen regions completed questionnaires just after a case-manager was assigned and one year later. In addition, face-to-face focus groups with 74 caregivers and online focus groups with 99 professionals (case-managers, GP’s, nurses and elderly care physicians) have been organized. 59% of the respondents had to 6 personal contacts with the case-manager in the first year after the start of case-management. Caregivers were satisfied with their case-managers (M=8 on scale 1-10). They showed several positive results as compared...
to caregivers without a case-manager, including feeling less lonely, being better informed and able to deal with problem behavior. They went less often acute to the GP.

**SESSION 170 (SYMPOSIUM)**

**OPTIMIZING EXERCISE FOR NEUROPLASTICITY IN PARKINSON’S DISEASE: NOVEL INSIGHTS FROM STUDIES ON TAI CHI, ADAPTED TANGO, A SPLIT BELT TREADMILL, AND FORCED-EXERCISE**

Chair: J. Nocera, Emory University, Atlanta, Georgia, Department of Veterans Affairs, Atlanta, Georgia
Discussant: C.J. Hass, University of Florida, Gainesville, Florida

Parkinson’s disease (PD), which currently afflicts approximately 1.5 million Americans, is a chronic progressive disease of the central nervous system. The cardinal features of PD include rigidity, tremor, bradykinesia and impaired postural control. As the disease progresses motor function as well as muscular and cardiovascular fitness decline due to both central degeneration and reduced physical activity. Further, additional adverse outcomes related to the non-motor symptomology are increasingly prominent during the disease progression. Importantly, exercise plays an important role in improving physical outcomes as well as non-motor complications. For example, recent work in humans indicates that aerobic, resistive and motor skill training can improve cardiovascular and muscular function as well as limit cognitive decline. While indeed these “traditional” forms of exercise have resulted in improved outcomes, herein we present data on more skilled/demanding paradigms aimed at optimizing functional outcomes in PD. Thus, we will present data on Tai Chi exercise (Nocera), Adapted Tango (Hackney), Split-Belt Treadmill exercise (Hass), and Forced-exercise (Alberts). This symposium will provide clinicians, scientists, and exercise specialists the evidence supporting the neuroplastic role of exercise in Parkinson’s disease as well as provide evidence based exercise recommendations. Moreover, this knowledge may promote interdisciplinary research leading to a better understanding of the vast potential of movement and exercise effects in special populations.

**TAI CHI EXERCISE TO IMPROVE THE NON-MOTOR COMPLICATIONS IN PARKINSON’S DISEASE**

J. Nocera, Emory University, Decatur, Georgia, 2. Department of Veterans Affairs, Atlanta, Georgia

Tai Chi training has been shown to provide physical health benefits in multiple older populations with and without disease. Unfortunately, in addition to the demonstrated physical decline, a substantial number of individuals with Parkinson’s disease (PD) also exhibit debilitating non-motor symptoms that decrease quality of life. Non-motor symptoms such as progressive cognitive decline also contribute to the hallmark of worsening physical function. Because Tai Chi is a form of physical activity that demands high cognitive involvement it may serve as an effective modality for non-motor consequences of PD beyond the proven physical outcomes. In this context, we will present results from a recently completed study as well as review and discuss Tai Chi as a mode for improving the non-motor symptomology in PD. Importantly, this presentation will also serve to provide evidence based Tai Chi exercise recommendations aimed at alleviating the non-motor burden of PD.

**ASYMMETRIC LOCOMOTOR TRAINING ENHANCES REHABILITATION OUTCOMES IN PARKINSON’S DISEASE**

C.J. Hass, University of Florida, Gainesville, Florida

Mobility impairment and cognitive decline are of significant concern in older adults and patients with Parkinson’s disease (PD) as they are found to strongly predict dependence, falls, morbidity, and mortality. Despite growing fiscal resources aimed at ameliorating these age-related complications, locomotor disability and cognitive decline persists. Thus, there is a significant need for interventions that effectively target these vital aspects of health and independence. Innovative advances in physical rehabilitation technology have created a split-belt treadmill capable of providing this much needed intervention. When desynchronized, the split-belt treadmill imposes propulsive and stability demands independently on each leg such that the central nervous system must solve/ adapt to the challenge using both frontally-mediated locomotor and cognitive resources. Herein, we will lay out the basic science rationale supporting the application of split belt treadmill walking in persons with PD and will present exciting new results from a case series of patients undergoing this therapy.

**ADAPTED TANGO: A NOVEL PARTNER-DANCE APPROACH TO IMPROVING MOBILITY IN PARKINSON DISEASE**

M.E. Hackney, 1. Rehab R&D, Atlanta VAMC, Decatur, Georgia, 2. Emory University School of Medicine, Atlanta, Georgia

Recently, a series of studies have demonstrated that a program of partnered dance, adapted tango, has improved mobility, balance and quality of life in persons with Parkinson disease (PD). Adapted tango is specifically designed to target PD-specific motor impairments, including bradykinesia, rigidity, freezing of gait, backward walking, turning, and motor multi-tasking. We will present evidence to support adapted tango’s beneficial effects upon mobility, and the efficacy of various doses of adapted tango, i.e., long duration/short volume, vs. short duration/high volume programming. Importantly, we will present findings from a recent study involving dissemination and implementation of the adapted tango program for community settings, and delivered by non-clinically trained instructors. Finally, we will discuss evidence to support adapted tango’s utilization in comparison to other dances, and will examine the mechanistic bases, (e.g., externally cued and internally guided movement) for adapted tango’s beneficial effects.

**THE UTILIZATION OF FORCED-EXERCISE IN THE TREATMENT OF PARKINSON’S: EVIDENCE FOR ALTERING BRAIN STRUCTURE AND FUNCTION**

J. Alberts, 1. Cleveland Clinic, Cleveland, Ohio, 2. Louis Stokes VAMC, Cleveland, Ohio

Forced-exercise has resulted in neuroprotective effects and improved motor function in animal studies. These promising results have not yet been fully translated to humans with Parkinson’s disease (PD), as traditional exercise interventions have not typically yielded global improvements in motor or non-motor function. Forced-exercise in humans is operationally defined as a mode of exercise in which the voluntary efforts of the patient or participant are augmented which allows the patient to exercise at a rate faster than they could under voluntary conditions. It is important to note that forced exercise still requires active participation from the participant. The results from a novel forced-exercise intervention in PD patients participating in a clinical trial will be reviewed and discussed in the context of improving global motor, upper and lower extremity function, and non-motor function, olfaction, and the alteration of patterns of brain activation following acute and extended forced-exercise and voluntary exercise interventions. Collectively, the results of these studies indicate that forced-exercise is an effective means of reducing symptoms and may be a candidate to mitigate disease progression.

**SESSION 175 (PAPER)**

**CARE TRANSITIONS**

**TRANSITIONAL CARE OF MORBIDLY OBESE PATIENTS: WHAT ARE THE CHALLENGES?**

H. Felix, C. Bradway, 1. University of Arkansas for Medical Sciences, Little Rock, Arkansas, 2. School of Nursing, University of Pennsylvania, Philadelphia, Pennsylvania

Care challenges have been described for hospitalized morbidly obese (MO) patients and it is likely that these persist post-discharge. As a
result, nursing homes (NHs) may be reluctant to admit these patients, potentially leaving them “stranded in hospital” with subsequent deterioration and increased cost. This study sought to identify challenges NHs encounter when MO patients are transitioning from hospitals. We hypothesized that 6 factors would affect NHs’ willingness to admit MO patients: number of beds, occupancy rates, for-profit status, chain status, staffing levels, and equipment concerns. IRB-approved surveys were mailed to nursing directors of federally-certified NHs in Arkansas (AR; n=233) and Pennsylvania (PA; n=703) to collect NH experience in the admission of MO patients. Data were analyzed using descriptive and inferential statistics. In total, 360 surveys were returned (39% response rate; n=92 AR; n=268 PA). Two-thirds reported MO patients size acts as an admission barrier; although only 6% reported MO patients were always refused admission. A multivariate model with the 6 variables of interest found NHs with adequate staff were significantly (p=0.04) less likely to report obesity as a barrier; whereas, NHs reporting bariatric equipment concerns were significantly (p<0.001) more likely to report obesity as a barrier. Availability of bariatric equipment in NHs appears to negatively affect the care transition of MO patients. Additional research, including examination of current regulations and reimbursement policies, should be undertaken to understand NH equipment acquisition decisions. Such research will likely have important implications for research and optimal care of obese individuals during times of transition.

**AN EMERGENCY ROOM DECISION SUPPORT PROGRAM THAT INCREASED PHYSICIAN OFFICE VISITS, DECREASED EMERGENCY ROOM VISITS AND REDUCED COSTS**

J. Navratil-Strawn¹, K. Hawkins², T.S. Wells³, S.K. Hartley¹, R.J. Ozminkowski¹, H. Chan¹, R.J. Migliori¹, C.S. Yeh¹, 1. OptumHealth, Golden Valley, Minnesota, 2. OptumInsight, Ann Arbor, Michigan, 3. UnitedHealth Group, Minnetonka, Minnesota, 4. AARP Services Inc., Washington, District of Columbia

Methods: Adults with an AARP® Medicare Supplement Insurance plan insured by UnitedHealthcare Insurance Company (for New York residents, UnitedHealthcare Insurance Company of New York) were eligible to participate in the program. These included 7,499 individuals who elected to enroll in the ERDS program and an equal number of non-participants, who were eligible but either declined or were unreachable. Program-related benefits were estimated by comparing the difference in downstream healthcare utilization and expenditures between participants and non-participants after using propensity score matching to adjust for case mix differences between these groups. Results: Compared with non-participants, participants experienced greater quality of care, evidenced by an increase in physician office visits (p<0.001) and a greater reduction in emergency room visits (p<0.001). The program was cost effective, with a return on investment (ROI) of 3.65:1, which was calculated by dividing the total program savings ($5.95 million) by the total program costs ($1.63 million), implying that for every dollar invested in this program, $3.65 was saved, most of which was attributable to Medicare. Conclusions: This study focused on the quality and cost benefits associated with an ERDS program. The increase in physician office visits and decrease in emergency room visits may indicate the program helped participants establish relations with a primary care provider, which in turn may have led to reduced emergency room visits. The program resulted in significant cost savings for Medicare.

**DECREASED 30-DAY HOSPITAL READMISSION RATE AMONG DELIRIUM PREVENTION PROGRAM PARTICIPANTS**

M. Supiano, K. Anderson, M. Beattie, C. Clift, N. Joyce, E.W. Young, University of Utah, Salt Lake City, Utah

The Hospital Elder Life delirium prevention Program (HELP) has been shown to decrease delirium incidence, fall rates, and hospital costs. Its impact on 30-day hospital readmission rates has not been reported. HELP enrolled 558 University of Utah Hospital (UUH) inpatients (2011 through 2012) who were age ≥ 70 years, with an anticipated length of stay (LOS) > 2 days, and ≥ one delirium risk factor. The delirium incidence rate among HELP enrollees was 2.6%. 86 HELP patients (15.4%) were readmitted to UUH within 30 days of discharge. During the same time period, 3,021 patients age ≥ 70 years were admitted, but not enrolled in HELP. 614 of these patients (20.3%); P=0.02 compared to HELP group) were readmitted within 30 days. There was no difference in age in HELP vs. non-Help patients; mean ± SD; 79 ± 6 vs. 79 ± 6 years), however, average LOS in the entire HELP group was significantly less (4.5 ± 4.2 vs. 5.3 ± 3.9 days; P=0.001). In both groups LOS was significantly longer among patients who were subsequently readmitted – LOS for HELP enrollees was 7.6 ± 5.5 vs. 4.4 ± 4.1 days and for non-HELP 8.3 ± 7.7 vs. 5.2 ± 3.9 days; both P<0.001. These results suggest that enrollment in HELP is associated with a shorter LOS and a 25% reduction in readmission rate. In addition to transitional care programs to prevent hospital readmission, improving inpatient care quality through a multicomponent delirium prevention program may be another important intervention.

**ASSOCIATION OF LIVING ALONE AND HOSPITALIZATION FOR AMBULATORY CARE SENSITIVE CONDITIONS AMONG COMMUNITY-DWELLING ELDERS WITH AND WITHOUT DEMENTIA**

Background: Ambulatory care sensitive condition (ACSC) hospitalizations might be avoided with timely primary care yet occur frequently among older persons. Identifying associated risk factors may suggest opportunities to improve primary care. Certain factors—for example, living alone—may increase the risk of ACSC hospitalization, and their effect may be greater among persons with dementia. Methods: A retrospective analysis was conducted among 2636 participants in Adult Changes in Thought, a longitudinal cohort study of dementia incidence. Participants were aged 65+ enrolled in an integrated healthcare system who completed biennial follow-up visits to assess for dementia and living status. ACSC hospitalizations were identified using automated data. Logistic regression was used to examine the association of living alone with ACSC hospitalization; we fit models with and without an interaction term for dementia and adjusting for key covariates. Results: The mean age of participants was 79 years, 59% were female, 36% lived alone at baseline, and 18% developed dementia. Living alone was positively associated with being aged 85+, female, depressed, and having difficulty with 1+ activity of daily living, and negatively associated with being nonwhite and having dementia, heart disease, cancer, or diabetes. In a regression model adjusted for age, gender, comorbidity burden, and length of follow-up period, living alone was not associated with ACSC hospitalization (adjusted OR=0.90, 95%CI 0.75, 1.08). Dementia did not modify this association. Conclusion: In this research cohort of older adults with a routine source of healthcare, living alone was not associated with ACSC hospitalizations for persons with or without dementia.

**SIX-MONTH HEALTHCARE UTILIZATION COST AVOIDANCE ASSOCIATED WITH THE CARE TRANSITIONS INTERVENTION (CTI) FOLLOWING HOSPITALIZATION IN RHODE ISLAND**

S. Gravenstein¹²¹, R. Baier¹²¹, Q. Li², R. Gardner¹²¹, K. Butterfield³, E. Coleman⁴, 1. Medicine, Case Western Reserve University, Cleveland, Ohio, 2. Brown University, Providence, Rhode Island, 3. Healthcnetric Advisors, Providence, Rhode Island. 4. University of Colorado Denver Anschutz Medical Campus, Denver, Colorado

BACKGROUND: The cost-benefit for the Care Transitions Intervention (CTI), a post-hospital coaching intervention that aims to reduce...
SESSION 180 (SYMPOSIUM)

CAREGIVING AND CULTURE: RICHNESS IN VARIATIONS AND VALUES
Chair: C. Corley, Human and Organizational Development, Fielding Graduate University, San Gabriel, California
Co-Chair: R. Gupta, San Francisco State University, San Francisco, California
Discussant: H. Moody, AARP, Washington, District of Columbia

The discourse on family caregiving has been rich and this symposium addresses cultural dimensions and diverse perspectives. Traditional values such as filial piety will be examined, social exchange and the dance of independence/interdependence pondered, and expressions of care in diverse populations illuminated. New approaches to family caregiving such as conscious caregiving will be introduced. Following an overview setting the context of the symposium by Connie Corley and Rashmi Gupta, Mary McCall will discuss a values-based approach to decision-making and communication across values, David Willis will reflect on family caregiving in Asian cultures, Keiko Katagiri presents data on Japanese and Korean men and women and relationships with parents/in-laws, and Brian de Vries shares insights and data on informal caregiving and receipt of care among LGBT Baby Boomers in the U.S. As a discussant, Harry “Rick” Moody will highlight controversies in the family caregiving discourse, including family roles and ethical dynamics in addressing autonomy and dignity. As caregiving needs increase in the U.S. and other aging countries, understanding the similarities and differences that exist in these relationships, including a critical analysis of underserved populations (i.e., low-income, single and LGBT groups), may help create meaningful and appropriate social policies and support systems that allow care-receivers to maintain a sense of dignity.

DECISION-MAKING FOR ADULT CHILDREN: THE USE OF VALUES- AND EMPOWERMENT-BASED APPROACHES
M. McCall, 1. Psychology, Saint Mary’s College of California, Moraga, California, 2. Fielding Graduate University, Santa Barbara, California

As people live longer, the challenges for adult children grow, as they seek to support their older family members, while balancing their own personal and family needs. To deal with these pressures in a healthy manner, an understanding of one’s values is critical so that decisions can be made in an appropriate way. Good communication is a key component of healthy relationships. Adult children may also face the dilemma of how to empower their parents to the limit of their desires and abilities, while dealing with their own concerns and fears about something “going wrong.” This paper will discuss using a values-based approach to decision-making, utilizing the Hall-Tonna Values Inventory as a tool for both practitioners and researchers. How to successfully communicate across different values (based on the Inventory) will be discussed. The two-edged sword of empowerment for older persons is analyzed in the context of personal and societal values.

FAMILY CAREGIVING IN INDIA AND JAPAN: COMPARATIVE PERSPECTIVES
D.B. Willis, Fielding Graduate University, Santa Barbara, California

This paper will bring to our session together two examples of family caregiving, first, in a progressive Gandhian Ashram community in South India, especially around the end of life issues and approaches for Sri S. Jagannathan, the leader, who, along with his wife Krishnammal were recipients of the Right Livelihood Award, the Alternative Nobel Peace Prize. Sri Jagannathan passed away on February 12 while the author was doing research in India on their organization. The focus of the report will be on caring for the elderly and end of life issues as they are handled in traditional rural India. As a comparative stance, the paper will secondly also address end of life issues in a family in a working class community of Osaka, Japan, where the author lived for more than 30 years. It is hoped that this paper will shed light on two traditional Asian societies and their approaches as both similar to and different from mainstream North American society.

TRADITIONAL FAMILY NORMS AND ATTITUDE TOWARD FINANCIALLY SUPPORTING ELDERLY PARENTS IN TWO CONFUCIAN SOCIETIES
K. Katagiri, Institute for Social Gerontology, Nipponkoa Welfare Foundation, Tokyo, Japan

This study examines differences in traditional family norms and attitudes toward financially supporting elderly parents among 2,283 individuals (20–69 years old) in Japan and Korea. Data were obtained from the EASS 2006. Strongest support for traditional family norms, sex role norms, and four attitude types was found among Korean men, followed by Korean women, Japanese men, and Japanese women. Multiple regression analyses by country and gender were conducted. Overall results suggested that the stronger the traditional family norm, the more positive the attitude toward financial support. Positive attitudes were endorsed by higher social classes of Japanese men but lower classes of Korean men. Quadratic age effects were negative for the latter. Both countries are experiencing rapid changes in family norms and intergenerational support exchanges. A public support system may be needed owing to the decline in traditional values, especially for underprivileged older adults, to sustain an optimal aging society.

EXPECTATIONS OF CARE-RECEIPT: A FOCUS ON LGBT PERSONS
B. de Vries, SFSU, San Francisco, California

The study of caregiving has typically focused on the provision of care—less is known about care-receiving. Drawing from two studies of older LGBT adults, expectations of care-receipt and conversations...
about such care are studied. Comparing 1201 LGBT with 1206 persons ages 45-64 from the general population (MetLife, 2010), LGBT persons (especially women and transgender persons) were both more likely to have received recent care and to rely on friends for actual and anticipated needs. In qualitative analyses with 20 LGBT persons ages 50 to 75, it was the minority of persons who had had conversations with potential caregivers, often—and precariously—assuming they would be available. These data suggest avenues for further empirical and pro-grammatic pursuits, such as the design of materials to assist in the initiation and support of conversations about care.

SESSION 185 (SYMPOSIUM)

ENVIRONMENTAL CONTEXTS FOR OPTIMAL AGING: CONCEPTUAL AND EMPIRICAL ADVANCES
Chair: A.E. Scharlach, Social Welfare, University of California, Berkeley, California
Discussant: L. Carstensen, Stanford University, Stanford, California
More than 20 years ago, Paul and Margret Baltes asserted that “Optimal aging refers to… aging under development-enhancing and age-friendly environmental conditions” (Baltes & Baltes, 1990, p. 8). Yet, despite substantial interest in age-friendly communities and other environmental characteristics in recent years, the potential connections between environmental contexts and optimal aging are under-theorized and under-researched. Simply put, we do not yet have an adequate conceptual or empirical basis for defining or creating “optimal environments for optimal aging.” This symposium offers new ways to understand how physical and social environments influence human functioning and development in later life, using evidence drawn from a variety of relevant conceptual frameworks (e.g., environmental gerontology, geographical gerontology, lifespan developmental psychology, disablement theory), contexts (e.g., urban, rural), and modalities (e.g., individual coping, social support, environmental modifications). In the first paper, Scharlach proposes a conceptual framework for assessing the aging-friendliness of communities and other environmental contexts, drawing upon recent evidence regarding physiological, psychological, and social aspects of optimal aging. In the second paper, Golant examines the concept of resilient environments, drawing upon his earlier theorizing regarding residential normalcy; just as individuals adapt, so places may initiate adaptive efforts to respond to residents’ age-related needs. In the third paper, Walsh and colleagues examine the crucial role played by informal supports in rural communities, with important implications for conceptualizing community age-friendliness. Finally, Ekstam and colleagues report preliminary results from a controlled trial evaluating a conceptually and empirically-based model of housing adaptations for optimal aging.

OLDER PEOPLE: THE ROLE OF INFORMAL COMMUNITY ENHANCEMENTS
In conceptualizing/designing environments for optimal aging, rural communities have often been a challenging if not a neglected context. In service delivery, home and community-based services have expanded greatly, but nursing home use has stayed remarkably flat despite an increase in the number of older people. Moreover, a new paradigm of consumer empowerment and choice has taken hold in many states and dominates the policy discussion, even though few states have fully implemented this new approach. Finally, implementation of the Omnibus Budget Reconciliation Act of 1987 has transformed the quality assurance process in nursing homes with new stringent standards and processes for inspection and enforcement. The Minimum Data Set provides an extraordinary wealth of information on the status of residents, which is being used to set payment rates and to establish quality measures. Although quality assurance systems for home and community-based services lag behind nursing homes, the large increase in Medicaid expenditures for these services is increasing pressure on states to assess the quality of the services they are financing.

ENHANCING PERSON-ENVIRONMENT FIT FOR RURAL OLDER PEOPLE: THE ROLE OF INFORMAL COMMUNITY PRACTICES
K. Walsh1, E. O'Shea1, T. Scharf1, M. Shucksmith2. 1. Irish Centre for Social Gerontology, National University of Ireland Galway, Galway, Ireland. 2. Newcastle University, Newcastle, United Kingdom

In conceptualizing/designing environments for optimal aging, rural communities have often been a challenging if not a neglected context. Set amidst information gaps in rural environmental gerontology, this paper explores the role of informal practices across the state, private, voluntary and family/friend systems, in enhancing the potential for optimal aging. In doing so, we examine the relevance of concepts like 'age-friendly', and 'livable communities' to rural settings. Using focus group data, involving 62 community-stakeholders from ten communities across Ireland and Northern Ireland, we analyze: the four systems and their limitations; and the informal practices that underlie system interactions and older adult supports. Informal practices underpin many community responses to supporting older people and arose from collective interdependencies, multiple actor-roles, and positions of need. Participants will gain an understanding of deficiencies in environmental conceptualizations when applied to rural settings, and the potential of rural communities to be sites of optimal aging.

SESSION 190 (SYMPOSIUM)
LONG-TERM CARE IN 1988 AND 2013: SAME OR DIFFERENT?
Chair: J. Wiener, RTI International, Washington, District of Columbia
Discussant: D. Grabowski, Harvard University, Cambridge, Massachusetts

This symposium examines what has changed and what is the same in long-term care financing, delivery, and quality assurance over the last 25 years, and what the implications are for the future. For long-term care financing, funding remains dominated by Medicaid, but Medicare and private insurance are playing much greater roles. Major proposals to change long-term care financing by establishing new public long-term care programs in 1989, 1993, and 2009 were not enacted or were not implemented. In service delivery, home and community-based services have expanded greatly, but nursing home use has stayed remarkably flat despite an increase in the number of older people. Moreover, a new paradigm of consumer empowerment and choice has taken hold in many states and dominates the policy discussion, even though few states have fully implemented this new approach. Finally, implementation of the Omnibus Budget Reconciliation Act of 1987 has transformed the quality assurance process in nursing homes with new more stringent standards and processes for inspection and enforcement. The Minimum Data Set provides an extraordinary wealth of information on the status of residents, which is being used to set payment rates and to establish quality measures. Although quality assurance systems for home and community-based services lag behind nursing homes, the large increase in Medicaid expenditures for these services is increasing pressure on states to assess the quality of the services they are financing.

A QUARTER CENTURY OF CHANGE: IMPLICATIONS FOR QUALITY
V. Mos, Brown University, Providence, Rhode Island

Since the Institute of Medicine’s landmark report on Nursing Home (NH) care in 1986, quality assurance was transformed by federal legislation and efforts to improve NH quality have proceeded on multiple tracks with the introduction of mandatory resident assessment (the MDS), new inspection processes, quality measurement and public report-
ing. These federal changes occurred while states increased investment in home and community services, the private sector built almost a million assisted living beds and Medicare prospective payment for SNFs radically changed the composition of short- and long-stay residents in NHs around the country. This session will review the evidence for how these major changes have affected the quality of care provided in NH’s and patients’ experiences.

FOLLOWING THE MONEY IN 1988 AND 2013
J. Wiener, RTI International, Washington, District of Columbia

Since 1988, long-term care financing policy has remained largely unchanged, but has undergone considerable ferment. Medicaid remains the main source of financing for long-term care, providing funding for almost two thirds of nursing home residents. Financing for home and community-based services, especially Medicaid waivers, has skyrocketed. Changes in the Medicare definition of skilled care resulted in large increases in Medicare spending for skilled nursing facilities and home health, which were ramped down only partly by the Balanced Budget Act of 1997. Private long-term care insurance has grown substantially, and now covers about 12 percent of older people, but faces huge challenges in increasing market share. Proposals to expand public programs for long-term care were debated in the late 1980s and as part of the Clinton health reforms, but were not enacted. The Community Living Services and Supports (CLASS) Act was enacted, but not implemented because of potential financial instability.

EVOLUTION OF THE SERVICE SYSTEM: ALTERNATIVES TO NURSING HOME CARE

In the 1980s, older Americans in need of functional assistance or supervision due to physical disabilities or cognitive impairment still had few formal care options other than nursing home care. Assisted living now accounts for about one third of all facility-based long-term care. Nationally, over twenty percent of disabled elderly residing in the community are enrolled in Medicaid but only about one in four of them report receiving Medicaid-funded home and community-based services. We describe state variations in the percentage of Medicaid funding for long-term care for the elderly that goes to home and community-based services. We discuss the features of state’s long-term care systems (e.g., participant directed services) that quantitative analyses suggest have made some states more successful than others in re-orienting Medicaid funding for eldercare away from nursing homes toward home and community-based services.

SESSION 195 (SYMPOSIUM)

NO PLACE LIKE HOME: THE CHALLENGES OF HOMELESSNESS, INADEQUATE AND UNSTABLE HOUSING IN LATER LIFE
Chair: D. Waldrop, School of Social Work, Buffalo, New York
Discussant: D. Waldrop, School of Social Work, Buffalo, New York

Homelessness, inadequate and unstable housing are problems for growing numbers of older adults, who are often an invisible group with unrecognized needs and who remain “under the radar” of health and social service providers. This symposium illuminates the compelling issues of older adults who are homeless or near-homeless, have little choice but to live in inadequate or unstable housing and deal with cumulative disadvantage, trauma, adversity, health and mental health issues. The first paper reports findings from life history interviews with 32 older adults who were homeless and demonstrates how the cumulative experiences of trauma and adversity both precede and accompany homelessness. Focusing on the pathways that lead to unstable housing, the second paper presents findings from interviews with 20 homeless elders and identifies a series of events that contribute to “collective weakening” that results in homelessness. The third paper characterizes the challenges of older adults who receive federal housing vouchers and live with the “forced choice” of housing in poor neighborhoods and deteriorated conditions. The fourth paper addresses the use of budget hotels as a housing solution for older adults who live on the fringe of poverty and presents the narratives of older women who have been unstably housed. Addressing the use of healthcare among homeless adults, the fifth paper presents the results of a prospective cohort study which characterized the patterns and predictors of emergency department visits and hospitalization among 250 homeless adults. Understanding the causes and effects of poor housing can optimize aging through research.

AGING IN POOR PLACES: THE DIMINISHED RESIDENTIAL “CHOICE” OF SENIORS WITH HOUSING CHOICE VOUCHERS
K.L. Patterson, School of Social Work, University at Buffalo, Buffalo, New York

Older adults are increasingly vulnerable to their neighborhood environment. For the aging poor who live in federally subsidized housing, this problem is magnified because a growing proportion of these older adults are exposed to adverse environmental conditions which may impact their physical and mental health. Examining the intersection of aging and neighborhood effects is critical to understanding the various needs of this population as they age in place. The objective of this paper is to first determine where low-income seniors who participate in the federally subsidized Housing Choice Voucher Program reside in the Buffalo Niagara region of Western NY, and then to highlight both their demographics and the characteristics of the neighborhoods where they live. Based on previous research, it is hypothesized that these seniors will concentrate in poor neighborhoods with deteriorated conditions more than the general population and that this will especially hold true for minority voucher holders. Since mobility tends to diminish with age, low-income seniors will likely have no choice but to age in place. Therefore, it is incumbent on policy makers to advocate for subsidized housing which couples affordable housing with access to additional social services for this vulnerable population.

USE OF ACUTE CARE SERVICES AMONG OLDER HOMELESS ADULTS

Although the US homeless population is aging, little is known about the use of acute care services among older homeless adults. We conducted a 12-month prospective cohort study to characterize the patterns and predictors of frequent emergency department (ED) visits and hospitalization among 250 homeless adults aged 50 and older recruited from homeless shelters in Boston, Massachusetts. We found that over 12 months, 28.4% of participants had frequent (≥4) ED visits, and 33.6% were hospitalized. Several modifiable baseline characteristics were independently associated with frequent ED visits, including alcohol use problems, one or more falls during the prior year, and sensory impairment; hospitalization was similarly associated with baseline sensory impairment. These findings suggest that targeting modifiable factors associated with greater acute care utilization, such as alcohol use problems, falls, and sensory impairment, may help reduce costly and burdensome use of acute care services in older homeless patients.
PATHWAYS TO ELDER HOMELESSNESS: THE ROLE OF CUMULATIVE DISADVANTAGE AND DISADVANTAGE SATURATION
K. Melkis1, J.G. Gonyea2, 1. University of Vermont, Burlington, Vermont, 2. Boston University, Boston, Massachusetts

It is now widely accepted that the causes of elder homelessness are multifaceted, involving both structural problems and behavioral choices. Yet, the research remains sparse about the specific pathways that put at risk older adults’ ability to maintain stable housing. Using a constructivist, phenomenological approach, the authors explore these pathways through in-depth interviews with 20 homeless elders and 6 outreach workers conducted over one year. Findings suggest that it is not typically a single event (i.e., illness, unemployment, unaffordable housing, relationship strain) that leads to homelessness, but rather it is a collective weakening of arrangements or fraying of the safety net. The data also underscore that for some older adults this path is characterized by a process of cumulative disadvantage across the life course while for others it is about disadvantage saturation later in life. The implications of these divergent pathways for prevention and intervention strategies will be discussed.

AGING WITHOUT PLACE: TRAJECTORIES OF CUMULATIVE TRAUMA AND ADVERSITY AMONG OLDER ADULTS EXPERIENCING HOMELESSNESS
L. Thomas, Social Work, University of North Carolina at Charlotte, Charlotte, North Carolina

Older adults experiencing homelessness face vulnerabilities and disparities associated with age, race, socioeconomic health, mental health, and residential status, yet, the specific needs of these aging adults are rarely considered in research or practice. This paper reports findings from a project examining the life histories of 32 older adults, ages 50 – 69, experiencing homelessness in Charlotte, North Carolina. The life histories reveal cumulative experiences of trauma and adversity that precede and accompany homelessness, including patterns of housing instability over the lifespan, limited access to formal and informal social support, and homeless service experiences that exacerbate the negative effects of trauma and adversity. Life histories also detail internal and external resources that facilitate resiliency in the face of homelessness and multiple experiences of trauma and adversity as well as service practices considered effective by the research participants. The paper will conclude with implications for policy, practice, and research.

TRAUMATIC TRANSITIONS TO EXTENDED STAY HOTELS: HOMELESS WOMEN DESCRIPTIONS OF ABUSE, LOSS, AND FEAR
T. Lewinson, School of Social Work, Georgia State University, Atlanta, Georgia

Budget hotels are housing solutions for some who are on the fringe of street homelessness. Knowledge about hotel homelessness is still emerging, but associations between psychological trauma, depressive symptoms, and losing a home are well-established in the trauma literature. Adult trauma is both a precipitating event and a result of homelessness, which was compounded by loss and fear during housing transitions. Implications for practice include creating programs to improve housing status and psychological trauma for women in marginal housing situations.

SESSION 200 (SYMPOSIUM)

TURNING POLICY INTO SCIENCE: APPLYING THE AGE-FRIENDLY CITIES MODEL TO STUDYING ENVIRONMENT AND AGING
Chair: K. Fitzgerald, Center for Gerontology, Western Kentucky University, Affoltern am Albis, Switzerland
Co-Chair: A. Glicksman, Philadelphia Corporation for Aging, Philadelphia, Pennsylvania
Discussant: D.B. Bradley, Center for Gerontology, Western Kentucky University, Affoltern am Albis, Switzerland

Age-friendly models, including the Age-friendly Cities and Communities effort of the World Health Organization (WHO), are designed to influence policy and planning efforts across the globe. While researchers have contributed to the development, implementation and evaluation of this and other models less attention has been paid to how using these models can help us better understand the impact of environment on aging. This session offers four presentations on how using aspects of the WHO model can enhance our understanding of the interaction of health and environment for older adults. Fitzgerald and Beech will discuss the relation of age-friendly models to research on disaster planning. Ferris and her co-authors take elements from an age-friendly model and using structural equation modeling links those elements to need for services. Finally Ring and colleagues look at the impact of similar environmental elements on the mental health of older adults. Bradley will discuss how the results from these four papers demonstrate how scientists can use the WHO and other age-friendly models to advance our understanding of the interaction of environment, health and aging.

BELGIAN AGEING STUDIES: SUPPORTING THE PROCESS OF DEVELOPING AGE-FRIENDLY COMMUNITIES
T. Buffel1,2, N. De Witte1,2, L. De Donder6, S. Duruy7, A. Smetsoren2, D. Verté6, 1. The University of Manchester, Manchester, United Kingdom, 2. Vrije Universiteit Brussel, Brussels, Belgium, 3. Hogeschool Gent, Gent, Belgium

Policies and programmes directed at achieving ‘age-friendly’ communities are considered to require a wide range of interventions, including actions at the level of the social and physical environment. This paper aims to provide an overview of such approaches in Brussels, a city that has been recognised as ‘age-friendly’ by the World Health Organization (WHO) because of the development of policies encouraging the participation of older people within their respective communities. In particular, the paper will focus on the role of the Belgian Ageing Studies project in promoting age-friendly interventions. This project uses a participatory method involving older people to assess the age-friendliness of the city and develop a senior action plan based on an assessment of the findings. The paper concludes by discussing the key opportunities and barriers to the implementation of age-friendly policies.

THE POTENTIAL IMPACT OF THE PRESENCE OF AN AGE-FRIENDLY COMMUNITY EFFORT ON DISASTER PLANNING
K. Fitzgerald1, C. Beech2, 1. Center for Gerontology, Western Kentucky University, Affoltern am Albis, Switzerland, 2. Swansea University, Swansea, United Kingdom

While the concept of age-friendly cities and communities has built momentum on a global level, evidenced by the growing membership of the WHO Global Network of Age-friendly Cities and Communities, virtually nothing is known as to whether this concept has had an influence on disaster preparedness for older adults within those communities. Disaster preparedness is an essential feature of an age-friendly community, yet it seems to receive limited attention compared to features...
such as transportation and housing. A meta analysis was conducted to identify ways in which age-friendly efforts might contribute towards disaster planning for older adults. Through a review of published reports and other scientific materials, hypotheses regarding the relation between disaster planning and age-friendly community efforts were developed. Findings from these analyses support the need for a larger study to determine what extent disaster preparedness should be a key element in age-friendly community efforts.

PREDICTING UNMET SERVICE NEED: THE IMPORTANCE OF AN AGE-FRIENDLY CITY

R. Ferris, A. Glicksman, M.H. Kleban, Planning Department, Philadelphia Corporation for Aging, Philadelphia, Pennsylvania

Home and Community-Based Services for many older adults are an essential component of aging-in-place. Anderson developed the contemporary model used to predict service use, containing three sets of predictors: predisposing enabling and need. Researchers have modified the model to examine need. Studies that attempt to predict need have explained only 10-15% of the variance. This study is based on the supposition that lack of accounting for environmental factors has resulted in the small explanatory power. Through the use of survey data this study modeled predictors of unmet service need. Findings indicate access to healthy foods, housing quality and neighborhood safety, all targets of urban age-friendly efforts, have the most significant relationship to unmet service need. This model predicted 49% of the variance. Results of urban age-friendly efforts, have the most significant relationship to healthy foods, housing quality and neighborhood safety, all targets in the small explanatory power. Through the use of survey data this study modeled predictors of unmet service need. Findings indicate access to healthy foods, housing quality and neighborhood safety, all targets of urban age-friendly efforts, have the most significant relationship to unmet service need. This model predicted 49% of the variance. Results reveal environmental questions to ask in assessing unmet service need.

AGE-FRIENDLY EFFORTS AND THEIR IMPACT ON THE MENTAL HEALTH OF OLDER ADULTS

L.N. Ring, A. Glicksman, M.H. Kleban, Planning, Philadelphia Corporation for Aging, Philadelphia, Pennsylvania

Much of the research on the impact of Age-friendly efforts focuses on physical health and health related behaviors. Less attention has been paid to the potential impact of these efforts on the mental health of older adults. In 2009 Philadelphia Corporation for Aging initiated an “Age-friendly Philadelphia” policy effort. From its inception one concern was whether environmental factors are related to mental health. We conducted a series of analyses designed to determine if three key elements in that initiative: housing quality, food access, and transportation services, were associated with depression. Data came from a bi-annual omnibus health survey. All three were significantly related to depression. In 2012 the study was repeated. Confirmatory analysis discovered that the relations between the three environmental measures and depression score remained significant. By confirming the relation among these variables we are including mental health along with physical health improvements as goals of our Age-friendly effort.

SESSION 205 (POSTER)

DEMENTIA: RESEARCH, CARE, AND TREATMENT

PHYSICAL ACTIVITY AND ENERGY EXPENDITURE DURING LEISURE TIME FOR PATIENTS WITH COGNITIVE IMPAIRMENT IN TAIWAN: A PILOT STUDY

Y. Chiu1, C.N. Huang1, L. Lin1, T. Chang1, S. Lee1, W. Hsu1, 1. Healthy Aging Research Center, College of Medicine, School of Nursing, Chang-Gung University, Taoyuan, Taiwan, 2. Graduate Institute of Sports and Leisure Management, National Taiwan Normal University, Taipei, Taiwan, 3. Healthy Aging Research Center, College of Medicine, School of Medicine, Chang-Gung University, Taoyuan, Taiwan, 4. School of Health Policy and Management, College of Health Care and Management, Chung Shan Medical University, Taichun, Taiwan

Background: The prevalence rate of dementia was estimated to be 5% to 7%, with about 65.7 million people worldwide to be living with dementia in 2030. Western guidelines have recommended increasing structured activities as a non-pharmacological approach to manage behavioral problems of patients with cognitive impairment (PWCIs). However, the basic indicators of leisure-time physical activities and their relationships with behavioral problems were not intensively examined in PWCIs living in communities. Purpose: The purpose of this study was to describe frequency, duration (time), type, and energy expenditure (FTTE) of leisure-time physical activities in PWCIs and to explore the effects of FTTE on their neuropsychiatric symptoms. Method: It was a cross-sectional study of 58 dyads of patients (M ± SD age 79.2 ± 7.4 yr, 67.2% women, MMSE 17.8 ± 4.3) and their family caregivers (FCGs) living in northern Taiwan. FCGs completed 7-day physical activity recalls and Chinese Neuropsychiatric Inventory (CNI) for PWCIs. Results: Patients’ most frequent activities were strolling (70.7%), qigong (10.34%) and gardening (8.62%). The mean weekly activity frequency was 4.52 (SD = 4.27), the duration was 3.7 (SD = 4.38) hours, and the energy expenditure was 771.47 (SD = 886.38) kcal. FTTE were significantly correlated with patients’ neuropsychiatric symptoms, while the type of physical activity significantly predicted their mood and psychosis. Conclusion: Health professionals and park/recreation agents can apply the information of FTTE when designing various activities for PWCIS.

FAMILY MEMBER DEATHS IN CHILDHOOD AND ADULTHOOD INDEPENDENTLY PREDICT ALZHEIMER’S DISEASE RISK

C. Clark1, R. Pfister1, K. Smith1, J. Tschanz1, M.C. Norton1, 1. Utah State University, Logan, Utah, 2. University of Utah, Salt Lake City, Utah

Psychological stress associated with deaths of close family members has been a significant predictor of depression, medical morbidity and earlier mortality. Early parental death has also been associated with higher risk for Alzheimer’s disease (AD). However, the cumulative effect of multiple family deaths on AD risk has not been studied. Research of such stressors has mostly relied on retrospective self-reports. This dementia study used a Utah population-based sample of 3,785 initially non-demented participants (57% female; age M=74.9/SD=6.9 years) linked to the Utah Population Database to objectively ascertain a cumulative total of family deaths including death(s) of mother, father, sibling(s), spouse(s) and offspring, experienced during childhood (age birth-18) or adulthood (age 18-baseline interview). Cox regression modeled survival time from baseline interview to AD onset or right-censoring as a function of family deaths, baseline age group, gender, and presence of at least one copy of e4 allele at APOE. Age group was a significant moderator (p=.041) so models were then stratified by age (neither gender nor APOE were moderators, all p>.50). We report here results for persons aged 65-69 years at baseline (n=983). In separate models for childhood and adulthood deaths for this group, persons with 2+ deaths during childhood (HR=2.68, p=.021), or 2-3 (HR=2.23, p=.025) or 4+ deaths during adulthood (HR=2.71, p=.029) had significantly higher AD risk. In a combined model with both risk factors, these findings persisted. Results indicate that family member deaths during childhood and adulthood may each generate sufficient psychological stress to uniquely affect eventual AD risk.

THE RELATIONSHIP OF PET IMAGING TO CLINICAL SYMPTOMS AND DIAGNOSIS OF DEMENTIA IN A VA OUTPATIENT GERIATRIC CLINIC

M. Pallaki1,2, D.M. Kresovic1,2, C.J. Burani1,2, D.J. Harvey1, C. Gideon1, C.G. Reddy1, P. Chen1,2, 1. Cleveland VA Medical Center, Cleveland, Ohio, 2. CWRU, Cleveland, Ohio

The prevalence of Alzheimer’s Dementia (AD) is expected to increase to 13.2 million by 2050. Many individuals exhibit mild signs of CI (cognitive impairment or MCI) which progress to AD. Early diagnosis is crucial since early intervention offers the most benefit of slowing disease progression. Currently the diagnosis of AD is dependent on
Clinical measurement which has limited sensitivity or extensive neuropsychological testing that is not routinely feasible. Positive Emission Tomography (PET) imaging which measures changes in metabolism provides an adjunct measure for early detection of AD. This retrospective chart review study evaluated the temporal relationship between PET imaging, standardized cognitive tests and clinical notes used to confirm a diagnosis of AD. A sample of 179 charts of veterans with a mean age of 84 years, referred for evaluation of CI were reviewed and N=35 had complete data. While initial mini mental status exam (MMSE) scores did not support a diagnosis of AD, (range 24 to 30 with a mean of 27), 100% of pet scans revealed changes in metabolism suggestive of AD at that time. Charts were reviewed retrospectively by a panel of experts and included: Gerontologist, Psychologist, Neuropsychologist and Geropsychiatrist, and Radiologist to confirm the diagnosis of AD. The clinical diagnosis of AD was made on the average 2 years following the initial evaluation and PET scan. Time 2 MMSE mean of 25 was correlated with PET(r−=.58). A larger multisite study is needed to evaluate the efficacy of pet imaging for the early diagnosis of AD.

THE TYPE A BEHAVIOR PATTERN AND CARDIOVASCULAR DISEASE AS PREDICTORS OF DEMENTIA

K. Bokenberger1, N.L. Pedersen1, M. Gatz1, A.K. Dahl1, J. Karolinska Institutet, Stockholm, Sweden, 2. Jönköping University, Jönköping, Sweden, 3. The University of Southern California, Los Angeles, California

Objective: Research has suggested that greater psychophysiological reactivity to stress increases risk of dementia and that those with the Type A behavior pattern (TABP) are predisposed to elevated stress reactivity and cardiovascular disease (CVD), but no study has previously evaluated the association between TABP, CVD and dementia prospectively. Hence, the aim of the present study was to investigate dementia risk in relation to TABP and CVD. Methods: A population-based cohort of 1,066 persons aged 50-93 years at baseline from the Swedish Twin Registry was followed consecutively for 23 years. Based on self-reported items, TABP was measured using 6 scales: Ambition, Stress, Hard-driving, Neuroticism, Cynicism and Para-noia. CVD and education were self-reported and dementia was diagnosed adhering to DSM-III-R or DSM-IV criteria. Results: Significant interaction effects of stress with CVD and cynicism with CVD on dementia risk were observed (p=0.045 and 0.035, respectively). That is, those who had high scorers on stress and cynicism and had CVD had an increased risk for dementia, whereas those who did not have CVD, higher scores on stress and cynicism were associated with reduced dementia risk (HR=0.80, 95% CI=0.53-1.21; HR=0.52, 95% CI=0.31-0.89, respectively). Higher scores on ambition were associated with reduced dementia risk (HR=0.93, 95% CI=0.88-0.98). Conclusion: While CVD remains a risk factor for dementia, some features of TABP confer a protective effect for dementia, although more so for those without CVD than for those with CVD. When evaluating the risk of dementia, CVD and personality traits should be taken into consideration.

TOOLBOX FOR IMPROVING BEHAVIORAL HEALTH IN THE NURSING HOME: EDUCATION & LEADERSHIP

The goal of the education and leadership sub-group was to conduct a search to identify nursing education sources on existing non-pharmacological approaches to behavioral management in dementia care. We conducted a search of the websites of relevant long-term care, health care professional organizations, and leadership programs in LTC to identify education sources for review and incorporation in the toolkit for long-term care (LTC). A total of thirty-six different organizations’ websites were searched for educational materials for nursing staff on non-pharmacological interventions, the reduction of antipsychotic medication use in NHs, and general dementia care education when it included either of the above. Included in the review were the abstract, resource type or format, intended audience, educational objectives, competencies, time associated with modules, associated documents, CEU availability and type, date of most recent update and sponsoring agency. From these sites, a total of thirty-five educational products were found, reviewed and if appropriate, were included on the products list. In order to develop an inventory of programs that could enhance leadership skills in long term care, we did an initial search that primarily focused on nursing leadership development in a broader sense. We then applied the parameter of accessibility to external audiences beyond the offering institution and also highlighted geriatric specific programs relevant to long term care. In this presentation we will discuss the available products, the varying resource types with highlights or barriers to use of specific programs, and challenges encountered in the process.

CULTURALLY-BASED EXPLANATIONS OF DEMENTIA IN ASIAN COMMUNITIES: A SYSTEMATIC REVIEW

This poster will present findings from a systematic review of culturally-based explanations of dementia in the Asian community. It is estimated that the age-specific prevalence of dementia among Asian Americans is comparable to that of the general U.S. population. As the number of older Asian immigrants grows rapidly, so does the number of those affected by dementia. Examining Asian cultural beliefs that influence the understanding of dementia is fundamental to developing culturally appropriate interventions to reduce health disparities and improve clinical outcomes. Diverged from Western biomedical perspectives which construct dementia as biomedical diseases, Asian populations tend to view dementia as a consequence of normal aging, psychosocial distress, and traumatizing life experiences. This culturally-based explanation of dementia hinders medical and social service utilization in the Asian community, including clinical diagnosis and treatment, and supportive and respite care for family caregivers. Additionally, in the Asian community, dementia brings stigma, shame, and embarrassment to the persons with dementia and their family caregivers. Such cultural values in the Asian community further prevent the affected families from reaching out for necessary medical and social interventions until behavioral symptoms become unmanageable, leading to premature institutionalization of older Asian immigrants. A few studies have examined perceptions of dementia among older Asian immigrants and their family caregivers. However, little is known about ethnic Asian health providers’ perceptions of the disease, which may influence the quality of care received by the older persons with dementia. Future research and practice implications of these findings will also be discussed.

CARING FOR OLDER ADULTS WITH DEMENTIA IN A CHRONIC CARE HOSPITAL: STAFF KNOWLEDGE AND UNMET NEEDS

As the number of older adults with dementia increases there is a need for a health care work force skilled in caring for these individuals. The
purpose of this study was to examine knowledge level about dementia and education needs of staff on a chronic care hospital floor. The unit specializes in geropsychiatric disorders, the most prevalent being dementia-related neuropsychiatric behaviors. As nonpharmacologic management of behaviors is the recommended first-line treatment, knowledge of and skills in use of approaches is critical. Of 62 staff, 39 (62.9%), completed an anonymous survey. Most were female (n=37, 94.9%), 35 years or older (65.7%), 15 (38.5%) were nursing staff, 22 (56.4%) were therapy staff, and 2 (5.1%) were other (unit secretary & MD). The overall mean score for the Alzheimer’s disease Knowledge Test was 24.08 (sd = 2.61, range 15-27) out of 27 (89.2%) reflecting a high level of knowledge. Staff indicated wanting more information in managing behaviors non-pharmacologically (92.3%), enhancing patient safety (89.7%, n = 35), coping with care challenges (84.2%, n = 32), and involving patients in activities (81.6%, n = 31). Overall, most staff, nursing (80.0%) and therapy (86.4%) indicated they believed the care they provided contributed “a great deal” to patient well-being. Yet, frustration and being overwhelmed was indicated by almost 75% of staff. Understanding staff knowledge level and needs can be used to target and plan for work force preparation for working with dementia patients. Findings suggest that staff need better preparation to use nonpharmacologic strategies in everyday care.

EFFECTS OF ALZHEIMER’S DISEASE STORYBOOKS ON YOUNG CHILDREN AND PARENTS
E. Sakai, B.D. Carpenter, Washington University, St. Louis, Missouri

Health education about Alzheimer’s disease (AD) is important for the entire family unit. Storybooks are one method of introducing AD to young children. This study examined the effects of reading an AD storybook on children and parents. Utilizing a within-subjects design, fifty-five dyads, including a 7- or 8-year-old child and one parent, read and discussed a storybook about AD. Assessments at three time points targeted child and parent AD knowledge, attitudes about AD, willingness to approach people with AD, and emotional response, as well as parent self-confidence in discussing AD. Outcomes generally improved after reading, and in some cases, there were additional gains following the discussion. Child (p < .001) and parent (p < .001) AD knowledge were higher after reading the storybook. Child (p < .001) and parent (p < .001) attitudes about AD were more positive after reading the book. Both children (p = .002) and parents (p < .001) indicated greater willingness to interact with individuals with AD. Parent positive affect after discussion was lower than after reading the book (p = .002), but not different from baseline; there were no significant changes in child positive affect or child and parent negative affect. Parent self-confidence about discussing AD increased both after reading (p < .001) and discussing the book. Storybooks can provide information about AD, model adaptive behaviors, and improve attitudes about the disease, all without increasing distress in children and their parents. Further, storybooks may increase parent self-confidence in discussing a difficult health topic like AD.

COMPARING FORMAL AND INFORMAL CAREGIVERS’ PERCEPTIONS OF DELUSIONS AND HALLUCINATIONS IN DEMENTIA
J. Cohen-Mansfield1,2, H. Golander1, J. Heinik4, J. Herzog Institute on Aging, Tel Aviv University, Tel Aviv, Israel, 2. Department of Health Promotion, School of Public Health, Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel, 3. Department of Nursing, Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel, 4. Margolez Psychogeriatric Center, Ichilov Hospital, Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel

This study compares formal and informal caregivers’ perceptions of delusions and hallucinations in older persons with dementia. Participants were 151 community dwelling persons from Israel aged 65 and over with dementia. Assessments included the Behavioral Pathology in Alzheimer’s Disease Rating Scale (BEHAVE-AD), Neuropsychiatric Inventory (NPI), Etiological Assessment of Psychotic Symptoms in Dementia (EAPSID), Activities of Daily Living, and Mini Mental State Examination (MMSE). Informal caregivers reported higher rates and a higher level of severity of delusions and hallucinations in comparison to formal caregivers. Different caregivers showed varying degrees of empathy and of efforts to find the meaning of the delusion for the person experiencing it. Family members and staff members may see different parts of the total picture. Hearing both formal and informal accounts is important in order to enhance the understanding of the reality of the person with dementia and the different caregivers and thereby to clarify the options for intervention.

“THEY’RE REALLY KIND OF THE ‘FORGET ABOUT’ PEOPLE”: STAFF PERCEPTIONS OF A DEMENTIA CARE UNIT
A.D. Peeples, 1. Center for Aging Studies, UMBC, Baltimore, Maryland, 2. Doctoral Program in Gerontology, UMBC/UMB, Baltimore, Maryland

Dementia care units (DCUs) provide specialized care for residents with dementia and are usually situated within a larger long-term care setting. Often, residents of a DCU are subject to stigma from residents and staff members of other levels within the larger setting. This stigma becomes especially apparent when it is perceived that resources are limited, in that there may not be an equal allocation of funding or other material resources across levels. The experiences of more independent and vocal residents, who are most capable of advocating for themselves, may come to be viewed as a higher priority than the experiences of those who are less vocal, such as DCU residents. This presentation examines the ways in which staff members of a DCU perceive how the DCU fits into a larger long-term care setting including assisted living suites and independent living apartments. The discrepancy between the ideal and the reality of the treatment of DCU residents is discussed. Differences in food, décor, activities and other aspects of life in the DCU are described, as are the actions that DCU staff members take in an attempt to address these differences. Data for this presentation were drawn from two multi-year, NIA-funded qualitative studies, “Stigma and the Cultural Context of Residential Settings for the Elderly” and “Autonomy in Assisted Living: A Cultural Analysis,” and from an independent project on stigma. Data consisted of over 80 sets of observational field notes and more than 20 ethnographic interviews with staff, family, and residents of a DCU.

CLINICAL COURSE AND DRIVING RECOMMENDATIONS FOR VETERANS SEEN IN VA GERIATRIC EVALUATION AND MANAGEMENT (GEM) AND MEMORY CLINICS
P.R. King1, C.L. Vair1, L.O. Wray1, M. Wade1, A. Kusche1, J. Gass1, C. Saludades1, J. Chang1, 1. Department of Veterans Affairs, Buffalo, New York, 2. SUNY Buffalo, Buffalo, New York

As cognitive functions decline, the capacity to safely operate a vehicle does as well. Persons with cognitive impairment, most notably dementia, are at increased risk for driving hazards such as traffic accidents, travelling at unsafe speeds, and becoming lost. Despite increased risk of accidents, as many as 30% of patients with cognitive impairment continue to operate motor vehicles (Kennedy, 2009). Although best clinical practices incorporate assessment and intervention for impaired drivers, management of driving risk remains a notable challenge for clinicians. Additionally, there are important gaps in knowledge regarding the clinical trajectories of patients after intervention. As part of an investigation into the clinical course of Veterans with cognitive impairment assessed in specialty geriatric settings within the Department of Veterans Affairs, the present study sought to explore documented feedback practices and referral outcomes for patients advised to modify or discontinue their driving practices. Using a retrospective review of electronic medical records, 349 Veterans with cognitive impairment (age M

MEMORY LOSS AS A TOOL FOR INTERVENTION

EXAMINATION OF THE INDEX FOR MANAGING

Concerns will also be addressed.

cerns will also be addressed. Preliminary findings suggest that Veterans with cognitive impairment who reported driving at the time of intake were unlikely to follow-through with clinician-recommended driving evaluations. Additional results that describe follow-up visits to VA clinics, outcomes from visits, and healthcare utilization will be discussed. Clinical implications for safety recommendations and documentation of driving safety concerns will also be addressed.

ASSESSING COPING IN EARLY DEMENTIA:

EXAMINATION OF THE INDEX FOR MANAGING MEMORY LOSS AS A TOOL FOR INTERVENTION

RESEARCHERS

M.M. Hilgeman1,2, R.S. Allen2

1, Tuscaloosa VA Medical Center, Tuscaloosa, Alabama, 2. Center for Mental Health & Aging, The University of Alabama, Tuscaloosa, Alabama

Qualitative research examining the lived experience of individuals in the early to mild stages of dementia has offered insight into numerous coping strategies employed by individuals as they navigate diagnoses, declines in independence, and shifting social roles. Despite this work and increasing emphasis on including individuals with dementia in interventions to reduce distress—a well-validated scale quantifying coping strategies is not yet available. The current study presents preliminary psychometric data on the Index for Managing Memory Loss scale (IMMEL; a clinical tool developed by Keady & Nolan, 1995) using baseline assessment data from a small intervention pilot study. Eighteen individuals with mild dementia (M = 82.79 yrs old; 68.4% female; 53% African American) rated their use of 42 coping strategies. Endorsed items were also rated for helpfulness on a 3-point scale (very helpful to not really helpful). Scores were calculated using a count of coping strategies and a mean helpfulness rating. Results revealed good variability in scores (Range: 20-32, M = 25.72, SD = 3.77) and acceptable internal consistency (Chronbach’s alpha = .733). Item-level analyses were examined for frequencies as well as potential item deletions to improve reliability statistics and reduce participant burden. Bivariate correlations explored convergent validity with quality of life (-.52, p = .03), depressive symptoms (.54, p = .02), and related constructs. Examination of the IMMEL at post-intervention assessment revealed that it is sensitive to change over time following an intervention (Cohen’s d = 0.89). This scale shows promise for use in intervention research in the future.

PERCEIVED STIGMA IN PERSONS WITH EARLY-STAGE DEMENTIA: FINDINGS FROM A LONGITUDINAL STUDY

S.C. Burgener1, K.C. Buckingham2, Y. Perkhounkova2, M. Liu1, University of Illinois, Paxton, Illinois, 2. The University of Iowa, Iowa City, Iowa, 3. University of Taipei, Taipei, Taiwan

Experienced stigma related to dementia has been increasingly recognized as a factor impacting on outcomes with this growing older adult population. This longitudinal study examined perceived stigma in persons with dementia (PwD), with 50 PwD subjects and 47 (N = 97) corresponding family caregivers. Data were collected at baseline and at 6, 12, and 18 months regarding perceived stigma, measured by the Stigma Impact Scale (SIS) and quality of life (QoL) outcomes, including depression, anxiety, behavioral symptoms, personal control, physical health, self-esteem, social support, and activity participation. Findings included stability in perceived stigma which did not show a downward trend until 18 months. Significant differences at baseline were found only for geographic location (rural vs. urban) with persons living in urban areas having higher levels of SIS internalized shame compared to rural counterparts. Cognitive functioning was significantly, positively related to the SIS social rejection and social isolation subscales. Linear mixed model (LMM) or generalized LMM (for depression) analyses revealed some aspect of perceived stigma (SIS) was associated with each QoL outcome. Social rejection explained anxiety, behavioral symptoms, health, and activity participation. Internalized shame explained anxiety, personal control, health, self-esteem, social support understanding and assistance, and activity participation. Finally, social isolation explained depression, anxiety, personal control, health, self-esteem, social support understanding and activity participation. The complexity and relevance of perceived stigma in impacting QoL outcomes was evident from these findings.

THE ROLE OF POSITRON EMISSION TOMOGRAPHY IN DETECTION OF HIV-ASSOCIATED NEUROCognitive DISORDER: A PILOT STUDY

M. Pallaki1,2, D.M. Kresevic1,2, C.J. Burant1,2, D.J. Harvey1, V.G. Reddy1,2, J.E. Denton1, V.D. Armstrong1, 1. Cleveland VA Medical Center, Cleveland, Ohio, 2. CWRU, Cleveland, Ohio

Milder forms of HIV-associated Neurocognitive Disorder (HAND) are increasingly being recognized. Positron Emission Tomography (PET) has been used in detection of AIDS-dementia complex and may have utility with milder forms of HAND. The present study examined use of PET in detection of HAND via correlation with neuropsychological (NP) testing. A convenience sample of 15 HIV patients with suspected cognitive impairment was assessed via NP testing. Neurocognitive measures targeted vulnerable domains of processing speed, attention/working memory, executive functions, learning/memory and fine motor speed using established/standardized measures including the Wechsler Adult Intelligence Scale – Fourth Edition (WAIS-IV) Digit-Symbol Coding and Digit Span subtests, Wisconsin Card Sorting Test (WCST), California Verbal Learning Test – 2nd Edition (CVLT-II) and Grooved Pegboard. Seven patients had neurocognitive impairment based on NP testing. Eighty-six percent of these had abnormal PET scans. Hypometabolism within the anterior brain network was related to attention/working memory impairment based on WAIS-IV Digit Span (r = .75) and CVLT II Trials 1-5 (r = .100) scores. Additionally, hypermetabolism within the posterior cingulate region was associated with less fine-motor impairment based on Grooved Pegboard Dominant (r = .94) and Non-dominant (r = .83) performance. These preliminary results suggest PET could be useful in detection of HAND and the characterization of its underlying neuropathological substrates.

GENOME-WIDE ASSOCIATION STUDY OF RATE OF COGNITIVE DECLINE IN FOUR ALZHEIMER’S DISEASE SAMPLES

A.L. Gross1, R. Sherva2, S. Mukherjee3, S.J. Newhouse4, P.K. Crane1, R.C. Green5,6, 1. Institute for Aging Research, Hebrew SeniorLife, Harvard Medical School, Boston, Massachusetts, 2. Boston University School of Medicine, Boston, Massachusetts, 3. University of Washington, Seattle, Washington, 4. King’s College London, London, United Kingdom, 5. Division of Genetics, Department of Medicine, Harvard Medical School, Boston, Massachusetts, 6. Partners Healthcare Center for Personalized Genetic Medicine, Boston, Massachusetts

Background: Variability in cognitive decline in Alzheimer’s disease (AD) cannot be entirely explained by demographic, health, or clinical features, so genetics are likely partially responsible. Determining genetic underpinnings of the variability in the rate of cognitive decline in AD might help reveal previously unidentified biological pathways responsible for disease progression. Methods: We combined measures of global cognition across 4 large studies of persons with AD using psychometric methods. Studies included the Alzheimer’s Disease Neuroimaging Initiative (N = 301), National Alzheimer’s Coordinating Centers (N = 865), Religious Orders Study/Rush Memory and Aging Project (N = 323), and AddNeuroMed study (N = 123). We estimated genome-wide associations (GWA) using generalized estimating equations with an interaction between AD duration and SNP. Results: Rate of decline over a median 3.1 years in our pooled sample was heritable (h2 = 0.38).
GWA identified several variants strongly associated with rate of decline, including SNPs in MANB4A (P=8.28E-10), KCNJ14 (P=3.17E-09), MAP3K1 (P=1.36E-08), and HIBADH (P=1.36E-08). Conclusions: Genes influence rate of decline. These genes are distinct from those that influence AD risk. These findings have important implications for determining the genetic architecture of the rate of cognitive decline in AD. This new knowledge may contribute to clinical-physiological studies designed to reveal biological mechanisms to help researchers determine the etiology behind rates of clinical progression of AD.

IMPROVING SPECIALIZED DEMENTIA CARE ACCESS TO RURAL VETERANS: A DEMONSTRATION PROJECT

T.C. Andersen1, D.B. Kaplan1. 1. Neurology & Social Work, University of Utah, Salt Lake City, Utah, 2. Columbia University, New York, New York

The University of Utah in conjunction with the Office of Rural Health at the Veterans Affairs Medical Center in Salt Lake City, Utah, and the Institute for Cognitive Health at St. Johns Hospital in Jackson, Wyoming, designed a demonstration project in rural Idaho and Wyoming to improve access to specialized dementia care services to rural Veterans. This project has been running since 2011 and has served 210 rural Veterans. In a collaborative effort, neurologists, neuropsychologists, health educators and social workers developed a multi-step process to identify, contact and assess rural Veterans for memory complaints. Through mass mailings and other media outlets the details of the program were publicized throughout Western Wyoming and South East Idaho. Once identified, a social worker or health educator conducts a brief telephone memory screen and if the screen is positive, a follow-up visit is scheduled at closest VA community based outpatient clinic (CBOC). At this visit a more formal cognitive assessment occurs with mental status testing. If screened positive, a referral is made for a comprehensive neurological evaluation and neuropsychological testing. In order to complete this testing, a neuropsychologist from the University of Utah conducts an interview via telehealth, with a psychometrist assisting at the Jackson site. This comprehensive evaluation also included the proactive use of social work and health education services to assist the patient and family with unified care planning. Details of the program will be discussed and results from the outcome measures of the project will be presented.

RACIAL DIFFERENCES IN DEMOGRAPHIC, HEALTH, AND COGNITIVE FACTORS OF BEHAVIORAL SYMPTOMS OF DEMENTIA

F. Cothran1, R.W. Redman1, L. Struble1, A.L. Whatl1, R. Dunkle2. 1. Rush University College of Nursing, Chicago, Illinois, 2. University of Michigan, Ann Arbor, Michigan, 3. Oakland University, Rochester, Michigan

The Need Driven Dementia Compromised Behavior model explores the interaction between structural background factors and dynamic proximal factors that influence care recipient behavioral symptoms of dementia. The purpose of the study was to compare the influence of background factors of Black and White care recipients on behavioral symptoms of dementia. Secondary data analysis of caregiver/care recipient dyads from the Aging Dемographics and Memory Study was conducted. Subjects were n=148 Black and n=594 White dyads. Background factors included demographics (marital status, education), health status (dementia type, Blessed score), and cognitive factors (CDR, DSRS, and MMSE scores). Caregiver reports of care recipient behavioral symptoms of dementia (i.e., delusions, hallucinations, agitation, and depression) were also assessed. Background factors of Black and White dyads were compared with independent t tests or chi-square tests. Logistic regression was utilized to test associations between background factors and care recipient behavioral symptoms. Compared to White care recipients, Black care recipients had lower education, were less likely to be married, and had lower MMSE scores. Logistic regression indicated that higher Blessed, CDR, and DSRS scores were associated with increased odds of all dementia related behaviors in both black and white care recipients. Black care recipients had decreased odds of depression, female care recipients had more delusions and hallucinations than men, and older age was associated with increased odds of hallucinations and agitation. Results suggest that background factors may play a role in the report/recognition of behavioral symptoms of dementia and should be considered when working with families of persons with dementia.

SESSION 210 (POSTER)

DISABILITY, FALLS, AND MOBILITY

TRENDS OF DISABILITY IN THE OLDER ADULTS MAY VARY UNDER DIFFERENT MEASUREMENTS: AN ILLUSTRATION IN THE CHINESE ELDERLY POPULATION FROM 2002 TO 2008

Q. Feng1, Y. Zeng1. 1. Sociology, National University of Singapore, Singapore, [Select a State], Singapore, 2. Duke University, Durham, North Carolina

Activities of daily living (ADL) and Instrumental ADL indexes as the routine measures in disability trend studies, are both self-reported dependency/difficulty on the daily activities, and thus are limited to differentiate the contextual activity barriers and intrinsic body impairment in the elderly population. This study examines four types of disability measurements in the Chinese elderly disability trend analysis: 1) the self-reported difficulty in IADL, 2) the self-reported dependency in ADL, 3) the self-evaluated function performance, and 4) the objective performance in function tests. The data are from three waves of the Chinese Longitudinal Healthy Longevity Survey (CLHLS) in 2002, 2005 and 2008. The results showed contrasting trends co-existed under four different measurements in the same period. The fact that the negative trends based on objective performance was opposite to observed improvements in ADL and IADL among the Chinese older adults suggests that the ADL and IADL improvement could be largely due to the changes in the living environment of the elderly instead of the intrinsic improvement of body function. To better understand the source of disability in the elderly population is extremely important for medical interventions, elderly care and public policy development and we call for more attentions to such a measurement problem in the current disability trend studies.

AGE-RELATED IMPAIRMENT OF STEP-OVER ABILITY AND ITS SELF-ESTIMATION IN OLDER ADULTS WITH HIGH AND LOW FREQUENCY OF GOING OUTDOORS

R. Sakurai1,2, H. Suzuki1, N. Sakuma1, Y. Fujiwara1, M. Ishihara1, T. Higuchi1, K. Imanaka1, 1. Tokyo Metropolitan University, Hachioji-shi, Tokyo, Japan, 2. Tokyo Metropolitan Institute of Gerontology, Itabashika, Tokyo, Japan

Although an inactive lifestyle in older adults has been shown to cause a deterioration in daily physical function, this inactive lifestyle might have a greater role in the impairment of self-awareness/self-estimation of deteriorating physical function, which could result in action-related risks such as falls. We studied 202 older adults with high- and low-frequency-outing lifestyles who participated in both self-estimation and physical performing tasks of a stepping-over test (SOT). The high frequency of going outdoors group (HG) included older adults who tended to go out daily, whereas the low frequency of going outdoors group (LG) included those who went out every few days or with a lesser frequency. Both groups first performed the self-estimation task of the SOT, in which they predicted/estimated a maximum height (EH) that could be reached when stepping over a horizontal bar placed at a distance of 7 m. They then performed the physical performing task of the SOT, in which the maximum height (AH) of the bar was measured after the successful
IMPACT OF FALLS AND RECURRENT FALLS ON FUNCTIONAL DECLINE IN COMMUNITY-DWELLING OLDER JAPANESE ADULTS

Y. Okubo1,2, N. Yabushita3, S. Seino1,2, M. Nenomo1,2, S. Jung4, Y. Osaka5, R. Figueroa1, K. Tanaka1

1. Japan Society for the Promotion of Science, Tokyo, Japan
2. University of Tsukuba, Tsukuba, Japan
3. 2. Birmingham/Atlanta VA University of Alabama at Birmingham - Gerontology, Geriatrics & Palliative Care, Birmingham, Alabama, 2. Birmingham/Atlanta VA University of Alabama at Birmingham, Birmingham, Alabama, 3. Birmingham/Atlanta VA Geriatric Research, Education, & Clinical Center, Birmingham, Alabama

Background: Low functional status is both the cause and the result of incident falls but few have investigated the latter. The objective of the present study was to investigate the impact of falls and recurrent falls on the functional decline in community-dwelling older adults. Methods: This was a 1-year prospective study in 319 older adults (119 men and 200 women) aged 65-87 years (72.9 ± 5.4 yr). Trained testers performed baseline assessment of falls (>= 1) and recurrent falls (>= 2) and 1-year reassessment of the following outcome measures: gait speed, one-leg balance, Tokyo Metropolitan Institute of Gerontology index of competence (TMIG-IC). At 1 year of follow-up, participants who had declined by >= 1 standard deviation (SD) below the baseline mean value of each outcome measure were classified as “decliners”. Multiple logistic regression analysis was used to assess the impact of falls on functional decline in each outcome measure. Results: At baseline, prevalence of fallers and recurrent fallers were 16.9% and 4.7%. At 1-year follow-up, incidence of functional decline in gait speed, single-leg balance, and TMIG-IC were 6.2%, 8.8%, and 2.7%, respectively. Only fallers experienced significantly greater declines in gait speed and TMIG-IC. Multiple logistic regression analyses showed that previous fall was a significant independent predictor for decline in gait speed (adjusted odds ratio: 4.11, 95% confidence interval: 1.52-11.12, P < 0.01) but not significant for TMIG-IC. Conclusion: Falls including one time fall have a significant negative impact on gait in community-dwelling older Japanese adults.

THE TEMPORAL RELATIONSHIP OF LIFE-SPACE MOBILITY, COGNITIVE FUNCTION, AND DEPRESSIVE SYMPTOMS IN OLDER ADULTS

M. Crowe1, R.E. Kennedy2, P. Sawyer2, R.M. Allman1,2, 1. Psychology, University of Alabama at Birmingham, Birmingham, Alabama, 2. University of Alabama at Birmingham - Gerontology, Geriatrics & Palliative Care, Birmingham, Alabama, 3. Birmingham/Atlanta VA Geriatric Research, Education, & Clinical Center, Birmingham, Alabama

Background: Lower cognitive function in older adults is known to be associated with reduced spatial mobility measured by life-space, but the temporal association between the two is unclear and the potential longitudinal interrelationship with depressive symptoms is not known. Methods: Participants from the UAB Study of Aging (N=589) completed baseline and four-year in-home assessments, which included the Life-Space Assessment (LSA) as well as measures of cognitive function (composite index of the Mini-Mental State Exam [MMSE] and spontaneous clock-drawing test [CLOX1]) and depressive symptoms (15-item Geriatric Depression Scale [GDS]). Structural equation modeling with cross-lagged pathways was used to simultaneously examine the effects of these three baseline measures on each other at follow-up, adjusting for demographics, medical comorbidity, and transportation difficulty. Results: Life-space at four-year follow-up was positively associated with baseline cognitive function (p=0.043) and negatively associated with depressive symptoms (p=0.002). Cognitive function at year four was predicted by baseline life-space (p=0.024) but not depressive symptoms. Depressive symptoms at follow-up were predicted by baseline cognition (p=0.043) but not life-space. The effects of cognition and depressive symptoms on subsequent life-space were greater than the effects of life-space on cognitive and mental health. Conclusions: Life-space, cognitive function, and depressive symptoms show complex interrelationships over time. The primary effect was cognition and depressive symptoms predicting later life-space, although significant bidirectional effects were observed.

TRAJECTORIES OF PHYSICAL FUNCTIONING IN OLDER ADULTS WITH LATE-ONSET DIABETES: GENDER AND RACE/ETHNIC VARIATIONS

S. Ndao-Brumblay, J. Liang, Health Management and Policy, University of Michigan, Kalamazoo, Michigan

Objectives: To describe the trajectories of physical functioning upon diabetes diagnosis at age 50 and older, and explore race/ethnic, and gender variations in these trajectories. Methods: Hierarchical Linear Models of Health and Retirement Study data quantify the 14-year change in ADL/IADL and mobility disability upon diabetes diagnosis. Results: Over the course of late-onset diabetes, after controlling for age and cohort differences, both ADL/IADL and mobility disability accelerate according to a quadratic function. Compared to Caucasian men, minority women (specifically African American women), and Hispanic men, had the highest disability levels at diagnosis. Hispanic men experienced faster functional decline in ADL/IADL and mobility disability, and Hispanic women had faster decline in functional disability. Education significantly reduced racial/ethnic and gender differences at diagnosis and over the course of illness; but it did not account for the faster progression in Hispanic men. Conclusion: Even in old age, incident diabetes is characterized by accelerated disability. Minority women and Hispanic men are the groups at greatest risk of poor functioning upon diabetes diagnosis.

BALANCE EFFICACY IS MORE RELATED TO FITNESS THAN POSTURAL CONTROL IN OLDER ADULTS

V. Shannon1,2, A. Lee3, K. Deo4, W.E. Taylor5, J.R. Bigman6, C. Ray7, 1. Tarleton State University, Stephenville, Texas, 2. University of Texas at Arlington, Arlington, Texas

One in three older adults falls each year. Self-report measures are commonly used to assess an individual’s perception of their own balance ability. The purpose of this study was to determine how well a self-report measure (Balance Efficacy Scale [BES]) related to postural control, and to examine the effect of lower confidence on physical outcomes such as dynamic balance and fitness. One hundred and eleven community-dwelling older adults (71 females, 40 males) aged 61 to 91 (M=75.10, SD=6.12) completed the Sensory Organization Test (SOT; a measure of postural control), the BES, and the Senior Fitness Test (SFT). Results indicated a medium but significant relationship between BES scores and the SOT (r=.33, p<.001). However, the strongest relationships were between the BES and aspects of the SFT, specifically dynamic balance (8 ft up-and-go; r=.48, p<.001) and fitness (2-minute step test and 6-minute walk; both r>.50, p<.001). These findings suggest that some individuals with low balance efficacy may have adequate use of their sensory systems to maintain postural control. However, they may limit their activity and adopt a more sedentary lifestyle due to their lack of confidence. As a result, a decline in physical fitness and dynamic balance may occur. Therefore, individuals with low balance efficacy should have their postural control tested and have feedback provided so that they do not unnecessarily reduce...
physical activity. This work suggests the need for consideration of the psychological impact of confidence, or lack of confidence, on physiological outcomes.

PSYCHOMETRIC PROPERTIES OF THE FALLING QUESTIONNAIRE IN OLDER ADULTS
E.S. Bower1,2, C. Merz2, A. Petkus2, J. Wetherell3, E.J. Lenze3. 1. Psychology, San Diego State University, San Diego, California, 2. University of California San Diego, San Diego, California, 3. Washington University in St. Louis, St. Louis, Missouri

Hip fractures are one of the most serious injuries related to falls in older adults, often leading to permanent disability and death. Many older adults develop a fear of falling after suffering a hip fracture. Fear of falling predicts future falls and is associated with restriction in activity, decreased life satisfaction, and frailty. Therefore, developing reliable and valid methods for assessing fear of falling in this high-risk group can help researchers identify factors that may aid recovery and treatment. The Falling Questionnaire (FQ) is a new, shortened form of the Fear of Falling Questionnaire designed to assess fear of falling in older adults. The FQ was adapted for use with physically impaired older adults, and thus may be a valid alternative to the current gold standard when assessing older adults with activity restrictions. To this aim, the psychometric properties of the FQ were assessed in a large sample (N = 353; 76% female) of older adults (M = 78 years) undergoing rehabilitation after hip fracture as well as a comparison sample of healthy adults (N = 81; 67% female; M = 77 years). The FQ demonstrated strong internal reliability and test-retest reliability at 4 and 12 weeks following hip fracture. As expected, the FQ was positively correlated with the Falls Efficacy Scale International, offering support for convergent validity. Factor analyses were conducted and will be discussed. The results suggest that the FQ is a valid and reliable measure for assessing fear of falling in older adults after hip fracture.

SLEEP WELL: THE EFFECT OF SLEEP QUALITY ON FALLS IN OLDER ADULTS
P. Beck1,2, J.A. Ailshire3, 1. University of Southern California, Los Angeles, California, 2. Andrus Gerontology Center, Los Angeles, California, 3. Fall Prevention Center of Excellence, Los Angeles, California

Falls are the leading cause of injurious death in older adults. Sleep problems are a common disorder among older adults, and poor sleep, which can reduce cognitive and motor performance and decrease proprioception, may increase fall risk. We use data from the 2002 and 2004 waves of the Health and Retirement Study to determine if older adults who report sleep problems in 2002 have increased risk of falling between 2002 to 2004. We focus on three dimensions of poor sleep: frequent nighttime awakenings, frequency of waking too early, and feeling rested upon waking. We use logistic regression to examine associations between multiple indicators of sleep quality and risk of experiencing a fall, and experiencing an injurious fall. Frequent trouble sleeping through the night (OR: 1.17, 95% CI: 1.04–1.32) and waking up too early (OR: 1.17, 95% CI: 1.01–1.35) increased likelihood of having experienced a fall since the previous wave, suggesting that poor sleep quality increases the future risk of falls. Education (OR: 1.15, 95% CI: 0.99–1.33), being Hispanic (OR: 0.88, 95% CI: 0.72–1.05) or Asian/Other (OR: 0.82, 95% CI: 0.57–1.16), or having trouble falling asleep (OR: 1.14, 95% CI: 0.99–1.33), did not increase risk of falling. Chronic conditions (OR: 0.99, 95% CI: 0.93–1.06), trouble falling asleep (OR: 1.04, 95% CI: 0.82–1.31), education (OR: 1.06, 95% CI: 0.95–1.18), being Hispanic (OR: 1.24, 95% CI: 0.89–1.71) or Asian/Other (OR: 1.01, 95% CI: 0.48–2.15), did not influence risk of fall injury. Sleep quality appears to impact risk of falling among older adults.
Support (OR 1.671; 95% CI 1.08-2.58) and incontinence of the person cared (OR 1.671; 95% CI 1.08-2.58). After adjusting for age, gender, education, depression, leisure time activities and vacations having social support was the most important protective factor for burden of caregiver (OR=5.43; 95% CI 2.89-10.2) Conclusion. Initiatives aimed to enhance social support of family caregivers are crucial to ensure quality of care and QoL of both the carer and the recipient of care.

Caring is time-consuming for informal caregivers and balancing with their social life is one of their main concerns. Female caregivers will value social engagement more than men, and this will be especially true in the United States, where women are more likely to work outside the home and to value outside social activities, relative to Japanese women. Care duration is also an important factor in terms of developing coping strategies and in cumulative fatigue, especially in Japan where more caregivers are co-resident. In this study, we examine the relationship between caregiving and social activity restriction for informal caregivers in the US and Japan. Data are from the US National Study of Caregiving (NSOC) of the National Health and Aging Trends Study (NIATS) (n=2007), and the first wave of the Fukui Longitudinal Caregiver Survey in Japan (n=2510). Outcomes were the restriction of having time for themselves, visiting friends, and social groups. Most caregivers were female (67% in the US and 76% in Japan.) About half of US caregivers and one third in Japan had provided care for more than 5 years. Multivariate logistic regression models showed female caregivers in both countries were more likely than men to report that caregiving interfered with social activities with somewhat larger magnitude in the US. Longer care duration appears to be associated with worse social participation for Japanese caregivers, in particular, when they provide care more than 5 years. Features of gender roles and caregiving experience in both countries will be discussed.

THE INFLUENCE OF MOTHER’S HEALTH ON DAUGHTER’S DISTRESS: CAREGIVING AMONG MEXICAN AMERICAN ADULTS

S. Rote1, J.L. Angel2, K. Markides3, 1. Sealy Center on Aging, University of Texas Medical Branch, Galveston, Texas, 2. University of Texas at Austin, Austin, Texas, 3. University of Texas Medical Branch, Galveston, Texas

Caring and its related stressors have been shown to influence mental well-being. These associations tend to vary by the medical conditions of the person receiving care with mental health problems being more salient for caregivers’ well-being than physical health issues. In the current paper, we examine whether mental and physical health status of older mothers is associated with depressive symptoms in their caregiving daughters. We use data from the Hispanic Established Populations for the Epidemiologic Studies of the Elderly (Hispanic EPESE) a population-based sample of older Mexican American adults living in the southwestern U.S. Data collection first took place in 1993/1994 and follow-up data collection has been conducted every two to three years. In Wave 7 (2010/2011) when respondents were 80 years and older, they were asked to provide contact information for a child or person who gives them the most advice or help or knows them the best. Overall, 925 informants completed a survey on their own health, the caregiving experience, and the health and functioning of the respondent. In the current paper, we limit the sample to female caregivers and their mothers (N=298). We find that physical health conditions and disability are not significantly related to daughter’s depressive symptoms. However, having a mother with more depressive symptoms or a higher score on the Neuropsychiatric Inventory (NPI), a measure of psychopathology of dementia, was associated with more depressive symptoms among daughters. Findings highlight the evidence of concordant mental health problems among mothers and their caregiving daughters and the distress resulting from problematic behaviors associated with cognitive decline.

EMOTIONAL WELL-BEING AND SELF-PERCEIVED PHYSICAL HEALTH OVER TIME AMONG AFRICAN AMERICAN AND WHITE MALE CAREGIVERS OF OLDER ADULTS

This study is a longitudinal, secondary data analysis of the Family Relations in Late Life (FRILL) 2 study. Using the Pearlin stress process model (SPM) as a guide, the purpose of this study was to examine emotional well-being and self-reported physical health over 36 months among African American and White male caregivers of older adults living in the community. A two-level Hierarchical Linear Model (HLM) was used to predict changes over time for anger, anxiety, depressed affect, resentment, and self-reported physical health and examined the influence of race and constructs suggested by the Pearlin SPM. Race was not a significant predictor of any of the outcome variables, suggesting that African American and White male caregivers are similar in their responses to the demands of caregiving and that these responses remain relatively stable over time. Mutual communal behavior, activity restriction, and perceived social support were significant predictors of outcomes over time. Caregivers who reported higher mutually communal behavior reported less anxiety and resentment and better health over time. Greater activity restriction was linked to more anger, anxiety, depressed affect, and resentment over time, and more perceived social support was linked to less depressed affect and resentment over time. These findings are consistent with previous research showing that increased social isolation and lack of support from family and friends contributes to negative emotional well-being. Further, these deficits may have a cumulative effect over time for both African American and White male caregivers.

THE INFLUENCE OF ACCULTURATION ON KNOWLEDGE OF ALZHEIMER’S DISEASE AMONG LATINO CAREGIVERS

D.E. Jimenez1, V. Cardenas2, D. Gallagher-Thompson3, 1. Population, Family and Reproductive Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland, 2. Johns Hopkins University, Baltimore, Maryland, 3. National Center for Geriatrics and Gerontology, Ohu, Japan, 4. University of Tokyo, Tokyo, Japan

The present study examined the relationship between acculturation and knowledge of Alzheimer’s disease (AD). It is hypothesized that: (a) the response patterns of highly acculturated Latina caregivers will resemble that of their non-Latino White counterparts; and (b) high acculturated Latinas will have more accurate knowledge of AD than those with low acculturation. Latina and non-Latino White dementia caregivers were recruited (N = 183; 96 non-Latino White; 87 Latina). The Knowledge of Alzheimer’s Disease Questionnaire was used to assess attitudes and beliefs regarding AD. Finally, the Acculturation Rating Scale for Mexican Americans was used to assess for level of acculturation only in the Latina caregivers. Significant ethnic group differences in total number of correctly endorsed responses were found: non-Latino White caregivers were significantly more knowledgeable about AD than even the highly acculturated Latinas. No significant differences were found between high and low acculturated Latinas in total number of correctly endorsed responses. Item analyses indicate that the response pat-
terms of the less acculturated Latinas reflected more culturally bound beliefs regarding AD. Given the dearth of research on acculturation and its impact on health beliefs, these results may be used as a means of developing programs and tailoring educational materials. The current study builds a foundation for future research on acculturation and its impact on knowledge of beliefs concerning other chronic illnesses.

MEASURING CULTURAL JUSTIFICATIONS FOR CAREGIVING IN AFRICAN AMERICAN AND WHITE CAREGIVERS OF PERSONS WITH DEMENTIA
S.M. Powers, C.J. Whittatch, 1. University of Akron, Akron, Ohio, 2. The Benjamin Rose Institute on Aging, Cleveland, Ohio

Familial roles, responsibilities, and perceptions about illness and aging are a few of the concepts that, together with race and ethnicity, help form attitudes or beliefs about caregiving. This paper will describe the psychometric properties of the Cultural Justifications for Caregiving Scale (CICS, Dilworth-Anderson, Goodwin, & Williams, 2004) for a group of African American and White caregivers. The CICS measures the cultural reasons for and expectations about providing care to an older relative. CICS data were collected from 202 adults caring for an older relative with memory impairment. Data were analyzed for reliability, factor structure, and correlations with other measures pertaining to the caregiving experience. High levels of reliability were found for the CICS, and exploratory factor analyses suggested two underlying factors relating to Duty and Reciprocity. However, when the 10-item measure was examined for each subsample, differential factor loadings appeared for African American and White caregivers. More specifically, when the full sample was broken down by race, two items (i.e., provide care because of religious beliefs and provide care because my family expects me to) appropriately loaded onto differential factors (e.g., loaded at a .50 or above), resulting in the emergence of different subscales by race and supporting the improvement of reliability estimates. Findings suggest the CICS is a reliable measure for use with African American and White caregivers. Moreover, cultural motivations to provide care may differ for ethnically diverse CGs based on religious backgrounds and beliefs about family expectations.

LESSONS LEARNED FROM EXPOSING OLDER AFRICAN AMERICAN CAREGIVERS TO DANCE AND MOVEMENT THERAPY
M.P. Waters, University of Alabama at Birmingham, Birmingham, Alabama

With the increasing older adult population, increasing medical and formal care costs, and decreases in family size, optimal health of the caregiving population is essential to provide care to loved ones. Dance and movement therapy (D/MT) is a certified, clinical program that uses expressive and therapeutic techniques to improve physical, emotional, and cognitive health. D/MT is used primarily in clinical settings, therefore research investigating its use and acceptance by older community-dwelling African Americans is limited. However, African American caregivers may be responsive to a D/MT program since there is evidence that dance interventions have increased the functional capacity of African American women (Murrock and Gary, 2008). The primary goal of the current study is to examine the acceptability of a D/MT program for older African American caregivers by focusing on participant interest and belief in their ability to perform program techniques. Twenty African American caregivers, aged 65 and older, were recruited from Birmingham, Alabama to participate in a focus group and a telephone assessment. Caregivers viewed a brief video presentation demonstrating techniques tailored to older adults who may have a limited range of motion and no prior dance experience, which was created by a certified dance and movement therapist. During the focus groups, open-ended questioning obtained participant expectations about performing D/MT techniques and barriers to participating in a movement program. Additional data was collected over the telephone with standardized measures of quality of life, social support, and caregiver burden. Analyses of both the qualitative and quantitative data will be presented.

TRAJECTORY OF SELF-MANAGEMENT ACTIVITIES AMONG DIABETIC AFRICAN-AMERICAN PRIMARY CAREGIVING GRANDMOTHERS

Background: Because of their caregiving role, diabetic African-American caregiving grandmothers may face challenges in engaging in self-care necessary to manage their diabetes. However, no studies have longitudinally explored the trajectory of these activities in this population. Purpose: To explore the trajectory of self-management activities among diabetic African-American primary caregiving grandmothers. Methods: Using a convergent parallel mixed-methods design, six diabetic African-American caregiving grandmothers in North Carolina were interviewed in-depth 5 times over 18 months and completed a survey about frequency of diabetes self-care activities. The survey questions were repeated during the interview. During analysis, codes were developed and defined in a code book. Interviews were coded with data organized in a matrix facilitating deep understanding of each case and cross-case analysis. Qualitative and quantitative data were merged to compare results using side-by-side comparison. Results: Decreases in self-care activities were noted during “stressful” times such as graduation activities and illness of other family members. Conversely, increases in self-care activities were noted before appointments with healthcare providers. During the interviews, the participants provided more detail regarding their health behaviors. Multiple discrepancies were found between survey data and interview data. Conclusions: Caregiving stressors may impede diabetes self-care activities among diabetic African-American caregiving grandmothers. Results call into question whether surveys alone are an adequate method for collecting health behavior data. Future directions for research include developing interventions assisting this population in consistently engage in self-care activities. Additionally, exploration is necessary to find the most effective methods for collecting data on health behaviors.

SOURCES OF CAREGIVER STRESS AMONG AFRICAN-AMERICANS
S.F. Mohammed, C. Unson, M. Glendon, S. Dabiri, Southern Connecticut State University, New Haven, Connecticut

Purpose: This study identified sources of stress among African Americans caregivers. Method: A convenience sample of caregivers (N=110) who provided at least 5 hours of care per week to a relative 55 years old or older, was recruited from community settings in metropolitan areas in northeastern United States. They completed a self-administered questionnaire concerning caregiver stress and its potential determinants. Results: The average age of the caregivers was 42.5 (SD=15.3) years; 41.8% were employed full-time; 81.8% were females and 34.3% were sole caregivers; primary caregivers (65.1%) provided an average of 36.8 (SD=46.5) hrs. of care per week. The care recipient, on average, was 75.1 (SD=9.7) years old, had moderate functional status (ADL: 4.37 (SD=2.2) and IADL: 4.1 (SD=3.1)) mostly lived (51.8%) lived with a caregiver. The sample experienced low burden/stress (Zarit Caregiver Burden Interview (ZCBI), M=22, SD=13.58); positive perceptions of caregiving (Positive Aspects of Caregiving (PAC): 9.2 (SD=3.6)); moderate religiosity: 4.78 (SD=1.55) and moderate family disagreements: 2.28 (SD=1.13). High scores on CES-D scale (β=0.36**), lower scores on PAC (β=0.21**), more family disagreements (β=0.37**), and higher religiosity (β=0.27**), were significant predictors of ZCBI in regression analysis. They accounted for 50% of the variance in the ZCBI (Adj R2 .50**). IADLs, ADLs, weekly hours of care, and living with caregiver were not significant predictors. Conclusion: African American caregivers tend to experience low to moderate caregiver burden. The
HEALTH SERVICES IN INTEGRATED CARE SETTINGS: A PILOT STUDY

Introduction: Integrated behavioral health services increase service utilization and treatment success with older adults and high risk populations. This study assessed medical personnel’s attitudes and perceptions of behavioral health clinicians (BHC) using a new, brief self-report measure. Method: A 6-item survey was developed and given to medical providers from two healthcare systems (total N = 49) which include integrated behavioral health services designed for low-income individuals across the lifespan, including a specialty primary care clinic serving older adults. Survey items assessed providers’ attitudes and perceptions toward BHCs and included the following: Using BHCs improves my efficiency as a provider; Using BHCs improves overall patient care; BHCs help patients effectively address mental health concerns; BHCs help patients effectively address physical health concerns; BHCs help providers discuss mental health issues; BHCs are an important part of my practice. Providers rated each item from 1 (Strongly Agree) to 5 (Strongly Disagree). Results: In both health care systems, attitudes toward behavioral health were largely favorable. For all items, 73.3 to 100% of participants endorsed “Strongly Agree” or “Agree,” and no participant endorsed “Disagree” or “Strongly Disagree” on any item. Chi-square analyses in one sample revealed that those who interacted more frequently with behavioral health were more comfortable discussing mental health issues with their patients, x² (6, N = 49) = 13.43, p < .05. Discussion: Medical providers were found to hold favorable attitudes about BHCs in their integrated care settings. Some evidence suggests that increased exposure resulted in increased comfort using the services. Future studies should address medical providers’ opinions of BHCs in a variety of settings with larger samples to extend these pilot results.

EXPLANATORY FRAMEWORKS: OLDER WOMEN DISCUSS PLANNING FOR FUTURE HEALTH CARE NEEDS
L. Girling, L. Morgan, University of Maryland, Baltimore County, Baltimore, Maryland

Given population aging, it is critical to expand our understanding of how aging individuals consider and make decisions about implementing planning for potential future health care needs. This study expands the limited narrative data concerning health care preparation by identifying explanatory frameworks for future health needs among older women. This study utilized a phenomenological approach to examine older women’s narratives regarding experiences and perceptions of planning for anticipated health needs. Using data from “Lifestyles and Generativity of Childless Older Women,” a content analysis was conducted on 194 interviews with Caucasian and African-American women age 64-98. Answers to five relevant questions were open-coded and condensed into six main themes representing actions taken to date or reactions to the prospect of needing care. Examination of narrative data revealed that women describe and contend with potential care needs across a continuum of six categories including: (a) Planners for Autonomous Care, concrete steps towards future care needs; (b) End of Life Planners, only plans for death or funerals; (c) Externally Reliant, reliance on family, God, or institutions to provide potential care; (d) Aware of Preferences, expression of a preferred method or location for health care delivery; (e) Wishful Thinking, hope that future care would not be needed; and (f) Avoidant, refusal to think about potential care needs. Exemplars of the six themes will be presented.

OLDER ADULTS’ PERCEPTIONS OF THE CLOSURE OF A COUNTY HOSPITAL IN RURAL SOUTH CAROLINA
R. Wells, University of South Carolina, Columbia, South Carolina

As they age, many older adults face chronic conditions, which can necessitate frequent medical care and/or lead to increased concerns about medical care. Additionally, living in a rural community poses its own unique barriers to older adults’ access to care, transportation, and community services. In the last year, the Bamberg County Hospital closed in Bamberg County, South Carolina leaving residents without a nearby source for urgent care. According to the U.S. Census Bureau (2010), 28.3% of adults age 65 years old and over in Bamberg County live below the poverty level, compared with 9.4% of same-aged adults in the general U.S. population. The purpose of this study was to examine how the closure of a county hospital affected the lives of older adults in a rural, medically underserved area. A purposive convenience sampling technique was used to recruit older adults in Bamberg County through the county Office on Aging, local doctors’ offices, and senior centers. Utilizing qualitative in-depth interviewing techniques, participants were asked about their access to health care, transportation barriers, and perceptions on how the hospital’s closure has impacted their own personal health and the well being of the larger community. The themes that emerged about barriers to care can be used to inform policy makers and service providers about challenges facing rural older adults as they age in place. After attending this session, participants will be able to identify the challenges and needs faced by older adults within rural communities when their access to medical care is compromised.

SEASONAL INFLUENZA VACCINATION RATES OF NURSING HOME STAFF ACROSS RURALITY
T. Killian, University of Arkansas, Fayetteville, Arkansas

Vaccination of healthcare workers is a key component to reducing rates of seasonal influenza in nursing homes. The purpose of this study was to examine variations in vaccination rates of staff across rurality. Data from the 2004 facility file of National Nursing Home Study were used to examine variations in rates of vaccinations among employees working in nursing homes (N=1,111). All analyses implemented the use of sample weights to correct for unequal probabilities in complex sampling strategies. Weighted bivariate analyses suggested significant differences in vaccinations rates of employees by geography (chi-square = 29.04, df=12, p < .001). Specifically, 4.13% of rural nursing homes had vaccination rates of 100%, compared to 2.56% in micropolitan and less than 1% in metropolitan areas. Nursing homes were more likely to have vaccination rates of greater than 80% if they were in rural areas (23.95%), as compared to their micropolitan (13.98%) and metropolitan (11.96%) counterparts. Next, multinomial logistic regressions were used to model the relationship between geography and vaccination rates after controlling for covariates that included facility characteristics, primary pay sources of residents, and staffing characteristics. Results are complex, but they generally reinforce the bivariate analyses suggesting a small advantage for rural nursing homes in regard to vaccination rates of employees. Variations in nursing home quality across rurality have been an active area of research, with most studies focusing on rural disadvantages. This study contradicts that general trend finding slight advantages in vaccinations rates of employees in rural nursing homes.

USING TAI CHI TO FOSTER MOTOR AND BALANCE SKILLS IN RESIDENTIAL SENIORS
G.M. Brosvie, Rider University, Lawrenceville, New Jersey

Twenty randomly selected adults in assisted living completed a Simple Tai Chi Exercise Program (STEP), with results compared to 20
matched controls in the same residential unit. All participants were evaluated using the Falls Efficacy Scale, Timed Up and Go Test, Tinetti Balance Scale, Functional Reach, Berg Balance Scale and day-to-day living activities requiring reach, balance, and ambulation, at baseline and after completing 10, 20, and 30 STEP sessions. Multivariate analyses indicated that STEP participants demonstrated significant a) declines in the likelihood of falling and in time needed to stand and ambulate, and b) increases in functional reach, balance, and performance of day-to-day activities (all $F > 8.94$, all $p < .0001$); no changes were observed for controls. Upon completion of the 30 sessions, controls were offered STEP participation after which comparable improvements were observed in 17 of 20 former controls. Participants who independently continued STEP activities were judged by staff and medical attendants to require the lowest level of physical support during ambulation, to incur the fewest falls, and to evidence the greatest balance and reach during the completion of day-to-day living activities.

**FUTURE TIME PERSPECTIVE AND HEALTH IN OLDER PEOPLE: IS THERE A RELATION AND IS IT INFLUENCED BY SOCIODEMOGRAPHIC VARIABLES?**

M. Azevedo, L. Teixeira, C. Paúl. UNIFAL ICBAUS-UP, Porto, Portugal

Socioemotional Selectivity Theory (Lang & Carstensen, 2002) holds that as people grow older, perceived time left in life (Future Time Perspective-FTP) decreases, older people prefer emotional objectives and changes in social network are observed, promoting emotion regulation. Health has been described as influencing FTP. The aim of this study is to understand the relation between FTP and health in older people. Future Time Perspective Scale (FTP5), was administered to 207 Portuguese, 65+ years (Mean=77.17, $sd=7.53$; female=63.3%), living in the community or attending gerontological facilities. Psychometric properties of the scale and relations between FTP, sociodemographic variables, and health were tested. Factorial analyses of FTPs showed a unifactorial solution, good reliability ($\alpha=0.798$) and total variance explained of 37.2%. According to analyses of Cronbach’s Alpha if item deleted, no item was rejected. Subjects had a mean of 3.13 ($sd=1.26$) in FTPS and 2.55 ($sd=1.69$) diagnosis, average. FTP is related with age and gender (older people and women with more limited FTP), but no significant differences between education or occupation. Subjects with very good/good subjective health (24.6%) presented a significantly different ($p<.001$) higher mean than subjects with very bad/bad subjective health (35.7%). Number of diagnosis was negatively correlated with FTP. Considering the adjusted model for sex and age, the same associations were observed. Age and health (subjective/objective) seems to be independently explicative of FTP. Subjective health is a possible area to intervene with older people in order to make FTP more adaptive, possibly contributing to better wellbeing and satisfaction, diminishing negativity towards life.

**DEVELOPING AN ONLINE TRAINING FOR EVIDENCE-BASED FALL PREVENTION: PHYSICAL THERAPISTS AND THE OTAGO EXERCISE PROGRAM**

T. Shubert¹, C.B. Clarke¹, S.A. Bomberger², E. Roberts¹, J. Busby-Whitehead¹. 1. UNC Center for Aging and Health. Chapel Hill, North Carolina. 2. UNC School of Public Health, Chapel Hill, North Carolina

Widespread dissemination of evidence-based fall prevention programs has posed several challenges for healthcare, community providers, and older adults. In an effort to address this challenge, the Carolina Geriatric Education Consortium developed an interactive online training program to train physical therapists (PTs) in the Otago Exercise Program (OEP). PTs typically are not familiar with evidence-based fall prevention programs nor the concept of delivering the program with fidelity. We believed developing an easily accessible training program for PTs could help to close the dissemination gap, but it was not known if this format would be acceptable to physical therapists or facilitate learning. The curriculum for the program was developed and reviewed by subject matter experts and then piloted with 8 physical therapists, 3 who were knowledgeable about OEP, 3 who did not know about OEP but were clinicians with over 10 years of experience, and 2 with 5 years of experience. Results indicated the online format was acceptable and engaging, the content was clearly explained, by the end of the course the participants understood the concept of program fidelity and participants were likely to implement the program with fidelity in the clinical setting. Pilot testers on average scored 85% on the final exam, indicating acceptable knowledge competency. Recommendations for improvement included providing a better linkage between performance of physical assessments and exercise prescription and to include ability to view assessment protocols throughout the online training. The curriculum was modified based on feedback and launched in early March 2013.

**RISKY BUSINESS: HOW THE DEFINITION OF HEALTH LITERACY MAY AFFECT WHO GETS TARGETED FOR INTERVENTIONS**

A.S. Graf, J.H. Patrick. Psychology, West Virginia University, Morgantown, West Virginia

Health literacy has become an increasingly popular construct in explaining racial and education-related health disparities. Past studies have not consistently found gender differences, but this may have been due to the operational definitions and measures used. In a sample of adults recruited from Amazon’s Mechanical Turk ($N = 374, M_{age} = 54.49$), a MANCOVA was used to analyze gender and racial differences in health literacy, controlling for education. Gender ($p < .001$, $η^2 = 11$) and race effects ($p < .001$, $η^2 = .05$) were qualified by a significant interaction effect ($p = .03$, $η^2 = .02$) on the combination of health literacy measures, though inspection at the level of the individual measures revealed only significant main effects of gender and race. Specifically, men had significantly lower subjective health literacy ($p = .01$), lower conceptual knowledge ($p < .001$), and lower scores on a health performance task ($p = .01$). Numeracy scores did not differ by gender. Significant main effects of race were found for all four health literacy measures (all $p < .02$). Post-hoc tests revealed Latinos had significantly lower means than Whites on all measures of health literacy. Blacks differed significantly from Whites on two of the four measures, conceptual knowledge and a health performance task. Blacks and Latinos only significantly differed on subjective health literacy. These findings suggest that men and minorities could benefit from interventions to improve health understanding, but the particular aspects of health literacy that should be targeted need to be considered based on the measurements used.

**AGING AND THE QUANTIFIED SELF: TECHNOLOGY AND ADHERENCE TO PHYSICAL ACTIVITY PROTOCOLS**

J.H. Patrick¹, J. Steele², S. Stahl², E. Goedereis³. 1. Psychology, West Virginia University, Morgantown, West Virginia. 2. Radford University, Radford, Virginia. 3. University of Pittsburgh, Pittsburgh, Pennsylvania. 4. Webster University, St. Louis, Missouri.

The ‘Quantified Self’ approach refers to the trend among adults to monitor and share their behaviors, thoughts and moods using a variety of technologies. An increasing number of middle-aged and older adults are actively engaged in such monitoring, and the numbers are increasing. Distinct from tele-medicine, adults engage in self-monitoring for a variety of reasons, including: to establish a baseline against which to assess future behavior change, to monitor progress toward a specific goal, and to satisfy curiosity and maintain self-awareness (Wolf, 2011). One broad class of methods which enables people to monitor themselves is known as Experience Sampling Methods / Ecological Momentary Analysis. Using empirical data from projects in the Healthy Aging Lab at WVU, this paper illustrates middle-aged and older adults’ recording of physical activity behaviors using experience sampling approaches.
These studies share a similar protocol in which adults monitored behaviors up to five times a day for 6 to 10 days using palmtop computers. Among two samples of older adults (Steele, N = 42, M age = 71 yrs; Stahl & Patrick, N = 10, M age = 64 yrs), issues of accuracy and adherence to an activity regimen are examined. In a sample of middle-aged adults (Goedereis, N = 35, M age = 49 yrs), progress toward weight-loss goals are examined. All three studies contribute to our understanding of how self-monitoring may lead to behavior changes.

ALCOHOL, HEALTH AND IDENTITIES AMONG UK ADULTS IN LATER LIFE
C. Haighton1, G. Wilson1, A. Crosland2, J. Ling3, K. Smith2, E. Kaner1. 1. Institute of Health & Society, Newcastle University, Newcastle upon Tyne, United Kingdom, 2. Sunderland University, Sunderland, United Kingdom

Increasing alcohol consumption among older individuals is a public health concern. Lay understandings of health risks and stigma around alcohol problems may explain this increase. A qualitative study explored older people’s reasoning about drinking in later life and how this interacted with health concerns. In 2010 a diverse sample (ages 51-90) in North East England participated in interviews (n=24, 12m, 12f) and three focus groups (participants n=27). Data were analysed following grounded theory and discursive psychology methods. Experiencing impaired health was identified as a reason to reduce alcohol consumption while continued heavy drinking was positioned as normal if well-being was experienced, or if ill health was construed as unrelated to drinking. When talking about alcohol use older people oriented strongly towards distinct, polarised identities of normal or problematic drinker, defined by propriety rather than health considerations. Older people could display skepticism about health advice on alcohol when avoiding stigmatised identity as a drinker. Preventive interventions for older populations should consider and support associated identity change and encourage at community level the identification of heavy drinking as neither healthy nor synonymous with dependence. Future research should assess such approaches.

ILLNESS PERCEPTIONS AND HYPERTENSION SELF-CARE BEHAVIORS IN OLDER KOREAN PATIENTS WITH HYPERTENSION
H. Yeom, Nursing, Dongguk University, Gyeongju, Gyeongsangbuk, Republic of Korea

As a set of beliefs about health threats, illness perceptions of individuals guide behaviors to cope with illnesses. The purposes of this study were to investigate illness perceptions of older Korean patients with hypertension and to investigate their impacts on hypertension self-care behaviors. A cross-sectional descriptive study was conducted. A convenience sample of 108 older patients with hypertension (M=76.2 yrs) completed self-administered questionnaires including demographic and health-related information, Illness Perception Questionnaire-Hypertension scale, and hypertension self-care behaviors. Data was analyzed using multiple regression analysis. Participants lived an average of 7.8 years after hypertension diagnosis. Mean scores of illness perceptions were timeline-acute/chronic(3.03), timeline-cyclic(2.19), consequence(1.93), control – personal(3.10), control – treatment(3.81), coherence(3.18) and emotion(2.40). After controlling for the covariates, significant factors affecting hypertension self-care behaviors were timeline-cyclic(β = -0.31, p = .042) and coherence(β = -0.83, p = .050). The results indicate that older Korean patients with hypertension tended to believe their hypertension were chronic, predictable, and less serious. They also had stronger sense to control hypertension and coherence, and more negative emotion regarding hypertension. Regression analyses showed that patients who believed that their hypertension was more predictable or who had stronger sense of coherence were more likely to conduct self-care behaviors. This study highlights significant influence of illness perceptions related to predictability and coherence on self-care behaviors in older Korean patients with hypertension. The findings emphasize the importance of examining illness perceptions and the development of psycho-cognitive interventions based on individuals’ illness perceptions to improve self-care behaviors of older hypertensive patients.

INTERGENERATIONAL SOLIDARITY AND MEDICATION ADHERENCE IN COMMUNITY DWELLING ELDERS

Medication non-adherence, estimated at 50%, impairs optimal aging in part by leading to 70% of hospital readmissions (Cutler & Everett, 2010; New England Health Institute, 2009). There is a deficit of literature addressing adherence in older adults and the possible influence that family members and adult children in particular may have on adherence in CDEs. This non-experimental, correlational survey of a convenience sample (N = 121) of attendees (age 60 and older) at two senior centers in the mid-Atlantic region used the intergenerational solidarity (IGS) framework (Bengtson & Roberts, 1991) to explore the relationship between affectual, functional and associational solidarity and medication adherence. After controlling for cognitive impairment (Mini-Cog, Borson, Scanlan, Brush, Vetallano, & Dokmak, 2000), a logistic regression was run to predict adherence. Findings indicated adherence (64.5%), as measured by the CMMAS-8 (Morisky et al., 2008), was predicted by pill burden (OR = 0.62, p < .05), but not depression symptoms or IGS measures. Further analysis indicated functional solidarity, as measured by the ISS (Fingerman et al., 2010), had a small ability to predict adherence (OR = 1.04, p < .05) in participants with low levels of depression symptoms. For women, affectual solidarity, as measured by the positive subscale of the PARQ (Pitzer et al., 2011), increased the odds (OR = 1.2, p < .05) of adhering to medication. These results suggest that measures of IGS may have a small and complex relationship with adherence behaviors in older adults.

ASSOCIATIONS OF TRUNK EXTENSION STRENGTH WITH QCT-BASED TRUNK MUSCLE DENSITY IN OLDER ADULTS
D.E. Anderson1,2, N.E. Holt1, M.L. Bouxsein1,2, J.F. Bean2,3. 1. Beth Israel Deaconess Medical Center, Boston, Massachusetts, 2. Harvard Medical School, Boston, Massachusetts, 3. Spaulding Rehabilitation Hospital, Cambridge, Massachusetts

Reduced trunk muscle density measured in quantitative computed tomography (QCT) scans is associated with low back pain, impaired physical function, and hyperkyphosis in older adults. However, there has not yet been a direct comparison of trunk muscle density with trunk extension strength (TES). We performed QCT scans of the lumbar spine in a sample of subjects (34 women, 12 men, age 78±7 years) from Boston RISE, a cohort study of older adult primary care patients. TES was evaluated as the 1 repetition maximum performed on a seated trunk extension machine. Muscle density was evaluated as the average attenuation, in Hounsfield Units (HU), of muscles in the QCT scan at the mid-L4 level of the spine. Multivariable linear regression models were created predicting TES with independent variables of height, weight, and muscle HU. Overall HU of all trunk muscles combined was positively associated with TES (β = 0.30, p = 0.011). In separate models, HU of the external obliques (β = 0.29, p = 0.009) and the internal obliques (β = 0.35, p = 0.002) showed similar associations. HU of the multifidus (β = 0.23, p = 0.053) approached significance, but HU of the rectus abdominis (β = 0.20, p = 0.091) and the erector spinae (β = 0.15, p = 0.223) was not significant. These results suggest that, among older adults, muscle density contributes to overall TES independent of body size, but may be of greater importance in spine-stabilizing muscles (obliques and multifidus) than in the primary extensors (erector spinae).
ASSOCIATION BETWEEN SARCOPENIA, OBESITY, AND FRAILITY STATUS IN COMMUNITY-DWELLING OLDER WOMEN
M. Kim1, H. Kim1, H. Yoshida1, N. Kojim1, K. Saito1, Y. Yoshida1, T. Suzuki1, 1. Tokyo Metropolitan Institute of Gerontology, Tokyo, Japan, 2. National Center for Geriatrics and Gerontology, Aichi, Japan

BACKGROUND: Age-related muscle mass loss (sarcopenia) and fat mass increase (obesity) are reportedly associated with frailty. However, little is known about this association, the purpose was to examine the relationship between body composition phenotypes (sarcopenia, obesity, and sarcopenic obesity) and frailty in community-dwelling older adults. METHODS: This cross-sectional analysis included 558 women aged 79–89 years old who participated in a comprehensive health examination in October 2012 at Tokyo, Japan. Body composition phenotypes, assessed by dual-energy X-ray absorptiometry, were classified into 4 groups by appendicular skeletal mass divided by height squared cut-off point, ≤6.08kg/m2 and percentage body fat cut-off point, ≥32%. According to Fried’s phenotype, frailty and prefrailty were defined as the presence of ≥3 components, and 1–2 of the 5 components, respectively. Logistic regression analysis was used to calculate odds ratios (ORs) and 95% confidence intervals (CIs) for frailty, after adjusting for covariates. RESULTS: Mean subject age was 82.2 (±2.6) years. The overall prevalence of frailty, prefrailty, and sarcopenic obesity was 17.4%, 58.6%, and 5.9%, respectively. The distribution of frailty in body composition phenotypes were: 13.5%, normal; 22.8%, sarcopenia; 22.5%, obesity; and 12.1%, sarcopenic obesity. In an adjusted logistic regression model, sarcopenia (OR=2.14, 95% CI=1.16–3.94) and obesity (OR=2.07, 95% CI=1.18–3.63) were individually associated with frailty. Conversely, sarcopenic obesity (OR=1.25, 95% CI=0.47–3.33) showed no significant association with frailty. CONCLUSIONS: Sarcopenia and obesity are independently associated with frailty. However, sarcopenic obesity is not closely associated with frailty among community-dwelling elderly Japanese women.

DYADIC NUTRITIONAL STATUS OF COMMUNITY-DWELLING PEOPLE WITH DEMENTIA AND FAMILY CAREGIVERS
E. Beattie1,2, J.M. McCrow1, E.A. Isenring2, C. Dyce2, 1. Queensland University of Technology, Brisbane, Queensland, Australia, 2. University of Queensland, Brisbane, Queensland, Australia

Poor nutritional status in the elderly is a predictor of morbidity and mortality, particularly in people with dementia. This dyad-focused cross sectional study (N=26 pairs of people with dementia and caregivers eating at least 10 meals/week together) investigated nutritional status using a comprehensive battery of measures, including body weight, anthropometrics and a 3-day food record. Mean dyad energy intake per day (7458 kJ ± 1068) and mean dyad protein intake (60g ± 8.6) was not statistically different between dyad members. Mini Nutritional Assessment (MNA) results showed an expected high risk of malnutrition in those with dementia (62%, n=16) and one malnourished individual. While no caregivers were malnourished, almost a quarter (23%, n=6) were at risk of malnutrition. Dyad nutritional status analysis indicated that approximately 15% (n=4) of the dyads were at risk of malnutrition and 27% (n=7) dyads were well nourished. Of the remaining 15 dyads 8% two included only the carer at risk of malnutrition and only the person with dementia was at risk in 50% (n=13) of dyads. Of the carer sample, 9 (36%) did not meet their Estimated Energy Requirements (EER) and 6 (24%) did not meet their Estimated Protein Requirements (EPR). Alarmingly, 60% (n=15) of those with dementia did not meet their EER and 36% (n=9) did not meet their EPR. Between group differences were not statistically significant ($\chi^2 = 2.89, p = .089$). Results suggest further research is warranted to understand dyadic nutritional risk in this vulnerable group.

DOES THE SETTING MAKE A DIFFERENCE? NUTRITIONAL STATUS OF RESIDENTS IN SHARED-HOUSING ARRANGEMENTS AND NURSING HOMES
S. Meyer1, N. Fleischer-Schlechtiger2, J. Gräske3, A. Worch1, K. Wolf-Ostermann1, 1. Alice Salomon University of Applied Science, Berlin, Germany, 2. Volkssolidarität Leipziger Land/ Millenental e.V., Schkeuditz, Germany

Objectives: In Germany, shared-housing arrangements (SHA) for older care-dependent people and for people with dementia (PwD) evolved in the last years. SHA are small-scale living alternatives to traditional nursing homes. It is considered, that in SHA more attention is paid to including residents and their relatives in household chores like cooking and baking than in traditional nursing homes. Therefore, the study examines if different settings result in different risks of malnutrition. Methods: Data were collected in SHA and one nursing home in Germany, using standardized face-to-face interviews with caregivers. In addition to socio-demographic data the nutritional status using the BMI and the Mini Nutritional Assessment (MNA) and the cognitive abilities using the Mini Mental State Examination (MMSE) of residents were examined. Results: The residents (129 residents, 60 from 29 SHA and 69 from a nursing home) were predominantly female (76.7%) on average 80.4 years old and showing a moderate to severe cognitive decline (MMSE: 13.2). The average MNA-score (19.7) of all residents indicates a risk for malnutrition. Taking confounding factors in to account residents of SHA have a significantly higher MNA-score (21.2) and BMI-score (26.4) on average than residents in the nursing home (18.3 vs. 25.4) indicating a better nutritional status. Conclusion: The traditional diet concept in nursing homes does not seem to be as beneficial to the nutritional status of residents as the alternative concept in SHA. This indicates that more attention should be paid to individually tailored concepts for nutrition. Especially in nursing homes.

WAIST CIRCUMFERENCE, PHYSICAL ACTIVITY AND FUNCTIONAL OUTCOMES: DATA FROM 2006-2010 HEALTH AND RETIREMENT STUDY (HRS)
C.M. Germain1, E. Gruber1, J.A. Batis1, 1. Center for Aging and the Study of Human Development, Duke University, Durham, North Carolina, 2. University at Albany (SUNY), Albany, New York, 3. Geisel School of Medicine at Dartmouth, Hanover, New Hampshire

Background: Obesity has been associated with decreases in physical functioning and increases in self-care needs. Additionally, physical fitness is known to positively influence physical functioning and the ability to engage in daily tasks. It is unknown however, whether obese individuals who engage in physical activity have lower degrees of physical impairment or disability. Methods: Adults aged ≥60 with measures of waist circumference (WC) and physical activity (PA) were included from three waves of the Health and Retirement Study (HRS) (2006-2010). Functional limitations (FL) were defined in HRS as inability or difficulty in performing the following tasks: walking several blocks, walking 1 block, sitting 2 hours, getting up from chair, climbing stairs climbing one flight of stairs, stooping, reaching arms, pulling/pushing large objects, lifting weights and picking up a dime. Participants with 2 or more limitations were categorized as having FL. Measures of Activities of Daily Living (ADL/IADL) included difficulty or inability with bed transfers, eating, dressing, meal preparation, managing money or house and yard work. We defined PA as self-reported engagement in moderate/vigorous activity at least 1/week. High WC was classified as >88cm (females) and >102cm (males). We examined rates of functional limitation and impairment of ADLs. We also examined risk of FL and ADL impairment using multivariate logistic regression. Additional models adjusted for age, gender, education, ethnicity and cardiovascular comorbidities and grip strength. Results: The final sample included 9,831 subjects, mean age was 69±5.6, 5,341(54%) were female. Prevalence of FL was high in both groups 87% and 90% in adults with low vs. high WC. ADL and IADL impairment rates were 87% and 61%
among individuals with low WC and 85% and 62% in individuals with high WC. Participation in PA was reported at 38% and 39% in low vs. high. After adjusting for PA, risk of IADL limitations were OR 0.85 [CI: 0.75-0.96] and OR 0.82 [CI:0.75-0.92] for high and low WC; OR 0.80 [CI:0.63-1.20] and OR 0.76 [CI:0.59-0.98] for ADLs. There were no significant associations with physical limitations. Conclusions: Physical activity was significantly associated with functional impairment in older adults irrespective of degree of adiposity. Additional studies are needed in different populations to examine the impact of physical activity on functional limitations in older adults.

SESSION 225 (POSTER)

MINORITY AND DIVERSITY ISSUES

USE OF PROFESSIONAL HELPERS AMONG OLDER AFRICAN AMERICANS, BLACK CARIBBEANS, AND NON-HISPANIC WHITES

Aims: The purpose of this study is to examine racial/ethnic differences in professional help-seeking for a serious personal problem among older adults. Methods: This study uses the older subsample (n=1,439) of the National Survey of American Life, which is a nationally representative survey of African Americans, black Caribbeans, and non-Hispanic whites. Types of problems include physical (e.g., poor health), emotional (e.g., depression), interpersonal (e.g., divorce), economic (e.g., loss of assets) and bereavement. Logistic regression analysis was used to examine racial and ethnic differences of professional help utilization. Control variables include age, gender, income, education, health insurance, marital status, and type of problem. Odds ratios and 95% confidence intervals are presented. Findings: Respondents sought help from family doctors (34.4%), clergy (31.0%), other mental health professionals (16.5%), psychiatrists (12.8%), any other doctor (11.2%) and any other health professional (9.2%). 37% of respondents did not seek any professional help for their serious problem. Non-Hispanic whites are twice as likely than African Americans to utilize a mental health professional (OR=2.32; CI=1.25-4.31) and to utilize clergy (OR=1.96; CI=1.29-2.99) for assistance. Black Caribbean blacks are two times less likely to utilize a family doctor (OR=0.44; CI=0.23-0.85) for assistance in comparison to African Americans. Implications: This analysis has demonstrated a difference in professional service utilization between whites, black Caribbeans, and African Americans. Further research is needed to determine which specific variables mediate the relationship between race/ethnicity and service utilization among older adults. Interventions are needed to address the under-utilization of services for elderly black Caribbeans and African Americans.

LIFE SATISFACTION AMONG LATINA/O OLDER ADULTS: AGE-COHORT DIFFERENCES IN PSYCHOSOCIAL CORRELATES

Life satisfaction has long been studied among the general older adult population, but less is known about specific cultural subgroups. Familismo, the prioritization of supporting nuclear and extended family, is identified as an important cultural value within the Latina/o population, but it has not been linked to life satisfaction. Generational differences in familismo can contribute to high expectations of support in older cohorts of Latina/o, which in turn may influence quality of support and life satisfaction. This study examines how generational and social support differences impact life satisfaction. A Latina/o sample (N = 552; M age = 66; 59% women) was drawn from the Health and Retirement Study. Descriptive age-cohort differences (50-64; 65-74; 75-104) in social support and life satisfaction were initially examined using ANOVA. We subsequently conducted hierarchical multiple regressions controlling for gender, education, social network size, and functional limitations, to examine the unique effects of age-cohort, perceived positive and negative social support as indicators of familismo, and their interactions. Life satisfaction differed significantly among the three age-cohorts, with the 75+ cohort reporting highest levels. Perceived positive support uniquely predicted higher life satisfaction, whereas negative support was associated with lower life satisfaction. Furthermore, the effect of social support interacted with age-cohort: specifically negative support was more influential in reducing life satisfaction for the oldest cohort while positive support was more influential in enhancing life satisfaction for the two younger cohorts. These findings highlight the importance of considering psychosocial determinants of life satisfaction within the context of age-cohort and culture.

RACE/ETHNICITY AND MEASUREMENT EQUIVALENT OF THE EVERYDAY DISCRIMINATION SCALE

G. Kim, M. Sellbom, K. Ford, Center for Mental Health and Aging / Department of Psychology, University of Alabama, Tuscaloosa, Alabama

The present study examines measurement equivalence of the Everyday Discrimination Scale (EDS) across diverse racial and ethnic groups in the United States. Drawn from the Collaborative Psychiatric Epidemiology Surveys (2001-2003), adults aged 18 and older from four racial/ethnic groups were included in analyses: 884 non-Hispanic Whites, 4,950 Blacks, 2,733 Hispanics/Latinos, and 2,089 Asians. Multiple-group confirmatory factor analyses (CFA) were conducted to test measurement equivalence of the nine-item EDS. Results show that after adjusting for age and gender, the underlying construct of the EDS was invariant across the four racial/ethnic groups, with Item 7 (“People act as if they’re better than you are”) associated with lower intercepts for the Hispanic/Latino and Asian groups relative to the non-Hispanic White and Black groups. In terms of latent factor differences across racial/ethnic groups, Blacks tended to score higher on the latent construct compared to other racial/ethnic groups, whereas Asians tended to score lower on the latent construct compared to Whites and Hispanics/Latinos. Findings suggest that the EDS assesses the underlying construct of perceived discrimination equivalently across diverse racial/ethnic groups. At the same time, researchers should understand the risk that the construct of perceived discrimination over-predicts responses to the EDS Item 7 among Hispanic/Latino individuals. Implications are discussed in cultural and methodological contexts.

TRANSNATIONAL CARE: THE EXPERIENCE OF CAREGIVING FOR OLDER PARENTS FROM A FOREIGN LAND

I. Amin, University of North Texas at Dallas, Dallas, Texas

With increase of international migration and global aging, an emerging issue in caregiving literature is transnational eldercare. Little is known about how immigrants care for their older parents across the national border. Drawing on in-depth qualitative interviews with twenty-one Bangladeshi immigrants living in the United States, this exploratory study illuminates the nature and challenges of transnational caregiving. Participants were recruited through personal networks and snowball sampling technique where the inclusion criteria consisted of immigrants having at least one parent living in Bangladesh aged over 60 years. This study found that despite enormous geographical distance, immigrants are very much involved in emotional care for their parents. Technology has transformed the transnational caregiving experiences. Specially, Skype has made free visual communication in real time possible. This has greatly reduced the worries of not knowing what is exactly happening, and guilt of not being available to help. This study suggests...
that although migrant children are likely to spend less time in caregiving and only provide financial or emotional care, they are not free of caregiver cost and stress. Transnational caregivers’ stress, and particularly feelings of guilt is partially due to the unavailability or lack of available caregivers, such as siblings and kins in homeland. Closely connected with guilt is the feeling of worries for older parents’ well-being since formal support system for elders is practically non-existent in the home land. No gender difference was found in transnational caregiving practices. This study contributes to the limited but growing body of literature on transnational care.

MEASUREMENT EQUIVALENCE OF THE KESSLER-6 SCALE: THE EFFECTS OF RACE/ETHNICITY AND LANGUAGE
A.N. Bryant1,2,3, G. Kim1,2,3, J. DeCoster2, K. Ford1,2,3. 1. The University of Alabama, Tuscaloosa, Alabama, 2. The University of Virginia, Charlottesville, Virginia, 3. Center for Mental Health and Aging, Tuscaloosa, Alabama

Despite the general utility of the Kessler-6 scale (K6) to screen for serious mental illness, measurement equivalence of the K6 has not been explored in racially/ethnically and linguistically diverse populations. The present study aims to test measurement equivalence of the K6 across different racial/ethnic and linguistic groups in the U.S. Data were drawn from the 2009 California Health Interview Survey (CHIS). Five racial/ethnic groups (non-Hispanic whites, Blacks/African Americans, Hispanics/Latinos, Asians, and American Indian/Alaska Natives [AIAN]) and six languages (Cantonese, English, Korean, Mandarin, Spanish, and Vietnamese) were compared. Item response theory (IRT) was conducted to examine measurement equivalence. Results from differential item functioning (DIF) analyses show that four items (Items #1, #3, #4, #5) were biased by both race/ethnicity and four items (Items #1, #2, #3, #4) were biased by language. Three items (Items #1, #3, #4) were biased by both race/ethnicity and language. The findings suggest clear evidence of measurement bias in the K6 among racially/ethnically and linguistically diverse adults. Clinical implications are discussed.

CHALLENGES RECRUITING AND ENROLLING DIVERSE OLDER ADULTS IN RESEARCH: BALTIMORE EXPERIENCE CORPS® TRIAL OUTCOMES
E. Tanner1, E. Tan2, J.L. Martinez2, M. Carlson1, G. Rebok1, J.M. Parisi1, J. Huang1, L.P. Fried1, 1. School of Nursing and Center on Aging and Health, Johns Hopkins University, Baltimore, Maryland, 2. Florida International University, Miami, Florida, 3. Columbia University, New York, New York, 4. Senior Corps, Washington, District of Columbia

Older adults, racial/ethnic minorities, and medically underserved populations bear the burden of increased morbidity and mortality, yet are underrepresented in health-related research. This includes research ranging from clinical trials to longitudinal studies and community-based participatory research. Rationale for disparities in inclusion and enrollment of older minorities in research is varied, and explanations for lack of participation and retention are often unknown. The need to understand factors that impact participation and retention in research is imperative to enhance the generalizability and translation of research in order to implement effective interventions for improving health for minority older adults. A 5-step recruitment process with targeted strategies, including mass media, written and verbal targeted strategies, as well as word of mouth, was utilized to recruit older adults (N=2675) for the Baltimore Experience Corps® Trial (BECT), a health promotion program comprised of volunteering 15 hours per week for 2 academic years. 702 diverse older adults with a mean age of 67 were enrolled and randomized in the trial; 89% were African American and 85% were female, and 41% reported less than 12 years of education. After controlling for other factors, education (>12th grade versus ≤12th grade) (p<.0003) and the motive of “desire for better use of free time” (p<.0002) predicted enrollment (versus non-enrollment) in this RCT of volunteering as a health promotion program. Efficacy of strategies and implications of participants enrolled, reflecting the demographic characteristics and motivations for volunteering in this intervention for promoting health, will be discussed.

DOING THE HULA: SECOND GENERATION OLDER ASIAN AMERICAN PACIFIC ISLANDER WOMEN AND THE MEANING OF CULTURE
A. Choi, Department of Interdisciplinary Studies, California State University Dominguez Hills, Carson, California

With the rapid growth of first generation Asian American Pacific Islander (AAPI) communities, scant attention has been paid to the aging of earlier generations of AAPIs. California, in addition to more recent AAPI immigrant groups, is home to Asian immigrant communities that date to the 19th century and early part of the 20th century. The descendants of this “first wave” of Asian immigration, many who are now older adults, serve as a unique population to examine the meaning of culture and identity for individuals who are second and third generation immigrants. In particular, this study focuses on how one group of Japanese American women who grew up in Hawai‘i have become involved in hula dancing as older adults. In-depth interviews and participant observations were conducted over one year with twelve Japanese American older adult women who were involved in a hula troupe. Information was gathered about how involvement in hula impacted the composition and quality of their health and social networks. Additionally, this study examined the meaning and relevance of ethnic culture for second and third generation AAPI older adult women. Data were transcribed and independently coded to identify key patterns and themes. It was discovered that for Japanese American older adult women, an embracing of cultural identity later in life had numerous positive outcomes including denser social networks and improved health outcomes. This is particularly significant since these women grew up in an era where complete assimilation into mainstream American life was the expectation.

OPTIMAL AGING FOR COMMUNITY-DWELLING ASIAN OLDER ADULTS: UNDERSTANDING SERVICE AND SUPPORT NEEDS

Linguistic and cultural barriers among older Asian immigrants result in health disparities and the diverse challenges these older adults experience at the different stages of aging. This paper will present the results of a qualitative study of the expressed and perceived needs of Korean and Chinese American older adults to enhance their ability to remain in their preferred community residences. Focus group interviews were conducted with staff from an agency in South East Pennsylvania providing in-home personal care support, including direct care and administrative staff, Asian American older adults, and Asian American family caregivers. Focus group data were analyzed via NVivo software using grounded theory. The main themes identified through the focus groups included: challenges in accessing adequate care, barriers to aging in place, challenges for informal caregivers, challenges for personal care staff, and service gaps. Divergent perspectives among staff, clients and families will also be presented. Transportation concerns were important for both clients and direct care staff. Differences in expectations between direct care staff and clients, e.g. in some cases clients view staff as servants rather than professional service providers. Language barriers were identified as the biggest challenge faced by older Asian adults. Other representative themes include: lack of knowledge regarding aging issues among family caregivers, lack of ethnic food in mainstream service agencies, and challenges in medication management. Implications of
these findings for supporting racially and linguistically diverse populations to age in place in community will be discussed.

SESSION 230 (POSTER)

PRIMARY CARE AND SERVICES

DOCTOR-PATIENT RACE CONCORDANCE AND ITS ASSOCIATION WITH PERCEIVED HEALTH OUTCOMES AMONG OLDER ADULTS
S. Bodnar-Deren1, 2, S. Simon1, 1. Sociology, Virginia Commonwealth University, Richmond, Virginia, 2. Mount Sinai School of Medicine, New York, New York

Objective: A growing body of research suggests a correlation between doctor-patient race concordance and patient satisfaction and patient health outcomes. Few studies however have focused on older adults. In this analysis, we examine the relationship between doctor-patient race concordance and self-reported health (SRH) in a sample of African American (n=181) and White (n=274) adults age 65 and older, who received care in a primary-care setting. Method: Data came from the Commonwealth Fund 2006 Health Care Quality Survey (n=455), a nationally representative telephone survey of adults living in the U.S. that measures healthcare utilization and quality of care among a racially diverse sample of physicians and patients. Bivariate analysis was used to examine the relationship between patient race and doctor-patient race concordance and hierarchical logistic regression models predicting good/excellent SRH by race concordance were estimated controlling for socio-demographics, perceived discrimination, and comorbidities. Results: White respondents were significantly more likely than Black respondents to experience doctor-patient race concordance (79% vs 24%, p<0.001). In unadjusted models, race concordance was statistically associated with good or better SRH (OR=1.646, CI 1.07-2.53). However, in fully adjusted models, the association between race concordance and SRH was only marginally significant (OR=1.494, CI 0.98-2.75). Conclusions: There is some evidence to support that doctor-patient race concordance may be a factor in perceived health outcomes among older adults. Increasing the racial/ethnic diversity among healthcare providers may contribute to health outcomes and experiences for older adults in the primary care setting.

INTEGRATED CARE TRAINING: AN INTERPROFESSIONAL EXPOSURE MODEL EMPHASIZING GERONTOLOGY
B.N. Renn, N. Torrence, S.E. John, S. Qualls, D.L. Segal, University of Colorado at Colorado Springs, Colorado Springs, Colorado

Integrated care has emerged as a prominent model of optimal care for individuals with chronic disease and comorbidities, making it especially well-suited for gerontology. This flexible and effective model of care depends on interprofessional collaboration and service delivery; therefore, healthcare professionals need training in core competencies of integrated care. This training often occurs in medical school curricula through interprofessional education (IPE); however, psychology, nutrition, and health promotions are increasingly included within interprofessional teams despite frequently being left out of interprofessional training and collaboration. This poster describes an innovative integrated care student training model that extends traditional IPE programs to a university-based health center with emphasis placed on geriatrics and geropsychology training. This model aims to expose health professions students (including geropsychology, nursing, nutrition, medicine, and health promotions) to the competencies necessary for working and practicing on teams within an integrated care facility. The model developed through iterative consultation with practicing professionals and is based on the pedagogy of blended learning and a review of the literature. The proposed model consists of three levels of training: Level 1 emphasizes the foundations of integrated care; Level 2 extends this to the expansion and application of knowledge and attitudes; and Level 3 provides specialized training through experiential learning activities and student-led didactics. Traditional didactics are supplemented by simulations and case learning in group, individual, and online formats with special attention to accommodating various training trajectories and timelines, with each level designed to build upon one another or to stand alone.

NOT JUST ANOTHER JOB: MOTIVATORS AND CHARACTERISTICS OF EXEMPLARY CNAS IN NURSING HOMES
S. Snellgrove, Arkansas State University, Jonesboro, Arkansas

As frontline workers in nursing homes, certified nurses’ assistants (CNAs) have an enormous impact on resident care and quality of life. High CNA turnover has been identified as a threat to quality resident care. During the course of a qualitative study focused on resident-to-resident violence in nursing homes, data emerged regarding CNAs who choose to remain employed in nursing homes on a long-term basis even after being presented with more lucrative and influential career choices. Using a semi-structured interview guide, eleven CNAs were asked to share their resident care experiences in nursing homes. Data were analyzed using content analysis and constant comparison. Themes that emerged from the data included “it’s not just a job,” “I can’t leave them,” “doing what is right,” and “what if it was me?” These findings potentially assist nursing home administrators and directors of nursing in identifying, hiring and retaining exemplary CNAs. Additional findings also support previous investigations focused on the importance of personhood in maintaining quality resident care.

IMPACT OF FRONTLOADING OF SKILLED NURSING VISITS ON THE INCIDENCE OF 30-DAY HOSPITAL READMISSION
M. O’Connor, A. Hanlon, M.D. Naylor, K.H. Bowles, School of Nursing, University of Pennsylvania, Philadelphia, Pennsylvania

Aim: To evaluate the impact frontloading of skilled home health (HH) nursing visits has on the incidence of 30-day hospital readmission among Medicare-reimbursed HH recipients. Methods: Frontloading was defined as providing five or more skilled nursing visits within the first 14 days of skilled HH. A retrospective analysis of five Centers for Medicare and Medicaid-owned national data sets from 2009 was conducted (Outcomes Assessment Information Set, Home Health Agency Standard Analytic File, Medicare Provider and Analysis Review File, Beneficiary Summary and Provider of Services file). A hospital admission no more than 30 days prior to HH admission was an eligibility requirement. Patients who were readmitted to the hospital within 1 to 14 days of HH were excluded as frontloading was not possible. Propensity score analysis was applied prior to logistic regression analysis. An independent, randomized sample of Medicare-reimbursed HH recipients (n=4,500) was employed. Results: Despite the Home Health Quality Improvement National Campaign, only 40% of the sample was frontloaded. Overall, 3.89% of the sample experienced a hospital readmission 15 to 30 days following hospital discharge. Of those who had a 30-day readmission, 53% were not frontloaded, 47% were frontloaded. Frontloading skilled nursing visits was not predictive of 30-day hospital readmissions (p>0.741). Conclusions: Frontloading could be an effective tool in reducing the need for hospital readmission within 30 days of hospital discharge but additional research is required to further refine the frontloading definition, and to develop decision-support to determine the most appropriate patients who will benefit from frontloading.
UNDERSTANDING THE BEREAVEMENT SERVICE USE PREFERENCES AND MOTIVATIONS OF FAMILY CAREGIVERS

E.J. Bergman1, M. Metcalf2, Gerontology Institute, Ithaca College, Ithaca, New York, 2. Hospice of Central New York, Liverpool, New York

Bereavement services are an important part of end-of-life care with potential to ameliorate distress among bereaved caregivers. However, little is known about individuals’ preferences regarding structure, content, and delivery of services. This poster will present survey outcomes from 60 bereaved hospice caregivers who reported on bereavement service use and preferences regarding current and potential bereavement services. Respondents (31.7% male, 68.3% female) ranged in age from 38 to 91. Most were the spouse (53.3%) or adult child (25%) of the deceased. 55% utilized at least one hospice bereavement service, including individual counseling (18.3%), bereavement newsletter (18.3%) or library (15%), service of remembrance (8.3%), and educational presentations (8.3%). 40% utilized a service outside of hospice, including talking with clergy (23.3%), counselor/social worker (11.7%), physician/nurse (10%), or psychologist/psychiatrist (5%). 12.5% of respondents reported they needed or would have liked a service they did not receive. Participants read five descriptions of potential services and were asked to indicate level of appeal, likelihood of use, and expected helpfulness of each. The most favorable ratings were given to a service designed to occur before the loss and give participants an opportunity to learn about/discuss the anticipated loss. The least favorable ratings were given to a book club for recently bereaved individuals. Ratings of the other services (small group meetings focused on stress management/relaxation, individual counseling focusing on meaning in the context of religious/spiritual beliefs, informational sessions focused on grief education/resources) will be presented, along with an exploration of qualitative responses pertaining to all five services.

PREDICTORS OF SERVICES USE AMONG OLDER ADULTS WITH GENERALIZED ANXIETY DISORDER

S. Shrestha, S. Omowale, A. Bush, C. Kraus-Schuman, N.L. Wilson, M.A. Stanley, M.E. Kunik, Gerontology Institute, Ithaca College, New York, 1. Psychology, University of St. Thomas, Houston, Texas, 2. Houston VA Health Services Research and Development Center of Excellence, Michael E. DeBakey VA Medical Center, Houston, Texas, 3. Baylor College of Medicine, Houston, Texas, 4. VA South Central Mental Illness Research, Education and Clinical Center, Houston, Texas, 5. Sheltering Arms Senior Services, Houston, Texas

Generalized Anxiety Disorder (GAD) is the most common anxiety disorder (Bryant, Jackson, Ames, 2008; Kessler & Wittchen, 2002) and it is associated with multiple negative consequences (Bourland, et al., 2000; Jones, Ames, Jeffries, Scarinci & Branfley, 2001). Emergency and outpatient service use among individuals with anxiety disorders is high (Wetherell et al. 2007). Trends of high medical service use also exist among older adults with generalized anxiety disorder (Calleo et al., 2009; Porensky et al., 2009). The poster will examine predictors of service use among older adults with GAD. Data were drawn from baseline assessments in two primary-care-based studies. A behavioral model of health services use proposed by Andersen (1973) was used to identify pre-disposing, enabling and needs factors that can uniquely predict service use. Univariate analyses, first, identified, predictor variables with a p-value of .25 or higher to be included in subsequent stepwise multiple linear regression analyses for each of the two service use domains. A study variable was added to the model to control for differences between the two studies. Univariate analyses indicated that income level, physical status and worry severity were associated with outpatient medical visits; and age, gender, race and mental health status were associated with mental health visits. Stepwise multiple regression indicated that physical health status uniquely predicted outpatient medical visits such that lower physical health scores predicted higher medical service usage. Age and race uniquely predicted mental health visits; individuals with advanced age and non-White study participants had significantly fewer mental health visits.

A DESCRIPTION OF A COMMUNITY-BASED PROGRAM’S PROCEDURE TO SELECT AN EVIDENCE-BASED TREATMENT FOR DEPRESSION

R. Pepin, S.J. Bartels, Dartmouth Centers for Health and Aging, Lebanon, New Hampshire

Background: Community-based organizations infrequently implement evidence-based services for older adults. Referral Education Assistance & Prevention (REAP) is a statewide program throughout New Hampshire that has provided community-based outreach, preventative and education services to older adults. The program was tasked with adding an evidence-based treatment (EBT) for depression. Objective: To describe the procedure used to determine the EBT for depression that would optimize existing program strengths to increase likelihood of successful implementation and sustainability for a community-based program. Procedure: The workgroup used an iterative process to select an EBT and to develop and refine an implementation plan. Key features of this process included (a) a multidisciplinary workgroup of stakeholders comprised of state department representatives, REAP staff, and academic researchers; (b) identifying existing REAP strengths; (c) identifying logistic considerations; (d) identifying EBTs and an implementation plan that would capitalize on strengths and were compatible with logistics. Results: The group held 8 meetings: 4 focused on selecting an EBT and 5-8 focused on implementation planning. The group began with a breadth of options that were narrowed to those which seemed most likely to be implemented successfully and be sustainable. Members shared commitment to this initiative and experience working with older adults; however, different stakeholders performed unique roles. For example, researchers focused on evidence whereas REAP staff focused on service workflow. Conclusions: A multi-stakeholder workgroup using an iterative decision process is an efficient way to develop an implementation plan within a community-based outreach program. Other community-based programs could benefit from replicating this process.

ALZHEIMER’S DISEASE AND THE PATIENT-CAREGIVER-PHYSICIAN RELATIONSHIP

N. Solorzano, A. Abdol, P. Anglewicz, K. Andrinopoulos, C. Campbell, L. Pecchioni, Center for Aging, Tulane University, New Orleans, Louisiana, 2. LSUHSC-NO, New Orleans, Louisiana, 3. LSU, Baton Route, Louisiana

Among minorities, Alzheimer’s disease is under-diagnosed or diagnosed at later stages of development when medications are not as effective. Minorities are more likely to attribute memory loss to the aging process, be less likely to ask for information from physicians, and are more likely to have lower education levels which affect communication with physicians. Educational levels and disease information, both mediate patient satisfaction and health outcomes. Accordingly, further research is needed to identify facilitating or hindering factors related to patients and physicians that aid in disease diagnosis and treatment across populations. The aims of this study are: 1) To conduct focus groups with Alzheimer’s disease caregivers in order to identify factors that they perceive as facilitating and or hindering disease diagnosis, care, and management, and assess how these factors facilitate communication and negotiation with physicians, and 2) To conduct interviews with primary care physicians to identify factors they perceive as facilitating or hindering disease diagnosis, care, and management for their patients. Data for this study will be collected by conducting: 1) Focus groups with adults acquainted with someone diagnosed with the disease, 2) Intensive interviews with primary care physicians experienced in diagnosing and managing Alzheimer’s disease, and 3) Audio recordings of the patient-caregiver-physician triad interaction. The intensive interviews,
focus groups, and triad interactions, will be audio recorded and transcribed verbatim. Data will be analyzed using grounded theory and thematic analysis techniques to: 1) Identify and compare factors that have facilitated or hindered diseases diagnosis and management for older patients, their caregivers, and physicians, and 2) Evaluate how these factors may be used to improve Alzheimer’s disease diagnosis across diverse populations.

DISCREPANCIES BETWEEN CLINICIANS’ DECISIONS AND PATIENTS’ ACCEPTANCE OF POST-ACUTE CARE REFERRALS

Introduction: Recent evidence shows that providing post-acute care (PAC) after a hospitalization is an effective strategy to reduce readmissions. Discharge planners consider these services for over 13 million hospitalized older adults per year. This study revealed surprising rates of patient refusals of services and examined the reasons behind them. Methods: Data was collected from 758 older adults discharged from four medical units in an academic medical center. Information included clinical and socio-demographic information, whether or not the discharge planner offered a referral to the patient for post-acute services, and whether or not the patient was discharged with a referral for those services in place. From the discharge planners’ notes, the reasons for refusal were summarized and categorized. Findings: The patients’ mean age was 70 (SD 9.8), 47% female, 62% white and 35% black. 74% of patients were offered a referral for post-acute care; 22% refused. Almost half of the refusers (46%) gave no explanation, 34% said they did not perceive the need for PAC services, and 8% said they would rely on their caregivers. Discussion: There is a significant discrepancy between clinicians’ referral decisions and patients’ acceptance regarding their need for PAC. With nearly half the patients giving no reason for refusing, we have very little understanding about why what is offered does not match their needs. Further research is needed to understand patients’ perceptions of their PAC needs, and to develop strategies that increase acceptance of these important and effective services.

GENDER DIFFERENCES IN LONELINESS AMONG COMMUNITY-DWELLING OLDER USERS OF FORMAL HOME CARE SERVICES
S. Stott, A.V. Wister, Gerontology, Simon Fraser University, Vancouver; British Columbia, Canada

Many studies have examined the cost-effectiveness and utilization patterns of home care services by older adults; however, few have examined their social benefits. Formal home care services are commonly used to fill gaps in care provision when informal home care is limited or unavailable. Given that female spouses are the most common providers of informal home care services, the use of formal home care services by males often follows the loss of a spouse (Carrière, 2006). It is hypothesized that formal home care will buffer the effects of loneliness for older males more than females when controlling for other predictors. This study uses the 2008–2009 Canadian Community Health Survey (CCHS) to explore the relationship between types of informal and formal home care services and feelings of loneliness across gender among community-dwelling older adults 65 years of age and older (n=16,369). OLS regression analyses showed that males receiving formal home care services experienced lower feelings of loneliness than those who received informal or no home care services. This association remained robust after statistically controlling for living arrangement, health status and measures of social support. The results suggest the receipt of formal home care services can serve as a source of social support among community-dwelling older males and can protect against feelings of loneliness. Further research is needed in order to expand our understanding of the social benefits of formal home care services. Incorporation of this knowledge into policies addressing service organization serves to increase efficacy of care for older adults aging-in-place.

PILOTING A COMMUNITY-BASED PARTICIPATORY APPROACH TO SUSTAINING INTERGENERATIONAL PROGRAMS
S.E. Jarrott, R.H. Weaver, Human Development (0416), Virginia Tech, Blacksburg, Virginia

Project TRIP (Transforming Relationships through Intergenerational Programs) targets at-risk preschoolers and elders by training staff to implement best intergenerational practices at co-located child and elder programs. We incorporated a community-based participatory research (CBPR) approach with the goal to extend the life of TRIP beyond five years of grant funding; most intergenerational programs last less than two years. Sustainability of intergenerational programs is challenged by lack of stakeholder support, lack of evidence-based practices, and absent or underutilized outcome documentation. Sustainable programs demonstrate collaboration, responsiveness, staff involvement, and program results. We launched the TRIP Sustainable Community Project at three sites. Data collected during Year 1 at Site 1 via monthly “booster” training sessions, field notes, and individual interviews revealed an absence of CBPR practices and essential sustainability indicators. Feedback indicated that staff responsible for programming lacked administrative support (e.g., time for planning and collaboration) and material resources (e.g., staffing levels to support best intergenerational practices). Staff felt unheard and disconnected from the project. In response, investigators and administrators worked together to incorporate: (a) staff input, (b) a volunteer program to enhance staffing levels, (c) trial periods for new initiatives, (d) incentives for achieving project milestones, (e) enhanced accessibility of training materials, (f) standardized core training materials, and (g) individualized training that reflects staff and participant interests and needs. An annually administered index of connection among site staff revealed higher ratings on indicators of sustainability after participating in Project TRIP. Attention to CBPR best practices enhanced the quality and sustainability of the program.

SESSION 235 (POSTER)

RETIREMENT

KNOWLEDGE-BASED DIFFERENCES IN EXPECTED RETIREMENT SATISFACTION WITH LIFE
J. Koposko, H.C. Gutierrez, D.A. Hershey, Psychology, Oklahoma State University, Stillwater, Oklahoma

A number of theoretical models have examined dimensions that lead to effective retirement planning and satisfaction with life. Few studies, however, have linked these models to real-world intervention applications. The present study had two goals. The first was to test a theoretically-grounded model of retirement satisfaction, while at the same time, probing for differences as a function of one’s retirement planning knowledge. Image Theory (Beach, 1998) was used as a theoretical touchstone in constructing and analyzing the models. The second goal was to present a conceptual model of how the empirical findings could be applied to real-world intervention efforts. Participants were 722 college students from a large, Midwestern university. Ages ranged from 17-52 years, and the data were collected using an online survey approach. Two four-stage path models were constructed that were designed to predict expected retirement satisfaction with life (one model for low-knowledge individuals and a second for high-knowledge participants). Both models accounted for appreciable amounts of variability in expected satisfaction with life, with the high financial knowledge model explaining 47% of the variance, and the low knowledge model capturing a 16% share. Slope comparisons revealed differences between models for all but one path, with high financial knowledge individuals showing stronger relationships overall among predictors. Results are discussed in terms...
of ways intervention specialists can help individuals start and maintain a pattern of effective financial planning and saving, with an eye toward improving future satisfaction with life.

**INDIVIDUAL RETIREMENT PLANNING – AN INTERNATIONAL COMPARISON**

A. Franke, Heidelberg University, Network Ageing Research, Heidelberg, Germany

Due to an Increasing Life Expectancy in Most Western Countries, Individuals Live Longer than Their Parents and Their Grandparents Did. At the Same Time, Traditional Support Mechanisms, e.g. Pension Schemes are Challenged Because of the Demographic Changes and the Financial Crisis. All These Have Become Important Structural Features of Contemporary Life Courses, with New Challenges for Society but also for Individual's Experiences and Strategies for Successful and Optimal Aging (Havighurst, 1963). But How Do People in Third Age Plan Their Own Retirement for Optimal Aging? And Which Role Plays the Current Job Situation and Attitudes to the Future (see also Atchley, 1976; Ekerdt, 1986; Feldmann & Beehr, 2011; Malty, 2004)? The Goal of the Present Study Was to Examine these Questions using the U.S., Germany and Japan as an Example. Hence, the Analyses Refers to the Question of Retirement Planning and Differences between Employees and Self-Employed. To Illustrate Age Planning, this Study Comprises the Results of the Multivariate Data-Analyses of the Health and Retirement Study/HRS, the Survey of Health, Ageing and Retirement in Europe/SHARE and the Japanese Study of Aging and Retirement/JSTAR (Mean Age 59, Range: 48-74). The Findings Indicate that Self-Employed Stay Significantly Longer Active in the Labor Market, Especially Comparing to the Group of Civil Servants. This Is Also the Case in All Three Countries, as no Significant Differences Are Obvious in Job-Satisfaction or Satisfaction With Salary/Earnings. Thus, These Results May Indicate Variations in Planning the Individual Retirement as Self-Employed Have More Abilities to Adapt the Work Situation for a Longer Career. However, More Analyses Are Necessary to Get a Deeper Insight in the Cultural Distinctions of Attitudes, Strategies or Motivations of Older Employees and Self-Employed in Their Retirement Plans.

**RETRIEVAL FOR PARENTS WITH INTELECTUALLY CHALLENGED ADULT CHILDREN- A PRODUCTIVE AGEING PERSPECTIVE**

P. Yang, Social Work, National Taiwan University, Taipei, Taiwan

As life expectancy continues to increase in Taiwan, more and more parents with intellectually challenged adult children are reaching or have reached retirement age. Many are concerned about the so-called 'problem of double ageing' as these parents and their children both age and may require care. However, the author believes that these parents have stored a good reservoir of social capitals to face their children's and their own old age after retirement. Thus, this study takes the perspective of Productive Ageing while exploring these parents' retirement related thoughts and experiences. A qualitative approach was applied, including two focus groups of 8 sessions each (one in a care institution and the other in a community-based NGO) and in-depth interviews with key informants. Preliminary results show that: (1) Parents continue to learn through their past and present advocacy actions; (2) their experiences as care-givers have sensitized them with the importance of retirement planning, especially in the areas of financial planning and barrier-free housing; (3) many are active volunteers in rehabilitation units and Non-profit organizations, and (4) there is a strong solidarity among parents to face the multiple age-related challenges. In sum, this study found that many parents with intellectually challenged adult children demonstrate great potentials in all the four domains of productive ageing, i.e., paid work, life-long learning, volunteering, and care. Their decades of rich experiences caring and fighting for their children have unexpectedly prepared themselves for retirement and old age.
argued, however, that traditional models of retirement – based on men’s experiences - are inadequate in defining the retirement experiences of women, given the distinct work histories and social barriers that women have experienced in the labor force. This study sought to understand the complex experience of retirement and the meaning of identity for women who have recently retired from a professional career. The primary research question for the study was, “How does the experience of retirement impact the identities of older professional women?” A phenomenological lens was used to gather in-depth data from six information-rich cases. Through the use of qualitative methods, including 12 in-depth interviews, photo elicitation, and personal journaling, a fluid description of the meaning of identity among a sample of six retired professional women (age range 65-71) was constructed. Findings revealed five primary and five secondary themes related to retirement and identity for these women. As the primary themes have already been explored in previous work, the focus of this presentation is the collection of secondary themes. Secondary themes included a) sense of bravery, b) awareness of being a woman in the work world, c) enjoyment of retirement, d) beliefs about the process of identity in retirement, e) views on the distinctiveness of women’s retirement. Critical feminist, age stratification and continuity theories were used to interpret the findings.

IN VOLUNTARY LABOUR MARKET EXIT AND THE RISK OF DEPRESSION AND USE OF PRESCRIPTION ANTI-DEPRESSANTS
M. Hyde, L. Magnusson Hansson, C. Leineweber, H. Westerlund, Stress Research Institute, Stockholm, Sweden

Background: Involuntary labour market exit (ILME) in later life has been shown to impact general health, health behaviours and depression. However, studies have been limited to self-reported measures. This presentation will investigate the impact of ILME on subjective and objective measures of depression. Methods: The data are drawn from 4 waves of the Swedish Longitudinal Occupational Study of Health, 2006-2012. Analyses were restricted to respondents aged 50+ who had left work since 2006 (N = 1438). Respondents were asked whether they had chosen to leave work or not. Depression was measured using the SCL-6. Data on the use of prescription anti-depressants were taken from Prescription Drug Registers. Logistic regression analyses were used to examine the likelihood of reporting major depression or having been prescribed anti-depressants for those who left work involuntarily compared to those who left voluntarily. All analyses were controlled for age at labour market exit, sex, marital status, income, health, prior depression and anti-depressant use. Results: The results indicate that older workers who experienced ILME were at a higher risk of becoming depressed (OR, 3.32; CI 1.39-7.99) and being newly prescribed antidepressants (OR, 2.12, CI 1.03-4.49) than those who left work of their own volition. Conclusion: The analysis shows that ILME in later life is a risk factor for depression in Sweden. These results are in line with earlier studies in the USA and suggest programs need to be developed to help people who feel that they have been forced out of work in later life.

SOCIAL CONNECTEDNESS AND RETIREMENT STATUS AMONG OLDER AUSTRALIANS: RESULTS FROM SNAP
P. Riosco, 1. Australian Demographic & Social Research Institute, The Australian National University, Canberra, Australian Capital Territory, Australia, 2. ARC Centre of Excellence in Population Ageing Research, Sydney, New South Wales, Australia

The importance of social connectedness for older adult’s health and well-being has been widely recognized (e.g., Berkman et al. 2000). Studies have also linked health and well-being to retirement, which is one of the most important transitions of later life. However, the effect of social connectedness on retirement has not been examined in detail. This paper aims to explore the relationship between social connectedness and retirement status. Using data from the first wave of the Social Activity and Well-being of Older Australians survey, logistic regression is used to identify significant associations between social connectedness indicators and retirement status – retired/not-retired –, controlling for socio-demographic characteristics. Results indicate that males with high negative social exchanges with friends, moderate social interaction with family, fewer friends retired and keeping in touch with fewer family members, are less likely to be retired. Results for females show that those with fewer friends retired, and moderate or large support networks of family members are less likely to be retired. In addition, females with large support networks of friends and those who participate in group activities and voluntary work (p=0.051) are more likely to be retired. These results show that the differences in social connectedness – networks, engagement and support – between retirees and non- retirees are complex and non-linear. Implications for theories of social relations in older ages and research on retirement are discussed. This study is part of the Social Networks and Ageing Project (SNAP), based at the Australian National University.

CROSS-CULTURAL DIFFERENCES IN GOALS FOR RETIREMENT: THE CASE OF INDIA AND THE UNITED STATES
R. Gupta1, D.A. Hershey1. 1. Psychology, Oklahoma State University, Stillwater, Oklahoma, 2. IBS-Hyderabad, Hyderabad, Andhra Pradesh, India

India is a developing country with a rapidly aging population and a lack of a formal retirement system (Kaye, 2000). That being the case, it has become increasingly important to understand the retirement goals of working Indian adults. It has been suggested that the types of goals individuals hold for retirement reflect not only the values and beliefs of a given society, but that they can also provide a view into the well-being and life-satisfaction of its members (Lapierre et al., 1997). In the present investigation, we compare the retirement goals of Indian adults to published data on goals held by American adults. Participants were 158 Indian adults, 21-60 years of age. Respondents completed a questionnaire in which they reported the nature of the goals they held for retirement. The coding scheme used to categorize the goal set was based on the framework developed by Hershey, et al. (2002). For the most part, the types of goals enumerated by Indian workers were similar to those of Americans. However, Indians were found to place more on financial stability and “self” related goals, whereas Americans focused more on leisure and exploration activities. Moreover, Indian workers reported fewer retirement goals overall, and their goals were less concrete than those reported by Americans (on a continuum from abstract to concrete). Findings are discussed in terms of the way culturally-based differences in retirement systems can impact some aspects of future goals (e.g., frequency, concreteness), but not other aspects of goal structures (such as goal content).

WILLINGNESS TO ENGAGE A RETIREMENT PLANNING PROFESSIONAL: PREVALENCE RATES AND PRECURSORS
H.C. Gutierrez1, P. Gerrans2, D.A. Hershey1. 1. Psychology, Oklahoma State University, Stillwater, Oklahoma, 2. University of Western Australia, Crawley, Western Australia, Australia

Engaging a financial advisor can be a critical part of the retirement planning process, especially for individuals with a limited understanding of long-range planning and investing. However, little in the way of research has been carried out to examine the psychological variables predictive of the willingness to hire a financial advisor. In the present study, 1,273 Australian working adults were asked about the future likelihood of engaging a financial professional. We found that of those surveyed, 42% indicated that they would be likely to (or would certainly) engage a planning professional. A hierarchical regression analysis was then computed to explore the factors predictive of hiring a retirement planner. A set of demographic indicators were entered in the first hierarchical level of the model, which were designed to serve as control
GETTING USED TO A LIFE WITHOUT WORK: THE ROLE OF LIFE HISTORIES IN THE RETIREMENT ADJUSTMENT PROCESS

M. Damman¹, K. Henkens¹, M. Kalmijn², 1. Netherlands Interdisciplinary Demographic Institute (NIDI), The Hague, Netherlands, 2. University of Amsterdam, Amsterdam, Netherlands

Retirement is a major transition in the lives of older adults. Individuals differ considerably, however, in their ease of adjusting to retirement. The main theoretical frameworks that have been used to study retirement adjustment – role theory, continuity theory, and the life course perspective – suggest that retirement processes are related to experiences in the past. Empirical insights regarding the relationships between life history experiences and retirement adjustment are limited though. This study aims to improve our understanding of retirement adjustment, by studying the impact of earlier life experiences in different life spheres on both general retirement adjustment and adjustment to the loss of specific work-related resources (finances, contacts, status). Analyses are based on panel data collected in 2001, 2006-2007, and 2011 among Dutch older persons, who were employed at the first wave of data collection and retired within the ten years after that (N=953). The results show that family histories are important for understanding differences in retirement adjustment. Retirees who are divorced and did not repartner are more likely to experience adjustment problems, compared to the continuously married, repartnered, and never married groups. Although work history experiences are associated with missing money/income after retirement, for explaining general retirement adjustment earlier work and health experiences seem to be of little importance. A lack of control over the retirement transition is strongly related to all studied dimensions of retirement adjustment. Paying attention to the multidimensional nature of adjustment appears to improve our insights into the retirement adjustment process.

SELF-EMPLOYED OLDER WORKERS: HEALTH, WEALTH, AND RETIREMENT DECISIONS

Y. Lee, Family, Consumer, and Human Development, Utah State University, Logan, Utah

Using data from the 2008 Rand Health and Retirement Study (HRS), the objectives of this study were to examine the effects of health and wealth on the retirement decision and to identify socio-demographic factors influencing the retirement/work decision among self-employed older workers. The sample for this study included self-employed workers between the ages of 51 and 62 (N=428). The HRS asked respondents about the probability that they would work full-time after age 65 on a 0-100 scale. As a dependent variable in the empirical model, self-reported probability of working full-time after age 65 was included. The average probability of working full-time after age 65 was 47.8% (0-100% scale). The descriptive results also show that 18.7% of the respondents reported zero probability of working full-time after age 65, while 81.3% of them reported they would work full-time after age 65 between 1 and 100. This study focused on the effects of health and wealth on the probability of working full-time after age 65 among self-employed workers ages 51-62. The OLS results indicate that perceived health status, chronic disease, mental health were not significantly associated with the probability of working full-time after age 65, while net worth was a significant predictor of the probability of working full-time after age 65 among self-employed older workers. This study concludes that wealth was an important determinant of the retirement/work decision among self-employed workers. The OLS results also suggest that level of education, family size, and being males positively affected the probability of working full-time after age 65 among self-employed workers.

SESSION 240 (POSTER)

SPIRITUALITY AND RELIGION

DEVELOPING A MODEL OF SPIRITUAL CARE FOR ADDRESSING THE SPIRITUAL NEEDS OF OLDER HOSPITALIZED ASIANS

F. Sun, D. Hodge, Arizona State University, Phoenix, Arizona

Purpose: Hospitalization typically engenders a variety of spiritual needs. In light of the growing size of the elderly Asian population (US Census Bureau, 2011), and the lack of research on this cultural group, this study examined the relationship between addressing the spiritual needs of hospitalized older Asians and their overall satisfaction with service provision. Methods: The study was conducted with a national sample of Asians (N=805), age 50 and above, who were consecutively discharged from hospitals over a 12 month period. The sample was 50.8% female with 24.1% from the Northeast, 30.2% from the South, 14.2% from the Midwest, and 31.6% from the West. Former inpatients were surveyed regarding their spiritual needs, overall satisfaction, and eight potential mediating variables. Structural equation modeling (SEM) was used to test direct and indirect relationships. Results: As hypothesized, addressing spiritual needs was directly and positively associated with overall satisfaction (CFI = .992, RMSEA = .049, & SRMR = .011). Subsequent hypothesized mediation models were also confirmed. In the final model, the relationship between spiritual needs and overall satisfaction was partially mediated by four variables: satisfaction with nurses, physicians, the discharge process, and visitors (CFI = .955, RMSEA = .051, & SRMR = .034). Implications: As the first study to develop and test a model of spiritual care for older hospitalized Asians, the findings help practitioners target their service provision efforts. Suggestions are offered to assist nurses, physicians, and social workers address the spiritual needs of this population in a culturally relevant manner.

THE EXPERIENCE OF RELIGION AND SPIRITUALITY: HOW DO BABY BOOMERS COMPARE WITH OTHER GENERATIONAL COHORTS?

S. Harris, V.L. Bengston, N.M. Pumey, USC, Los Angeles, California

Many scholars have described the pivotal impact of Baby Boomers on religious experience in the US. But how do Boomers’ experiences compare and contrast to other generational cohorts? Here we examine aging and cohort differences in religion and spirituality with data from the Longitudinal Study of Generations (LSOG). Using a mixed-methods approach, we draw from quantitative survey data collected over 35 years from some 2,000 members of 358 four-generation families, and in-depth interviews with 156 members of 25 multigenerational families of diverse religious backgrounds selected from the original longitudinal panel. Qualitative analyses suggest several emergent trends in religion and spirituality across generational cohorts. First, younger groups are more likely to describe God in immanent, personal, and individualistic terms. Second, “religion” is increasingly distinguished from “spirituality,” conceptually and in terms of the site of each practice. Finally, spirituality is increasing central to the experience of the faithful with each successive generational cohort. Quantitative analyses suggest cohort differences in self-rated religiosity, with members of the oldest
generation (the “G1s”) having the highest cohort trajectory. Our findings suggest that Boomers (“G3s” in the LSOG) show many characteristics that are contiguous with, rather than significant departures from, the religiosity patterns of other age groups, although Boomers introduce some trends that characterize younger generational cohorts. We discuss implications of these findings for future research and the importance of recognizing time-related effects on religiosity, including individual maturation and aging, as well as the shared experiences of members of generational cohorts.

RELIGIOUS SERVICE ATTENDANCE INCREASES DAILY POSITIVE AFFECT FOR CARE PARTNERS OF PERSONS WITH MCI

L.M. Butner1, T. Savla1,2, R. Blieszner1, K.A. Roberto1,2, 1. Human Development, Virginia Tech, Blacksburg, Virginia, 2. Virginia Tech Center for Gerontology, Blacksburg, Virginia

Everyday stressors associated with providing care to a spouse with mild cognitive impairment (MCI) can interfere with care partner positive affect. Care partners may turn to spiritual and religious activities as a way of coping with these care giving stressors. To assess the protective effects of attending religious services, we examined 30 spousal care partners’ responses to behavior problems exhibited by their spouses with MCI and to other non-care-related stressors on same-day and next-day positive affect. Participants recorded daily activities and completed telephone interviews on 7 consecutive evenings. Multilevel models reveal that care partners reported higher positive affect on days they attended a religious service, particularly on a low stressor day. The benefits of attending a religious service persisted even on the following day (B=-1.33, p=0.03). However, attending a religious service on a high stressor day was associated with lower positive affect that day (B=-7.26, p=0.05). Results suggest that religious service attendance may provide solace on low stressor days but may not be as helpful on high stressor days. Findings are reviewed in the light of qualitative interviews. Implications of the findings for interventions are discussed.

CENTENARIANS OWN PERCEPTIONS ABOUT THEIR EXTREME LONGEVITY

Centenarians exhibit extreme longevity and a remarkable compression of morbidity and investigations about their special ability to avoid and/or overcome major constrains of life are being conducted all over the world. A special emphasis has been paid on the influence of biological and genetic factors (Poon & Cheung, 2012), but little attention has been given to life as a centenarian (Serra et al., 2011). With the main purpose of identifying how centenarians perceive their longevity and justify having reached 100 years old, a selected sample of 50 persons with 100 and more years old from the Oporto Centenarian Study (PT100) was selected considering their ability to provide extended in-depth face-to-face interviews. Main aspects pointed out as reasons to have reached extreme longevity include the value of hard work, good lifestyle choices (internal locus of control), God will (external locus of control), and even in a more transcendent justification, centenarians highlight their own responsibility in engaging in religious beliefs and practices, such as praying and celebrating masses. These results are analyzed according to the Portuguese cultural context, major assumptions of spirituality and self-transcendence theories and the relation between internal and external locus of control and longevity. Gerotranscendence may provide a theoretical basis for the development of interventions that can foster a sense of meaning in life, well-being and life satisfaction as nearly as possible to the end of life.

RELIGIOUS COMMITMENT AND ATTENDANCE AMONG COMMUNITY-DWELLING OLDER CHINESE IMMIGRANTS IN CHICAGO METROPOLITAN AREA

E. Chang1, R. Chen1, C. Li1, Y. Cal1, M.A. Simon2, X. Dong2, 1. Rush Institute for Healthy Aging, Rush University Medical Center, Chicago, Illinois, 2. Northwestern University, Chicago, Illinois

Background: Religiosity is associated with one’s health and well-being. Positive effects of religion have been show in the aging population. Research suggests that religious commitment, attendance, and practices may help increase immigrant older adults’ resilience to cope with acculturation stress, illness and disability. However, religiosity among Chinese elderly immigrants remains relatively unexplored. Methods: We conducted a cross-sectional study with 3,018 Chinese older adults in Chicago metropolitan area. In the survey interview, we administered a 3-question religious scale to explore the importance of religion in their lives, attendance to organized religious service and attendance to home religious service. Results: Among surveyed participants (N=3,018), the mean age was 73 and 60% were women. 93% were born in mainland China. In total, 36% of Chinese older adults perceived religion as important or very important. As for attendance at religious services, 76% have never attended organized religious services. However, participants were more likely to perform religious services at home. 54% of the participants held home services at least once a year, and 10% did daily. Conclusion: Religion remains an important part of life for Chinese older adults. In addition, ancestor worship and religious services performed at home were common in this population. The findings should be interpreted within the unique cultural and historical contexts of Chinese older adults. Further research is needed to examine the association of religiosity and immigrant older adults’ physical and psychologi-cal well-being.

IMPACT OF NEGATIVE INTERACTIONS ON MARITAL SATISFACTION: A COMPARISON OF YOUNGER AND OLDER ADULTS

J.D. Wilmoth1,2, A.D. Blaney1, 1. School of Human Sciences, Mississippi State University, Mississippi State, Mississippi, 2. National Strategic Planning and Analysis Research Center, Mississippi State, Mississippi

Four negative interaction patterns—escalation, invalidation, negative interpretation, and avoidance/withdrawal—have been shown to predict marital distress or dissolution (e.g., Gottman, 1993; Halfford, Hahlweg, & Dunne, 1990; Markman, Stanley, & Blumberg, 1994). However, to our knowledge, no published research has investigated how negative interactions may vary across age. The purpose of this study is to determine whether there are differences in negative interactions between age groups, explore whether these differences are associated with variance in marital satisfaction, and determine whether religiosity affects this association. Method: Data were collected from participants of the national Family Needs Survey (N = 45,387). Predictor variables included the Negative Interaction Scale (Stanley, Markman, & Whitton, 2002), age (older or younger than 60), and a 4-item religiosity scale measuring self-rated level of spiritual development, church attendance, Bible reading, and prayer. The dependent variable for this study was marital satisfaction (Kansas Marital Satisfaction Scale; 1986). To examine the association of negative interactions in explaining marital satisfaction across age, an ANCOVA was performed, with religiosity entered as a covariant. Results revealed significant main effects of religiosity, F(1,24356) = 23.56, p < .001, and negative interactions, F(10, 24356) = 236.47, p < .001. There also was a significant interaction effect between age and negative interaction, F(10, 24356) = 3.414, p < .001.
SESSION 245 (POSTER)

SUCCESSFUL AGING

CHILDHOOD SCHOOL SEGREGATION AND CHANGES IN ADULT SENSE OF CONTROL IN THE AFRICAN AMERICAN HEALTH COHORT

Objective: Cross-sectional associations between childhood school segregation and adult sense of control and physical performance have been established in the African American Health (AAH) cohort. Here we extend that work by estimating the effect of childhood school segregation on two-year changes in adult sense of control. Method: Data on 542 older AAH men and women were used to estimate the crude and adjusted effects of childhood school segregation on changes in the sense of control. Exposure to segregation during primary and secondary schooling was self-reported in 2004. Sense of control was measured in 2008 and 2010 using Blom rank transformations of Mirowsky and Ross’ eight-item scale. Covariates included demographic factors, socioeconomic status, self-rated health, racial attitudes and beliefs, and religiosity. Multiple linear regression analysis with propensity score re-weighting was used. Results: The unadjusted effect (Cohen’s d) of having received the majority of one’s primary and secondary education in segregated schools on two-year changes in adult sense of control was 0.21 (p = 0.008). Adjustment for demographic factors, socioeconomic status, self-rated health, racial attitudes and beliefs, and religiosity did not appreciably change that effect, (Cohen’s d = 0.19, p = 0.020). Exposure to less segregated primary and secondary schooling did not have a significant effect in either model. Conclusion: While AAH cohort participants who received the majority of their primary and secondary educations in segregated schools improved their sense of control during the economic downturn, their counterparts did not.

EXPLORE THE MEDIATING EFFECT OF FAMILY SUPPORT ON THE ASSOCIATION BETWEEN LIVING ARRANGEMENTS AND SUBJECTIVE HEALTH IN CHINESE OLDER ADULTS: EVIDENCE FOR RURAL-URBAN DIFFERENCES

R. Fu1, D.J. Waters2,3, 1. Purdue University, Center on Aging and the Life Course, West Lafayette, Indiana, 2. Center for Exceptional Longevity Studies, West Lafayette, Indiana, 3. Gerald P. Murphy Cancer Foundation, West Lafayette, Indiana

A popular assumption in gerontology states that environmental influence increases throughout the life-span with non-normative environmental influences. Social support and living arrangements are both important environmental factors that have been indicated to predict health outcomes in old age. However, the mechanisms underlying the association between living arrangements and health have not been well explored, particularly for a non-Western population. To better understand the possible mechanism behind the association between living arrangements and health, we examined the mediating effect of family support upon this association. Using the 2002 and 2005 waves of the Chinese Longitudinal Healthy Longevity Survey (CLHLS), we examined the time-lag effects of family support and living arrangements at T1 on the self-rate health at T2 (3 years later) among 16,064 Chinese older adults aged 61 to 120 years. Using multiple linear regression models and the Sobel test for mediation, we found the effects of living arrangements on subjective health were partially mediated by family support for urban older adults, but not for their rural counterparts. For urban older adults, frequent contact with their adult children was associated with better health trajectories. For rural older adults, adopting an extended-family style (co-residing with more children) at T1 strongly predicted better subjective health at T2; this effect was not mediated by levels of family support. Our findings underscore the need to explore further the mechanisms underlying the link between living arrangements and health in rural Chinese older adults.

SELF-REGULATION STRATEGIES AND SUBJECTIVE WELL-BEING AMONG OLDER COUPLES IN JAPAN

H. Okabayashi, Psychology, Meisei University, Hino-City, Tokyo, Japan

While self-regulation strategies are known to enhance subjective well-being in older adults, it is unclear whether these strategies, if adopted by only one partner in a couple, can influence the other partner’s well-being. This study examines relationships between self-regulation strategies and subjective well-being among older couples in Japan. Methods: 498 couples’ responses were collected through a mail survey to 1500 randomly selected community-dwelling older couples in a suburban area of Tokyo. The four components of the Selective Optimization with Compensation construct (SOC), Tenacious Goal Pursuit (TGP), Flexible Goal Adjustment (FGA), Life Satisfaction, and Depression were measured. Results: After controlling for demographic and social network variables among husbands and wives, we estimated effects of SOC, FGA, and TGP on subjective well-being using Hierarchical Linear Modeling. While FGA of husbands and wives was positively related to their own life satisfaction, FGA of husbands was also positively related to life satisfaction of wives. And while FGA of husbands and wives was negatively related to their own depression, one of the SOC components (“Compensation”) of husbands was negatively related to depression in their wives. Conclusions: These results suggest that a flexible attitude toward accepting avoidable negative life events was important for both husbands and wives among older couples in Japan. Even more striking were the crossover effects from husbands to wives, where we found that husbands’ flexible attitudes toward accepting unavoidable negative life events or in adopting compensating strategies for losses associated with aging are important for the well-being of their wives.

THE IMPACT OF NEW INTIMATE RELATIONSHIPS IN LATER LIFE ON LIFE SATISFACTION

P. Oberg1, T. Bildtgård2, 1. University of Gävle, Gävle, Gävle, Sweden, 2. Social work, Stockholm university, Stockholm, Sweden

Studies about intimacy in old age have mostly focused on institutionalized life-long marriages. Little research has focused on re-partnering in later life and the impact these relationships have on life satisfaction. Framed by Giddens’ Transformation of intimacy and Laslett’s Third age, as well as changing social and geographical conditions, this paper focuses on how different forms of new intimate relationships impact on life satisfaction in later life. Qualitative interviews were conducted with a strategic sample of 28 Swedes, 63–91 years, who were married, cohabiting and living apart together in new intimate heterosexual relationships initiated after the age of 60 or who were currently dating. The results showed the significance of new intimate relationships the experience of life satisfaction in later life: The importance of being needed and confirmed by one’s partner, for intimacy and sexuality, for unloading children’s care responsibility, for sharing experiences in everyday life and for safety. The results also showed the importance of the partner as a resource for new experiences and a healthier life style. In conclusion, the results will be theorized in a time frame: First, in the light of new post (re)productive free time in the third age. Second, in the light of the finite remaining life-time. The results from the qualitative study will be contextualized by results from a representative survey on intimate relations among 3,000 60–90 year old Swedes (data collection has just finished).
Emotional well-being and social support among older adults may contribute to everyday life decision-making (DM) and overall health. This study examined the relation of social support and indicators of well-being on capacity for independent living among older adults receiving assistance in the community or living in retirement communities (N = 33; M age = 67.36; SD = 7.29). Sixty-four percent of the sample was white, 33% African American and 3% Asian. Sixty-four percent were classified as having mild cognitive impairment (MCI) according to the SLUMs. Social support was associated with cognitive status (r = -.37, p < .05). In an analysis of racial differences with positive affect (r = -.38, p < .05) and negatively correlated with (MCI) according to the SLUMs. Social support was associated with cognitive status (r = .48, p < .01). DM capacity was correlated with self-reported health status (r = .38, p < .05) and income adequacy (r = .40, p < .05), such that those with higher scoring DM capacity had better self-reported health and higher income adequacy. Scores on a functional health questionnaire (VES) were correlated negatively with positive affect (r = -.38, p < .05) and negatively correlated with cognitive status (r = -.37, p < .05). In an analysis of racial differences between white and African American participants, white participants scored significantly higher on measures of health literacy (t = 2.51(10.71), p < .05) and DM capacity (t = 2.37(14.42), p < .05). Notably, no relation was found between capacity and social support; however, individuals frequently mentioned members of their support network as resources in dealing with everyday problems (e.g., if locked out of the house, I could call my husband). Given the high proportion of the sample with MCI and the racial differences found in health literacy and DM, additional validation of the DM measure is necessary.

ACTIVE AND PASSIVE SOCIAL ENGAGEMENT THROUGH SHOPPING ACTIVITY
E. Evans, K.M. Bennett, C. McCracken, Psychology, University of Liverpool, Liverpool, United Kingdom

Social engagement has been linked to better physical and mental health outcomes and may alleviate social isolation. For those in later life, shopping can be an opportunity to engage in social interaction and to socialise with others; however, relatively few papers have looked at how these two phenomena interact. This paper represents one of the first attempts to identify the social activities associated with shopping behaviours in an older British cohort. Adopting a qualitative approach, semi-structured interviews were conducted with at least 30 community-dwelling participants and transcripts were analysed using grounded theory. Interview questions included shopping frequency, motivation and decision making. In the current sample there is evidence that shopping provides an opportunity for social stimulation. The data reveal that male and female participants experience shopping both actively and passively as a socially stimulating activity. Examples of active social engagement are shopping with friends or family members as a social occasion or day out. In addition, people may go shopping to get out of the house and to be around others, particularly if they live alone. Passive forms of social engagement when shopping include unplanned social interaction such as bumping into people they know and talking to shop workers or other customers. Both active and passive forms of social interaction are expressed as positive experiences. The findings presented here show that shopping activity may promote wellbeing and is a valuable area in which to study social engagement in later life.

DEVELOPMENT AND PSYCHOMETRIC PROPERTIES OF THE MAASTRICHT PERSONAL AUTONOMY QUESTIONNAIRE (MPAQ) IN OLDER ADULTS WITH A CHRONIC PHYSICAL ILLNESS
J. van Eijk1,2, G. Mars3, G.I. Kempen1,2, 1. Social Medicine, Maastricht University, Maastricht, Netherlands, 2. Department of Social Medicine, Maastricht, Netherlands, 3. Department of Health Services Research, Maastricht, Netherlands, 4. Statistics Netherlands, Heerlen, Netherlands

Methods: Achievement of personal autonomy is conceptualized as correspondence between the way people’s lives are actually arranged and the way people want their lives to be arranged. A field test was conducted in three waves (n = 412, n = 125 and n = 244) among a random sample of people older than 59 years with either Chronic Obstructive Pulmonary Disease or Diabetes Mellitus. Construct validity, internal consistency, reproducibility and responsiveness were evaluated. Results: The MPAQ consists of three scales: degree of autonomy, working on present and prospective goals and cognitive status. Spearman’s rho for responsiveness was 0.28 and mean change was larger (0.54) than was SRDgroup (0.11) in patients who had deteriorated, but smaller in patients who had improved (0.07). Conclusions: The MPAQ has good validity and internal consistency and moderate reproducibility. Responsiveness is weak, although better for deterioration than for improvement.

DYNAMIC PROCESSES OF DAILY HEALTH-GOAL PROGRESS AND DAILY AFFECT
S. Choun, S. Mejia, K. Hooker, Oregon State University, Corvallis, Oregon

Optimal aging is strongly related to personality factors along with health behavior habits. While many studies found links between traits and health (Lahey, 2009; Siegler, Hooker, Bosworth, Elias, & Spiro, 2010), less is known about more process-oriented personality constructs, such as goals and self-regulatory strategies. In the process of self-regulating goals, it is important to explore the associations between what people are trying to do and what people are feeling. The successful or unsuccessful pursuit of desired outcomes arouses emotions such as happiness or dejection (Lockwood, Jordan, & Kunda, 2002). We examined the within-person coupling of personality processes over time as well as the cross-lagged associations of personality processes by tracking daily within-person variations and between-person differences in the associations between affect and health-goal progress. The analyses utilized data from the Personal Understanding of Life and Social Experiences (PULSE) Project, a 100 day internet-based, microlongitudinal daily study (N = 99). Multilevel models revealed that daily health-goal progress was positively coupled with daily positive affect and negatively coupled with daily negative affect within persons. The associations between daily health-goal progress and daily positive affect and between daily health-goal progress and daily negative affect varied between individuals. The cross-lagged associations between variables demonstrated that health-goal progress on the previous day was positively related to concurrent positive affect and negatively related to concurrent negative affect. Positive affect on the previous day was positively related to concurrent health-goal progress. The study was funded by the Center for Healthy Aging Research at Oregon State University.

THE BEST PREPARATION FOR BETTER MEMORY TOMORROW IS BETTER COPING TODAY: EFFECTS OF ANTICIPATORY COPING ON MEMORY FAILURES AND REACTIVITY TO INTERPERSONAL STRESSORS
S.D. Neupert, J. Ramsey, A. Davis, NC State University, Raleigh, North Carolina

Previous research has established that daily stressors, and especially arguments, are associated with increases in memory failures (e.g., Neu-
pert, Almeida, Mroczek, & Spiro, 2006) and poorer performance on cognitive tasks (e.g., Sliwinski, Smyth, Hofer, & Stawski, 2006) in older adults. The current study implemented an 8-day daily diary to examine the within-person relationships among daily anticipatory coping (e.g., coping that takes place before a stressor occurs) and memory failures on a subsequent day in a sample of 43 older adults (M age = 74.3, SD = 7.5, range = 60-93). Participants completed questionnaires on anticipatory coping, daily stressors, and memory failures for eight consecutive days. Results from a multilevel model revealed increased reactivity to daily arguments (i.e., increases in memory failures associated with increases in arguments) when the previous day’s anticipatory coping was low. Comparatively, there was no increase in memory failures associated with arguments when the previous day’s anticipatory coping was high. These results suggest that engaging in anticipatory coping behaviors on the day before a stressor occurs provides an important adaptive advantage for reactivity to daily arguments in older adults.

**EXPLORING PREDICTORS FOR COGNITIVE FUNCTION USING KOREAN NATIONAL LONGITUDINAL DATA: FROM THE MID AGED TO THE LATE ELDERLY**

S. Joo, H. Jun, H. Chai, child and family studies, Yonsei University, Seoul, Republic of Korea

This study focused on cognitive function, a critical element of dementia and in the model of successful aging suggested by Rowe and Kahn. We aimed to explore predictors of cross-sectional cognitive status and longitudinal change in cognitive function in the mid and late life. The mid and late-life was divided into 3 stages; 45-64 as mid, 65-79 as old and over 80 as the oldest. We examined whether predictors of cognitive function differ according to these stages. Data from the Korean Longitudinal Study of Aging (N=8,688) was utilized for the analysis. The model was tested with Latent Growth Modeling using Mplus 6.12. Results indicated that the three age groups tended to share more similar predictors of cognitive function during the same period, while differences were more prevalent among predictors of the longitudinal change of cognitive function. Variables including physical health, physical function, positive health behavior, depression, age, gender, education, and the interaction between gender and education all had significant effects on cognitive function in terms of the cross sectional analysis. However, with regard to the longitudinal rate of change in cognitive function, with the exception of physical function and the interaction between gender and education, each group showed different relationships with various predictors. These results imply that mid, old, and the oldest groups are not homogeneous. Therefore, different strategies need to be applied for each group, for them to cognitively function well for successful aging. This provides base line data in preventing cognitive deficits and when developing cognitive intervention programs.

**THE SENIOR STRUCTURED LIVING PROGRAM (TRUE GRIT): A THERAPEUTIC MODEL PROMOTING HEALTHY AGING BEHIND BARS**

M.T. Harrison1,2, M.L. Adams2, E. Dampsey2, T. Grabreck2, J. Iribarne2, T.L. McMullen2, K. Koperfa-Freye2, R. Aday1, 1. Psychology, Nevada Department of Corrections, Carson City, Nevada, 2. Fielding Graduate University, Santa Barbara, California, 3. Middle Tennessee State University, Murfreesboro, Tennessee, 4. Sierra Tucson Counseling Center, Tucson, Arizona, 5. University of Maryland Baltimore Campus, Baltimore, Maryland, 6. University of Louisiana, Monroe, Monroe, Louisiana

Increased sensitivity to graying of our prisons and soaring medical expenses are stimulating discussion about how best to respond to special needs of geriatric offenders. Since health statuses are closely interconnected with prison adjustment, policymakers are seeking “best practice” solutions that enhance older incarcerated adults’ mental, physical and functional health status. This research examines important linkages between successful aging and inmate participation in the Senior Structured Living Program (True Grit) at a Nevada prison. One hundred thirty-six True Grit (TG) participants (mean age – 68 years) were surveyed using both open and closed ended questions examining inmate’s physical and mental health concerns and coping strategies. Major dependent variables included prison adjustment, life satisfaction, depression, and activities of daily living. The importance of religion as a coping mechanism was included as a secondary variable. Pearson correlations indicated significant relationships between the number of TG activities participated in and prison adjustment. Inmates who were most satisfied with TG participation reported higher scores on prison adjustment and life satisfaction. Findings from a Linear Regression Model support TG participation as an important predictor of prison adjustment. In response to open-ended questions, inmate narratives reinforce the positive impact of the TG structured program in creating self-efficacy strategies for successful aging. Over 80% of respondents reported their prison life was much better as TG participants compared to living in the general prison population. Policy implications and the need for replication are addressed.

**SUCCESSFUL AGING AND BEHAVIORAL CHANGE: EFFECTS OF THE “I AM ACTIVE” PROGRAM**

N. Mendoza Ruvalcaba, E. Arlas-Merino, M.J. Arias-Merino, J. Cueva Contreras, Universidad de Guadalajara, Guadalajara, Mexico

Introduction: I AM ACTIVE is a program designed to encourage successful aging in people 60 years and over, through behavioral change and improved physical activity, healthy nutritional habits and cognitive functioning, that promotes better quality of life. The objective of this study is to assess the effectiveness of this program. Methods: Longitudinal Design (RCT). 64 healthy elderly (experimental n=31, control n=33) participated in a program based on the Precaution Adoption Process Model (PAPM), consisted in theoretical-practical sessions of physical exercise, nutrition habits and cognitive training. A pre-post and 6 month follow-up assessment was conducted. Mean differences and effect size was calculated. Results: Groups were similar at baseline. Most of the experimental group progressed of stage in the behavioral change from PAPM between pre-post test, and maintained at follow-up, while the control group remained without significant changes. After the program the experimental group improved significantly in the different areas compared with the control group: Physical activity: risk of falls(p<.05,d-Cohen=.34), balance(p<.05,d-Cohen=.40), range of motion(p<.05,d-Cohen=.65), self-efficacy for physical activity(p<.001,Cohen-d=.76). Nutrition: nutrition self-efficacy(p<.01,d-Cohen=.61), nutritional status(or<.05), water consumption(p<.05). Cognitive performance: processing speed(p<.001,d-Cohen=.50), working memory(p<.05), self-efficacy to improve memory(p<.001,d-Cohen=.89). QOL: general(p<.01,d-Cohen=.63), health-functionality(p<.01,d-Cohen=.54), psychological and spiritual(p<.05,d-Cohen=.44), and family(p<.05,d-Cohen=.36). In the follow-up, improvements remained at risk of falls, self-efficacy for physical activity, self-efficacy for nutrition, processing speed, QOL general and its spiritual and psychological component. Conclusion: Findings show that the program promotes a behavioral change for the enhancement in domains of successful aging as well as in quality of life in healthy elders.

**WORKING WITH EXTENSION TO UNDERSTAND OPTIMAL AGING IN IOWA: MID LIFE AND BEYOND INITIATIVE**

As one of the oldest states Iowa faces great challenges and opportunities. The aim of this research and Extension Outreach project was to explore how younger and older adults can work together to make changes within their communities. Study Circles were utilized to begin community discourse and discussion guides for these sessions were designed based on the Everyday Democracy (Everyday Democracy:
HOW DID YOU BECOME 100?: FINDINGS FROM THE FORDHAM CENTENARIAN STUDY

Is there anything we can do to reach our 100th birthday? We asked this question to individuals 95 and older within the Fordham Centenarian Study, which investigated 119 individuals living in New York City (mean age 99, range 95-107, 78% females). Open-ended questions were used to assess whether centenarians felt that they had a specific recipe that allowed them to reach their very advanced age, or whether they had lived according to a specific life motto. Answers were later coded with a theme-based qualitative approach, using a coding schema developed for this study. The higher-order categories found were: health, lifestyle, work, social aspects, psychological aspects, well-being, spirituality, leisure, specifics about aging (e.g., feeling much younger), and luck. The categories most often mentioned by participants at least once were psychological factors (62.5%), lifestyle (44.6%), social resources and behaviors (42.9%), as well as religious beliefs (30.4%). The specific categories mentioned most often were coping strategies (53.6%), having faith (30.4%), prosocial behavior (25%), virtues (25%), and genes (18%). Among coping strategies, focusing on one day at a time was the strategy most often mentioned (20%). It is also noteworthy that about one-third of the sample said at one point during the interview they had no idea how they became that old, and 9% was attributed their age to pure luck. In sum, although discussions on longevity mostly focus on health and lifestyle, centenarians offer mostly psychological aspects as reasons for their very advanced age.

LAY PERSPECTIVES OF SUCCESSFUL AGING IN A LIFE-SPAN SAMPLE

D.S. Jopp, M.M. De Feo, S. Jung, S. Jeswani, Psychology, Fordham University, Bronx, New York

To what extent the perception of lay people match scientific definitions of successful aging has received increasing attention in recent years. The present study examined a sample of 133 individuals aged 18 to 96 years (females 59%) living in the wider New York area with respect to how they define successful aging and what contributes to successful aging in their view. The answers to the open-ended questions were later coded with a theme-based qualitative approach, using a coding schema developed for this study. Overall, individuals mentioned 14 central theme categories. The category most often mentioned at least once was health (72%), followed by social aspects (58%), activities (49%), beliefs (47%) and coping strategies (46%). About one fifth of the sample mentioned independence, meaning in life, and specific aging issues. The importance of knowledge/education was mentioned by 17%, finances by 16%, and success/respect by 10%. Additional themes mentioned by only a few individuals included macro and micro environment, and need for stability. It is of note that the answers for definitions and determinants did not differ in terms of themes mentioned. We also found only limited evidence for gender or age differences. In sum, the findings suggest that lay persons have a multifaceted understanding of successful aging, and consider a much larger number of factors as important than most theoretical models and empirical studies on successful aging.

TOWARD A BRIEF PRODUCT AND PROCESS MEASURE OF SUCCESSFUL AGING

G.T. Reker, Psychology, Peterborough, Ontario, Canada

This research reports on the development of a brief multifaceted measure of successful aging that incorporates conceptual content from 4 well-known models of successful aging. The 14-item, 7-point Successful Aging Scale (SAS) and other measures were completed by 336 older adults. Studies 1, 2 and 3 report on item analysis, factor analysis, reliability and validity. In Study 1, all 14 SAS items were found to contribute significantly to the total score. Factor analysis identified three underlying dimensions: Healthy Lifestyle, Adaptive Coping, and Engagement with Life. The alpha coefficient for the SAS was 84 and ranged from .72 to .75 for the three dimensions. Test-retest stability (12-weeks) for the SAS was found to be .71. Research has shown that successful agers are very resilient, high in emotional intelligence, and enjoy good physical and mental health. The results of Study 2 supported these validity predictions and also demonstrated that the SAS is free of socially desirable responding. Moreover, successful agers have been found to be optimistic, to be high on personal meaning, to be open-minded, and to embrace spirituality. Study 3 also supported these validity predictions. In conclusion, the SAS is a useful measure of successful aging developed from well-known product and process models. Future studies will need to examine the correlation of the SAS with other measures of successful aging. The SAS is recommended as a brief research and clinical screening tool to access successful aging in the later years.

HEALTHY AGING IN MASSACHUSETTS: REPORTING INDICATORS, IDENTIFYING RESOURCES & ACTIVATING ALLIES

We report on an initiative supported by the Tufts Health Plan Foundation to determine indicators of healthy aging (HA) and current resources. HA is multidimensional including: physical health (self rated health, recent fall w injury, tooth loss, disability), mental health (depression, life satisfaction, poor mental health days), nutrition/diet (obesity, access to healthy foods, daily fruits/vegetables, smoking, alcohol use), safety/security (violent crime rate, elder abuse rates), proactivity in health behaviors (physical activity, cancer screening, flu-pneumonia-shingles vaccines, dental exams, cholesterol screening), social engagement and having meaningful roles, and health care utilization/access variables. Sociodemographic variables were also analyzed (age, gender, race, education, marital status, % Medicaid dually-eligible). First, we analyzed data from multiple existing sources (CMS 2009-2011 Master Beneficiary Summary files, 2006-2011 Behavioral Risk Factor Surveillance System for Massachusetts, 2010 Area Resource File, County Health Rankings and Roadmap, Food Environment Atlas County Data, 2005-2007, Dartmouth Atlas of Health Care Physician Supply, and MA state administrative data) to calculate rates on indicators. Next, we employed GIS analyses to map indicators of healthy aging representing the conceptual domains. Mapped indicators are reported at actionable geographic units to highlight successes/failures across the state. Concurrently we conducted an environmental scan of HA programs to...
provide a snapshot of available resources and gaps. Results of the environmental scan and indicator report disseminated to researchers, advocates, older adults, and interested parties in supporting healthy aging enable communities to customize strategies to address their unique challenges. This approach provides a model for other states to optimize healthy aging.

SUCCESSFUL AGING AND THE MIND-BODY CONNECTION IN LATER LIFE: PERCEPTIONS OF CONTROL AND ACTIVITIES OF DAILY LIVING IN THE MEN OF THE MANITOBA FOLLOW-UP STUDY

A.U. Swift, R.B. Tate, Manitoba Follow-up Study, University of Manitoba, Winnipeg, Manitoba, Canada

When asked for their definitions of successful aging, many older men mention independence. Evidence exists in the psychology literature of a “mind-body connection”, suggesting that certain thoughts are positively linked to physical and psychological well-being. In light of this, we sought to examine whether and how perceptions of control related prospectively to functional ability in 1745 older men (mean age 76.6 ± 3 years) who were part of the Manitoba Follow-up Study, one of the longest-running studies of health and aging in the world. Our specific objectives were to test whether perceptions of primary and secondary control (i.e., different ways of feeling in control) in 1996 related to both basic and instrumental functional ability four years later. Even with age and functional ability in 1996 controlled, primary and secondary control/acceptance significantly predicted reporting fewer activity limitations in 2000. In particular, men whose lay definitions of successful aging included themes of primary control in 1996 were significantly less likely to report limitations in basic and instrumental activities of daily living in 2000 than were men whose successful aging definitions did not include themes of primary control: OR-BADL=.64, 95% CI (.42, .97); OR-IADL=.64, 95% CI (.44, .93). A similar pattern of findings emerged for the acceptance component of secondary control: OR-BADL=.64, 95% CI (.46, .90); OR-IADL=.71, 95% CI (.53, .93). These findings suggest that perceptions of control may indeed be part of the “mind-body connection” in older men, and that they could conceivably contribute to enhanced functional well-being in later life.

RISK OF PLACEMENT IN A CARE FACILITY: THE ROLES OF SOCIAL ACTIVITY, SLEEP, PAIN, AND DEPRESSION

L.M. Miller1, N.F. Dieckmann, N.C. Mattek, K.S. Lyons1, J. Kaye2, J. School of Nursing, Oregon Health & Science University, Portland, Oregon, 2. Oregon Health & Science University, Portland, Oregon

Placement in a long-term care facility is a costly and often undesirable outcome for many older adults. The purpose of this study was to determine whether several modifiable factors—social activity, sleep, pain, and depression—predicted placement in a care facility, over and above cognitive impairment, functional impairment, medical conditions, and age. The data were derived from the Intelligent Systems for Assessing Aging Changes study, a prospective cohort (n=229) of community-residing older adults (mean age 83.4±5.6), with a low rate of cognitive impairment (n=34.15%) at baseline. Within 5 years, a total of 44 (19%) of the 229 participants had moved to assisted living or nursing home care and 55 (24%) were cognitively impaired. Findings of a multivariate logistic regression analysis controlling for cognitive impairment, functional impairment, medical conditions, and age, indicated that each unit decrease on a 20-point social activity scale was associated with a 25% increase in the risk of placement in a care facility (p=0.002), and each unit decrease on a 5-point scale indicating the frequency of restful sleep was associated with a 60% increase in the risk of placement in a care facility (p=0.008). Although pain and depression significantly increased risk of placement in the unadjusted analysis, they were not significant individual predictors of placement in the multivariate model. Findings will be discussed with regard to minimizing risk of placement by improving restful sleep and increasing social activity outside of the home for community-dwelling older adults.

WELL-BEING: BENEFITS OF PARTICIPATION IN A SENIOR WOMEN’S SOCIAL GROUP

P.R. Gould, Social Work, Binghamton University, Binghamton, New York

This study examines the psychosocial benefits of senior women’s participation in social groups. The findings illustrate a relationship between social connectedness and well-being, with participants describing the importance of the group as an integral component of their support network and continued personal development. Group work established a venue to build relationships that provide relational empowerment, reciprocal support and caring, stimulation, and personal growth. Through their relationships, women find the emotional connections to support successful adaptations to life-altering changes. Collectively, these experiences suggest that group members engaged in a process of redefining themselves in the context of new social roles; they increased their sense of personal ability to adapt to change, culminating in an enhanced state of well-being.

RACIAL DIFFERENCES IN EXPERIENCES AND APPRAISALS OF STRESSFUL LIFE EVENTS AMONG URBAN ELDERS

T. Goler1, T. Bhatta1, B. Kahana1, E. Kahana1, 1. Case Western Reserve University, Cleveland, Ohio, 2. Cleveland State University, Cleveland, Ohio

In this paper we consider racial differences in reported experiences and appraisals of recent life events, comparing African American (AA) and Caucasian older adults. The sample of 409 respondents (M=79, SD=5.74) were randomly selected urban community residents. Respondents included 79% women and 25% African Americans. Findings reveal that AA respondents generally reported more negative life events compared to Caucasians. Notably, AA elders reported more frequent loss of a close friend (p<.004) and greater financial difficulties compared to Caucasian elders (p=.001). Event appraisals on the life events, however, yielded a different pattern. Caucasian elders consistently appraised negative life events as more problematic than their AA counterparts. Our findings call attention to selective similarities and differences in racial patterns of late life stress exposure. These data offer support for the role of stress appraisal process (Lazarus & Folkman, 1984) in buffering the impact of stress on psychological well-being. Indeed, in spite of generally higher levels of stress exposure reported by AA elders, their domain specific satisfaction was similar to those of Caucasian elders in terms of both social life and standard of living. Only in the area of satisfaction with one’s neighborhood did AA elders express significantly lower satisfaction. These findings suggest the role of cognitive appraisals in contributing to greater psychological well-being among AA elders compared to Caucasian elders in the community.

PSYCHOSOCIAL DEVELOPMENTAL IMAGES IN LATER LIFE AMONG OLDER ADULTS IN JAPAN

K. Hoshino1, S.H. Zarit2, 1. University of California at Berkeley, Berkeley, California, 2. Pennsylvania State University, State College, Pennsylvania

PURPOSES: This study explores psychosocial developmental images in later life among older adults in Japan and analyzes qualitative data that was evaluated by the Sentence Completion Test for Gero-transcendence (SCTG), which we developed. METHODS: The sample included 235 Japanese older adults (128 men, 107 women), whose mean age was 69.17 years old (SD=4.72). They answered a question-
The Gerontological Society of America

TECHNOLOGY

IN-HOME HEALTH MONITORING: REACTIONS AND PERCEPTIONS OF OLDER ADULTS IN SUBSIDIZED HOUSING
K. Wild1, P. Carder2, J. Weinstein3, J. Kaye1, 1. Oregon Health and Science University, Portland, Oregon, 2. Portland State University, Portland, Oregon

Research in the area of in-home technology acceptance and use has established that the “digital divide” between older and younger adults has been shrinking in the last decade. What remains is a continuing disparity among older adults based on socioeconomic status. The health-related technology needs and preferences of low-income older adults have been largely neglected. This study used two approaches to begin to describe the attitudes toward in-home technology of a sample of older residents in subsidized housing. Surveys were distributed to residents of two urban subsidized apartment buildings to assess their access to daily technology applications. A subset of respondents was then invited to participate in focus groups to further discuss their attitudes and perceptions regarding in-home technologies. Ninety-three participants responded to survey questions regarding use of everyday technologies such as cell phones, medical alert systems, and computers. Twenty-eight percent reported owning a computer, 49% owned cell phones, and 17% of this medically vulnerable population had some kind of medical alert system. Analysis of focus group transcripts yielded themes related to the balance between privacy and maintaining independence, human contact vs. objectivity of technology-driven data, and sharing of information with health care providers vs. family members. It is becoming clear that low-income older adults have less access to technology than the general population. Yet their needs and preferences are remarkably similar to those expressed by their higher-income counterparts (Wild et al., 2008). Technologies that promote health as well as social connectedness are vital to successful aging in place for all older adults.

USING THE LANGUAGE ENVIRONMENT ANALYSIS (LENA) SYSTEM TO STUDY SOCIAL ENGAGEMENT AMONG OLDER ADULTS IN A RETIREMENT COMMUNITY
L. Li1, 2, A.R. Vikani1, G. Harris4, F.R. Lin2, 4, 1. University of Oklahoma College of Medicine, Oklahoma City, Oklahoma, 2. Johns Hopkins University, Baltimore, Maryland, 3. The George Washington University School of Medicine and Health Sciences, Washington, District of Columbia, 4. Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland

Background: Social engagement is a strong determinant of health and morbidity in late-life. A current limitation in assessing social engagement in older adults is the lack of an objective and quantitative metric for measuring social behavior. This study investigated the feasibility of using the Language Environment Analysis (LENA) system as a novel method to objectively quantify social engagement in older adults within their natural environment. Methods: Thirty-seven participants aged 64-91 residing in a retirement community were asked to wear a digital language processor (DLP) to record their auditory environment during one waking day. Recordings were analyzed with the LENA software to derive quantitative estimates of the individual’s social environment (e.g. number of spoken words heard, percent of time spent around meaningful speech versus television/radio). Questionnaires on social engagement, lifestyle activities, and health-related quality of life were concurrently administered. Results: Adequate LENA recordings that began before 10 A.M. and lasted for ≥10 hours were collected from 24 participants. The mean duration of recording was 13 hours and 13 minutes, and individuals spent a mean of 26.7% (range=4%—58%) of their waking day near a television or other electronic sounds. The projected mean word count over a maximum of 16 hours was 33,141 with nearly a 14-fold range between the lowest and highest observed values (range=5120—77,882). Conclusion: High-quality objective data on the auditory and social environment of older adults can be feasibly measured with the LENA system. Findings from this pilot study may guide future studies investigating social engagement in older adults.

PREDICTORS OF OLDER ADULT TECHNOLOGY ADOPTION
M.S. Heinz, P. Martin, Human Development and Family Studies, Iowa State University, Ames, Iowa

The technology acceptance model (Davis, 1989) has grown in notoriety among those researching technology use. However, little focus has been given to predicting older adult technology use. A modified version of the technology acceptance model is presented taking into account the influence of age, education, personality traits, perceptions of technology ease of use, perceptions of technology usefulness, and attitudes toward technology influencing general technology adoption. This modified model is titled the technology adoption model. It was tested with Mplus and indicated a good fit χ² (df = 28) = 38.67, p < .05, CFI = .98; TLI = .96; RMSEA = .05 and SRMR = .04. Specific findings indicated that attitudes of technology on technology use were positively related, indicating that individuals with more positive attitudes toward technology were more likely to use technology. Other interesting findings included significant direct effects between agreeableness and perceived usefulness of technology and conscientiousness and perceived usefulness of technology while controlling for age and education. These findings suggest that agreeableness and conscientiousness personality traits impact perceptions of technology that may ultimately impact technology adoption. The main finding shows that the technology adoption model is a good fit and significantly predicts older adult technology adoption.
IMPACT OF USING TELECONFERENCE COGNITIVE BEHAVIOR THERAPY ON WORKING ALLIANCE AND TREATMENT OUTCOMES FOR CO-OCcurring INSOMNIA AND DEPRESSION IN OLDER ADULTS

Objective: There is limited research investigating whether delivering cognitive behavioral therapy (CBT) through teleconferencing impacts working alliance and/or therapeutic outcomes. The present study aims to address this question by examining therapeutic alliance and treatment outcomes for a CBT intervention delivered to older adults via teleconferencing. Method: We are reporting data on five participants that were enrolled in a pilot study of CBT for co-occurring insomnia and depression in older adults. However, data on 46 older adults will be available at the meeting. Participants received 10 individual CBT teleconferencing sessions, as well as pre-, post- and 2-month follow-up assessments (including self-report measures of insomnia and depression). Therapeutic alliance was assessed using the Observer-rated 36-item Working Alliance Inventory (WAI), which yields overall and subscale (task, bond, and goal) scores. An audio-recorded session from early in treatment (Sessions 2-5) and from late in treatment (Sessions 6-9) were randomly chosen and rated by a trained independent rater. Results: The sample included predominately female (80%), Caucasian (100%) older adults (M = 65.8, SD = 10.4). The overall and subscale WAI scores were comparable to those obtained in other clinical trials with older adults (Early Session Composite = 182.0; Late Session Composite = 175.8). Participants demonstrated clinically significant improvements in sleep onset latency, wake time after sleep onset, insomnia severity, and depression at post-treatment and follow-up. Conclusions: This study demonstrates that teleconferencing CBT may be an effective mean of providing treatment to older adults, particularly in underserved populations. Acknowledgement: National Institute of Mental Health MH086643.

IMPACT OF COMMUNICATION TECHNOLOGY USE ON DEPRESSION AND HEALTH STATUS OF OLDER ADULTS DWELLING IN RETIREMENT COMMUNITIES

H.Y. Lee1, J. Kim2, 1. School of Social Work, University of Minnesota, Twin Cities, St. Paul, Minnesota, 2. Idaho State University, Idaho, Minnesota

Background: Older adults increasingly utilize the Internet or email for social connections and networks. However, there is no evidence how the communication technology use impacts on older adults’ health and mental health status. This study examined (1) the level of communication technology use among older adults residing in the retirement communities and (2) the impact of the communication technology use on older adults’ depression and self-rated health status. Methods: A sample of 594 older adults residing in the retirement communities was drawn from the 2011 National Health and Aging Trend Study. About half of the sample (43%) used communication technology which includes email, texting, and internet and about one third participated in routine exercises (37%) and vigorous physical activities (36%) such as swimming, running, or biking. Results: We separately performed logistic and multiple regression analyses to examine factors associated with depression and self-rated health status respectively. While controlling for other relevant variables, communication technology use showed a significant negative relationship with depression and a significant positive association with health status. Conclusion/Implications: A significant predictive role of communication technology use on health and mental health status implies that health care providers and health services researchers should understand the importance of communication technology in the provision of health promotion and mental health treatments. Communication technology may function as a prime medium to improve health and wellness of older adults in long-term care settings.

WEB-BASED STAFF TRAINING FOR ASSISTED LIVING RESIDENCES (WEB-STAR)

E.A. Hilderman, L. Teri, D.M. La Fazia, C.A. Coulter, School of Nursing, University of Washington, Seattle, Washington

Assisted living (AL) remains the fastest growing residential care option for older adults. Optimal aging in such settings can only be achieved with well trained staff, competent to address challenges presented by older residents with cognitive impairment. STAR (Staff Training in Assisted Living Residences) has been found, via randomized controlled clinical trials (RCTs) to effectively diminish behavioral problems in residents with dementia and increase staff skill and satisfaction in providing care. Thus far, STAR has only been conducted by highly trained professionals intimately involved in its development. It requires a commitment of 2 months, both from the professionals as well as the ALs for which they provide such training. Consequently, the dissemination of STAR to interested agencies is limited by the availability of professional trainers. To address this issue and enhance the uptake and spread of this evidence-based program, a web-based toolkit has been developed to enable in-house trainers to provide STAR and to sustain its implementation. Two core modules are presented that include a systematic blueprint to guide the novice trainer through the process of training preparation, implementation and maintenance. Using both online surveys and semi-structured telephone interviews, information was obtained from users about the feasibility of this medium for training; namely clarity of content, implementation barriers, staff response, and supports to adoption. These results suggest clear directions for future development and offer strategies that are of use, not only to STAR, but to other programs directed towards enhancing staff training in long term care.

WHAT HEALTH METRICS DO OLDER ADULTS WANT TO TRACK?

J.L. Davidson, C. Jensen, Oregon State University, Corvallis, Oregon

Many smartphone app creators fail to do a valid needs assessment of their end-users. To rectify this issue, we involved older adults (aged 65+) in the beginning stages of designing a health and wellness application. We conducted a participatory design study, where 5 groups of older adults created 5 designs. Four groups had at least 1 health metric that is not currently offered in either the iPhone app store or the Google Play store. For example, one group proposed an app that not only tracked exercise routines, but also tracked restful activities such as meditation, naps, and hobbies. At the end of the sessions, we administered a questionnaire to determine what health metrics they would like to track via smartphone or tablet. Their designs included 13 health metrics that were not on the questionnaire. The majority (17 of 18) of participants expressed interest in tracking health metrics using a smartphone/tablet despite having little experience with those devices. This shows the research community in both human-computer interaction and gerontology, that older adults have unique ideas that are not being considered by current technology designers. Interestingly, we found that 93.75% of participants would like an app that would track health appointments, but no one included this in their own app designs. Therefore, we should not only involve older adults in participatory design sessions, but we should also do interviews/questiornaires to get a broader picture of their needs. This work was supported by the National Science Foundation under Grant No. DGE 0965820.

PATIENT-CENTERED CONTINUITY-OF-CARE WITH SIMPLIFIED, INNOVATIVE TECHNOLOGY

G.T. Savage1, B. Leon2, J. Brokel2, 1. MISQ, University of Alabama at Birmingham, Birmingham, Alabama, 2. Techway, Inc., Blue Springs, Missouri

Whether managing several chronic diseases with multiple providers or monitoring changes to quality-of-life and functional health indicators through case-management services, patient-centered continuity-of-care should be accomplished with the use of simple technology. In an
effort to leverage electronic medical records (EMR) and introduce patient-centered information with personal health records (PHR), we develop simple but innovative ways that informatics can create a single patient view. The goal is to reduce revolving door visits through the ER, hospital, clinic, residential and home care environments by focusing on shared patient information. While the direct correlation between specific patient activities, medications, procedures, and follow-up seem to reside with the actual patient care giving facility, sharing patient information (e.g., orders, prescriptions, and diagnoses) falls short of staying with the patient/caregivers who continue the care. Coordination-of-care within residential, assisted-living, skilled nursing, and home health should include simplified technology, thus providing a single patient view for patient-centered continuity-of-care. In this pilot study, we transform several paper-based continuity-of-care processes (handoffs) into a PHR for patients undergoing transfers from acute care to assisted-living to home care environments. We then demonstrate how this PHR is compatible with existing EMR systems. Lastly, we gather data on (1) the time health providers devote to obtaining and sharing personal health information and (2) the accuracy of this personal health information for both paper-based methods and via a PHR. We conclude by highlighting the advantages of a PHR for continuity-of-care processes.

**PSYCHOSOCIAL PREDICTORS OF WILLINGNESS TO WEAR AN EMERGENCY ASSISTIVE DEVICE IN ADULTS OVER 50**

D. Tsukerman, D. Fishel, J.V. Gallegos, M. Horn Mallers, K.S. Wilson, L. Zettel-Watson, California State University, Fullerton, Fullerton, California

As the baby boomers age and chronic conditions become more prevalent, the healthcare needs of the older population are expected to surpass available healthcare resources. Consequently, older adults will need to be more reliant on themselves and informal care when it comes to their health. Social support and personality variables, such as health locus of control and self-efficacy, have been found to predict the extent to which individuals engage in self-care behaviors aimed at maintaining independence. Further, assistive technology (AT) helps older adults in place while simultaneously reducing the strain on the formal health care system. The emergency pendant is one popular AT device that serves to promote independent living, but little is known about what factors predict usage of these pendants. Using a sample of 166 tech-savvy adults over age 50 (M=70.8, SD=8.0; 61% female) the current study predicts usage of these pendants. We transform several paper-based continuity-of-care processes (handoffs) into a PHR for patients undergoing transfers from acute care to assisted-living to home care environments. We then demonstrate how this PHR is compatible with existing EMR systems. Lastly, we gather data on (1) the time health providers devote to obtaining and sharing personal health information and (2) the accuracy of this personal health information for both paper-based methods and via a PHR. We conclude by highlighting the advantages of a PHR for continuity-of-care processes.

**PREDICTORS FOR THE USE AND WILLINGNESS TO USE REMOTE TELECARE IN OLDER AMERICANS**

R. Best¹, A. Antonietti², N. Charness¹, H. Kort². 1. Florida State University, Tallahassee, Florida, 2. Hogeschool Utrecht, Utrecht, Netherlands

E-Health technologies are a valuable tool for addressing the rising health care needs of the aging American population. Specifically, remote telecare technologies (RTC), such as videoconferencing systems used between doctors and patients, are useful for reducing time spent traveling to health centers while maintaining healthcare quality. Unfortunately, a lack of skills and knowledge related to RTC may present a barrier for adoption (Kort & Van Hoof, 2012). The purpose of the current study was to determine the identity of variables that are predictive of older adults’ use and willingness to use RTC technologies. An exploratory factor analysis was conducted on questionnaire data collected from older adult participants in the United States. The questionnaire, compiled by researchers from Florida State University and Hogeschool Utrecht addresses demographics, technology experience, and attitudes and concerns related to e-Health and RTC technologies. Data were fit to the Unified Theory of Acceptance and Use of Technology (UTAUT) model (Venkatesh et al., 2003) using a multiple regression analysis. The results are intended to inform the design of training courses developed to address concerns related to RTC and increase the likelihood of RTC adoption in the older adult population.

**SESSION 255 (POSTER)**

**TRANSPORTATION**

**DO OLDER ADULTS NOTE THE CREDIBILITY OF A HEALTH INFORMATION SOURCE?: A MIXED METHODS HUMAN COMPUTER INTERACTION STUDY**

T.M. Lugér², J. Suls¹, T.K. Houston¹. 1. Center for Health Quality, Outcomes and Economic Research, Dept. of Veteran’s Affairs, Bedford, Massachusetts, 2. University of Massachusetts Medical School, Worcester, Massachusetts, 3. University of Iowa, Iowa City, Iowa

Previous studies of online health information-seeking have shown that seekers either do not pay attention to the source of health information encountered (Eysenbach & Köhler, 2002; Lugér, Suls, & Houston, in preparation), or perceive sources as equally credible (Eaustin, 2001). As a result, seekers may act upon erroneous health information (Cline & Haynes, 2001). This may particularly impact those searching to diagnosis a condition online; current estimates suggest that 35% of U.S. adults are “online diagnosticians,” and a third are aged 50 years or older (Fox & Duggan, 2013). Our objective was to examine variation in older adult attention to credible sources through a mixed methods human-computer interaction study. Participants (N=79; 50–84 years) were randomly assigned to use Google search engine or WebMD’s Symptom Checker to attempt to diagnose the symptoms of either mononucleosis or scarlet fever as depicted in a vignette. Participants engaged in a “think aloud” while searching, and general linear modeling was used to examine previously coded qualitative themes and quantitatively measured covariates. We found that participants discussed the credibility of information sources between 0 and 14 times in the search for symptom information. The multivariate model (F(56) = 19.73, p<001) showed that age and the perceived interactivity of the internet tool (Google vs. Symptom Checker) were significant predictors of discussions of credibility. Significant interactions between age, internet tool, and perceived interactivity were also predictive. Our findings may be used to inform web design to assist older adults to navigate the web and acquire accurate health information.

**DOES THE DREAM STEERING WHEEL OF OLDER AND YOUNGER DRIVERS DIFFER?**

M. Mossey¹, J.O. Brooks¹, P.J. Venhovens¹, P.J. Rosopa². 1. Clemson University International Center for Automotive Research, Greenville, South Carolina, 2. Clemson University, Clemson, South Carolina

Historically, the steering wheel has been viewed as a stylistic or utility component of the vehicle; however, as in-vehicle technology increases, the steering wheel may provide a way to integrate technologies into the vehicle. In this study, participants from three age groups used a paper prototyping method to design their ideal steering wheel for a concept vehicle, by building the steering wheel out of cardboard parts. Fifty-five participants (20 older adults 47 to 65 years of age, 20 young adults 18 to 30 years of age, and 15 male automotive engineering graduate students 18 to 30 years of age) were given an outline of a steering
wheel and asked to choose their ideal steering wheel functions (e.g. volume up/down, engine tuning adjustments, cruise control, etc.) as well as the types of controls (e.g. button, rocker switch, knob, etc.) for those functions and stylistic features. Images of each steering wheel design and follow-up questions were analyzed. Results did not reveal a universally consistent design; however, there were trends among the groups. The three groups selected largely similar controls, but tended to locate them differently. They created unique steering wheel structures and express their desires differently when asked about their designs. Based on the trends observed in participant designs for each group, two prototype steering wheels were designed to satisfy the needs of aging drivers. Next, these designs will be shared with automotive engineers with long term goal of proving a steering wheel specifically designed for the aging driver.

COMPARISON OF STEERING WHEEL GRIPPING PREFERENCE BETWEEN GENERATION Y AND BABY BOOMER DRIVERS

Y. Xi, M. Mossey², J.O. Brooks¹, P.J. Rosopa², P.J. Venhovens¹, 1. Clemson University International Center for Automotive Research, Greenville, South Carolina, 2. Clemson University, Clemson, South Carolina

The drivers’ experience with the steering wheel as well as the other vehicle interior components is of great importance for both safety and comfort. This may be especially true with regard to aging drivers involved in complex driving scenarios. This study explored the driver interactions with production steering wheels in four vehicles by using anthropometric data, driver hand placement, and driver grip design preferences for Generation-Y (defined as born between 1977 and 1994) and Baby Boomer (defined as born between 1946 and 1964) participants. Thirty-two participants (sixteen in each age group) selected their preferred grip diameters, responded to a series of questions about the steering wheel grip as they sat in the four stationary vehicles, and ranked ordered their preferred grip design. Drivers exhibited different assessments of preferred grip location. More than half of the drivers prefer to grip the steering wheel symmetrically on the top part. The others (n=15) who exhibit atypical hand placements are significantly shorter. Those hand placements include gripping with only one hand in at least one vehicle (n=5), gripping with asymmetrical hand placement (n=5) and gripping on the lower half of the steering wheel in more than one vehicle (n=5). A significant positive correlation between body height and preferred gripping diameter was found. The results of this study provide insight into the characteristics of driver interactions with the steering wheel and provide design guidelines to address the needs of the aging population.

THE EFFECT OF INDIAN CULTURE, CUSTOMS AND DEMOGRAPHICS ON MOTORCYCLE DESIGN

N. Shroff¹, T. Vallabhaneni¹, P.S. Deshpande¹, A. Sahai¹, H. Kazan¹, P. Tyler², J.O. Brooks¹, 1. Clemson University International Center for Automotive Research, Greenville, South Carolina, 2. Clemson University, Clemson, South Carolina

The motorized two-wheeler is vital in urban and rural areas of India due to its low cost and convenience. However, the side-saddle position of many older female passengers presents a challenge to manufacturers as the traditional Indian saree does not provide the freedom to sit cross-saddle. This may unbalance the motorcycle, and the long saree fabric may get sucked into the drivetrain, causing severe injuries or crashes. This project investigated seating behavior in a sample of Indian motorcycle riders and passengers in order to aid the design of a new seat and saree guard. A total of 35 male and 30 female Indian respondents with experience as either a motorcycle driver with a passenger or as a rider sitting side-saddle or cross-saddle were interviewed. In order to document diverse preferences and experience, participants were limited to ages 18-30 years or 40 years and above. Interviews revealed that driver behavior was affected by the age, weight and seating style of the passenger and that both the younger and older female riders desired a flatter, longer and wider seat. A larger saree guard, less protruding rear shocks, and a longer and wider foot rest were recommended for passenger comfort and safety. This session will describe how feedback about culture and customs from interaction with users of varying ages can inform product design to meet needs of older adults.

DRIVING AND OTHER MODES OF TRANSPORTATION USED BY RETIREMENT LIVING SENIORS

A.M. Myer1,2, C. Jansen-Grieve¹, S. Sousa¹, S. Gooderham¹, A. Crizzle¹,2, S.G. Brown¹, K. Pfeifer1. 1. University of Waterloo, Waterloo, Ontario, Canada, 2. Schlegel-UW Research Institute on Aging, Waterloo, Ontario, Canada

To learn more about the transportation patterns of this growing segment of the older population, surveys were obtained from 399 residents (272 women and 127 men) from four retirement villages in southern Ontario ranging in age from 65 to 100 (mean age 86.8 ± 5.7). Twenty-one percent of residents were still driving, compared to 68% who had stopped driving and 11% who had never driven. While younger drivers were predominately women (p<.001) consistent with findings on community dwelling seniors, there was no gender difference for current or former drivers. Those still driving were significantly younger (F = 3.48; p <.03), more independent (p<.001), and less likely to receive rides from others (p<.001) or use other modes of transport (p<.001). A logistic regression (N=365 -Log Likelihood Ratio = 233.876; Nagelkerke R² = .478), showed that level of independence (based on service use), receiving rides from others and using other modes of transport were significant predictors (p<.001) of driving, while age, gender and how long they had lived in the village were not. Not surprisingly, those still driving were less likely to use other forms of transportation, including rides from others (p<.001). A large proportion of the residents (82%) however, did receive rides from others (on average 5 times a month), most often from their children (62%), followed by other relatives (29%) and friends (23%). About half used the shuttle service provided by their village, while 44% used other forms of transportation; most often taxis (73%). Only 19% used public buses.

IS DRIVING GOOD FOR MENTAL HEALTH? FINDINGS FROM THE HEALTH AND RETIREMENT STUDY

E. Dugan, C. Lee, M. Devine, B. Gaines, Gerontology Dept, University of Massachusetts Boston, Boston, Massachusetts

Driving cessation may be associated with social isolation, depression, and mortality. This study investigates whether maintaining driving status over time is associated with psychological and emotional outcomes. Specifically, we examine the association over a 4-year period (2006-2010) between driving and alcohol consumption, depression, loneliness, social participation, and satisfaction with aging. Data were from participants in the Health and Retirement Study. Inclusion criteria for this study were: age 65 and older in 2006, a current driver in 2006, and complete data in 2010 (N=6,554). Alcohol use was coded heavy drinker and other (none, some), depression was measured by the CESD, social participation was the summed frequency of 7 items including: activities with grandchildren, volunteer with youth, charity or volunteer work, attend sports/social club, attend non-religious organizations, attend educational events, and play cards or games, loneliness was a 3-item scale (alpha 0.81, 3-9 range), and satisfaction with aging was determined by a single item. For the social participation, loneliness, and satisfaction with aging analyses subjects had to have completed the HRS Leave Behind Questionnaire in 2010 (N=7,378). Descriptive, bivariate, multiple and logistic regression analyses were conducted. Results showed that maintaining driving status was associated with being classified a heavy drinker (OR 2.53; CI 1.28-5.00, p=0.008), and higher social participation (B=1.45; CI 0.46-2.44, p=0.004). No statistically significant association was observed for loneliness, depression, or satisfaction with aging. The finding that heavy drinking was associated with continued driving is counterintuitive.
EQUALLY surprising was the lack of association between depression and driving cessation.

USING DRIVING SIMULATORS TO TRAIN DRIVERS FOR ADAPTIVE EQUIPMENT USE

M. Crisler1, E. Love1, M. Collins1, A. Baskins1, S. Scharf4, V. Hirth4, N. Drouin2, J.O. Brooks3, 1. Clemson University International Center for Automotive Research, Greenville, South Carolina, 2. Roger C. Peace Rehabilitation Hospital, Greenville, South Carolina, 3. Greenville Health System, Greenville, South Carolina, 4. Palmetto Health, Columbia, South Carolina

Training of aging drivers has become increasingly important over the past decade with the burgeoning aging population in the US. While on-road driver training provides realistic practice and preparation for on-road assessment, training using a driving simulator provides a safe and repeatable opportunity to supplement on-road training. This research details a process for training drivers to use adaptive equipment using a DriveSafety CDS-250 driving simulator. Such devices may be necessary after an injury or due to physical limitations associated with aging. This study was used to train the use of a left-foot accelerator (LFA). The training procedure was tested with young adults, and a subset of the tasks were piloted with older adults to ensure that they were able to complete the tasks effectively. Young adults completed a directed training procedure without and then with the LFA. The training exercises were designed to prepare the participants for common on-road driving maneuvers (braking, steering, etc.) by making directed control inputs (e.g. red light -> apply brake). After completing the exercises, participants completed more advanced simulated driving tasks. Participants then repeated the procedure using the LFA. Each task was repeated until they performed similarly to their non-LFA performance. Results suggest that LFA training using the CDS-250 simulator was successful and that the interactive exercises completed by both younger and older adults showed expected differences in performance across age groups (e.g., increased response time amongst older adults). Further research should utilize the full training procedure with older adults and compare to on-road training methods.

PERSONALITY AND LATE-LIFE DRIVING STATUS

E.A. Gadois, University of Massachusetts Boston, Boston, Massachusetts

Given the importance of driving to personal mobility and late life independence, understanding factors that predict driving status is needed. Environmental, roadway, and biomedical risk factors for driving cessation have been examined, but older driver temperament has not. Previous research has found that personality is predictive of driving behavior in youth and middle-age, but this has not been fully explored in older drivers. This study investigates the relationship between driving status and personality — specifically the factors identified in the Big Five model (i.e., neuroticism, extroversion, agreeableness, conscientiousness, and openness). Data are from the 2008 wave of the Health and Retirement Study (n=4,208 after excluding respondents who didn’t complete the Leave Behind Questionnaire (n=9,540) and those who never drove (n=204)). Driving status (operationalized as “no longer drive”, “still drive but not currently”, “currently drive with limitations”, and “currently drive without limitations”) was the dependent variable, and the Big Five personality scales (neuroticism, extroversion, agreeableness, conscientiousness, and openness) were independent variables. Statistical analyses included descriptive, bivariate analyses, and multinomial logistic regression. Preliminary analyses confirmed our hypothesis that personality is associated with late-life driving status. Results showed that that being high in neuroticism (F(3,50)=26.19, p<.001), low in extroversion (F(3,50)=25.68, p<.001), high in conscientiousness (F(3,50)=15.13, p<.001), or high in openness (F(3,50)=43.17, p<.001) was associated with current driving status. However, these relationships were attenuated by the inclusion of control variables in the fully adjusted model. This study demonstrates that personality adds a unique contribution to the prediction of late-life driving status.

ARE OLDER PEDESTRIANS AT INCREASED RISK? AN EXAMINATION OF OLDER PEDESTRIAN CASUALTY COLLISIONS IN VICTORIA, AUSTRALIA

J.A. Oxley, Accident Research Centre, Monash University, Monash University; Victoria, Australia

Driving is the major and safest form of transport for the elderly, however, a substantial proportion use alternative transport options, including walking. While walking has obvious benefits for health and well-being of individuals and the environment, older people are at greater risk as unprotected road users than they are as car occupants. Given the potential for increased numbers of older adults to be walking and walking further distances, it is essential that we understand the risks associated with walking and crossing roads. An analysis of pedestrian casualty collisions amongst adults aged 18 years extracted from the Police-reported casualty crash data between 2006 and 2011 was undertaken to gain a better understanding of the contributing factors to older pedestrian collisions, compared with younger adults. The findings showed that overall, pedestrian collisions were an urban phenomenon, with clusters around high pedestrian activity environments. Older adults aged 65+ years comprised 26 percent of all adult casualty pedestrian collisions, and were over-represented in fatal outcomes. Older pedestrians also tended to be over-involved in collisions with near-side and far-side vehicles, and collisions at driveways. They were also over-involved in serious injury collisions on roads with lower speed zones. This study has enabled a detailed description of adult pedestrian collisions and crash types in Victoria. These findings have implications that extend to the development of engineering, behavioural and enforcement countermeasures in particular to the elderly, such as reducing vehicle speed, and provision of safer crossing environments, and training opportunities aimed at improving elderly pedestrian crossing decisions.

EXAMINING THE NEEDS OF YOUNGER AND OLDER MOTORCYCLISTS AND RECOMMENDATIONS FOR FUTURE RESEARCH

M.A. Rupp, A.R. Dewar, M. Gentzler, Psychology, UCF, Orlando, Florida

Drivers aged 75 and older account on average for twice as many vehicle crashes as compared to drivers 45-54 years old (McGwin & Brown, 1999). In 2005, motorcyclists were 32 times more likely to be involved in a crash than a four-wheeled vehicle (NHTSA, 2005). As the Boomer Generation continues to retire, the number of older motorcyclists will continue to increase. Therefore, it is important to understand the unique issues of older motorcyclists. While the majority of the motorcycle research focuses on accident prevention, there is relatively little research examining the needs of older motorcyclists. In the present study, a sample of current motorcyclists between the ages of 55 – 71 were surveyed on several topics pertinent to safe riding. While many older motorcyclists reported few changes to riding due to the onset of normative aging declines, several reported changes to vision and reaction time as compared to younger riders. An additional theme identified by older motorcyclists was conspicuity of the motorcycle, which forced riders to become hyper-vigilant while on the road. Other common themes included further practice with safety maneuvers in motorcycle training courses, an increased need for customization (particularly in various weather conditions), and an increase in safety features (e.g., conspicuous lighting, anti-lock brakes). Anecdotally, a majority of older riders reported that the aging process did not hinder their riding ability. For some participants motorcycling has become a way of life, even therapy. Therefore, it is pertinent that the needs of older riders are further explored.
FACTOR ANALYSIS OF THE ASSESSMENT OF READINESS FOR MOBILITY TRANSITION QUESTIONNAIRE

N.W. Mullen1, B. Weaver2, T.M. Meuser1, M. Berg-Weger1, S. Marshall1, H. Tuokko6, M. Bedard1,2,3, 1. Centre for Research on Safe Driving, Lakehead University, Thunder Bay, Ontario, Canada, 2. Northern Ontario School of Medicine, Thunder Bay, Ontario, Canada, 3. University of Missouri-St. Louis, St. Louis, Missouri, 4. Saint Louis University, St. Louis, Missouri, 5. Ottawa Hospital Research Institute, Ottawa, Ontario, Canada, 6. University of Victoria, Victoria, British Columbia, Canada, 7. St. Joseph’s Care Group, Thunder Bay, Ontario, Canada

The Assessment of Readiness for Mobility Transition (ARMT) is a 24-item questionnaire (4 sub-scales) to measure emotional and attitudinal readiness to cope with mobility loss. In developing the ARMT, Meuser et al. (2011) used principle component analysis (PCA) followed by varimax rotation of components with eigenvalues >1. Recent guidelines suggest that: 1) factor analysis may be preferred to PCA when searching for underlying latent constructs, 2) the “eigenvalues >1” criterion may retain too many factors, and 3) oblique rotation may be preferred to orthogonal rotation. We conducted this study to determine if these guidelines would identify the same latent constructs as Meuser et al. reported. Data from 119 participants aged 72 to 92 were subjected to exploratory factor analysis (principal axis factoring, number of factors determined by scree-plot, oblimin rotation). This analysis identified 2 correlated factors (r = .389), which accounted for 39.9% of the variance. Twenty-two items had factor loadings ≥.3; 17 loaded on Factor 1, 5 on Factor 2, and 2 items on neither factor. Factor 1 concerned anxiety about mobility loss decreasing independence and becoming a burden; Factor 2 concerned resistance to address mobility loss, perceiving it as detrimental to quality of life. The total score and 4 subscales of the 24-item ARMT are intended to encourage discussion and planning in advance of mobility loss, and identify individuals who may benefit from mobility counseling. Further research will need to establish whether the 22-item ARMT and 2 sub-scales can help achieve these goals more effectively.

SURVEYING MOTORCYCLE RIDERS TO UNDERSTAND THEIR TECHNOLOGY USE

J. Brooks, M. Mossey, C. LaMance, E. Lowe, M. Crisler, P.J. Venhoven, Clemson Univ, Greenville, South Carolina

Motorcycle fatalities among aging riders have dramatically increased in the last decade. The growing interest in motorcycle riding and shifting demographics of riders towards older rider present considerable challenges to reducing motorcycle crashes. For years, motorcycle crash safety has been of concern and has been focused primarily on safety elements like helmet use and engineering aspects such as Anti-Lock Braking Systems. Motorcycle safety involves many aspects of vehicle and equipment design as well as operator skill and training that are unique to motorcycles. However, little research has focused on riders’ use of technologies (i.e., cell phone, navigation system, etc.) or the types of riders who use them. This survey sought to create an overview of the types of riders who own Harley-Davidson motorcycles, the kinds of technologies they use while riding, issues or non-issues with these technologies, as well as rider demographics and riding behavior. Riders interviewed tended to be aging males (M = 50.81 years) with approximately 25 years riding experience who ride an average of 10,223 miles per year. The most common technologies reportedly used by participants included: smart phones (52%), standard radios (34%), mp3/iPods (27%), cell phones (24%), and navigation systems (21%). Overall, riders suggested that the technology they use is relatively easy to use. The mean rating of each technology ranged from 4.15 to 4.46 where 1 is very confusing and 5 is very easy. The prevalence of technology use in aging populations in vehicles as well as motorcycles.

SESSION 1410 (POSTER)

EDUCATIONAL EVALUATION

ACTIVE, MULTIMODAL TEACHING STRATEGIES EFFECTIVE FOR GERIATRIC EDUCATION IN GROUPS > 100!

D.L. Brown1, J. Kuester1, G. Manzi1, N.E. Havas1, S. Denson1, K. Denson1, D. Simpson1, E.H. Dubie1, 1. Medical College of Wisconsin, Milwaukee, Wisconsin, 2. Aurora Health Care, Milwaukee, Wisconsin

Family Medicine residents at the Medical College of Wisconsin attended a series of half-day educational sessions during 2011-12 designed to promote quality clinical care for elders. A multidisciplinary collaborative designed a 20-hour geriatrics curriculum utilizing multiple media formats and active learning strategies. Residents’ positive overall curriculum effectiveness ratings [5.6 where 7 = excellent] prompted the collaborative to extend and adapt this approach to practicing providers. The adapted residency sessions yielded a five-session geriatrics educational track as part of a continuing professional education accredited course for primary care providers [January 2013]. As with residency modules, didactic instruction was replaced with interactive teaching/learning strategies ranging from game playing (e.g., incontinence bingo), case based learning, hands-on exercises using adaptive devices (e.g., cane, walker) to simulations (e.g., a hearing test mimicking specific types of hearing loss common in older patients and glasses for specific vision loss), many supported by multimedia (e.g., videos, interactive websites including Cornell University’s Environmental Geriatrics http://www.environmentalgeriatrics.org/). 220 primary care providers (70% MDs) attended at least one session with the geriatrics sessions recording the highest number of attendees (30 to >100) despite running concurrently with other sessions. The overall geriatrics curriculum effectiveness rating = 6.11 (7= excellent). Caring for geriatric patients requires learners to actively engage with and apply evidence-based concepts and principles. Active participatory teaching strategies can be successfully accomplished for health care professional groups of >100 as demonstrated by attendance and participant ratings.

INTEGRATING TEAM-BASED LEARNING (TBL) WITH WORKSHOPS IN GERIATRICS CLERKSHIP: A PILOT TEACHING PROJECT TO ENHANCE THE 3RD YEAR MEDICAL STUDENTS’ ACTIVE LEARNING, CLINICAL PROBLEM SOLVING, AND DECISION MAKING IN TREATING OLDER ADULTS WITH FALLS

H. Cheng, medicine, university of virginia, Charlottesville, Virginia

Background: TBL was designed to enhance active learning and problem solving in health professions education. UVA has made a shift from giving lectures to training students’ ability to solve clinical problems by successfully implementing TBL during the pre-clerkship year in Next Generation Curriculum since 2010. However, TBL in clerkship was not reported in geriatrics clerkship in the literature and has not been disseminated to the clerkship year yet at UVA. Therefore, this pilot teaching project was designed to integrate TBL with an existing case-based fall prevention workshop and thus potentially to enhance students’ active learning, problem solving, and decision making for the 3rd year medical students. Methods: the fall prevention workshop was re-designed by integrating and applying TBL essential principles and components as following 1). Remove powerpoint slides; 2). Email learning objectives, TBL logistic, and required reading materials to each student via email 2-3 days before the class. Students were asked to read required reading materials before the class; 3). Two teams were formed by themselves (2-6 per team) in the class to complete Individual Readiness
Efficacy Scale, a valid 44-item survey. Data from these assessments
testing the development of this educational initiative.

One of the primary goals of our Hartford Center for Geriatric Nurs-

ing Excellence is to increase the number of nurse faculty able to pro-
vide effective teaching-learning experiences for nursing students that
improve their knowledge of geriatrics and nursing care of older adults
and that ultimately lead to better care and better health outcomes for
the geriatric population. The program targets nurse faculty at associate
and higher degree programs in the Upper Midwest, and in Tribal Colleges.
The program developed to achieve this goal is called Facilitated Learn-
ing to Advance Geriatrics (FLAG); the objectives of FLAG are to: 1)
develop nursing faculty knowledge of geriatrics and gero-informatics;
2) improve their teaching effectiveness; and, 3) develop leadership abili-
ties in implementing education change in their home institutions. Learn-
ers participate in a 4-5 day workshop, and engage in a year-long men-
tor relationship with FLAG faculty. Evaluation of effectiveness of the
program is based on participants’ assessment of their achievement of
the program’s objectives, and their self-evaluations of teaching effect-
iveness before and after the workshop, using the College Teaching Self
Efficacy Scale, a valid 44-item survey. Data from these assessments
have been collected from 2008-2013, the term of the funding. Matched
t-test analysis results comparing pretest to posttest ratings from 100 par-
ticipants demonstrates significant increase in CTSES scores each year.
Demographics on this sample show no significant differences with the
overall sample of 165. The FLAG program has facilitated participants’
increased teaching effectiveness and overall meeting of intended objec-
tives.

OUTCOMES FROM WEB-BASED INTER-PROFESSIONAL
LEARNING AND EVALUATION ON A LARGE SCALE

P. Boling, A. Dow, S. Hobgood, D. DiazGranados, Virginia
Commonwealth University, Richmond, Virginia

Background: Logistical challenges hinder longitudinal in-person
small-group experiences for interprofessional education so we created
an interactive web-based system to foster and measure collaboration
between virtual patients. Methods: We created a case system that
annually engages more than 600 senior students from the schools of
medicine, nursing, social work and pharmacy in small teams for sev-
eral weeks. In a complex unfolding geriatric case, every student receives
discipline-specific patient information, shares data in an electronic chart,
and answers questions individually and then collaboratively, building
competency in geriatrics and teamwork. Each choice for 50 questions
may be selected, forcing 526 decisions, linked to core competencies.
Results: Team scores from the first 295 users on 40 teams varied from
2850 to 6530 (90% of maximum possible). Social work students’ scores
(Mean = 1480), were significantly lower (p<0.01) than mean scores
for students from medicine (3780), nursing (3540), and pharmacy (3220),
which were statistically similar. This reflects a “medical” focus of many
questions. Strongest univariate predictors of team score were individ-
ual scores, logins, and post views by the team. Preliminary regression
analyses show that number of team views of the dialogue box is the
strongest predictor. Competency-specific performance is also measured.
Conclusions: A virtual case system supports asynchronous inter-pro-
essional learning and discriminated between individual performance
and team performance, and created a means of evaluating the strengths
and weaknesses of the curriculum. This system represents a novel, effec-
tive way to teach and assess geriatric knowledge and inter-professional

SESSION 265 (POSTER)

END-OF-LIFE

UNDERSTANDING OLDER ADULTS’ DECISION MAKING
THROUGH AN EXTENDED MODEL USING PROSPECT

THEORY

R.D. Romo1, A.K. Smith2, C.S. Dawson-Rose3, A.M. Mayo3,
M.I. Wallhagen1, 1. University of California, San Francisco - School
of Nursing, San Francisco, California, 2. University of California,
San Francisco - School of Medicine, San Francisco, California, 3.
University of San Diego - Hahn School of Nursing, San Diego,
California

Purpose: Prospect theory is a decision-making theory that provides
a framework to understand how decisions are made and has been used
by researchers examining older adults’ decisions at the end-of-life. We
explored its use and propose an extended view of the theory. Method:
We searched online databases (PubMed, CINAHL, PsychInfo) and
reviewed existing literature on the use of prospect theory as a frame-
work for end-of-life decision making among older adults. Finding:
Prospect theory posits that decision makers’ value options based on how
“close” or “far” the options are relative to a neutral reference point. They
then choose between options accordingly. This view is limited because
that the reference point is based on a single attribute, such as health
status and may not capture the full complexity of decision making. This
limitation could also explain inconsistencies found in research. We
extend prospect theory to include a reference point based on multiple
factors, including prognostic awareness, disease/health experience, qual-
AN INTERPROFESSIONAL INSTRUMENT TO EVALUATE KNOWLEDGE OF END OF LIFE CARE: MODIFICATION OF THE ELNEC-KAT

J. Lange1, D.R. Mage2, 1. Quinnipiac University, Hamden, Connecticut, 2. Fairfield University, Fairfield, Connecticut

Purpose: As part of the ELDER (Expanded Learning and Dedication to Elders in the Region) Project, the aim of this study was to evaluate the psychometric properties of a modified tool measuring EOL care knowledge among interprofessional healthcare providers. Ninety-three nurses, aids, therapists, social workers and pastoral care providers from five home or long term care agencies completed the 50-item, multiple choice ELNEC-KAT-I. Model: The ELNEC-KAT is a condensed version of the original 106-item test (Ferrell et al., 2005) measuring nursing EOL care knowledge. Original items were derived from the literature in nine content domains. Strongest items from each domain were selected for the 50-item version, and psychometrics compared favorably with the original test (Lange et al., 2010). In this study, item wording was modified from the 50-item ELNEC-KAT to suit varied provider roles and education levels. Outcomes: Internal consistency estimates for the ELNEC-KAT-I exceeded those of the 50-item ELNEC-KAT in all but two domains. The total scale internal consistency estimate was .91, versus .84 on the 50-item ELNEC-KAT and .92 on the original version. Biserial correlations and item difficulty indices revealed that all but one item discriminated well between high and low performers, and all but two items were at appropriate difficulty levels. Implications: ELNEC-KAT-I is a useful tool to evaluate baseline knowledge and the effectiveness of EOL training among varied healthcare providers employed in home and long term care settings. Testing is needed to evaluate its utility in disciplines not included in this sample and in other care settings.

PROBLEM SOLVING THERAPY FOR HOSPICE CAREGIVERS: THE PISCES TRIAL

Stress and caregiver burden can negatively impact the health of informal caregivers of hospice patients, namely the spouses, family, friends or others who take care of a loved one at the end of life. Emotional needs of individuals caring for dying persons in their home are not well attended. We are examining a cognitive behavioral intervention based on principles of problem-solving therapy designed to foster adaptive situational coping and behavioral competence. This paper presents preliminary findings of this ongoing trial. The intervention is labeled Problem-solving Intervention to Support Caregivers in End of Life care Settings (PISCES). We are conducting a randomized clinical trial in which informal hospice caregivers are randomly assigned to a group receiving standard hospice care with the addition of “friendly visits” providing social support (attention control group) or a group receiving standard hospice care with the addition of PISCES delivered face to face (intervention group 1) or a group receiving standard hospice care with the addition of PISCES delivered over video (intervention group 2). We are using various video-conferencing tools to account for various residential infrastructures and degrees of experience with computer technology in the home. To date, we have assessed 695 subjects for eligibility. Of these, 495 subjects were excluded either because they did not meet inclusion criteria (n=55), declined to participate (n=256) or could not be contacted (n=184). Two hundred hospice caregivers have been enrolled in the study (65 in the attention control group, 68 in the face-to-face PISCES group, and 67 in the video- PISCES group). Findings indicate that hospice caregivers see value in the use of video for the delivery of a supportive intervention and appreciate the structure of an intervention that is designed specifically for the context of hospice care.

AUTONOMY AND SUPPORT IN DYING: A PHENOMENOLOGIC VIEW OF DEATH AT HOME

D.N. Solomon, OHSU, Portland, Oregon

Purpose/Aims: 1) Explore lived experiences of family members of a patient who died at home; and 2) Interpret how dying at home may influence patterns of bereavement. Rationale/Conceptual Basis/Background: Fifty to 94 percent of terminal patients express a desire to have a peaceful death at home, surrounded by family. Yet only 25 to 31 percent of Americans are able to accomplish this. Dying at home saves healthcare resources, extends survival, and is associated with improved mental health for patients and family. The widening gap between patient and family wishes for preferred place of death and actual place of death is of growing clinical and policy concern. Methods: This study followed family of a 78-year-old female diagnosed with Amyotrophic Lateral Sclerosis. In line with her wishes to die at home with self-determination, she voluntarily forewent food and drink. Qualitative interviews were conducted with the patient before death and bereaved family members after. Interviews were analyzed for paradigm cases, exemplars, and themes. Results: For family members, staying home with a dying patient evoked a sense of sanctity, dignity, peacefulness, grace, and life completion. Themes included patient autonomy (driving her own course), not being a burden via acceptance of end of life so family members could accept as well, and healthy bereavement due to open communication and sharing of emotions before death. Implications: With increasing numbers of hospital deaths, it is hoped this study will inform research promoting optimal end of life care.

INTER-PROFESSIONAL RELATIONSHIPS: AN OVERLOOKED INFLUENCE ON END-OF-LIFE TRANSITIONS FOR OLDER ADULTS: A QUALITATIVE STUDY IN ENGLAND

B. Hanratty, N.K. Valtorta, E. Lowson, G. Grande, J. Addington-Hall, S.A. Payne, J. Seymour, Hull York Medical School, University of York, York, North Yorkshire, United Kingdom

Context: Transitions between care settings are vulnerable points in the care pathways of older adults at the end-of-life. This study focuses on inter-professional working around end-of-life care transitions. Objectives: 1) After attending this activity, participants will be able to understand patient, family caregiver and professionals’ perspectives on how inter-professional working influences end-of-life care transitions. 2) Attendees will be encouraged to discuss how a renewed focus on outcomes for patients and carers, rather than processes, may improve experiences of transitions. Methods: In-depth qualitative interviews were conducted with 30 end-of-life patients aged 75+: 118 family carers of elderly decedents; and 43 providers and commissioners of services in primary care, hospital, hospice, social care and ambulance services in England, UK. Results: A number of themes will be discussed, including: information transfer; organisational and cultural divides; professional responsibilities. Participants described how caregivers move within and between settings with incomplete or absent information. Resulting deficiencies in care were a concern for family carers, who felt obliged to fill any gaps, whereas staff identified implications for their own decision-making. Factors that detracted from good patient care ranged from organisational (e.g. IT systems) to cultural differences, such as an organisational focus on performance targets. Professionals tended to attribute deficiencies in care to their opposite numbers in health or social care,
though family physicians’ disregard for protocols was a shared source of frustration. Professionals rarely acknowledged responsibility for the impact of inter-professional tensions on patients and families. Conclusions: Inter-professional relationships are an important influence on patient and family experiences of end-of-life care, and may be an overlooked source of inequity.

CHANGE IN DYSPNEA SYMPTOMS OVER TIME AMONG TERMINALLY ILL HOME CARE CLIENTS IN ONTARIO, CANADA
S. Freeman1, J. Hides1, T. Frise Smith2, 1. Health Studies and Gerontology, University of Waterloo, Waterloo, Ontario, Canada, 2. Nipissing University, North Bay, Ontario, Canada
INTRODUCTION: Dyspnea is one of the most disturbing experiences for individuals and their caregivers towards the end of life. This study investigated dyspnea symptoms among community dwelling individuals receiving palliative home care services in Ontario, Canada. METHODS: Secondary data analysis, using the interRAI Palliative Care (interRAI PC) assessment at initial and follow-up assessment (N=6,756) examined changes in and predictors of dyspnea symptoms. The interRAI PC gathers comprehensive information as part of regular clinical practice and is now mandated for all palliative homecare and hospice clients residing in Ontario, Canada. RESULTS: Dyspnea was present in 56.8% of clients at initial assessment, decreasing to 47.2% at follow-up. Dyspnea symptoms improved for 20% yet worsened for 25%. Of those who did not exhibit dyspnea at initial assessment, 35% exhibited new signs of dyspnea at follow-up. In comparison, among those with dyspnea at initial assessment, 21% no longer exhibited dyspnea at follow-up. Changes in dyspnea symptoms are discussed in relation to estimated prognosis as well as clinical characteristics including functional, cognitive, psychosocial, and demographic variables. Regression models support the strength in predicting these changes. Results are discussed in the context of the interRAI PC Dyspnea clinical assessment protocol as a resource for care staff. CONCLUSION: Integrated approaches using information from the interRAI PC dyspnea clinical assessment protocol assist in recognition and treatment of clients at risk; inform decision making during care planning to address dyspnea at the person-level, and thereby improve quality of care and quality of life at the end of life.

SESSION 270 (POSTER)

FAMILY CAREGIVING

USING OASIS ITEMS TO PREDICT RE-HOSPITALIZATION FOR HOME HEALTHCARE ELDERLY PATIENTS
H. Tao, University of Wisconsin Milwaukee, Milwaukee, Wisconsin
Background: Research to date on the prediction of re-hospitalization has not been conclusive. Social environment factors such as living arrangement, primary informal caregiver, type of primary informal care, and frequency of informal care received have been examined, each with limitations or uncertainty. Objectives: to examine the high risk factors including social environmental factors to predict re-hospitalization among patients receiving home healthcare. Methods: This study is a retrospective study using Outcome and Assessment Information Set (OASIS) data. Results: Among 1268 elderly home health care patients who were 65 years or older, 212 (16.7%) were re-hospitalized within 30 days after discharge from acute care hospital. Being male, or had medium cognitive impairment increased the likelihood of re-hospitalization; Receiving informal assistance other than the ADL and IADL, or had a higher functional ability decreased the likelihood of re-hospitalization. Patients receiving more informal care, or had a high clinical status tend to have a higher functional ability, thus unlikely to be re-hospitalized; while those being older, obesity, or receiving ADL and/or IADL tend to have a lower functional ability, thus more likely to be re-hospitalized. Discussion: Among the predictors, social environmental factors influenced re-hospitalization directly or indirectly through impacting the functional ability. Considering type of social environmental supports influenced on re-hospitalization by both ways, more studies are needed to explore more fully the necessity of some types of assistance, such as environmental support, psychosocial support, facilitated medical care, health care agent and conservator of person, and the linkages between these and re-hospitalization outcomes.

RESOURCEFULNESS TRAINING FOR WOMEN DEMENTIA CAREGIVERS: FEASIBILITY OF TWO PRACTICE METHODS
D.L. Morris, J.A. Zauszniewski, T. Au, B. Napoleon, University Center on Aging & Health, Case Western Reserve University, Cleveland, Ohio
Almost 44 million women in the United States are caregivers for elders with dementia and experience extreme stress that compromises their health. Interventions to teach them resourcefulness skills for managing stress may promote their optimal health and facilitate continued caregiving. However, before testing the effectiveness of resourcefulness training (RT), evaluation of its feasibility is important. Aims. This pilot intervention trial examined the feasibility of two methods for practicing skills taught during resourcefulness training (RT) to 63 women dementia caregivers, including journaling (J) and digital voice recording (R). Methods. Data were collected from the caregivers after resourcefulness training (RT) with journaling (J) or digital recording (R). Caregivers were asked to describe challenges encountered during RT, including the training session when the skills are taught and its practice components. Number of journal entries and recordings and word counts for both practice methods were examined. Results. Caregivers in both groups described similar challenges: time management (n=11); collecting thoughts (n=9); managing feelings (n=7); and using RT skills (n=5). Caregivers in RT-J listed journaling (n=8) and privacy (n=1) while caregivers in RT-R noted recording (n=6) and honesty (n=1). Caregivers in RT-R used more words (M=5446) than those in RT-J (M=2792). However, those in RT-J journaled more frequently (M=27) than caregivers in RT-R recorded (M=17). Conclusion. The findings showed journaling was more frequent than recording, but more words were expressed during recordings. Because intervention feasibility is important for future RT effectiveness testing, alternatives to the journaling and recording methods for practicing RT skills should be considered.

NEED FOR RESOURCEFULNESS TRAINING FOR WOMEN CAREGIVERS OF ELDERS WITH DEMENTIA
D.L. Morris, J.A. Zauszniewski, T. Au, W. Yolpant, University Center on Aging & Health, Case Western Reserve University, Cleveland, Ohio
Nearly 44 million American women are caregivers of elders with dementia and may experience overwhelming stress that adversely affects their health. Interventions to teach them resourcefulness skills for managing stress may promote their optimal health and facilitate continued caregiving. However, the effectiveness of resourcefulness training (RT) cannot be examined until its need is established. Aims: This pilot intervention trial with 138 women dementia caregivers examined the need for RT in women dementia caregivers using subjective and objective data. Methods. Data on resourcefulness, stress, and depressive symptoms were collected before and after RT. Data analysis focused on baseline resourcefulness scores (higher scores = lower need), scores for caregivers who dropped from the study versus those who stayed in it, correlations among resourcefulness, stress, and depressive symptoms, and caregiver post-RT evaluation of need for self and others. Results: Baseline resourcefulness scores were normally distributed; only 4% (n=5) scored in the uppermost 15% of the possible scoring range. Reasons for ending participation were unrelated to need for intervention, however caregivers who dropped out scored two points higher on average on the resourcefulness scale than those who remained in the study. Lower resourcefulness was associated greater stress (r=-.37, p<.001)
and depressive symptoms ($r$=-.53, $p$<.001). Of the 63 caregivers who received RT, 82% (n=52) reported a felt need for RT; 93% (n=59) believed other caregivers need RT. Conclusions: The results suggest a substantial need for RT in women dementia caregivers and support moving forward with testing RT effectiveness for reducing caregiver stress and depressive symptoms.

**CAREGIVER STRESS AFTER A FAMILY MEMBER ENROLLS IN A DAY PROGRAM FOR MEMORY DISORDERS**

C.L. Williams, R.M. Tappen, L. Wiese, M. Corbett, Christine E. Lynn College of Nursing, Florida Atlantic University, Boca Raton, Florida

When a family member is cognitively impaired, caregivers experience high levels of emotional stress with subsequent increased risk of negative health outcomes. Conflicting findings exist on effectiveness of day programs in reducing caregiver stress. The purpose of the study was to compare caregiver stress levels from enrollment of a family member in memory center day program to 1 month following enrollment. The sample consisted of 23 caregivers. Caregivers (CG) were spouses (64.5%) children (32.3%) or siblings (3.2%). Family member-enrollees had varying degrees of cognitive impairment (mean MMSE = 20.3, SD = 7.2). Sixteen subjects were mild, (MMSE =19-28), four moderate (10-18), and three severe (0-9). Subjects were middle to upper income and all spoke English as their primary language. CG stress was measured by self report using the Perceived Stress Scale (PSS) and the Depression, Anxiety, Stress Scales (DASS). Systolic blood pressure was used as a physiologic indicator of stress. Paired t-tests showed that stress measured by the DASS stress subscale ($t$ = 2.7, $p$ < 0.01) and blood pressure ($t$ = 2.24, $p$ < 0.03) decreased significantly over time. Mean scores on the PSS also decreased and t-test results approached significance ($t$ = 1.95, $p$ < 0.06). Although men and women’ BP did not differ at enrollment, women’s BP was significantly lower than men’s at one month after enrollment ($t$ = 2.4, $p$ < .02). Further study is needed to examine differential effects on men and women as well as spouses and other family members.

**INFLUENCE OF FILIAL OBLIGATIONS AMONG AFRICAN AMERICAN, HISPANIC AND NON-HISPANIC CAUCASIAN FAMILY CAREGIVERS**

F. Epps, Our Lady of the Lake College, Baton Rouge, Louisiana

Filialism and filial piety influences a caregiver’s sense of obligation to provide care. This sense of obligation to care is often overlooked in exploring ethnic caregivers’ positive appraisal of caregiving for dependent, older adult family members. With the nation’s increasing diversity in older persons and their caregivers, it is important to better understand the impact of obligation on family caregiving. The purpose of this research was to examine the relationships between filial obligation and positive appraisal of caregiving in African American, Hispanic and non-Hispanic Caucasians residing in southeastern Louisiana. Data was retrieved from a larger study that explored cultural values, religiosity and the positive appraisal of caregiving among family caregivers of dependent elders. Sixty-nine African American, Hispanic and non-Hispanic Caucasian family caregivers participated in the study completing the Obligation and Positive Appraisal of Care Scales. Overall scores on the Obligation Scale for all family caregivers ranged from 14 to 35 (maximum score) with a mean score of 29.88. There was an overall significant correlation between filial obligation and positive appraisal of caregiving. African American and non-Hispanic Caucasian family caregivers revealed a significant correlation between filial obligation and positive appraisal of caregiving. African American family caregivers positive appraisal of caregiving scores were significantly higher than Hispanics and non-Hispanic Caucasians. Filial obligation is pertinent to the family caregiver’s positive appraisal and may influence ability to adapt positively to the caregiving experience. Further research is necessary to plan culturally responsive and sensitive interventions to meet the needs of family caregivers of diverse populations.

**HELP IS HERE: A PILOT STUDY OF A NOTEBOOK RESOURCE FOR FAMILIES OF PERSONS WITH DEMENTIA**

M. Hodges1, A.P. Hill2, G. Luhr3, M. Petrovic1, J. Green1, H. Allen1, B. Wright3, 1. Center for Outcomes Research and Education, Providence Health & Services, Portland, Oregon, 2. Providence Medical Group, Providence Health & Services, Portland, Oregon, 3. Columbus University School of Social Work, New York, New York

Family caregiving for persons with Alzheimer’s disease or a related dementia (ADRD) is stressful, and caregivers are often ill-prepared for the responsibilities. The objective of this pilot study was to examine the effects of an educational resource for increasing family knowledge, self-efficacy and reducing stress. The notebook Help is Here was written to equip primary care physicians with a means to educate and support the family caregivers of patients with ADRD. The sample included 420 caregivers whose family members received care from five primary care clinics within the Providence Health & Services network in Portland, Oregon. Using a post-post comparative design, a treatment group received the notebook after completing a baseline survey (n=223), with a follow-up survey four months later to examine the notebook’s effects on caregiver self-efficacy and other outcomes. A control group (n=197) completed the surveys but received no notebook. Treatment group participants saw an increase in caregiver self-efficacy, from 7.51 at baseline to 7.83 at follow-up ($p$<.01). There was no comparable change among the control group. Likewise, treatment group participants saw a reduction in psychological distress, from 4.59 at baseline to 3.99 at follow-up ($p$<.01), with no comparable decline among controls. Effects were maintained through multiple regressions controlling for other differences between the two groups. Findings suggest the Help is Here notebook is a useful resource for family caregivers of persons with dementia in improving caregiver self-efficacy and other health outcomes, and that it may effectively encourage caregivers to seek more emotional support for buffering caregiver stress.

**PREDICTORS OF SLEEP IN FAMILY CAREGIVERS OF INDIVIDUALS WITH DEMENTIA**

H. Peng, Y. Chang, SUNY-Buffalo, Amherst, New York

Introduction: Caregivers of individuals with dementia pose special challenges. The nature and severity of these difficulties vary according to illness and may differentially affect the well-being of family. This study was based on insomnia 3P model (predisposing, precipitating, and perpetuating factors) to identify significant predictors (depression, coping, caregiver burden, caregiver health status, sleep hygiene, and care-recipients’ sleep) of caregivers’ sleep. Methods: This study used a cross-sectional design. Participants were recruited from the Alzheimer’s Association Western New York Chapter at Buffalo. Caregivers’ sleep were measured by Actigraph (a wrist-watch measuring movement and light; wore for 7 days) and Pittsburg Sleep Quality Index (PSQI). Other measures included the Center for Epidemiologic Studies Depression Scale (CES-D), Caregiver Burden Inventory (CBI), the Cumulative Illness Rating Scale (CIRS), the Sleep Hygiene Index (SHI), and Brief Cope. Regression statistics were used for data analysis. Results: Forty-three caregivers participated in the study. Approximately 92% of caregivers experienced poor sleep quality. The mean sleep hours was 5.99 (± 1.56) with 37.2% of them sleeping less than 5 hours per night. Caregiver depression, caregiver sleep hygiene, and care-recipients’ sleep were significant predictors of caregiver subjective sleep quality, explaining 59.4% of the total variance. Caregivers’ coping and health status were significant predictors of caregiver objective total sleep hours as measured by Actigraph, explaining 19.4% of the total variance. Conclusion: Family caregivers often experience sleep problems that was influenced by several factors. The study findings provide evidence for
future research to identify effective interventions to improve caregivers’ sleep quality.

COMPASSION FATIGUE IN ADULT DAUGHTER CAREGIVERS FOR OLDER ADULTS WITH DEMENTIA
J. Day, School of Nursing, Duke University, Durham, North Carolina

Purpose: Family caregivers for a parent with dementia often experience negative emotional consequences. These caregivers may also be at risk for compassion fatigue, an adverse consequence of caring for individuals in need, resulting in avoidance and detachment. Compassion fatigue has not been fully studied in family caregivers and this research explored the concept to provide a detailed description of compassion fatigue in daughter caregivers for older adults with dementia.

Design and Methods: This qualitative descriptive study included in-depth interviews with 14 adult daughter caregivers for parents with dementia. The limited knowledge development on compassion fatigue lends itself well to a qualitative descriptive method. Interviews were analyzed using qualitative content analysis. Results: Daughter caregivers articulated contributing factors, particularly an exposure to suffering and an empathic response. Data also provided evidence for indications of compassion fatigue, including helplessness and a decreased relationship quality between caregiver and care recipient. Daughter caregivers remained emotionally attached to their parent and stated a moral obligation to continue caring, even in considerably difficult circumstances. Attachment may represent a protective factor against compassion fatigue. Implications: Findings from this study clarify the concept of compassion fatigue in adult daughter caregivers. Future research steps may include exploring trajectories of compassion fatigue, including its development and impact over time through a longitudinal study. Knowledge from this study facilitates the development of instruments to measure and screen for compassion fatigue and the development of nursing interventions to reduce compassion fatigue through improving relationship quality, decreasing perceived suffering, or other supportive measures.

MEDICATION MANAGEMENT AMONG MALE AND FEMALE CAREGIVERS OF PATIENTS WITH MEMORY LOSS
C.M. Amspaugh, L.K. Tamres, M.L. Knox, J. Lingler, M. Happ, J.B. Seaman, J.A. Erlen, University of Pittsburgh School of Nursing, Pittsburgh, Pennsylvania

Background Family caregivers are integral to enabling patients with memory loss to live at home. Fewer males than females take on this role, and may require different caregiving support. Research comparing differences between male and female caregivers is limited; findings are conflicting on utilization of resources and other support. This study examined differences in medication management between male and female family caregivers. Methods This secondary analysis included 54 caregivers participating in a randomized-clinical trial that sought to improve caregiver medication management. Female (n = 27) and male (n = 27) caregivers were matched on age, race and relationship to patient. We measured medication management errors, use of formal/informal support, co-morbidities, and patient symptom severity. Differences were examined using t-tests and Chi square. Results Both male and female caregivers made an average of 3 medication management errors, reported similar levels of social support (p = .56), and were caring for patients with an average of 8 co-morbidities. Patient behavioral and memory problem scores and cognitive status were equivalent between the two groups. Fewer males (26%) reported receiving help with medications than females (38%), a finding that was statistically significant (p < .001). Conclusions Despite making as many medication errors as female caregivers, male caregivers were less likely to receive help managing the patient’s medications. Further research is required to develop and test interventions that help male caregivers maximize available support for managing caregiving responsibilities including medication management.

CAREGIVER BURDEN AND HEALTH-RELATED QUALITY OF LIFE OF INFORMAL CAREGIVERS IN 8 EUROPEAN COUNTRIES
M.H. Bleijlevens, S.M. Zwakhalen, R. Consortium, Health Services Research, Maastricht University/CAPHR, Maastricht, Netherlands

The literature extensively reports on caregiver burden and health-related quality of life (HRQoL) of informal caregivers of persons with dementia (PwD). However, country differences are rarely taken into account. In addition, little is known about these outcome measures when PwD make the transition from home to institutional long-term care (ILTC) facilities. As part of the RightTimePlaceCare project, we investigated differences in caregiver burden and HRQoL of informal caregivers of PwD in 8 European countries and 2 changes after transition from home care to ILTC. This cohort study (using a 3 month FU) comprises two groups of participants: informal caregivers of PwD who 1) were recently admitted to an ILTC facility and 2) receive formal home care. Outcome measures included caregiver burden (Zarit Burden Interview) and HRQoL (EQ-5D). Statistical analyses focused on descriptive comparisons between groups and countries. Changes after transition of PwD were analysed with independent-sample t-tests or Chi2-tests. Overall, informal caregivers of PwD at home experienced more burden compared with informal caregivers of PwD in ILTC facilities (32.4 vs. 24.9; p < .001). HRQoL of informal caregivers was only slightly higher when PwD lived in ILTC facilities (0.78 vs. 0.76; p < .05). Large differences between countries on both outcome measures were found. Informal caregivers of PwD who made the transition to an ILTC facility experienced less burden (22.4 vs. 35.4; p < .001). Our results provides insight in the significant impact on informal caregivers of providing care for PwD and highlight the positive impact on caregiver burden after transition to an ILTC facility.

STRESSED OUT: FACTORS INFLUENCING BEHAVIORAL VARIANT FRONTOTEMPORAL DEMENTIA CAREGIVER STRESS
B.E. Morgan1, L.M. Massimo1, M. Ersek1, M. Grossman2, I. University of Pennsylvania School of Nursing, Philadelphia, Pennsylvania, 2. University of Pennsylvania School of Medicine, Philadelphia, Pennsylvania

Caregivers of individuals with bvFTD experience more stress than caregivers of individuals with AD and other forms of dementia. Only one previous study has examined factors related to caregiver stress in each stage of the disease. This study examines the associations between caregiver stress and factors affecting stress early and late in the duration of bvFTD disease progression as compared to AD. A cross-sectional design compared 23 bvFTD and 18 AD caregivers of subjects with early (< 5 years symptom duration) and late (≥ 5) stage disease. Zarit Burden Inventory (ZBI) was the dependent variable and measure for caregiver stress. Independent variables were: Philadelphia Brief Assessment of Cognition (PBAC), TRAILS, Digit Span Backwards, and Neuropsychiatric Inventory. Student’s t-tests were used to compare groups and Pearson’s correlations to assess independent variables asso- ciated with caregiver stress. Groups were demographically matched for sex and education, but not age (bvFTD = 61.7±10; AD = 72±9). Comparison showed early-bvFTD caregivers reported higher stress than early-AD caregivers (bvFTD = 47±18, AD = 34±14), although the dif- ferences were not significant (p = 0.07), while caregiver stress in late-bvFTD was statistically equivalent to late-AD. Early-bvFTD stress was associated with higher patient executive dysfunction and behavioral impairments, including depression and irritability, while late-bvFTD stress was associated with patient behavioral impairments, including anxiety, sleep disturbances, and agitation. Study findings are consistent with previous studies indicating that bvFTD caregivers report higher stress levels than those in AD.
SESSION 275 (POSTER)

LONG TERM CARE

ELICITING NURSING HOME (NH) RESIDENT FAMILY’ GOALS PRIORITY OF DRUG THERAPY VIA A GROUP FAMILY MEETING: A PILOT STUDY ON PATIENT-CENTERED OUTCOMES

H. Cheng, medicine, university of virginia, Charlottesville, Virginia

Background: NH residents are often unable to make decision on drug therapy due to their dementia. Drugs could achieve one or more of the following five goals: 1). Relieve symptoms; 2). Reduce complications; 3). Live longer; 4). Reduce hospitalization; 5). Improve independent function. However, one drug could achieve one goal while it could worsen other goals. This study was to explore how NH resident families to rate goal priority of drug therapy. Methodology: This study was done at a community NH in New York City. Families were invited to attend a family meeting to discuss medical care of their NH relatives. Each attendance was asked to rate goals priority of drug therapy from most important to very important, important, less important, and maybe important. Descriptive analysis was performed with SPSS. Results: Eleven of 20 NH resident families came to the group family meeting. 8/11 (73%) completed the form and rated goals priority of drug therapy. Mean age for family members was 62y/o (range of 22-89 years old). 9 of 11 (82%) were female. Improving independent function was rated as the most important goal and living longer rated as the least important goal of drug therapy. Conclusions: this small pilot study demonstrated that eliciting goals priority of drug therapy could be done via a group family meeting. Priority of drug therapy among NH residents’ families was not to prolong life. Providers need to re-think their prescribing life-prolonging drug therapy in NH setting. A large study is urgently needed to confirm this study.

AGE AND CLOSENESS OF DEATH AS DETERMINANTS OF LONG-TERM CARE USE IN FINLAND FROM 1998 TO 2006

L. Forma, M. Aaltosen, P. Rissanan, J. Raitanen, M. Jylha, School of Health Sciences, University of Tampere, Finland

In Finland as in many other European countries, long-term care (LTC) of old people has moved from institutional care to supported housing. We analyzed, whether the recent changes have been similar among those who live their last years of life and among those, who live longer. The data were derived from national registers which cover the whole population and all long-term care. The study population consisted of 222 967 case-control pairs. Cases were living their last two years of life and controls (individually matched on age, gender and municipality of residence) lived at least two years longer. The cases died at the age of 70 years or over: we included all those who died in 1998 or 2002–2006 and a 40% random sample of those who died in 1999–2001. Use of LTC was studied for the last two years for cases and for the same calendar days for controls. Use of LTC in total increased slightly both among the cases (39.5, 42.9%) and among the controls (8.5, 12.9%). Use of public residential home decreased slightly among the decedents (20.3, 19.4%), but increased among the controls (4.5, 5.8%). Use of health center hospital stayed similar among the cases (16.2, 16.6) and decreased among the controls (3.9, 2.7). Use of sheltered housing increased in both groups (private: cases 4.4,.6,9, controls 1.7, 3.2, public: cases 2.9, 5.9, controls 0.9,.2,4). LTC in sheltered housing and health center hospital concentrates more than earlier on the care of old people in their last years of life. The users of LTC are more disabled than earlier, and in these care facilities skills to end-of-life care are needed.

FACTORS ASSOCIATED WITH DAYTIME SLEEPINESS IN LONG-TERM CARE RESIDENTS

J. Li, Y. Chang, D. Porock, University at Buffalo, Buffalo, New York

Background: About 50% to 70% long-term care (LTC) residents are experiencing excessive daytime sleepiness (DS). Excessive DS is referred as a characteristic of LTC residents’ everyday life and lead to increased risks for falling and elevated mortality. However, current literature does not provide sufficient evidence regarding factors associated with DS in LTC residents. Purpose: This study examined factors associated with DS in LTC residents using the Minimum Data Set (MDS) comprehensive assessment data. Method: This retrospective, cross-sectional study was conducted with residents in a LTC facility during January 2005 to March 2010. Measures included DS, illness burden, Cognitive Performance Scale (CPS), pain scale, time involved in activities, social involvement, and depression scale in MDS 2.0. Descriptive statistics, Spearman correlation, and logistic regression were utilized for data analysis. Results: MDS records from 300 residents were analyzed. Seventy-eight percent of the residents experienced DS. DS was significantly associated with illness burden (r = 0.15, p < 0.05), CPS (r =.17, p < 0.01), depression (r = 0.14, p < 0.05), and social involvement (r = -0.31, p < 0.01). CPS, illness burden, and social involvement significantly predicted the occurrence of DS. Social involvement was the strongest predictor (β~-.73, Wald χ2 (1) =11.34, p<.01). Conclusion: DS is a common problem in LTC residents. It is positively associated with residents’ cognitive performance and negatively associated with their social involvement. The findings suggest that engaging LTC residents in more social activities is essential for decreasing residents’ DS, especially for those with dementia.

PALLIATIVE CARE FOR PERSONS WITH DEMENTIA (PwD) - THE ROLE OF NURSES IN THE DECISION-MAKING PROCESS

E. Berkemete1, H. Remmers2, A. Kruse1, 1. Network Aging Research, University Heidelberg, Heidelberg, Germany, 2. Faculty of Human Sciences, Division of Nursing Science, University Osnabrueck, Osnabrueck, Germany, 3. Institute of Gerontology, University Heidelberg, Heidelberg, Germany

The transition for PwD towards a palliative care approach is discussed as being beneficial. Therefore, the role of health care professionals is pivotal, particularly in nursing homes, where PwD build up the largest group. Nurses can play a crucial role in guiding and performing palliative care for residents with dementia. Which factors are important and what role these factors play in the clinical decision-making towards palliative care for PwD requires more clarification. The aim of the study is to explore and describe the decision-making process in guiding and performing palliative care for residents with dementia from the nurses' perspectives. This study focuses on the subjective understanding of palliative care, the actions and interactions of nurses in decision-making towards palliative care for PwD. Grounded theory methods were used for data collection and analysis. Therefore 18 semi-structured interviews were collected from nurses in four nursing homes in urban areas in Palatinate/Germany from November 2011 up to February 2013. Most of the nurses were women (n =16) and experienced in long-term care (Mean 20 years, SD 9.30). Their age ranged from 24-61 years (Mean 47, SD 11.26). How nurses deal with uncertainty is important to provide appropriate palliative care due to the high and complex needs of PwD. The findings emphasize meaningful factors (e.g. perceptive attentiveness, nurse-resident-relationship, professional experiences, teamwork) and strategies which influenced decision-making and acting from nurses' perspectives.
EVERYDAY VS. REPORTABLE PAIN: HOW NURSING HOME CERTIFIED NURSING ASSISTANTS (CNAS) UNDERSTAND RESIDENT PAIN
E. Halifax, M.I. Wallhagen, Physiological Nursing, University of California, San Francisco, San Francisco, California

Background: Pain is often unrecognized and under-treated in nursing home residents yet is a frequent and serious problem that can result in loss of function and independence. CNAs are often well-placed to perceive and respond to residents’ pain. Purpose: The goal of this study was to explore how CNAs understood residents’ pain and how licensed nurses perceived the role of CNAs in pain management. Methods: Using Grounded Theory qualitative methods, interviews were conducted with 16 CNAs and 10 licensed nurses in 2 nursing homes in an urban environment. Findings: In data that related to CNAs’ perception of pain CNAs were found to differentiate between everyday pain (accepted by CNAs as a normal and predictable experience for residents); and reportable pain (a change from baseline). There were no differences in the ways CNAs perceived everyday and reportable pain. Thus, even if they did not report pain, they still responded to a resident’s pain using a range of strategies that they believed would relieve pain. However, non-reporting was a barrier to professional assessment and management of everyday pain. Implications: CNAs do not report all pain they perceive their residents to have and consequently everyday unreported pain remains untreated. To improve pain management for residents CNAs need to understand the importance of reporting all pain, and strategies that allow licensed nurses the time and capacity to deal with these additional reports need to be implemented.

TRENDS IN USE OF MEDICATIONS WITH ANTICHOLINERGIC PROPERTIES AMONG NURSING HOME RESIDENTS WITH DEMENTIA
J.B. Palmer1, S.K. Dutcher2, G.B. Ratner3, X. Liu1, L.D. Walker1, Z. Kiptanui1, X. Shen1, I.H. Zuckerman1, 1. University of Maryland, Baltimore, Maryland, 2. Fairleigh Dickinson University (FDU), Teaneck, New Jersey

Objectives: Medications with anticholinergic properties (MAP) have potential to decrease cognitive and physical functioning in dementia patients. We examined trends in use of MAP among Medicare beneficiaries with dementia (MBD) residing in a nursing home (NH) during 2007-2008. We also identified trends in and factors contributing to concomitant use of MAP and anti-dementia medications (ADM) (acetylcholinesterase inhibitors/memantine). Methods: Monthly prevalence of MAP use was analyzed using linked data from the Minimum Data Set (MDS), and Medicare claims. Dementia diagnoses were determined from the Chronic Condition Data Warehouse algorithm and MDS assessments. MAP were classified, using the Boustanian anticholinergic cognitive burden scale, as Level 1-3 based on increasing anticholinergic activity. Analyses were conducted using the Cochrane Armitage trend test and generalized estimating equations. Results: 69,877 MBD had at least one NH-stay between 01/2007-12/2008. They were predominantly female (78.7%) with a mean age of 84 years. On average 77% of MBD residing in nursing homes used at least one MAP. Prevalence of Level-1 use was the highest at approximately 67% each month. A small yet significant decrease in Level-3 MAP monthly prevalence of use was observed from 1/2007(32.2%) to 12/2008(30.0%), p<0.001. Average monthly prevalence of concomitant Level-3 MAP and ADM was 12.2%. Younger age, lower physical and moderate cognitive functioning were associated with concomitant Level-3 MAP and ADM use. Conclusions: High prevalence of MAP use was observed in NH residents with dementia. The observed concomitant MAP and ADM use may impact the desired effects of either medication.

UNCOVERING HETEROGENEITY IN INTENT-TO-LEAVE AND INFLUENTIAL FACTORS IN TAIWAN NURSING HOMES
I. Chen, R.L. Brown, B.J. Bowers, School of Nursing, UW-Madison, Madison, Wisconsin

Background: Taiwan is experiencing high turnover rates among nursing home (NH) nurses, leading to increases in the cost of health care and undermining care quality. Turnover research to date has looked at nurses in the aggregate, and has not distinguished inter-individual variance in intent-to-leave (ITL) within a group of nurses, making it difficult to efficiently target retention efforts. Further, job redesign is a way to improve nurse retention; however, little research guides what should be addressed in job redesign. Purpose: 1) investigate individual nurse differences in ITL; 2) examine job demand, job control, and social support related to subgroups of ITL. Methods: A cross-sectional survey using a sample of 186 NH nurses was conducted. Latent class analysis was used to classify nurses. Multinomial logistic regression was used to determine whether job demand, job control, or social support predicted group membership. Results: Three groups were found: Group 1: potential leavers with withdrawal plans (n=22); Group 2: potential leavers withdrawing suddenly (n=101); Group 3: low-risk potential leavers (n=63). Only job control predicted group membership. Specifically, nurses with higher job control were more likely to belong to Group 2 than Group 3. Conclusion: Results from this study indicate that some nurses are at higher risk of leaving than others. A large proportion of nurses intending to leave suddenly are influenced by giving too much control over the performance of their job. The contradictory result implies future research should be further investigated job control.
RECURRENT FALLS IN THE NURSING HOME SETTING: CRITICAL INFLUENCING FACTORS
B.M. Doucet, S. Fisher, M. Watford, Rehabilitation Sciences, University of Texas Medical Branch, Galveston, Texas

Purpose: This study identified the personal, medical, functional, and environmental factors related to nursing home facility residents identified as recurrent fallers and compared these to non-faller residents. This was collected to provide administrators information to improve overall quality of care at the facility. Methods: Participants included 10 faller and 8 matched control non-faller residents. Physical function tests, walking behavior, functional performance evaluations, cognitive/emotional assessments, environmental analyses, and medical histories were conducted to identify salient contributing factors. Results: Average age was 73.4 (+/- 7.1) years and 72% were female. Residents with a history of falls had significantly lower scores on the Barthel Index (p<0.01), Timed Up & Go (p<0.01), and Functional Reach (p=0.01) tests. Knee extensor (p<0.01) and hip flexor (p=0.02) strength was significantly lower in the residents who fell. Step monitoring through accelerometry indicated that fallers averaged 947 steps/day as compared to 4090 steps/day for non-fallers. All residents with a history of falls were unable to perform the 5X Sit-to-Stand Test for even one repetition, whereas all non-fallers performed the task successfully. Other environmental factors such as cluttered rooms and wheelchairs in disrepair may have contributed as well. Conclusions: Varied personal, functional, and environmental factors may contribute to recurrent falling in nursing home facilities. Identification of these issues is critical to optimize safety, reduce falls, and optimize residential quality of care.

PROMOTING WELL-BEING IN OLDER ADULTS. LIFE REVIEW THERAPY RECALLING SPECIFIC POSITIVE EVENTS (REVISEP)

The aim of this study is to evaluate the effectiveness of life review therapy based on specific positive events in non-depressed cognitive unimpaired older adults taking part in an active ageing programme. Older were randomly assigned into two groups: an experimental group and an active control group. A six-session individual training of life review therapy based on specific positive events was carried out with the experimental group. The active control group undertook a “media workshop” of six sessions in small groups of four or five focused on learning journalistic techniques. Pre-test and post-test measures included life satisfaction, depressive symptoms, experiencing the environment as rewarding, and autobiographical memory scales. We discuss the results. Life review therapy focusing on positive events can be an effective component of emotional wellbeing in active ageing programmes and also be useful to prevent symptoms of depression in older adults.

THE INTERSECTION OF RESIDENT-CENTERED CARE AND BEST PRACTICES FOR NUTRITION CARE IN LONG-TERM CARE
A. Cammer, S. Whiting, D.G. Morgan, University of Saskatchewan, Saskatoon, Saskatchewan, Canada

The objective of this presentation is to describe the intersection of resident-centered or person-centered care in long-term care (LTC) with nutrition care best practices in order to understand where nutrition policy initiatives could enhance quality of care for LTC residents, especially those with dementia. Resident-centered philosophy of care was contrasted with current best practices in nutrition care with particular attention to points of convergence and dissonance. Formally recommended best practices and adopted standards of care for LTC nutrition were collected, examined, and compared with resident-centered care directives. Health care aides provide the majority of direct resident care within LTC, with relatively little training in nutrition care. Policies and standardized care procedures help to eliminate ‘guesswork’ in nutrition care provision by aides, but the philosophical bent of resident-centered care does not easily accommodate highly structured nutrition care protocols. Tension exists between the tenets of a healthcare system in providing quality care and the intention that LTC is, first and foremost, the resident’s home. This disconnect is highly visible with regard to nutrition care. Examination of the intersection of resident-centered care and best practice guidelines for nutrition care can help identify potential policy solutions to enhance resident care and quality of life within LTC. Policies that increase staff understanding of nutrition care goals, empowerment, and engagement in the nutrition-care decision-making process may be more successful at meeting both aims than structured or rigid nutrition care policies and protocols.

INTERVENTION IN LONG-TERM CARE: AN INTERDISCIPLINARY COLLABORATIVE MODEL
G. Hersch, A. Birch-Evans, H.A. Davidson, W. Freysteinson, K. Tsai, School of Occupational Therapy, Texas Woman's University, Houston, Texas

Through this presentation, the team will introduce the audience to the occupation-based, cultural heritage intervention (OBCHI). The uniqueness of this research lies in the successful implementation of an interdisciplinary approach to research including the disciplines of nursing, occupational therapy, and health care administration from Texas Woman’s University, Houston Center. The three major objectives include: 1) report on current findings from a NIH funded OBCHI research study that was developed and implemented for elders relocated to long-term care (LTC) facilities; 2) describe the interdisciplinary approach used in developing and implementing the study; 3) explain a collaborative model that has been utilized in planning future studies. During the presentation the team will highlight the significant findings of improvement in quality of life and social connections from the quasi-experimental nonequivalent control group design demonstrated by pre- and post- tests scores; showcase the perspectives from each of the three disciplines of their contributions to this research; and offer projections for future research studies that describe the cost effectiveness of such interventions by incorporating the OBCHI into current residential staff patterns. This kind of evidence-based knowledge can assist long-term care practitioners in developing more meaningful interventions for elders that provide a person-centered approach during the transition of care.

CNA’S PERCEPTIONS OF POSITIVE AND STRESSFUL ASPECTS OF THEIR JOBS: IMPACT ON JOB SATISFACTION, STRESS, AND CONTROL
B.B. Shadden, J. Henry, M. Gray, R. DiBrezzo, I. Fort, University of Arkansas, Fayetteville, Arkansas

CNAs provide the majority of care for residents of long term care (LTC) facilities. An extensive body of research documents factors influencing CNA job satisfaction and stress. In this study, questionnaires were developed and sent to all LTC facilities in the state of Arkansas. Each facility received five surveys, with 519 returned. The research question was: Does experience of a perceived stressor or positive aspects of the job (“best”) influence rating of job satisfaction, job stress, and sense of control in the job? CNAs were asked to indicate which stressors and “bests” they experienced, then rate job satisfaction, sense of control, and stress (5 point scales). In order of most to least often selected “best” variables were: helping residents (96%), making residents smile, getting to know residents, being part of a team, getting to know resident’s family, and feeling valued by coworkers (57%). From most to least often selected stressors were: pay (56%), understaffing, difficult families, difficult patients, not feeling respected, not feeling part of a team, too many residents, schedule, too many responsibilities, administration, and common disorders of residents (11%). Outcomes are described in terms of differential effects of each “best” and stressor on job satisfaction, stress, and sense of control and implications for change. For example, the top two “bests,” which are other-directed, had no impact.
on the dependent variables, whereas experience of being part of team and feeling valued was associated with significantly higher job satisfaction and sense of control, as well as lower overall stress.

SESSION 280 (POSTER)

NEUROSCIENCE AND NEURODEGENERATIVE

FALLS: AN EARLY BIOMARKER OF FUNCTIONAL BRAIN DISCONNECTIVITY AND SUBSEQUENT COGNITIVE DECLINE (CNS)

C.L. Hsu1, M.W. Voss2, T.C. Hardy1, J.C. Davis1,2, L.S. Nagamatsu1, A. Chan1, N. Bolandzadeh1, T. Liu-Ambrose1, 1. University of British Columbia, Vancouver, British Columbia, Canada, 2. University of Iowa, Iowa City, Iowa, 3. Vancouver Coastal Health Research Institute (VCHRI), Vancouver, British Columbia, Canada

Background: Falls are a common geriatric syndrome and are the third leading cause of chronic disability worldwide. Key fall risk factors include impaired physical function, such as impaired balance, and cognitive decline. It is now recognized that even subtle changes in neurocognitive function are associated with increased falls risk. Recent neuroimaging studies demonstrate that impaired cognitive function is associated with disruptions in functional connectivity of large-scale networks within the brain. However, we have little understanding of the relationship between functional connectivity and mobility. In a 12-month prospective study, we examined the relationship between functional connectivity, mobility, and cognitive function. We aimed to determine: 1) whether there were difference in between- and within-network connectivity between fallers and non-fallers; and 2) whether these differences are associated with changes in executive functions and mobility over a 12-month period. Methods: A 12-month prospective fMRI study with 44 seniors aged 70 to 80 years; 21 fallers (with history of ≥ 2 falls in last 12 months) and 23 non-fallers (≤ 1 fall in the last 12 months). Participants performed a finger tapping task during fMRI scanning. Clinical measures of mobility and executive functions were assessed at baseline and 12 months. Results: Fallers showed decreased connectivity between the fronto-parietal network (FPN) and the motor network (MotN); and increased connectivity between the default mode network (DMN) and FPN. No significant differences were found within the networks. Baseline disconnectivity between MotN-FPN was associated with poorer Short Physical Performance Battery score and Stroop Test score. Conclusion: Compared with non-fallers, older fallers demonstrated disrupted between-network functional connectivity. Critically, greater disruptions at baseline were significantly associated with greater decline in both mobility and executive functions over a 12-month period. Our results suggest that a history of falls may be an early biomarker of risk for cognitive decline and impaired mobility. Furthermore, as our study participants were community-dwelling and functionally independent, between-network connectivity disruption may precede within-network connectivity with aging and/or neurodegeneration.

IMPROVING THE TRANSLATION OF SCIENTIFIC EVIDENCE INTO PRIMARY PREVENTION OF ALZHEIMER’S DISEASE

In 2010, an NIH State-of-the-Science panel concluded that, despite extensive research for 20 years, no modifiable risk factor has been proven to decrease the risk of Alzheimer’s disease or age-related cognitive decline. In response, the Alzheimer’s Drug Discovery Foundation convened an advisory panel on April 22-23, 2013 with experts from epidemiology, clinical trial design, evidence-based medicine, and decision-making frameworks. Panelists included the authors of this abstract and Sandrine Andrieu, UMR1027 Inserm-University of Toulouse; Deborah Blacker, Harvard University & AlzRisk; Allan Green, MD, PhD, JD, LLC; Francine Grodstein, Harvard Public School of Health; Victor Henderson, Stanford University; Joseph Lau, Brown University; Pei-Jung Lin, Tufts Medical Center; James McNally, University of Michigan & National Archive of Computerized Data on Aging; Barnaby Reeves, University of Bristol & Cochrane Non-Randomised Studies Methods Group; Molly Wagster, NIA; Kristine Yaffe, UCSF; Raj Shah and Bryan James, Rush University; Laurie Ryan, NIA; and Bruno Vellas, European Alzheimer’s Disease Consortium. The panel had 3 primary goals. First, identify challenges in developing practical clinical recommendations for Alzheimer’s prevention. Second, define the strengths and limitations of available sources of data for Alzheimer’s prevention including randomized controlled trials, analytic epidemiology, administrative databases, and systematic reviews. Third, develop strategies and identify opportunities to improve the translation of available evidence into clinical or population-based guidelines. We will present the panel’s conclusions and recommendations including potential strategies to tailor RCT design, reduce selective reporting, improve meta-analysis of non-randomized studies with guidelines to recognize primary study bias, and encourage the use of decision-making frameworks.

SYNCHRONOUS ELECTROMYOGRAM ACTIVITY REVEALS THE CNS CONTRIBUTION TO MOBILITY TASKS IN OLDER ADULTS

D.J. Clark1,2, S. Kautz3, Y. Chen1, E. Christou2, 1. Brain Rehabilitation Research Center, Malcom Randall VA Medical Center, Gainesville, Florida, 2. University of Florida, Gainesville, Florida, 3. Medical University of South Carolina, Charleston, South Carolina

The corticospinal pathway is critical for control of walking in humans, particularly under challenging walking conditions such those involving obstacle avoidance or uneven terrain (e.g., community ambulation). Accumulating evidence suggests that the corticospinal contribution to movement can be gauged by the amount of synchronous electromyogram (EMG) activity contained within the 30-60Hz (Piper) frequency band. However, whether this approach is sufficiently sensitive to detect task-dependent differences in the corticospinal contribution to mobility tasks is not known. This capability is important for revealing the extent to which CNS integrity affects the performance of various mobility tasks in older adults. Seventeen healthy older adults and thirteen adults with chronic post-stroke hemiparesis participated in this study. Each individual performed four different walking tasks: normal walking, fast walking, cognitive dual-task walking, and walking plus taking an occasional longer step. EMG was recorded from soleus and gastrocnemius muscles, and EMG synchrony was assessed with cross-wavelet spectral analysis. Relative to Piper band EMG synchrony during normal walking, Piper band EMG synchrony was significantly reduced during dual-task walking, unchanged during fast walking and significantly increased during a long step in healthy older adults. These results are consistent with the known corticospinal demands of each walking task. In the paretic leg of post-stroke participants, there was an absence of significant task-dependent modulation of Piper band EMG synchrony. This result is consistent with stroke-induced damage to the corticospinal pathway. This study demonstrates the utility of EMG frequency analysis for non-invasively gauging the corticospinal contribution to mobility tasks in older adults.

MICROALBUMINURIA IS LINKED TO BRAIN TISSUE ATROPHY IN OLDER ADULTS WITH TYPE 2 DIABETES MELLITUS

D.B. Mehta1, M. Núñez2, B. Manor1, V. Novak1, 1. Beth Israel Deaconess Medical Center, Boston, Massachusetts, 2. Centro de Investigaciones Biomédicas y Clínicas (CINBIOCLI), Hospital José María Cabral y Béez, Santiago, Dominican Republic

Aging and diabetes both independently contribute to cognitive decline and dementia in elderly adults. Microalbuminuria (MA), a marker of renal microvascular disease, has also been associated with global brain atrophy and neurovascular changes in older adults. The aim of this study was to determine the effects of MA on regional brain structure in older adults with and without DM. We performed a secondary analysis of prospectively collected data from 255 participants aged 65±7yrs, which included 112 individuals with DM (62 males, 50 females); duration of DM=11±9yrs; HbA1c=(7.2±1.2) and 143 age and gender- matched controls. 3D magnetization prepared rapid acquisition with gradient echo MIs were acquired to quantify regional gray and white matter volumes. Least square models were used to determine relationships between MA, defined by urine albumin-creatinine ratio (30-300mg/g), and regional brain volumes. Models were adjusted for age, sex, hypertension and blood glucose levels. Groups did not differ in the prevalence or severity of MA. In the DM group, MA was associated with lower gray matter volume in the frontal lobe, occipital lobe, cerebellum and the orbitofrontal gyrus (p<0.01), and less white matter volume within the frontal lobe and orbitofrontal gyrus (p<0.03). Within the control groups, no significant associations were observed. Our results indicate that in DM patients, MA may be independently associated with brain tissue atrophy, particularly within multiple regions supporting cognitive function. Further studies are needed to determine the functional implications of these observations.

FROM GLOBAL METABOLOMICS TO CANIDATE METABOLITES: LINKING CNS AND NEUROCognitive PHENOTYPES IN AGING

S. Sapkota1, S. Pearson2, T. Tran3, J. Zheng3, L. Li3, R.A. Dixon2,1, 1. Centre for Neuroscience, University of Alberta, Edmonton, Alberta, Canada, 2. Department of Psychology, University of Alberta, Edmonton, Alberta, Canada, 3. Department of Chemistry, University of Alberta, Edmonton, Alberta, Canada

Metabolomics is a global approach to detecting perturbations in metabolic pathways that reflect diseases of the central nervous system, including Alzheimer’s (AD). The metabolome, the end product of gene-environment interactions, is clinically useful for characterizing metabolic signatures of specific diseases, identifying preclinical transition states, and predicting related phenotypes. We present two converging studies applying salivary metabolomics procedures to profiling mild cognitive impairment (MCI), a precursor condition to AD, distinguished from normal aging (NA). Biological and cognitive data were from the Victoria Longitudinal Study and included N=40 adults (64-75yrs) with validated classifications as NA or MCI (both groups n=20, 50% female). Study 1 developed a 13C/12C isotope dansylation labeling method in conjunction with liquid chromatography mass spectrometry to detect over 1000 metabolites from which the top 18 (e.g., taurine) discriminated NA from MCI (Zheng, Dixon, & Li, 2012). Study 2 applied the same procedures (Tran et al., unpublished data) but focused on complementary analyses of associations among 20 metabolite fingerprints (e.g., isoleucyl/proline) of MCI with neurocognitive phenotypes (executive functions, memory, speed), stratifying by clinical classification, gender, and serial rank (1-20 and quartiles). ANOVAs showed expected and uniform clinical group differences, but these were qualified by differential gender-related effects specific to aging MCI men. Using correlations and regressions, numerous substantial (r>-.5) metabolite-cognition effects (p<.05) were observed, including systematic patterns of magnitudes (memory) and variable patterns of direction (by classification). Using converging methods, global metabolomics identified the key discriminative metabolites of MCI and specific metabolite analyses identified differential effects across neurocognitive phenotypes.

IDENTIFYING AND EVALUATING NEW POTENTIAL THERAPIES TO DELAY COGNITIVE AGING AND DEMENTIA

A major challenge facing aging populations is how to make the best choices for cognitive health with available information that is limited, inconclusive, and often biased. The ADDF Aging and Alzheimer’s Prevention Program provides independent evaluations of the efficacy and safety of drugs, supplements and other approaches proposed to prevent cognitive aging and dementia, and accelerate the development of evidence-based recommendations for prevention. Here we highlight available evidence and research needs for four proposed approaches. Some data suggest both coffee and caffeine could potentially delay cognitive aging and incident dementia but randomized controlled trial (RCT) data is lacking and epidemiologic evidence is limited and needs more standardized, detailed methodologies. Non-steroidal anti-inflammatory drugs (NSAIDs) are associated with decreased risk of dementia in many epidemiologic studies but subsequent RCTs found either no cognitive benefits or increased risk. It remains unresolved whether this conflicting evidence is due to bias/selective reporting or to issues like timing, duration, and treatment population. Ashwagandha, an herbal supplement of growing popularity, is neuroprotective in some pre-clinical non-human research. However, it lacks sufficient safety and efficacy data from rigorous RCTs and epidemiology. These data for all four analyses illustrate significant gaps, yet patients and providers still have to make clinical decisions based on inadequate data. In conclusion, our evaluations highlight current problems with the translation of inadequate data to clinical care. By identifying research gaps and evaluating the quality of available evidence, we can accelerate translational research and give patients and providers improved information.

GENE-ENVIRONMENT INTERACTIONS ON COGNITIVE DECLINE: FINDINGS FROM THE CHICAGO HEALTH AND AGING PROJECT

K.B. Rajan, N.T. Aggarwal, D.A. Evans, Rush University Medical Center, Chicago, Illinois

Genetic studies have identified APOE ε4 allele as a susceptibility allele for several neurodegenerative conditions including cognitive decline. However, little is known of the interaction of this risk allele with environmental factors with regards to race/ethnicity. Our objective is to present gene-environment interactions in an attempt to elucidate the underlying biological and molecular pathways underpinning cognitive decline for race-specific differences. We considered three environmental factors: alcohol consumption, physical activity, and body mass index. The standardized global cognitive score was derived from the mini-mental state exam, immediate and delayed recall tests, and the symbol digits test in a population-based cohort of 4160 subjects followed for an average of 9.6 years (maximum of 18.7 years), with triennial data collection cycles. Our analysis found that cognitive decline was significantly slower in black subjects, with one or more copies of APOE ε4 allele, who consumed moderate amounts of alcohol compared to their white counterparts who showed no association of cognitive decline and alcohol consumption. We also found that blacks with one or more copies of APOE ε4 allele with higher body mass index also had slower cognitive decline than their white counterparts. Finally, higher physical activity in white subjects with one or more copies of APOE ε4 allele was associated with slower cognitive decline compared to their black counterparts. The findings from this large population-based study suggest that the association of the APOE ε4 allele varies among ethnic

NUTRITION AND BODY COMPOSITION

IMPACT OF WAIST CIRCUMFERENCE ON FOUR YEAR QUALITY OF LIFE AND FUNCTION IN THE ELDERLY: THE OSTEOARTHRITIS INITIATIVE

J.A. Bates1,2, A. Zbikowski1, L.K. Barre1, J. Bynum1, S.J. Bartels2, 1. General Internal Medicine, Dartmouth-Hitchcock Medical Center, Lebanon, New Hampshire, 2. Geisel School of Medicine at Dartmouth, Hanover, New Hampshire

Background: Waist circumference (WC) is a marker of visceral adiposity that predicts mortality. Its association with function and quality of life in older adults is incompletely understood. We examined the impact of visceral adiposity, measured by WC, on four-year functional and health outcomes. Methods: We identified adults aged ≥60 years from the longitudinal Osteoarthritis Initiative and stratified the cohort into quartiles based on WC. Our primary outcome measures of function at 48 months included: self-reported quality of life [Short Form-12 (SF-12)], physical function [Physical Activity Scale for the Elderly (PASE)] and disability [Late-life Disability Index (LLDI)]. Linear regression analyses predicted 4-year outcomes based on WC quartile category (lowest=referent), adjusted for age, sex, race, education, knee pain, smoking status, Charlson co-morbidity index and baseline scores, where available. Results: Of 2,434 baseline participants, complete outcome data was available on 1,727 (71%). Mean age was 68.2±4.4 years, 60.5% were female and 83.3% were white. Subjects in the highest WC quartile compared to 50-75th, 25-50th or lowest quartile, were on a greater number of medications (4.2, 4.0, 3.6 and 3.2 [p<0.001]), had lower gait speeds (1.22, 1.28, 1.32, and 1.33m/s[p<0.001]), had higher rates of osteoarthritis (50.4, 61.3, 73.6%[p<0.001], higher Charlson co-morbidity scores and greater knee pain (WOMAC scores) (all p<0.001). At 48 month follow-up, adjusted SF-12 physical function subscale and PASE scores, as measures of quality of life and physical function respectively, were lowest in the highest WC quartile as compared to 50-75%, 25-50% and lowest quartile ([SF-12 scores: 31.3±3.8, 32.9±3.8, 33.7±3.8, and 34.1±3.3[p<0.001]], and [PASE scores: 212.5±36.1, 226.5±36, 226.1±36, and 234.4±31.7 [p<0.001]]. The LLDI limitation subscale for disability differed in the ≥70 age group as compared to the 60-70 year group with subjects in the highest WC quartile having lower scores (86.5±5.7, 88.3±5.6, 90.3±0.3, and 91.5±4.1[p<0.001]). Conclusions: In a cohort at risk for osteoarthritis, elevated visceral adiposity, as measured by WC was associated with lower quality of life, a decline in physical function, and a slightly higher risk of disability over time. Intervention studies are needed to prevent functional decline in this high risk population.

SARCOPENIC OBESITY, GAIT SPEED, AND BODY MASS INDEX IN ELDERLY JAPANESE INDIVIDUALS, AGED 65 - 74

T. Fujita1,2, A. Kono1, 1. School of Nursing, Takarazuka University, Osaka, Japan, 2. Graduate School of Nursing, Osaka City University, Osaka, Japan

Objective To describe the prevalence of sarcopenic obesity among elderly Japanese individuals, and to clarify gait speeds and BMI in sarcopenic obesity. Methods Body composition and normal gait speed were measured in 259 Japanese subjects, aged 65-74 years, using bioelectrical impedance analysis (InBody720, Biospace Inc., Seoul, South Korea). Skeletal muscle index (males <6.87 kg/m2, females <5.46 kg/m2), defined as the quotient of appendicular muscle mass (kg) divided by height (m) squared, as well as percentage of body fat (males ≥25%, females ≥30%) were used to divide subjects into the categories of sarcopenic obesity, sarcopenic, normal, and obesity. Subsequently, multiple comparisons were conducted, using Tukey’s honestly significant difference test. Results The prevalence of sarcopenic obesity was 13.5% (n=35), with a notable gender-based disparity of 15.7% (n=20) in males and 11.4% (n=15) in females (P = .006, Cramer’s V = 0.22). Males in the sarcopenic obesity group had slower gait speeds than those of the normal group [1.16 (0.27) m/s versus 1.31 (0.21) m/s, P = .029, d = 0.66]. A large disparity was observed in the BMIs of males from the obesity group [23.22 (1.92) versus 25.7 (2.08), (P<.001, d = 1.21)] and in females from the sarcopenic group [22.7 (1.76) versus 18.7 (1.45) (P<0.001, d=2.52) and the obesity group [22.7 (1.76) versus 24.6 (2.59) (P<0.001, d=2.59)]. Conclusions The prevalence of sarcopenic obesity in males is higher than in females. Gait speed may be an indicator of sarcopenic obesity.

MUSCLE FUNCTION AND BODY COMPOSITION IN ACTIVE MEN AND WOMEN AGED 50 YEARS AND OVER

S. Barbat-Artigas1,2, C. Pion1,2, C. Brule-Estebé1, M. Aubertin-Leheudre1,2, J. Kinesiology, University of Quebec At Montreal, Montreal, Quebec, Canada, 2. Research Center of the Montreal Geriatric University Institute, Montreal, Quebec, Canada

Introduction: Supervised physical activity programs are known to improve muscle function and body composition. However, the relationship between these variables and voluntarily and autonomously practiced physical activity is unclear. The aim of this study was to investigate the relationship between muscle function, body composition and physical activity profiles. Methods: Five-hundred-and-five individuals (146 men, 359 women) aged 50 year and over were recruited in the YMCA’s of Montreal. Physical activity profile and general health perception (GHP) were estimated by questionnaire. Handgrip and knee extension strength, body composition (muscle mass and fat mass) and maximum oxygen consumption (VO2max) were evaluated. Individuals with less than 2hrs of physical activity per week were considered as a control group (CG; n=81). Individuals with more than 2hrs of physical activity per week were subdivided into three groups (resistance (RT; n=142), endurance (ET; n=215) and mind and body (MB; n=67)) depending on dominant type of activity. Results: In men, significant differences were observed between groups for BMI (p=0.037), muscle mass index (0.021), fat percentage (p=0.034), trunk fat (p=0.018) and VO2max. The RT group had the lowest BMI, fat percentage, trunk fat, and the highest VO2max. The ET group had the highest muscle mass index. In men, no significant differences were observed except for GHP (p=0.03); highest in the MB group. Conclusion: Our results revealed strong differences between men and women. Results also suggest that physical activity, when voluntarily and autonomously practiced, is not as effective and beneficial as when supervised.

J. Alwerdt, B. Small, School of Aging Studies, University of South Florida, Tampa, Florida

The presence of phytoestrogens from an individual’s diet has been associated with positive consequences in the overall health of older adults. However, much less is known about the role of phytoestrogens on the cognitive health, especially among older adults. In the current study, we examine urinary phytoestrogen concentrations in relation to speed of processing measured by the Digit Symbol Substitution Test. Participants were drawn from The National Health and Nutrition Examination Survey (NHANES 1999-2002) and consisted of 565 individuals who ranged in age between 65 and 85 years of age. This group constituted of a random sample of one third of the NHANES population was measured for phytoestrogens throughout the study. A stepwise regression was conducted that included covariates: age, gender, education, and race in the first model and the phytoestrogens in the second.
Higher values of O’desmethyldaidzein were associated with better performance in speed of processing. There was a curvilinear relationship with daidzein (DAZ). Results suggest that specific levels of phytoestrogens may have a positive impact on cognitive performance and suggest that these measures may be a potential intervention target to maintain cognitive health among older adults.

DETERMINANTS OF UNDERNUTRITION: AN IN-DEPTH STUDY IN OLDER ADULTS RECEIVING HOME CARE

R. van der Pols-Vijlbrief, H. Wijnhoven, M. Visser, Health Sciences, VU university, Amsterdam, Netherlands

Background Undernutrition is highly prevalent among older persons receiving home care, difficult to treat, and associated with negative health outcomes. The purpose of this study was to identify factors that predict undernutrition in this vulnerable group. Methods In total, 308 older men and women living at home were screened by home care nurses for undernutrition with the SNAQ65+ screening tool and completed the questionnaire. Information on demographics, physical activity, nutritional intake, appetite, functional, cognitive and health status, depression, social network, oral health, sight and hearing difficulties and pain was asked. Multivariate backwards logistic regression analyses were used to identify the predictors of undernutrition. Results Of the participants, 29.3% was undernourished or ‘at risk’ and 60.7% was well nourished. Mean age was 81.9 years (SD: 7.0). The results suggest that increased physical activity, being married, having a good appetite, not needing help with grocery shopping, and eating more snacks lowers the risk for undernutrition. Furthermore, ADL problems, higher number of falls, intestinal problems, and low income increased this risk. Conclusions Undernutrition seems a multi-factorial problem with various predictors in different domains. Many factors are modifiable and could provide starting points to develop future prevention strategies aiming to reduce undernutrition in community dwelling older adults.

RELATIONSHIP BETWEEN BMI AND LIFESTYLE FACTORS OF ELDERLY JAPANESE PEOPLE IN MEDICAL HOME CARE

K. Saito1, R. Ohtsuka2, H. Ohta1, M. Kuzuya1, K. Maeda1, H. Miura2, 1. Tokyo Metropolitan Institute of Gerontology, Itabashi-ku, Tokyo, Japan, 2. National Center for Geriatrics and Gerontology, Obu, Aichi, Japan, 3. ASMSS Health Corporation, Oyama, Tochigi, Japan, 4. Nagoya University Graduate School of Medicine, Nagoya, Aichi, Japan, 5. Mukogawa Woman’s University, Nishinomiya, Japan

Background Nutritional status is one of the most important indicators of health status in home care elderly people, which is closely related to quality of life. Body Mass Index (BMI) is an important measurement of basic nutritional status, however difficulties arise in measuring the elderly, especially bedridden elderly, in home care services. We assessed the relationship between BMI and lifestyle factors of elderly Japanese people in medical home care. Methods A cross-sectional study was conducted on 990 elderly people receiving home medical care in Japan, in October 2012. Eligible subjects were over 65 years, receiving medical care services at home, such as medical, dental, nursing, rehabilitation, nutritional guidance and medical guidance. We examined anthropometric measurements including height, weight, BMI, triceps measurement, nutritional status, ADL and lifestyle assessments. Trend tests were used to observe trends between BMI and other dependent variables. Results Mean age (± standard deviation) was 83.37 ± 8.31 years, and 61.2% female. The mean of BMI was 20.75 ± 4.10 (n=757). Prevalence of low (<18.5), normal (18.5-25) and high BMI (>25) was 30.6%, 55.9% and 13.9%, respectively. Trend tests for BMI showed that for age, there was an increasing trend with increasing BMI (P<0.001); a decreasing trend for ADL score with decreasing BMI (P<0.001); an increasing trend in aspiration was observed with decreasing BMI (P<0.001). Conclusion Interesting trends were observed between BMI and lifestyle factors. Therefore, developing ways to measure BMI in elderly people receiving at home care, particularly those bedridden, is very important.

IRON STATUS IS RELATED TO DEPRESSIVE SYMPTOMS IN THE INCHIANTI ELDERLY

L. Chen1, K. Patel2, L.E. Murray-Kolb1, 1. The Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland, 2. University of Washington, Seattle, Washington, 3. The Pennsylvania State University, University Park, Pennsylvania

Limited data examines longitudinal relations between iron status and depressive symptoms. We did so in 1,000 individuals (440 males, 560 females) in InCHIANTI, a community-based mobility study of older Italians in two areas of Italy, Greve in Chianti and Bagno a Ripoli. Iron measures included a complete blood count, serum iron, transferrin receptor, and ferritin. Iron deficiency was defined by a minimum of two abnormal iron status indicators. The Center for Epidemiologic Studies Depression Scale (CES-D) measured depressive symptoms. Of the 1,000 individuals, 36 were classified as iron deficient anemic (IDA), 50 as iron deficient (ID), 317 as iron sufficient (IS), and 155 as having elevated ferritin (EF); 442 were not able to be clearly categorized, given the strict definitions used for ID and IDA. The mean CES-D score at baseline was high, at 12.83 (SD 8.75). Fully adjusted longitudinal Generalized Estimating Equation (GEE) models controlling for sex, site, age, education, widowed status, smoking, alcohol, vitamin B6, vitamin B12, folate, omega-3, Mini-Mental State Examination (MMSE) score, antidepressants, and medical conditions suggested that iron deficient individuals had, on average, a 1.93 point lower CES-D score compared to iron sufficient individuals (95% CI (-3.81, -0.05)). In contrast, for every 1 g/dL increase in hemoglobin, the odds of depressive symptoms (CES-D≥20 based on previously published InCHIANTI literature) were 14% lower in the fully adjusted model (Odds Ratio 95% CI (0.77, 0.97)). Results support a relation between iron and depressive symptoms relevant to clinical populations of iron deficient and depressed individuals.

SESSION 290 (POSTER)

RESEARCH METHODS POSTERS

VALIDITY AND RELIABILITY OF THE RURAL AND REMOTE MEMORY CLINIC TELEHEALTH SATISFACTION QUESTIONNAIRE

D.G. Morgan, J. Kostenuik, N.J. Stewart, C. Karunanayake, R. Beever, Canadian Centre for Health & Safety in Agriculture, University of Saskatchewan, Saskatoon, Saskatchewan, Canada

This research is part of a larger study aimed at determining the acceptability of telehealth videoconferencing in the Rural and Remote Memory Clinic (RRMC) in Saskatchewan, Canada. We report on the psychometric properties of a satisfaction questionnaire that was adapted for use in the clinic. RRMC patients and their caregivers participate in a 30-minute pre-clinic assessment conducted by a nurse and neuropsychologist via telehealth. This study includes data from 223 patient-caregiver dyads seen between March 2004 and July 2011, who attended pre-clinic assessment and completed a Telehealth Satisfaction Questionnaire (TSQ) before April 2011. Principal components factor analysis was conducted to evaluate the 10-item TSQ, 5-item telehealth system satisfaction subscale, and 5-item team satisfaction subscale within the TSQ. The items within each of the three scales formed one construct per scale, as indicated by scale eigenvalues of 2.7 – 3.2 and item factor loadings of 0.54 - 0.84 across scales. The items within each scale also exhibited high internal consistency reliability, as demonstrated by Cronbach’s alpha scores for the 10-item telehealth satisfaction scale (0.90), telehealth system satisfaction subscale (0.78), and team satisfaction subscale (0.86). The results of the study support the construct validity and internal consistency reliability of a 10-item telehealth satisfaction scale.
to evaluate patient satisfaction with team-delivered telehealth services. Study findings also provide evidence that construct validity and reliability are maintained when the 10-item telehealth satisfaction scale is separated into a 5-item subscale to evaluate patient satisfaction with team-delivered care and a 5-item subscale to measure satisfaction with telehealth-based care.

COMPARING DISEASE BURDEN MEASURES AMONG OLDER ADULT CANCER SURVIVORS

Research Objective: Older adult cancer survivors live with multiple co-existing chronic conditions, which require valid disease burden measures to classify their risk for adverse events. This study, using prospectively collected data (n=359) from Health Related Quality of Life: Elders in Long Term Care (Mary D. Naylor, PI), compared Latent Variable Analysis (LVA) of co-existing chronic conditions with Charlson Comorbidity Index (CCI) as a disease burden measure in an analysis of the association between hospitalizations and cancer diagnosis. Study Design: The dependent variable, hospitalizations, was abstracted from medical records at study baseline, 3, 6, 9, and 12 months. Baseline chronic conditions, including cancer diagnosis, were also abstracted from medical records. LVA, a technique similar to cluster analysis, and CCI scores were generated to represent disease burden. Poisson regressions of number of hospitalization fit by GEE were used. Results: The LVA demonstrated three patterns of co-existing chronic conditions representing low, medium, and high disease burden, whereas the CCI generated continuous scores ranging from 0 (low burden) to 6 (high burden). Poisson GEE models using either LVA or CCI showed older adults with high disease burden had significantly greater number of hospitalizations than those with low disease burden (both analyses p<.002). Cancer diagnosis was not associated with number of hospitalizations using either LVA or CCI as disease burden measure. Conclusions: The findings suggest that LVA may be comparable to CCI as a disease burden measure in studies of older adult cancer survivors. However, LVA provides added information on patterns of co-existing chronic conditions.

VALIDITY OF 16 AND 8 ITEM VERSIONS OF THE LATE-LIFE DISABILITY INSTRUMENT (LLDI) IN TWO LATIN AMERICAN OLDER POPULATIONS

A. Vafaei1, M. Zunzunegui2, J. Guralnik3, J. Gomez Monters4, C. Curcio5, R. Guerra1, B. Alvarado1, 1. Queen’s University, Kingston, Ontario, Canada, 2. Departement de medecine sociale et preventive Faculte de medecine, Universite de Montréal, Montreal, Quebec, Canada, 3. Department of Epidemiology and Public Health, University of Maryland School of Medicine, Baltimore, Maryland, 4. University of Caldas, Manizales, Colombia, 5. Universidade Federal do Rio Grande do Norte, Natal, Brazil

Background: LLDI is a sensitive comprehensive disability measurement tool and includes two sub-scales, measuring frequency and limitations in performing activities. The LLDI has been validated in Spanish, German, and North American populations, but not in Latin American populations. The main objective of this study is to evaluate if the LLDI provides similar factorial structure in two Latin American (Manizales, Colombia; Natal, Brazil) older adults populations. Approach: 300 subjects, 150 women and 150 men, aged 65-74 living in the community were sampled. The LLDI (16 and 8 item versions) was used to assess physical disability. Factor analyses were performed to assess the factor structural (the underlying components and their internal consistency) of the LLDI, in both frequency and limitation sub-scales. Results: Two factor solutions failed to separate underlying personal and social components of frequency items and instrumental and managerial components of the limitation items. One factor solution of the LLDI frequency (excluding three items) and limitation sub-scale (all 16 items included) was acceptable in both populations with relatively high internal consistency (Cronbach Alpha in Manizales 0.79 for frequency, 0.89 for limitation; in Natal 0.73 for frequency, 0.90 for limitation). In both populations and for both subscales factor loadings and internal consistency of the shorter version of the LLDI was lower. Conclusion: Despite failing to separate components of frequency and limitation sub-scales, the 16 item LLDI remains a valid measure of disability in Latin American older adults. The use of the short 8 item version seems to be not appropriate for similar populations.

EVALUATION OF RECRUITMENT AND RETENTION FOR A MULTI-YEAR INFLUENZA VACCINATION TRIAL IN HEALTHY AND HIGH-RISK OLDER ADULTS

Purpose: To evaluate the effectiveness of strategies to recruit and retain participants in a multi-year influenza vaccination trial. Methods: We analyzed recruitment methods, age, gender, race/ethnicity of individuals who were screened, eligible, and enrolled in five one-year studies. Recruitment targets (total=170) each year were: healthy older (HO) adults (n=75) and high-risk older (HR) adults with congestive heart failure (n=75), both aged ≥60; and healthy young (HY) (n=20), aged 20-40. Results: 940 individuals were screened, of which 820 were eligible, and 307 enrolled at least once in five one-year studies. Females comprised 63.4% and whites comprised 95.5% of the enrollees. The average ages were 75.3 for the older groups and 30.6 for the younger group. 56.7% of the 307 participants enrolled at least twice over the 5 years. On average, respondents re-enrolled 2.56 (SD=1.6) times. Older respondents compared to younger (p<.001); and whites compared to minority respondents (p=.004) were more likely to re-enroll. Each year enrollment was between 8 (2005) to 24 participants (2006) below target. Of those screened for eligibility over the 5 years, 50.2% were HO adults and 17.2% were HR that had been participants from previous study years or other institutional studies, 4.4% were HR that were patients of a congestive heart failure clinic recruited by their physician, 12.4% were HY that were research institution staff recruited by email. The HY group had the largest enrollment deficits. Conclusions: Enrollment/re-enrollment was facilitated by a database of past participants. Ways to increase recruitment effectiveness of high-risk older persons needs further research.

ACHIEVING A NATIONAL SAMPLE OF NURSING HOMES: BALANCING PROBABILITY TECHNIQUES AND PRACTICALITIES

E. Fielding, E. Beattie, M. O’Reilly, Dementia Collaborative Research Centre, Queensland University of Technology, Brisbane, Queensland, Australia

Most nursing home studies employ purposive or other non-probability sampling techniques. This poster will illustrate the challenges of achieving a diversified, national sample of nursing homes for a study of the quality of life of people with dementia in Australia. National samples are difficult and expensive to achieve, given the need to engage multiple data collection teams and to travel significant distances. In this study, we were successful in achieving diversity, while remaining within practical and budgetary limits, by balancing selective exclusion of homes with disproportionate stratified random sampling. In the end, the majority (89%) of nursing homes in Australia had a non-zero probability of being chosen for the study sample. Starting from a sampling frame of all Australian nursing homes (n=2774), very small (n=238) or geographically remote (n=22) homes were excluded. Those remaining were stratified by state, geographic type (large, medium, small), and organization type (government, charitable/religious, private). Each list was placed in a random order and recruitment proceeded from the top of
the list until the designated number of homes was reached. To ensure representation of less common types, the probability of selection varied by list, from 0.7% for charitable/religious homes in large cities in the highest population state to 14% for public or private homes in small towns in a low population state. Data collection has proceeded in 53 homes (1.9% of the total). The poster will conclude with a section on lessons learned and suggestions for other researchers wanting to employ probability sampling techniques.

QUICK, OBJECTIVE MEASURES OF BALANCE AND GAIT RELATED TO AGING WITH OR WITHOUT NEUROLOGICAL DISEASE
F.B. Horak, C. Curtz, M. Mancini, M. Nomura, J. Park, Neurology, Oregon Health and Science University, Portland, Oregon

We recently developed a novel, instrumented Stand and Walk test (ISAW) using body-worn inertial sensors to allow nonexperts to quickly obtain objective measures of standing balance, step initiation, gait and turning. The ISAW automatically provides over 100 measures of balance and gait. We hypothesized that these measures could be grouped into a small subset of mobility domains. We also hypothesized that measures of dynamic postural stability during turning would be related to both age as well as severity of Parkinson’s disease. Subjects included 104 people with Parkinson’s disease (53–80 years old), Hoehn-Yahr II-IV and 66 age-matched control subjects (53–77 years old). All subjects were community-dwelling and could stand and walk independently without an assistive device. Subjects wore 6 Opal sensors and performed the ISAW using APDM’s Mobility Lab System. The ISAW involved standing still for 30 seconds, followed by walking 7 meters, turning 180 degrees, and walking back and each subject performed 3 trials. Factor analysis showed that the ISAW consists of 5 independent mobility domains: static balance, dynamic balance, pace, upper body control, and asymmetry. Measures of dynamic balance such as turning duration separated behavior of PD from controls (p<0.01) and showed significant correlations with both age (Controls r=0.254, p=0.05; PD r=0.360, p<0.001; corrected for severity of PD r=0.368, p<0.001) and severity of PD (r=0.524; p<0.001). The portable ISAW test automatically provides quantitative measures of balance and gait in any setting that are sensitive to aging in people with and without neurological disease.

MIBBO: A TOOL TO ASSESS MEANINGFUL PHYSICAL ACTIVITIES FOR NURSING HOME RESIDENTS
E. van Rossum, M. Kleynen, S. Braun, A. Beurskens, 1. Maastricht University, Maastricht, Netherlands, 2. Zuyd University of Applied Sciences, Heerlen, Netherlands, 3. Adelante, Hoensbroek, Netherlands

Inactivity is highly prevalent among nursing home residents. This has many disadvantages, both physically and mentally. Hence, it is very important to develop and offer a challenging span of meaningful physical activities, matching with the preferences and abilities of residents. Tools to assess preferred activities systematically are hardly available yet. We therefore developed and tested such a tool (“MIBBO”): Assessment of Meaningful Physical Activities for Elderly People. An interdisciplinary team of care professionals and researchers constructed the tool, specifically aimed at residents in longterm care facilities. Its feasibility was evaluated among 10 nursing home residents (both in somatic and psychogeriatric wards) and their caregivers. The approach consists of three steps and takes about 30 minutes to administer. It starts with a photo interview; residents assess and rank photo’s of 30 physical activities (e.g. walking, gardening; if needed family members are involved). These photo’s are sorted into two piles (“yes, I like to do that” versus “no, I’m not interested”). As a next step the resident is asked to select her/his top 5 of activities, including preferences regarding performing the activity (e.g. alone or in a group, preferred time of the day). Finally, an individual plan is made regarding the preferred activities. Both residents and care staff assessed the systematic approach as feasible and promising, especially the photo interview part. Further research is needed to determine the added value of this tool in reducing residents’ inactivity, and implementation of the activity plan in overall care plans.

INCORPORATING BRANCHING PATH SIMULATIONS INTO TREATMENT FIDELITY PLANS
C.R. Kovach, Milwaukee, Wisconsin

This presentation describes the incorporation of branching path simulations into a comprehensive strategy for monitoring and enhancing treatment fidelity in randomized controlled trial testing of a clinical decision support intervention based on analytical decision-making theory. Branching path simulations, which allow users to examine consequences of actions, are ideal for examining clinical decision making represented in terms of: a) a flow of action steps; and b) a “route” of critical thinking through a sequence which is designed to achieve a desired result. A brief demonstration of one branching path exercise will augment discussion of the ways in which interactive branching paths can reveal specific deficits in critical thinking and adherence to the required action steps. Sixty-seven nurses acting as interventionists in thirty-two nursing homes participated in fidelity testing. Results of branching path simulation fidelity testing revealed that 15 (22%) scored below the prior 85% criterion for full retraining and restesting. Of the remaining 52 interventionists, 30 (45%) needed partial retraining in specific areas. Deficits were most common for assessment (n = 26; 39%) followed by acting to mobilize necessary resources (n = 21; 31%), identification of change in condition (n = 19; 13%), and cue interpretation (n = 19; 13%). There were no statistically significant differences in errors between nurses employed at proprietary and not-for-profit nursing homes. Fidelity testing using branching path simulations provided critical information on competence and adherence of interventionists to the required action steps.

A METHOD TO PRESENT RESULTS OF PROCESS EVALUATIONS OF COMPLEX INTERVENTIONS
F.C. Bakker, A. Persoon, Y. Schoon, M. Olde Rikkert, Geriatrics, Radboud University Nijmegen Medical Center, Nijmegen, Netherlands

Background: Process evaluations are highly important to understand the content, implementation, integration and effects of complex healthcare interventions, but there is no clear framework available which helps to uniformly report findings of process evaluations next to results of effect studies. Methods: A literature review of process evaluations of complex interventions was performed. Objectives, methods and value of results of process evaluations of the included articles were analyzed. Subsequently, key elements which are valuable for scientists and policy makers were deducted. Results: A graphical representation of the results of a process evaluation as an effect measure and as a tool for understanding results of effect outcome measures was created. Use of this figure for process evaluations was demonstrated in a complex intervention which aims to improve hospital care for frail older persons. Conclusion: A method for graphical representation of results of process evaluations of complex interventions was developed. Use of this method is needed in order to show the added value in understanding and comparing study results of complex interventions.

DEVELOPING ACTIVITY PROFILES OF CARE COORDINATION USING A NATURAL LANGUAGE PROCESSING METHOD
L.L. Popejoy, C. Galambos, V. Lyons, M. Popescu, M. Khalilia, M.J. Rantz, L. Hicks, University of Missouri, Columbia, Missouri

Care coordination is a multidisciplinary mechanism for managing complex care that improves transitions, rehospitalization rates, medication management costs, and self-management skills. Building on prior research, this study used and compared electronic healthcare records (EHR) from 4,112 home healthcare patients (HHC) and a subset of 217 patients enrolled in an enhanced care coordination aging in...
place model. A total of 347,000 nursing care notes were extracted from a HHIC EHR that incorporated Omaha system standardized language. We retrieved 188,509 narrative notes, specific to the Omaha case management category describing activities performed during patient visits. Metamap, a Natural Language Processing package, was used to process, parse, and extract the concepts from every note, resulting in the extraction of 16,755 unique concepts. These concepts were further refined using an iterative approach of: (a) concept extraction, (b) refinement against previously hand-abstracted terms, (c) concept ordering by frequency, and (d) expert review. This process resulted in an ontology with 395 concepts organized in a hierarchy of 66 activities, 165 foci, 91 problems, 54 people, and 19 places. Concepts from the ontology were used to build activity profiles for 41 out of the possible 75 target interventions used by care coordinators in the Omaha system category case management. These care coordination activity profiles may be used to: (a) specify activities used in care coordination, (b) tailor the work of care coordination practice and research, and (c) describe care coordination for use in EHRs. This paper will present the extraction process model, and the care coordination activity profiles.

INCREASED RISK FOR HIP FRACTURE AMONG SPOUSES - EFFECT OF HOMOGAMY?
V. Sundh1, B. Johansson1, A. Oden2, M. Karlsson3, B. Rosengren3, J. Kanis4, M. Lorentzon1, D. Mellström5,
1. Dept of Psychology, University of Gothenburg, Gothenburg, Sweden, 2. Chalmers University, Dept of Biostatistics, Gothenburg, Sweden, 3. Lund University, Dept of Orthopedics, Gothenburg, Sweden, 4. University of Sheffield, Centre for Metabolic and Bone Diseases, Sheffield, United Kingdom, 5. Sahlgrenska Academy, Geriatric Medicine, Dept of Medicine and Clinical Nutrition, Center for Bone Research, Univ of Gothenburg, Gothenburg, Sweden

Genetics is important for bone density and fracture risk. Lifestyle factors like physical activity, smoking and nutrition are also significant contributors to variation and risk. We analysed whether there is an increased risk for joint hip fracture in married couples. All patients with hip fracture (n=276,366) in the national inpatient register in Sweden from 1987 to 2002 included. This data was linked with the registers for multi-generation, causes of deaths, census register from 1970-1990 and the register of the entire population. All married couples (n=1,268,400) born 1902-1951 and married for at least 5 years were drawn for the analyses. The population was followed for 36 million person-years. The hip fracture risk was estimated using a Poisson regression model. In the period 1987-2002 hip fracture occurred in both spouses in 5049 couples. The HR for hip fracture among married women after a hip fracture in husbands was 1.16 (CI 1.11-1.21). The corresponding HR for the men was 1.18 (CI 1.12-1.25). The risk was elevated from age 55 to 90. The HR for hip fracture in married women aged 55-70 was 1.6 (CI 1.14-2.09) following a hip fracture in husbands. The increased risk for hip fracture among spouses remained after adjustments for age, calender yera, income, education, latitude and urbanisation. We show for the first time an increased risk for hip fracture among spouses. Likely reasons for the homogamy are shared life style and assortative mating.

DEVELOPMENT AND VALIDATION OF A RISK SCORING SYSTEM TO IDENTIFY OLDER ADULTS AT RISK FOR UNMET NEED FOR ADL DISABILITIES
L.P. Sands, H. Wang, E. Lim, G. DePalma, R. Spoentgen, B.A. Craig, School of Nursing, Purdue Univ, West Lafayette, Indiana

BACKGROUND: Disabled community-living older adults are rarely screened by primary-care providers for unmet need for activities of daily living (ADL) disability despite the costly health consequences of unmet ADL need. Busy clinic schedules make it unfeasible to screen all disabled older adults for unmet ADL need. An accurate risk scoring system is needed to efficiently identify which disabled older adults would benefit from screening. METHODS: ADL functioning, unmet ADL need, health, and demographic data from 2,977 community-living older adults with at least one ADL disability were retrieved from the 2011 National Health & Aging Trends Study. RESULTS: Thirty percent reported unmet need for one or more ADL disabilities. Ten-fold cross-validation of a logistic regression model revealed excellent accuracy (C-statistic=0.87, average correction rate=80%). Risk scores developed from the model included: four points for toileting disability, three points for disability in getting around inside, two points for bathing disability, and one point each for disability in dressing or transferring from a bed, female gender, Medicaid eligibility, hospital admission in the prior 12 months, diabetes, and heart disease. Risk scores were summed; the prevalence of unmet need for quartiles of risk scores was 4% for the first quartile, 16% for the second quartile, 41% for the third quartile, and 71% for the fourth quartile; P<0.001). CONCLUSION: Accurate identification of which patients should be screened for unmet ADL needs would promote referrals to community support providers whose services could alleviate unmet ADL need.

CONSTRUCT AND CONVERGENCE VALIDITY OF THE LATE-LIFE DISABILITY INSTRUMENT (LLDI) IN TWO LATIN AMERICAN OLDER ADULTS POPULATIONS
A. Vafaei1, M. Zunzunegui2, J. Guralnik3, J. Gomez Monters4, C. Curcio5, R.O. Guerra6, B. Alvarado7, 1. Queen's University, Kingston, Ontario, Canada, 2. Département de médecine sociale et préventive Faculté de médecine, Université de Montréal, Montreal, Quebec, Canada, 3. Department of Epidemiology and Public Health, University of Maryland School of Medicine, Baltimore, Maryland, 4. University of Caldas, Manizales, Colombia, 5. Universidade Federal do Rio Grande do Norte, Natal, Brazil

Background: LLDI is a sensitive comprehensive disability measurement tool and includes two sub-scales, measuring frequency and limitations in performing activities. The LLDI has been validated in Spanish, German, and North American populations. We previously showed that the long version (16 item) of the LLDI is able to measure disability in two Latin American (Manizales, Colombia; Natal, Brazil) older adults populations. In this study we assessed the construct and convergent validity the LLDI in the same populations. Approach: The LLDI was used to assess physical disability of 300 older adults aged 65-74 living in the community. ANOVA and t-test were used to determine the construct validity of the LLDI by exploring associations with self-reported health, depression, cognitive function, as well as with sex, education, and income. Convergent validity of the LLDI was assessed by examining its associations with physical performance test (Short Physical Performance Battery), mobility limitations (Nagi scale), and activity of daily living (ADL) measures. Results: Participants with better physical function, less mobility limitations, better self reported health, and good cognitive function reported to have more frequent activities and less mobility limitations as measured by the LLDI, indicating good convergent and construct validity of our mobility measure (LLDI). Conclusion: Construct and convergent validity of the LLDI support the use of the LLDI sub-scales as a good measure of physical performance in Latin American and similar populations.

RELIABILITY OF FREE WEIGHT 1RM TESTING AMONG SENIOR ADULTS
H. Kosteckezy, J.E. Wright, S. Smith, M. Powers, P. House, Kinesiology, University of Central Oklahoma, Oklahoma City, Oklahoma

In order to initiate strength training programs that prevent the decrease in ability to perform activities of daily living, it is important to have effective tools set in place to be able to determine muscular strength. The purpose of this study was to examine differences in subsequent one repetition maximum (1RM) testing of bent over row (BOR), bicep curl (BC), lateral raise (LR), knee curl (KC), and chest press (CP) in older adults. The 1RM is considered to be the maximal amount of weight that can be lifted one time correctly through the full ROM.
Ten senior adults over the age of 78 completed 1RM testing for BOR, BC, LR, KC, and CP. Participants warmed-up by lifting one set of eight repetitions with no resistance, followed by a 60-second rest period. Participants then completed one set of three to five repetitions at 40-60% of their estimated 1RM, followed by another 60-second rest period. The weight was increased at assessor’s discretion until 1RM was achieved. 1RM testing was completed on two different days within a 10 day period. Dependent t-tests and correlations were conducted to determine the reliability of 1RM tests. A significant difference was found for KC (p=0.000). Non-significant differences were found for BOR (p=0.064), BC (p=0.648), LR (p=0.153), and CP (p=0.662). A strong, positive relationship was found between the two 1RM tests for each of the different exercises. The results indicate that 1RM testing may be a reliable test to determine maximal muscular strength in older adults.

HOW DO DEMENTIA BEHAVIORS CLUSTER?
IDENTIFYING BEHAVIORAL CLUSTERING RELATIONSHIP TO CORTISOL
D.L. Woods1, M. Yefimova2, M. Brecht3, A. Aliotti2, A.L. Antonio2, 1. Center for the Advancement of Gerontological Nursing Science University of California, Los Angeles, Los Angeles, California, 2. University of California, Los Angeles School of Nursing, Los Angeles, California

Behavioral symptoms in persons with dementia (BSD), such as yelling, wandering, and restlessness, are extremely challenging to elders, their clinicians and caregivers. Progress in developing and refining tailored interventions to address BSD has been hampered by the ability to detect and characterize complex recurrent clusters and the relationship to altered circadian rhythm. The purpose of this study was to develop a measurement method to more precisely characterize the relationships between BSD and circadian rhythm. Using the modified Agitated Behavior Rating Scale (mABRS) (low, moderate or high intensity), we coded the BSD of 60 participants over a 4-day period. Data were analyzed using pattern recognition software (THEME). We categorized THEME patterns of high intensity behaviors into clinically significant escalation/de-escalation categories. Factor analysis identified clusters of these behavior categories. We used correlation and chi-square tests to test the association between identified factors, age, gender and cortisol (an index for circadian rhythm). Cortisol was categorized as normal or abnormal. Factors 1 and 2 explained 12—16% of the variance. The remaining factors 3-16 explained 1-6% of the variance. Participants with normal cortisol rhythm exhibited higher vocalization when staff or residents were present (Factor 3) than those with abnormal cortisol (p <0.05). Older age was correlated with less pacing and screaming in the presence of staff (p<0.1). Men had increased moderate intensity pacing and searching (Factor 8) than women (p<0.05). Relating clusters of behavior to participants' characteristics using innovative analysis identifies those more likely to exhibit BSD. Interventions can be specifically refined and timed.

STUDYING MULTIPLE OUTCOMES AFTER AURAL REHABILITATIVE TREATMENT: STUDY DESIGN AND BASELINE RESULTS
C. Blake, L. Li, B. Shpritz, D.J. Genther, D. Chen, J. Betz, J. Brandt, F.R. Lin, Johns Hopkins School of Medicine, Baltimore, Maryland

Context: Age-related hearing loss (ARHL) affects nearly two-thirds of older adults over 79, and the prevalence of hearing loss doubles with every decade of life. Recent research has demonstrated that hearing loss is independently associated with incident dementia, cognitive functioning, social isolation, and health-related quality of life (HRQL). Hearing aids and cochlear implants have been shown to improve HRQL; yet, whether these interventions could also affect cognitive functioning, physical functioning, stress, or social isolation is unclear. Methods: Patients aged 50 years and older receiving hearing aids or cochlear implants were recruited from the Johns Hopkins Department of Otolaryngology and prospectively followed at 6 and 12 months after intervention. At each visit, a standardized outcome battery was administered to assess: (1) cognition, (2) loneliness, (3) communication, (4) depression, (5) HRQL, (6) cortisol levels, (7) physical functioning, and (8) dual task performance. Results: Baseline data have been collected on 107 participants (49 CI; 58 HA). Cochlear implant participants are significantly more likely to have a higher Geriatric Depression Score (p < .001) and higher rating on the UCLA Loneliness Scale (p < .001) than hearing aid participants. Conclusion: A prospective study assessing the effects of aural rehabilitative therapies on social, cognitive, and physical functioning may provide additional insight into the potential impact of hearing loss treatment. These preliminary results will guide the planning of a definitive randomized clinical trial to investigate the role of aural rehabilitative treatments on reducing declines in cognitive and physical functioning.

STRATEGIES FOR STUDYING PROFESSIONAL NETWORKS USING A WEB-BASED TOOLS
A. Rao1, L.K. Evans1, C. Mueller2, E. Lake1, 1. School of Nursing, University of Pennsylvania, Philadelphia, Pennsylvania, 2. University of Minnesota School of Nursing, Minneapolis, Minnesota

This poster will describe the development, pre-testing and use of an investigator-designed, web-based survey administered to all of the nursing home directors of nursing (DONs) employed by a national, for-profit nursing home corporation in order to study the DONs’ professional networks, professional support, and intentions to leave their roles. Web-based surveys are an increasingly popular data collection method despite prevalent concerns regarding data quality and response rates. Due to survey length and complexity, collecting network data via web-based surveys can be particularly challenging. Using Qualtrics software, we designed this survey to explore DONs’ demographic characteristics and their professional networks, professional support, perceptions of support quality, and intent to leave. These elements correspond to the major concepts of the Convery Model of Social Relations. We pre-tested the survey tool with DONs outside the sample population to mitigate data quality concerns and worked with a programming consultant to make the tool visually appealing and simple to use. To recruit participants, we used several techniques including an initial webinar presentation outlining the study’s purpose, risks, and benefits, email invitations and reminders to participate, and follow-up phone calls. These techniques effectively increased participation. 302 DONs were invited to participate and 216 (71.5%) enrolled. Encouraging DONs to complete the study was more challenging. Many DONs chose not to provide network data. Those who did, however, were able to complete the survey, including a network diagram, accurately. Ultimately, 133 (44%) DONs provided complete data and were included in the final sample.

RURAL PRIMARY HEALTH CARE FOR DEMENTIA: A COMMUNITY-BASED PARTICIPATORY RESEARCH APPROACH
D.G. Morgan1, J. Kostenciak1, M. Crossley1, M. O’Connell1, A. Kirk1, N.J. Stewart1, V. Dal Bello-Haas2, D.A. Forbes2, 1. Canadian Centre for Health & Safety in Agriculture, University of Saskatchewan, Saskatoon, Saskatchewan, Canada, 2. University of Alberta, Edmonton, Alberta, Canada, 3. McMaster University, Hamilton, Ontario, Canada

Community-based participatory research (CBPR) approaches focus on issues of importance to communities, involve stakeholders throughout the research, and emphasize capacity building, empowerment, and action. A CBPR approach is being used to develop an interdisciplinary, cross-jurisdictional (Canada-UK) Rural Dementia Action Research Program (RaDAR) in primary healthcare (PHC) for individuals with mild cognitive impairment (MCI) and dementia, in the Canadian prairie province of Saskatchewan. Following a systematic review of collaborative care models for dementia and interviews with 10 rural PHC directors, a 1-day Planning Session was held with 53 stakeholders (families, healthcare professionals, administrators, government, Alzheimer Society) and 13 academic partners to establish relationships, identify gaps
in rural dementia care, and design innovative service delivery models. These topics were further explored at a subsequent 1-day meeting with 15 stakeholders. Identified gaps included: symptoms of MCI and dementia may be attributed to normal aging and diagnosis may carry a stigma; families do not seek help until a crisis; post-diagnostic services are difficult to access; long-term care admission is often premature or crisis-driven. Recommendations included improving early detection, diagnosis, and post-diagnostic care; and supporting caregivers to reduce distress and delay long-term care. Stakeholders identified four research priorities addressed developing a research network to facilitate innovation at the health region level; a capacity-building/mentoring program in dementia care for PHC professionals; a public awareness program aimed at dementia risk factors and early detection; and chronic disease management strategies. These findings have informed the development of a 5-year collaborative research program.

THE SUPPORTED LIVING RESEARCH NETWORK (SLRN): A COMMUNITY/ACADEMIC PARTNERSHIP FOR ASSESSING AND MEETING THE NEEDS OF OLDER ADULTS

D.V. Liebel, K. Barsz, T. Olsan, School of Nursing, University of Rochester, Rochester, New York

Background/Objective: As access to resources change, health care systems must innovate to serve a growing older adult population. Our newly-developed Supported Living Research Network (SLRN) includes nurse research faculty and 20 agencies which support those who cannot live independently. We aim to conduct/communicate research meeting needs identified by the agencies. Method: Semi-structured interviews with agency stakeholders identified agencies which address supported living and determined their research needs. Online surveys measured the community’s needs, validated the direction of the SLRN, and assessed its capacity to conduct research. Findings: Content analyses identified four needs: Quality improvement and comparative effectiveness research developing ground-breaking programs; Screening and Characterizing Populations defining unmet needs using recognized methods/instruments; Transitional Care to reduce re-hospitalizations; translational research to Identify Best Clinical Practices. Our description of a quality improvement collaborative of nursing homes will demonstrate how a network accelerates the translation of system improvement knowledge in ways that are not possible for any single agency to accomplish alone. Conclusions: Community agencies serving those who bear a disproportionate burden of disability are eager to work with nurse investigators to assess and meet the needs of older persons in an era of changing healthcare environments. Availability of funding was not a motivation for SLRN participation. We are creating a sustainable infrastructure for the SLRN by developing a Research Toolbox to educate providers about evaluation programs and instruments, enabling members to mobilize their strengths and address their individual needs, and providing training programs, networking resources, and an internet structure to facilitate community-based research.

SESSION 295 (POSTER)

COGNITION AND MENTAL HEALTH

THE IMPACT OF INTERPROFESSIONAL TRAINING ON IMPLEMENTING THE CONFUSION ASSESSMENT METHOD IN AN ACUTE CARE SETTING

R. Filinson¹, P. Clark², P. Burbank, J.A. Stoukides³, 1. Sociology, Rhode Island College, Providence, Rhode Island, 2. University of Rhode Island, Kingston, Rhode Island, 3. Roger Williams Medical Center, Providence, Rhode Island

Approximately 15-60% of older patients experience delirium during hospitalization, however the diagnosis is missed in up to 70% of cases. Delirium is associated with poor outcomes including prolonged hospitalization, functional decline, increased likelihood of nursing home admission and increased use of physical and chemical restraints. Individuals at risk for delirium should be assessed daily using a standardized tool to facilitate prompt identification. The Rhode Island Geriatric Education Center, funded by the Health Resources and Services Administration of the USDHHS, has implemented an interprofessional education program aimed to increase adoption of an evidence-based protocol (Confusion Assessment Method - CAM) to improve detection of delirium in the hospital setting. The CAM is a validated assessment method for delirium, can be administered in less than 5 minutes, and correlates with other measures of mental status. Training was implemented in two units of a local hospital and is being replicated at a second hospital. An outcome of the training was that the major risk factor for delirium—older age—now triggers CAM assessments of older patients on every shift during hospitalization. An analysis of the impact of training found that administration of the CAM on the units receiving the training increased from 36% prior to the training to 76% post-training in the six months afterward. By a year later, implementation was between 88-94%. For those positive for delirium, the interventions resulted in decreased delirium days as well. High levels of implementation at the units NOT trained warrant further study.

IT'S NOT THE RESIDENTS: DEMENTIA CARE STAFF'S PERCEPTIONS OF WORK-RELATED STRESSORS

R.J. Karaski¹, J. Berry¹, 1. Gerontology, St. Cloud State University, St. Cloud, Minnesota, 2. Dementia Care Foundation, Darwin, Minnesota

Caring for persons with dementia, especially those with dementia related behavioral issues can be extremely stressful (Brodaty et al., 2003) and lead to high levels of staff burnout and turnover (Castle & Engberg, 2006; Coole et al., 2007). Training, length of time on the job, and a person-centered care approach have been found to impact care providers' levels of stress (Zimmerman et al., 2005). The current study examines the types of stressors identified by care staff in a person-centered, specialized dementia care home. Care staff (n=42) were asked to identify work stress factors. Of 22 possible stress factors, none of the top 8 related to residents or their care. Rather, concerns regarding coworkers (n=28, 72%), pay (n=23, 60.5%), time (n=19, 50%); respect (n=14, 36.8%); agency policies (n=12, 31.6%), and residents’ family members (n=10, 26.3%) were at the forefront. Only 7 (18.4%) cited residents’ behaviors as a source of stress. Open-ended responses similarly found residents apt to the ‘What do you like best about your job?” list, while residents and/or resident behaviors were absent from the “What do you like least about your job?” response list. No differences were found in stressors with regard to length of employment, although respondents who indicated they were somewhat or extremely likely to leave their job within the year were more likely to cite pay and time as stressors. These findings are currently serving as the basis for a larger regional study examining dementia care staff perceptions regarding training, support, stress and factors of employment.

VISUAL EXIT BARRIERS: DETER EXIT-SEEKING IN HOME-DWELLING ELDERLY WITH DEMENTIA?

D.H. Moore¹, J. Fozard², W.D. Kearns³, A.M. Houston³, M. Mccrannie¹, V. Larson¹, 1. James A. Haley VA Center of Excellence, Tampa, Florida, 2. USF Department of Gerontology, Tampa, Florida, 3. Florida Mental Healht Institute, Tampa, Florida, 4. University of Toledo, Toledo, Ohio, 5. Xavier University, Cincinnati, Ohio

Background: “Exit seeking (ES)” or repetitive exit door approaching is common among persons with dementia who wander (PDW). Multiple studies report “visual exit barriers (VEB)” efficacious to reduce ES selectively and subjectively, i.e., among PDW only based on impaired cognition. However studies were of poor quality and established VEB
efficacy in nursing home (NH) but not domestic home environments. Methods: Twenty-nine home-dwelling PDW/CG dyads were recruited from a VA hospital outpatient population. One main exit doorway in dyad homes was sequentially equipped with door and floor cover VEB. A one group cross-over repeated measures design with two intervention and two no-intervention periods was used. Exit-seeking, defined as PDW incursion into a 6-foot zone in front of exit doors, was continuously measured for eight weeks using ultra-wide radio frequency identification methods. Results: Of VEB tested, door but not floor covers reduced ES among PDW. Clinical Implications: The fact that fire codes now prohibit door cover VEB usage in NH as egress impediments suggests door VEB efficacy as physically not subjectively based. Door cover VEB should NOT be used within any care environment pending confirmation of the source of door VEB efficacy. Conclusion: Confirming door cover VEB efficacy to reduce ES as subjectively and selectively based requires: (1) tracking the exit door approaching as well as exit door transiting of PDW and all study site occupants; (2) differentiating sanctioned versus unsanctioned episodes of such PDW transiting and (3) monitoring the locomotive behavior of all residents at both VEB-equipped and non-equipped exit doors.

EVALUATION OF A KNOWLEDGE TRANSLATION AND EXCHANGE INITIATIVE IN RURAL AND REMOTE DEMENTIA CARE

A. Cammer, D.G. Morgan, A. Innes, Bournemouth University, Bournemouth, United Kingdom

The objective of this research was to evaluate a knowledge translation and exchange (KTE) initiative aimed at rural and remote dementia care in order to gain a better understanding of the processes that best support KTE in this area. Formed in 2008, a yearly Summit meeting comprised of researchers, decision-makers, and knowledge users has been organized within the province of Saskatchewan, Canada to facilitate knowledge exchange and research efforts in the area of rural and remote dementia care. Decision-makers and knowledge users who participate in the Summit include frontline and administrative healthcare providers, clinicians, government officials, non-profit organization staff, consultants, physicians, researchers, students, and family members of persons with dementia. The Summit includes a research poster presentation evening followed by a full-day meeting including a keynote speaker, panel discussions, and working groups. The aims of the Summit are to further practice, research engagement, and KTE. In 2011, a formal evaluation was conducted to examine how the Summit functions as a KTE initiative. Semi-structured interviews were conducted with a sample of twelve Summit attendees representing all categories, followed by five focus group discussions with thirty-two attendees. Thematic analysis of the transcripts was conducted by two researchers and findings were compared. The thematic categories were ‘Connecting’, ‘Being in the Same Room’, ‘Contribution’, ‘Galvanizing’, ‘Commitment’. Implications of the findings include recommendations to better design KTE strategies, such as tailoring the focus, developing shared goals, balancing contribution and gain for participants, developing relationships among stakeholders, and supporting engagement.

THE FEELING TONE QUESTIONNAIRE (FTQ) AND AN UPDATE REGARDING ITS PSYCHOMETRIC PROPERTIES: ASSESSING DEPRESSIVE SYMPTOMS IN DEMENTED, COMMUNICATION-IMPAIRED OLDER PERSONS

This research aimed at developing a means of uncovering the subjective inner life of persons who are seriously limited in their ability to communicate feelings of distress associated with depression and other affective disorders. These analyses add to the existing published and previously presented reports of the reliability and validity of measuring affective disorder in communication-impaired elderly demented persons using the Feeling Tone Questionnaire. The FTQ builds upon the existing knowledge in the field of assessment of depression in dementia by combining a direct assessment focus and clinical observation method and adding behaviorally anchored ratings of affect, or feeling tone. It consists of 16 questions and 16 corresponding observation ratings of affect and was specifically designed for use with the communication-impaired demented patient. The FTQ uses standardized questions with simple wording. The total sample size was 764 respondents from four samples of respondents in New York City and upstate New York nursing homes and a psychiatric hospital. Additionally, 122 respondents participated at a New York City nursing home. The mean age of the combined sample was 84. Internal consistency reliability and interrater reliability were good across all samples, as was test-retest reliability. Concurrent convergent construct validity and discriminant validity coefficients were generally high. Criterion-related validity was provided in two samples using DSM ratings by geriatric psychiatrists. These findings provide support for the view that the FTQ works well as a method of facilitating the recognition of depressive signs in the more severely communication impaired group of demented older persons. Preliminary findings regarding the current application of the FTQ in an evaluation study of staff training being conducted by the Consortium of New York Education Centers (CNYGEC), will be discussed.

VETERAN CHARACTERISTICS, PERCEIVED SOCIAL SUPPORT, AND DEPRESSION AMONG OLDER VETERANS

M.S. Yang, J.A. Burr, Gerontology, UMass Boston, Boston, Massachusetts

Projections indicate that by 2020 there will be more than eight million veterans age 65 and older in the U.S. This study examined the relationship between depression and military service characteristics among a nationally representative sample of older community-dwelling male veterans. Following the stress-health model, the study also examined whether social relationships mediated the association between depression and veteran’s military characteristics. Data from the 2008 Health and Retirement Study were used to estimate logistic regression models. The study sample included males veterans age 51 and over (N=2,956). Depression was assessed with the CES-D-8. Military characteristics included war service era (WWII, Korean, Vietnam), professional military rank, and combat exposure. Models were also adjusted for a rich array of sociodemographic and health status covariates. The results for the unadjusted models indicated that serving in combat, having enlisted rank, and being a war era veteran was related to the risk of being depressed in later life. After adjusting for the covariates, Korean war status and combat exposure remained associated with depression. The social relationship index was negatively related to the likelihood of being depressed. The analysis showed that social relationships did not mediate the association between military service characteristics and depression. These results suggested that years after military service had ended, some conditions of military service were still associated with health among this sample of older veterans. This study was unique in part because it is among the few studies to use nationally representative data to analyze depression among older veterans.

PATIENT AND FAMILY VIEWS ON CURRENT AND FUTURE APPROACHES TO DIAGNOSTIC ASSESSMENT IN MCI

L. Hu, A. Hunsaker, J.B. Seaman, J. Lingler, University of Pittsburgh, Pittsburgh, Pennsylvania

Background: Only a fraction of individuals affected by mild cognitive impairment (MCI) present for cognitive evaluations. Little is known of how such individuals view the neurocognitive assessment process.
Although the field is shifting toward the increased use of biomarker testing, perceptions of such testing remain unexplored. This study characterizes the subjective experience of the evaluation process for MCI and explores views on amyloid-based biomarker testing in MCI. Methods: Ten individuals with MCI and their caregivers received hypothetical brain amyloid status results and related Alzheimer’s disease risk in mock disclosure sessions, following protocols developed in a parent study. Eight participants joined in a subsequent focus group, provided their views on the disclosure sessions, and discussed their experience of completing a cognitive evaluation resulting in an MCI diagnosis. Qualitative content analysis was used to analyze transcripts. Results: The presence of a threat emerged as an overarching theme related to living with MCI symptoms and completing a cognitive evaluation. Threat of the unknown and threat of stigma were primary domains. Three approaches to minimizing threats were evident: legitimizing the experience, seeking control of information, and seeking social support. Participants provided recommendations for improving the diagnostic disclosure process, and viewed learning amyloid status as a valuable component of assessment. Conclusion: This study may inform guidelines for communicating evaluation results, including biomarker findings, to persons with MCI and caregivers. Understanding the significance of providing diagnostic information within the context of living with MCI helps future research and practice to be more attentive to those affected.

EXPLORING BELIEFS ABOUT ALZHEIMER’S DISEASE RISK AND PREVENTION IN A COMMUNITY SAMPLE OF URBAN AFRICAN AMERICAN ADULTS

D.F. Edwards, P.J. Izard, C. Gleason, Kinesiology-Occupational Therapy, University of Wisconsin Madison, Madison, Wisconsin

African Americans (AA) are at significantly higher risk of AD than whites. Diagnosis of AD in AA occurs later than in whites when treatment is less effective; care is costlier, and family burden heavier. Studies suggest lower AD awareness in the black community. Lower awareness combined with cultural attitudes and beliefs regarding AD risk, treatment and prevention affect willingness to seek diagnosis of AD, make lifestyle changes or participate in prevention programs. We assessed awareness of AD/MCI, perceived risk factors, willingness to seek diagnosis of AD or MCI and intent to participate in prevention activities in an urban black community sample (N=101) recruited from non-health related community events. Levels of awareness of AD and contact with persons with AD and other dementias were higher than those previously published: the majority (60%) reported spending time with someone with AD and 36% helped care for a person with AD (36%). Fifty nine percent reported they were worried about developing AD. Despite greater than expected contact with persons with AD and concerns about AD risk, only 17% were willing to have a memory evaluation by a doctor or to take medications that would delay the onset of AD (14%); only 6% indicated that AD/MCI could be prevented. Low endorsement of modifiable causes was observed including diet (8%), physical activity (22%), and stress (12%). Significant age and gender differences in risk ratings and willingness to engage in prevention activities were found. Our findings reinforce the importance of culturally tailored education, diagnosis and prevention programs.

EQUINE ANIMAL-ASSISTED INTERVENTION FOR PERSONS WITH DEMENTIA: NOT JUST “HORSING AROUND”

H. Dabelko-Schoeny1, G. Phillips2, E. Darrough3, S. DeAnna4, M. Jarden5, D. Johnson6, G. Lorch7. 1. The Ohio State University - College of Social Work, Columbus, Ohio, 2. The Ohio State University - Center for Biostatistics, Columbus, Ohio, 3. The Ohio State University - College of Veterinary Medicine, Columbus, Ohio

The purpose of this pilot study was to determine the feasibility and effectiveness of using guided interactions with horses as a nonpharmacological intervention to improve the physiological and behavioral states of persons with dementia. A convenience sample of persons with dementia was recruited from an adult day health center (N=16). A multi-component intervention was implemented comprised of opportunities for grooming, painting and leading horses. Using a randomized pretest-posttest crossover design, researchers compared participants receiving the equine-assisted intervention with participants receiving treatment as usual. Older persons with Alzheimer’s disease and related dementias engaged positively in animal-assisted therapy with horses. A reduction in behavioral problems was found post intervention in contrast to the comparison group. Pre-intervention measures showed that participants exhibited lower levels of disruptive behaviors compared to the control group on the days they were scheduled to work with the horses. Interestingly, cortisol levels used as a physiological measure of coping with stress were elevated after the intervention in participants with higher Mini Mental State Examination score. Equine-assisted interventions are feasible and possibly beneficial for adults with Alzheimer’s disease or a related dementia disorder, such as those enrolled in adult day health programs. Future studies should utilize multiple methods of assessing impact and include process measures to delineate which specific activities seem to provide the most benefit.

TRAJECTORIES OF ELDERLY DEPRESSION: EFFECTS OF CHILDHOOD ADVERSITY ON MENTAL HEALTH AMONG KOREANS ELDERLY

H. Jun1, M. Kim2, H. Lee1, 1. Yonsei University, Seoul, Republic of Korea, 2. Duke University, Durham, North Carolina

In the past, researchers emphasized socioeconomic circumstances in the adult years when examining the social inequality in health status. Recently, more social scientists have begun to consider childhood experience as one of the crucial predictors of adult health conditions. However, few researchers have examined the late-life trajectories of depression or the extent to which they are influenced by childhood adversity. In this study, we sought to examine how childhood adversity may affect depression of Korean elderly via using longitudinal data of South Korea Welfare Panel Study collected from 2007 to 2010. 3,779 subjects aged 65 in 2007 were analyzed for estimated latent growth curve models (LGM) of depression. Childhood poverty, school dropout, foster care experience, and parents’ level of education were included for childhood adversity items. Current SES (level of education, household income), health factors (health behaviors, hospital use rates, perceived physical health), and psycho-emotional factors (social relationship satisfaction, self-esteem, informal support size) were also asked. Depression was measured with Center for Epidemiology Studies-Depression Scale short form. The results suggest that adverse experiences of the early years are likely to influence depression in the later years. Socioeconomically disadvantaged background is associated with a higher level of depression at baseline even after considering current SES, health, and psycho-emotional factors. In other words, efforts to alleviate childhood adverse experience may have long-term benefits for mental health. These findings imply the need for policies and resources to provide appropriate environment for children in order to improve public health.

CONSUMER DEBT AND MENTAL HEALTH OUTCOMES AMONG MID-AGED AND OLDER AMERICANS

Objectives. This study examines the associations of unsecured debt and two distinct mental health outcomes: depressive symptomatology and psychological well-being. The associations of perceived control over one’s financial situation are tested independent of unsecured debt on both mental health outcomes. Methods. Using the 2006 Health and Retirement Study (HRS), we studied 5,817 adults aged 51 and older,
who responded to the core survey and a psychosocial leave-behind questionnaire (LBQ). Hierarchical regression analysis is used to estimate the relationships. Results. Thirty percent of the respondents have unsecured debt. Unsecured debt had a positive effect on depressive symptomatology (1.9%) and a negative effect on psychological well-being (1.3%). Perceived control over one’s financial circumstances influenced the size and magnitude of the linkages between unsecured debt and the mental health outcomes, boosting explained variance in psychological well-being and depressive symptomatology by 83 and 12 percent, respectively. Discussion. Perceived control over one’s financial circumstances strongly influences the psychological well-being of mid-aged and older Americans. Accordingly, interventions that influence control over one’s financial circumstances may enhance psychological well-being significantly. This study provides new evidence regarding perceived control over one’s financial situation as a factor that affects the relationship between unsecured debt and mental health outcomes.

ENVIRONMENTAL SCAN OF SELF-DIRECTION IN BEHAVIORAL HEALTH: FINDINGS AND RECOMMENDATIONS
L. Simon-Rusinowitz1, B. Croft3, D.M. Loughlin1, K.J. Mahoney2, 1. Health Services Administration, University of Maryland, College Park, Maryland, 2. Boston College Graduate School of Social Work, Chestnut Hill, Massachusetts, 3. Human Services Research Institute, Cambridge, Massachusetts

Approximately one in four persons age 55 and over experience behavioral health disorders. Experts project that this number, as well as demand for service, will increase significantly in the future. For example, they expect the need for substance abuse treatment to increase from 1.7 million elders in 2000 and 2001 to 4.4 million in 2020. By 2030, the number of elders with major psychiatric illnesses is expected to reach 15 million, more than double the current prevalence. With health care reform focusing on integration of behavioral health and primary care, and expanded Medicaid coverage, a greater need for services is likely. Self-direction (SD) is based on the premise that people with disabilities can and should make their own decisions about their services. Currently, SD programs help people of all ages and with all types of disabilities maintain independence. However, these programs have not focused on a model that allows participants to direct a budget and manage their services. An environmental scan aimed to understand barriers and facilitators to SD in behavioral health, and ascertain interest among stakeholders. It comprised four components: 1) a literature review examining current knowledge; 2) webinar, surveys, and interviews with state and county agency directors; 3) interviews and focus groups with key stakeholders (i.e. consumers and providers); and 4) recommendations. Results indicate that a majority of project participants are interested in a large-scale demonstration and evaluation of self-directed behavioral health services. The authors will discuss next steps for integrating self-direction into the behavioral health arena.

PERCEIVED STRESS IN A COMMUNITY-DWELLING U.S. CHINESE POPULATION: FINDINGS FROM A CROSS-SECTIONAL STUDY OF CHINESE OLDER ADULTS IN CHICAGO
R. Chen1, E. Chang1, J. Ruan1, Y. Li1, C. Li1, M.A. Simon2, X. Dong1, 1. Rush Institute for Healthy Aging, Chicago, Illinois, 2. Northwestern University, Chicago, Illinois

Background: Perceived stress is related to increased physical illnesses and decreased sense of life satisfaction in late life. Language and cultural barriers may compound stress facing minority immigrant older adults. This study was conducted to examine the prevalence of late-life perceived stress among Chinese immigrant older adults. Methods: Data are from a cross-sectional survey of 3,018 Chinese older adults living in great Chicago area. We administered Perceived Stress Scale-10 (Cronbach’s alpha = 0.86) in an-in-person interview. Community-based participatory research approach was utilized to partner with Chicago Chinese community. Results: Among surveyed participants (N=3,018), the mean age was 73(SD 8.3) and 59.3% were women. Data shows feeling that things were not going their way was present in 40% of the participants. In addition, 36% reported lack of confidence to handle personal problems, 30% felt they were unable to control irritations in life, 24% felt they were unable to control important things in life, and 23% felt that they were unable to cope with all things that they had to do. Conclusion: Study findings reveal that Chinese older adults perceived their lives as stressful. Further longitudinal research is needed to better understand the common life stressors and protective factors. Public health intervention strategies for better stress-management skills are urgently called for.

PSYCHOLOGICAL WELL-BEING AMONG OLDER AMERICANS: THE EFFECTS OF COMMUNITY VOLUNTEERING AND ABILITY TO USE THE INTERNET
A.C. Mui, S. Kim, N. Jiang, School of Social Work, Columbia University, New York, New York

The secondary research is based on the WAVE I (2011) of the National Health and Aging Trends Study (n = 8245). The sample respondents were drawn from all Medicare enrollees in the U.S. who are age 65 or older. The sampling design is age-stratified and participants are randomly selected from 5-year age brackets between the ages of 65 and 90, and from among persons aged 90 and older. The purpose of this study is to explore the effects of community volunteering participation and the ability to use technology among older Americans’ psychological well-being in terms of depression. Sample characteristics for this study showed that there were more females than males; 68.6% White, 21.8% Black, 5.7% Hispanic, and 2.8% other racial groups. Results are consistent with aging mental health literature. The community volunteer service participation rate was 22.5% and the ability to use internet technology was 29.1%. Multiple regression results indicate that older adults who reported lower levels of depression tend to be males, married, educated, reported better perceived health, greater sense of life satisfaction, more involved in community volunteering services and were more likely to be engaged in regular internet activities. Data support that meaningful social engagement through community volunteering service and internet use may be important protective factors for older adults’ sense of depression.

THE CONTRIBUTIONS THAT SEXUAL PROBLEMS AND LIFE SATISFACTION MAKE TO DEPRESSION IN OLDER WOMEN
A.K. Hughes1, O. Rostan2, 1. Michigan State University, East Lansing, Michigan, 2. University of Michigan, Ann Arbor, Michigan

The focus of much research in older women’s sexual health tends to be the biophysiological aspects of sexual function. However, sexual problems negatively impact older women’s lives in ways that exceed function alone. This study examined the relationship between sexual dysfunction, life satisfaction and depression in a non-clinical, community-based sample of older US women. A cross sectional survey was conducted with a random sample of women aged 60+. Women were asked about current sexual dysfunction, general health, days of decreased function, and demographics. Measures included the Satisfaction with Life Scale (SWLS), and the Brief Screen for Depression (BSD). Analysis included multiple regression to examine the relative strength of predictors of depression. N=956. Race/ethnicity: 71% Caucasian, 18.2% African- American, 10.8% other. 67.1% of women reported at least one type of sexual dysfunction. General health was good for a majority of the sample (69.5%). Mean depression scores indicated clinical depression. The regression model was significant (F = 30.46, p < .0001) and accounted for 18% (adjusted R squared = .174) of the variance in

66th Annual Scientific Meeting
Attitude Toward Elderly Residents 

ACCULTURATIVE STRESS AMONG IMMIGRANT 
NURSING HOME AIDES: AS A PREDICTOR OF ABUSIVE ATTITUDE TOWARD ELDERLY RESIDENTS

Y. Kim, S. Hong, H. Kanno, K. Jeong

Background: With an increase of immigrant workforce in U.S. long-term care facilities, there is growing interest in the influence of immigrants’ cultural adaptation on their job performance. Adapting to a new culture generates emotional strain and heightened feeling, such as a state of alertness and anxiety, and this phenomenon is referred to as acculturative stress. Given that immigrants experience acculturative stress—which may influence their interpersonal relationship and job performance—it is imperative that researchers and practitioners examine whether immigrant workers’ acculturative stress is a predictor of work attitude and job performance. The aim of this study was to investigate the effect of acculturative stress on abusive attitude among immigrant front-line workers in long-term care. Methods: Participants were 154 female immigrant aides from nursing homes in California. A 7-item abusive attitude scale was developed and validated by factor analyses. Work-related stressors and experience were assessed using the Burnout Inventory and Nurse Aide Job Satisfaction questionnaire. Perceived discrimination and acculturative stress were measured by the Acculturative Stress Scale. Results: Regression results showed that abusive attitude was significantly predicted by burnout, job satisfaction, and acculturative stress after controlling for demographics, F(7,142)=12.41, p<.001, R2=.38, adjusted R2=.34. High levels of acculturative stress increased abusive attitude (β=.47, t(142)=5.52, p<.01, sr2 =.13), suggesting that immigrant aides with high acculturative stress are less likely to treat elderly residents patiently and respectfully. Conclusion: Immigrant aides who experience severe acculturative stress are at risk for engaging in abusive attitude. Guidelines for elder maltreatment prevention and counseling for acculturative stress are discussed in this study.

WORKING “DOUBLE-DUTY”: EMPLOYMENT OUTCOMES OF CRITICAL CARE REGISTERED NURSES CARING FOR OLDER FRIENDS AND FAMILY

L.J. Clark-Shirley, University of Hawaii, Department of Geriatric Medicine, Honolulu, Hawaii

Despite a rich literature documenting effects of caregiving on work-related outcomes, little is known about how providing care to older persons impacts certain professions. For example, only a limited number of studies have explored the impact on registered nurses (RNs) providing “double-duty” informal caregiving alongside formal employment. This study examines relationships between informal caregiving and work outcomes important to nursing. A web-based survey was administered to 882 critical care RNs measuring burnout, intent-to-leave, and job changes. Respondents self-identified as informal caregivers via a single item; caregiving characteristics (e.g., burden and quality of support) were collected for self-identified caregivers. 41.2% (n=363) of RNs self-identified as informal caregivers. Linear regression models explored effects of caregiver status and caregiving characteristics on burnout and intent-to-leave. Logistic regression tested effects of caregiver status and characteristics on whether RNs had made a job change within the past year. All regressions included personal, professional, and family attribute controls. Caregiver status was not associated with burnout or intent-to-leave. Among the caregiving subsample, higher subjective (B=.101, p<.001) and objective (B=.205, p<.01) burden and lower quality of support (B=-.539, p<.01) predicted higher burnout; only subjective burnout predicted higher intent-to-leave (B=.086, p<.05). However, caregiver status had a small but significant association with having made a negative job change (OR=1.696, CI 1.256-2.290, p<.01). Within the caregiving subsample, more hours spent caregiving predicted slightly higher odds of past job change (OR=1.037, p<.01). Results demonstrate specific effects of caregiving on nurses’ employment and underscore the importance of certain caregiving characteristics for future studies.

AGING ADULTS WITH INTELLECTUAL DISABILITIES AND INTENDED STAFF TURNOVER: A COMPARATIVE STUDY

C.B. Laws, S. Kolomer
1. Institute on Human Development and Disability, University of Georgia, Athens, Georgia, 2. UNC School of Social Work, Wilmington, North Carolina

Direct support professionals (DSPs) face a myriad of challenges on the job which are intensified by the complexities of supporting aging clients. Previous research indicates that high demand and low control contributes to voluntary staff turnover. The purpose of this study was to explore if DSPs who primarily support aging adults (over the age of 45) with intellectual disabilities differ significantly from DSPs who primarily support younger adults when the factors predicting voluntary turnover are compared. A cross-sectional survey was used to collect data from ninety-seven DSPs in Ohio on variables identified as antecedents to retention/turnover and turnover intent. The findings indicate that DSPs who primarily support aging adults with disabilities reported significantly lower levels of psychological empowerment and descriptive data suggest that they are at higher risk of attrition than those supporting younger adults. Lower scores on the meaningfulness of the work and a DSP’s confidence in her ability to do her job suggest that DSPs who support the aging feel that they have less skill discretion, feel less able to independently go about the tasks of their job, and have low control within their department. These findings are important as the occupational strain hypothesis maintains that a combination of the high job demands and low control leads to job strain such as exhaustion, health complaints, and job dissatisfaction. Recommendations for organizational practice include building staff knowledge related to aging as it affects adults with disabilities, empowering staff to work autonomously, and including staff in departmental decisions.

THE HOME HEALTH WORKFORCE: A DISTINCTION BETWEEN WORKER CATEGORIES

R. Stone, J. Pagan-Sutton, N. Bryant, A. Adams, M. Squillace

Personal care and home health aides are the 1st and 2nd fastest growing occupations in the U.S., respectively. There are increasing concerns about the sustainability and capacity of this workforce. Home health workers receive low wages and little training and have high turnover. It is difficult to recruit and retain workers to improve clinical outcomes. This study uses data from the 2007 National Home Health Aide Survey to compare characteristics of the various subgroups of aides.
home health workers (home health aides, certified nursing assistants, home care aides, and hospice aides) and how they differ in terms of socio-demographic characteristics, compensation and benefits, as well as satisfaction and retention. Hospice aides fared better than other categories of home health workers in terms of wages, benefits and access to full time employment. All categories of home care workers were satisfied with their jobs. They reported higher levels of satisfaction with the intrinsic aspects of the job (e.g., learning new skills) compared to the extrinsic aspects of the job (e.g., compensation). One-fifth of respondents were “currently looking for another job” and one-third reported that they are “likely to leave the job in the next year.” Hospice aides were far less likely than their peers to express intention to leave their job. Given the increasing attention to hospice and palliative care by policymakers and consumers and the growth in this sector, more research is needed to understand why the hospice worker occupation is more competitive than other agency-based frontline home health jobs.

PERSONAL AND HOME CARE AIDE STATE TRAINING: COMPARISONS ACROSS THE DIRECT CARE WORKFORCE IN MASSACHUSETTS
L.E. Bercaw1,2, L. Gurgone3, 1. Heller School for Social Policy, Brandeis University, Waltham, Massachusetts. 2. Commonwealth Corporation, Boston, Massachusetts. 3. MA Council for Home Care Aide Services, Waltham, Massachusetts

Funded through the Affordable Care Act (ACA), the Personal and Home Care Aide State Training (PHCAST) program provided three-year, federal grants to six states for development and implementation of a training program for the growing population of direct care workers who assist older adults and persons with disabilities. One of those grantee states, Massachusetts, sought to bridge an existing gap between agency-managed direct care workers, who received agency-based training prior to entering the workforce, and consumer-managed workers, who were not required to receive any formal training. The challenges in meeting the needs of both groups resulted in multi-organizational partnerships with key stakeholders throughout Massachusetts to develop a rigorous curriculum that supports an adult-learner-centered teaching approach and incorporates a total of 13 core competency modules. Evaluation results from written pre-/post-tests, hands-on skills assessments, satisfaction surveys, and focus groups allowed comparisons to be made between these two different types of workers. Additionally, comparisons were made with a separate control group of Massachusetts direct care workers who had not received the PHCAST training. These non-PHCAST trainees completed the same post-test and skills assessment used for PHCAST trainees. Some members of this comparison group were workers who received past training through an agency, and others had received only on-the-job training from the consumers for whom they provide care assistance. This comparison group, though not an ideal match to the PHCAST trainees, allowed the Massachusetts evaluation team to draw conclusions about the benefits of the PHCAST training over other, existing models in the state.

FACTOR STRUCTURE OF BURNOUT AND ITS SOCIO-DEMOGRAPHIC CHARACTERISTICS AMONG PROFESSIONAL STAFF IN COMPREHENSIVE COMMUNITY SUPPORT CENTERS IN JAPAN
I. Hisanori, Human Welfare Studies, Kwansei Gakuin University, Nishinomiya, Hyogo, Japan

Purpose: Comprehensive Community Support Centers (CCSC) in Japan were established when LTCI Law was revised in 2006. The number of CCSC in Japan has been increasing since 2006 and it is necessary to improve the quality of professional staff in CCSC because they have to work with various and complicated cases. This study aims to clarify factor structures of burnout and describe its socio-demographic characteristics among professional staff in CCSC in Japan. Method: Subjects were selected randomly from the local authority list. The survey was conducted by mail in February, 2011. There were 1145 respondents from social workers, care managers, and nurses who were working in CCSC. The revised Japanese version of the Maslach Burnout Inventory (MBI), which consisted of 17 items, was used as a dependent variable. Organizational factors such as social support, locus of control and so forth, were independent variables. Results: As a result of principal factor analysis with promax rotation, three factors such as “emotional exhaustion”, “depersonalization”, and “personal accomplishment” were extracted with 15 items. The reliability (cronbach’s alpha) was 0.794 for EE, 0.810 for DP, and 0.811 for PA. The results of one-way ANOVA using burnout scores by socio-demographic variables showed that there was a significant difference of their ages and years of experience. Conclusion: The result indicated that three factors of burnout were extracted in this study and it was the same finding as other studies in Japan. There was no significant difference among three professions such as social workers, senior care managers, and nurses. There was a significant difference of ages and years of experience. This result suggested that it has been necessary for local authorities to put experienced professionals in position in CCSC.

GERONTOLOGY EDUCATION IN RUSSIAN: FROM THE INSIDE LOOKING OUT
B. Hills, Coastal Carolina University, Conway, South Carolina

This presentation will examine the readiness of higher education in Russia to embrace the aging of the country’s population through an analysis of data collected in Russia describing types and state of development of gerontology education courses and programs. The current demographic crisis in the Russian Federation has led government officials to look to social policy changes to offset short- and long-term declines in overall population. Initiatives proposed and enacted by the current administration, however, can also be seen to primarily support young persons, recently characterized by Russian officials as collectively representing the future of the country. Missing in the policy initiatives now unfolding in Russia are comprehensive programs and services geared toward helping older adults, who, as it has turned out, were neither financially- nor psychologically-prepared to live in post-Soviet Russia. After the collapse of the Russian economy in the 1990s and the erosion of savings by inflation that has extended forward into the 2000s, most pensioners in Russia currently live on government payments insufficient to keep pace with the modernization of Russia. This presentation will show that the slow growth and development of gerontology in Russia has been affected by numerous factors, some related to Russia’s history and current economic status and some specifically related to gerontology. Highlighted through the presentation will be specific examples of gerontology education currently available in Russia and examples of types of programs most likely to be developed in the near future.

A STATEWIDE ANALYSIS OF RURAL AND URBAN REGISTERED NURSE WORKFORCE IN LONG TERM CARE
I. Chen, School of Nursing, UW-Madison, Madison, Wisconsin

Background: Understanding the differences between the rural and urban long-term care (LTC) registered nurse (RN) workforce is crucial to ensuring that rural aging populations receive quality health care. Current literature has indicated a shift in the distribution of nurses across the nation towards equity between rural and urban areas. There is limited data to reflect current differences in LTC RNs in rural versus urban settings, making it difficult to develop recruitment and retention efforts. Purpose: (1) Explore the distribution of RNs in rural and urban LTC settings; (2) identify factors influencing the future employment and career plans of LTC RNs. Methods: Data of 5,523 RN in LTCs from the Wisconsin 2012 Registered Nursing Survey was used. Results: Forty-five percent of the RNs in LTC are located in rural areas. Nurses with bachelor’s degrees are more likely to work in urban areas. Approximately 18% of both rural and urban nurses plan to leave either their positions...
or career within two years. However, the reasons differ. Urban nurses are more likely to report general dissatisfaction with their current position (21%) compared to rural nurses (16%), while rural nurses are more likely to report promotion/ career advancement (20%) to urban nurses (13%). Family/personal issues are the top concern for both rural and urban nurses in their career decisions. Implications: Given the differences between rural and urban work settings, policy for RN recruitment and retention strategies should consider geographic differences.

CERTIFIED NURSING ASSISTANT CHALLENGES AND NURSING HOME CULTURE: A CALL FOR TRAUMA INFORMED CARE

N. Kusmaul, D. Waldrop, T. Nochajski, University at Buffalo, Buffalo, New York

Certified Nursing Assistants (CNAs) provide 80-90% of direct care in nursing homes. Life experiences shape their attitudes towards caregiving. Previous research has described demographics of this population as largely people of color with low incomes and who disproportionately experience exposure to potentially traumatic events. The purpose of this study was to describe CNA life circumstances and to understand how they relate to attitudes toward formal caregiving. Participants completed surveys including the Life Events Checklist, Nursing Home Survey on Patient Safety Culture, Caring Behaviors Inventory and MSHAKE. Trauma events were compared with a national sample using the Mann-Whitney U Test. The most frequently reported event was a “transportation accident,” (n=71 or 67%) experienced one or more. Physical assaults during one’s lifetime were experienced by n=49 (46.2%). Approximately one quarter of participants experienced an “assault with a weapon” (22.5%), “serious accident at home, work, or during recreational activity” (24.5%), “other unwanted or uncomfortable sexual experience” (23.6%), “sudden, unexpected death of someone close to you” (23.6%), and “sexual assault” (21.7%). These rates are significantly higher than those reported in the National Comorbidity Survey. The results suggest CNAs experience significantly higher levels of potentially traumatic events than the general population. Trauma informed care is person centered care that considers that all persons in an agency, staff and clients, may have past traumatic events and creates safe spaces for all. These results have implications for nursing home culture change in the setting of trauma informed care.

MEETING THE CHALLENGES OF WORKFORCE DEVELOPMENT IN DEMENTIA CARE

C.A. Alder1, M. LaManta2,3, L. Ditzelman4, A.H. Cottingham1, M. Boustan1,2,3, M.G. Austrom1,2,3, N. Kusmaul1, 1. Wishard Health Services, Indianapolis, Indiana, 2. Psychiatry, Indiana University School of Medicine, Indianapolis, Indiana, 3. IU Center for Aging Research, Indianapolis, Indiana, 4. Dept of Medicine, Indiana University School of Medicine, Indianapolis, Indiana

With a CMS Innovation Challenge Award, we have expanded our collaborative care model serving 200 patients in primary care to more than 2000 Medicare and Medicaid beneficiaries with dementia or late-life depression. Key has been the recruitment and training of a new care worker, the Care Coordinator Assistant (CCA) to serve as liaison between patients and caregivers and the hospital-based collaborative team including an NP/RN, MSW, and Medical Director. This model employs “task shifting” to assign responsibilities requiring less training and expertise to less expensive CCAs operating under close supervision of the hospital-based team. This new work force offers a cost-effective way to improve care, increase patient and caregiver satisfaction, and reduce unnecessary hospitalizations and ER visits. We hired and trained 20 CCAs utilizing innovative interviewing and recruitment processes. Candidates participated in preliminary screens including assessments of quality of experience with and attitudes toward the elderly. Selected candidates participated in a six-station Multiple Mini Interview process simulating real life situations - emotional families, agitated patients, and 4 “urgent” telephone calls. This process, time consuming and initially costly, helped us identify candidates capable of demonstrating empathy and understanding while delivering calm responses in challenging situations. Successfully hired CCAs participated in an intensive 10-day training program designed to prepare them to work in multi-disciplinary teams. Content included AD and depression education, non-pharmacological interventions, team building, simulation sessions, role plays, application of knowledge, and home visits with team members followed by debriefing. The CCAs are currently providing high quality care to our patients.

PREPARING THE DIRECT CARE WORKFORCE: INCUMBENT WORKERS, THE UNEMPLOYED AND OLDER TRAINEES

J. Morgan1, C. Rosenoud2, C.E. Barmol1, 1. Georgia State University, Atlanta, Georgia, 2. University of North Carolina at Chapel Hill, Chapel Hill, North Carolina

Population aging is driving an increase in the need for direct care workers (DCWs) across a variety of settings in long-term care. Most of this projected increase will be in the categories of Personal and Home Care Aides and Home Health Aides; key supports to older adults preferring to age in place. The purpose of this paper is to 1) compare demographics, work values, career self-efficacy and career intentions among incumbent workers, unemployed and older trainees and 2) understand persistence through training phases. This study uses baseline data from students enrolled in a Personal and Home Care Aide State Training (PHCAST) program, a federally sponsored initiative funded under the Affordable Care Act (N=383). Methods include descriptive statistics and logistic regression to predict persistence. Descriptive results indicate that older trainees had significantly lower career self-efficacy than younger trainees. Unemployed trainees were more likely than incumbent worker trainees to indicate a willingness to go back to college for job training. Although older trainees (50+) were willing to complete job training programs for specific skills at similar rates to younger trainees, they were less willing to enroll in college. Finally, 86% of trainees indicate that they will be working as a direct care worker within the next year. Selection models suggest that males are less likely to persist in direct care worker training after realistic job previewing. Implications for the development of training models for direct care workers in terms of both supports needed and trainee recruitment will be discussed.

FACTORS ASSOCIATED WITH SELF-EFFICACY IN ASSESSMENT AND INTERVENTION AMONG SOCIAL WORKERS IN AGING

According to the U.S. Bureau of Labor Statistics (2012), the need for social workers in health care is expected to rise by 34% during the present decade due to population aging. However, there is little knowledge of factors that enhance social workers’ self-efficacy and competencies for practice in aging beyond the classroom. To address this knowledge gap, this research sought to identify the extent to which social workers’ qualifications and the characteristics of their clients influenced their confidence for geriatric practice specifically related to assessment and intervention skills. As part of a broader workforce survey of gerontological social workers in Toronto, Canada, the Hartford Geriatric Social Work Competency Scale-II was completed online by a convenience sample of full-time social work practitioners (N = 100). A model of self-efficacy indicated that average years of social work and gerontological practice experience (β = .30, p < .01), degree of client acuity (β = .28, p < .01), and proportion of clients over 85 (β = .27, p < .05) were positive and significant predictors of confidence in geriatric assessment (R2 = .30, F = 5.44, p < .001). Client acuity (β = .32, p < .01) was found to be the only significant predictor of confidence in geri-
A NATURALISTIC EXAMINATION OF THE EVOLUTION OF THREE SPECIALTY GROUP HOMES FOR DEMENTIA-RELATED CARE OF ADULTS WITH INTELLIGENTIAL DISABILITIES

Agencies responsible for care of older adults with intellectual disabilities (ID) are developing small dementia-care group homes that can serve as community care alternatives. Such small group homes are designed to be ‘dementia-capable’ and provide for extended older age care. As dementia affects adults differentially, both with respect to symptoms and to the pathway of decline, it was hypothesized that given different timelines and patterns of decline such dementia care homes will eventually be defined by the nature of their residents in terms of residual functional skills and personal care needs. Given stage-specific changes that eventually occur, a longitudinal study was undertaken of three such dementia-care community-based group homes (which were opened simultaneously) to observe progression of decline and alterations in care practices. One aim was to see if home specialization would occur. It was found that dementia care was affected by differences in complexity of impairments and co-incident conditions found in adults with ID and dementia. Specifically, there were significant differences in the number of comorbidities, staff time devoted to specialized care, and frequency of occurrence of dementia-associated behaviors between dementia-care group home residents and controls. Also, residents with Down syndrome were younger and had significantly less comorbidities. With respect to specialization, some trends were evident of differentiation among the homes over the two years (with evident decline patterns), but it was not statistically significant. Results point to potential specialization over time if agency reassigns residents by level of care needs.

THE INFLUENCE OF DEMENTIA AND STROKE ON THE DEGREE OF CONSENSUS BETWEEN USERS AND CASE MANAGERS IN GRASPING USER’S SITUATION

R. Hata1, M. Shirasawa1, K. Masuda2, 1. School of Social Welfare, Hokusei Gakuen University, Sapporo, Japan; 2. J.F. Oberlin University, Shinjuku, Japan

Dementia and stroke are known as the factors that make it difficult for case managers to assist the elderly. The aim of the present study was to explore the influence of dementia and stroke on the degree of consensus between users and case managers in grasping the user’s situation. We conducted a study of the grasping user’s situation by matching the case managers who have more than 5 years’ experience, and the elderly who require nursing care in 2012. Independent t-tests were performed to examine for the differences in the degree of consensus on both sides for physical (6 items), psychological (4 items) and social aspects (3 items) by dementia or stroke. As the results of t-tests, it was revealed that the degree of consensus for the physical conditions (t(110)=2.16, p<.05) was significantly lower in dementia group. T-tests also indicated that the degree of consensus for social situation (t(107)=2.38, p<.05) was significantly higher in dementia group. No statistically significant differences were noted in the degree of consensus for all aspects on stroke. According to these results, dementia is the factor which makes it more difficult for case managers to assess the elderly’s situation than stroke. It also showed that case managers tend to give high priority to assess the social aspects of the elderly with dementia. Therefore, it is necessary for case managers to assess the physical aspect of the elderly with dementia carefully.

SESSION 305 (POSTER)

FRIENDSHIP AND SOCIAL SUPPORT

MAKING SENSE OUT OF THE “SOCIAL” VARIABLES: ASSESSMENT OF MULTIPLE CONSTRUCTS OF SOCIAL INTEGRATION FOR OLDER ADULTS IN NURSING HOMES

S.N. Leedahl1, K. DePaolis2, 1. University of Rhode Island, Department of Human Development & Family Studies, Kingston, Rhode Island; 2. University of Kansas, School of Social Welfare, Lawrence, Kansas

Objective: Various terms and measures have been used in the literature to denote being socially integrated, and many studies of older adults focus on only social networks or social support or aspects of either concept and often only include those living in the community. The purpose of this study was to assess multiple constructs of social integration (i.e., social networks, social capital, social support, and social engagement) for older adults in nursing homes using theoretical support and standardized measures. Methods: Data were collected from 140 older adults at 30 nursing homes in Kansas using random sampling techniques. We interviewed older adults’ in-person using a survey questionnaire and incorporating a planned missing data design. Multi-level confirmatory factor analysis was used to analyze the data, controlling for socioeconomic status, cognitive status, and activities of daily living. Results: The final model had acceptable fit based on the fit statistics, the significance of the factor loadings, and assessment of measurement error (χ²=156.68; df=103; p <.01; CFI =.94; RMSEA =.06; SRMR-W =.07; SRMR-B =.10). The results showed that the proposed model, which included all constructs, was supported at the individual-level. At the between-level, social networks and social support were supported. Implications: Study results have theoretical, methodological, and practice/policy implications for the study of older adults in long term care settings. In particular, this study contributes to understanding how to operationally define and differentiate social integration variables in studies of older adults, particularly when study data is hierarchical.

SCALE DEVELOPMENT OF SELF-EFFICACY SCALE FOR PREVENTING AND ALLEVIATING SOCIAL ISOLATION AMONG THE COMMUNITY-DWELLING ELDERLY PEOPLE (SES-PAS): COMMUNITY VOLUNTEERS

E. Tadaka1, A. Kono2, Y. Kanaya2, Y. Inamatsu1, Y. Dai1, W. Itoi1, 1. Medicine, The Yokohama City University, Yokohama, Japan; 2. The Osaka City University, Osaka, Japan

The Competency for preventing and alleviating social isolation among older people by community volunteers is an important issue in geriatrics, but no valid instrument exists to measure such competency. Our aim was to develop the Self-Efficacy Scale for Preventing and Alleviating Social Isolation among Older People by Community Volunteers (SES-PAS). The SES-PAS was developed as a self-administered questionnaire based on the Self-efficacy theory by Bandura. Self-efficacy is the belief that one has the power to produce a particular effect by completing a given task related to that competency. Construct validity was determined by an exploratory factor analysis with varimax rotation on 1,297 community volunteers in Japan. Internal consistency was calculated by Cronbach’s α. The Generative Concern Scale (GCS-R) and the Community Commitment Scale (CCS) were also administered to assess the criterion-related validity of the SES-PAS. The number of responses was 859 (response rate: 66.2%). Item analysis and factor analysis identified 8 items from 12 item pools, which were classified under the domains “community networking” and “neighborhood watching” for the elderly people (cumulative contribution 0.54). Cronbach’s α of the SES-PAS was 0.87, and Cronbach’s α of the subscales of “community...
ELDER CARE NETWORKS: HISPANIC AND ANGLO COMPARATIVE CASE STUDY

From 2005-2050 the ethnic composition of the United States population age 65 and older will increase from 6% to 17% for Hispanic elders and decrease from 82% to 63% for non-Hispanic Caucasian elders. With increased resource constraints elder care is shifting toward more reliance on informal care provided by family, friends and neighbors and away from formal or “paid” care. This is particularly relevant in rural areas of the United States. The purpose of this presentation is to describe how elders in one rural Midwestern community acquired the things they needed to live. As part of a larger ethnographic community study, formal and informal interviews, participant observation and comparative case study network analysis of a representative non-Caucasian Hispanic and an Anglo elder provide beginning understandings of elder needs and the care exchange networks of these elders. The setting is a rural Midwestern farming community that had a rapid growth population of immigrants primarily from Mexico. Key health issues include diabetes, cardiovascular disease, depression, no public transportation, elder abuse and poor access to formal health care. Time in the community, language, elder and family reputation, and care needs influenced the number of care network ties/components and strength of these ties. Independence-Interdependence was the core theme of the network process. Recommendations for elder care programming and research include “elder” as a cultural construct, cultural understandings regarding the quality of the exchange content, accessibility, and immigration public policy.

SOCIAL CONTEXT AND VOLUNTEER PARTICIPATION: THE ROLE OF SOCIAL TIES AND RESOURCES OF OLDER ADULTS

S. Dury1, N. De Witte2, A. Smetcoren1, D. Brosens1, T. Buffel1, L. De Donder1, D. Vente1, 1. Vrije Universiteit Brussel, Brussels, Belgium, 2. University College Ghent, Ghent, Belgium

There is strong evidence that social ties of older adults are correlated with volunteer participation. However, the process to which the relation between social ties and volunteer participation may vary remains underexplored in aging research. Using a mixed-method approach consisting of two consecutive phases, this article aims to identify social contextual factors that either promote or impede older people’s volunteer participation. In the first phase, quantitative data from the Belgian Ageing Studies (N= 67,144 from 141 municipalities) were used to positively select six municipalities: low, mediocre, and high rates of volunteering. In the second, qualitative phase, three focus groups with local policy-makers, as well as with professionals working in local organizations and associations, and older people were conducted in each of the six case study areas in order to explain and build on the quantitative results. Research findings indicate that membership in an association and length of residence are key determinants for volunteering in later life. The article concludes by discussing practical and policy issues raised by the research.

THE MEDIATING EFFECTS OF SOCIAL SUPPORTS ON THE RELATIONSHIP BETWEEN OUTNESS AND LONELINESS AMONG LESBIAN, GAY, BISEXUAL AND TRANSGENDER OLDER ADULTS

S.A. Keary, Boston College, Chestnut Hill, Massachusetts

Social support networks are important resources for the well-being of older adults. Little is known about the support networks of lesbian, gay, bisexual and transgender (LGBT) American older adults and the ways in which their support networks contribute to their well-being. Available evidence suggests that LGBT networks may be different from the networks of heterosexual older adults: LGBT older adults are less likely to rely on biological family members and instead have social support systems that are comprised of close friends and chosen families. This study investigates relationships between LGBT social support networks, outness (the extent to which LGBT individuals are open about their sexual orientation or gender identity) and loneliness. The study sample consists of 130 LGBT older adults age 60 years old and older who attended congregate meal sites in the greater Boston area between 2011 and 2012. Ordinary least squares regression was used to test the relationship between level of outness and social support on loneliness among LGBT older adults. Social support was found to mediate the relationship between level of outness and loneliness among LGBT older adults. These findings have important implications for health and mental health care providers who work with LGBT older adults to consider how their patients’ level of outness may affect their social supports and influence their sense of loneliness.

FACTORS ASSOCIATED WITH THE AMOUNT OF TIME CLERGY COUNSEL OLDER ADULTS

J. Pickard, S.D. Johnson, H. Shen, University of Missouri-St. Louis, School of Social Work, St. Louis, Missouri

Background: Clergy provide substantial amounts of counseling services to older adults. This study used Mental Health Literacy as a framework to determine which factors are associated with the percentage of work time that clergy spend counseling older adults. Methods: This study used Dillman’s tailored design method for a mailed survey. Responding clergy (N=494) residing in St. Louis Metropolitan areas completed a parsimonious questionnaire that included information on the amount of counseling they do with older adults, training they’ve received that is specific to older adults and that is specific to mental illness, their attitudes towards older adults’ depression, their relationships with mental health professionals, their knowledge of resources for referring people for additional help, and demographic data. OLS regression was used to examine the factors associated with the percentage of work time that clergy spend counseling older adults. Results: Study participants who were African American (p<.00), who were Catholic/Roman Catholic (p=.02), and who had more training specific to mental illness (p<.00) spent significantly more time counseling older adults. Discussion: Public-private partnerships should be formed between mental health centers and clergy to provide education and training to increase clergy ability to identify mental illness in older people and make appropriate referrals. As they already provide more counseling to older people than their counterparts, specific outreach efforts should be made toward African American clergy and Catholic clergy.

HEALTH AND SOCIAL SERVICE AGENCIES RESPONSIBLE FOR DISASTER PREVENTION FOR OLDER ADULT IN MARGINAL VILLAGES

K. Kitagawa, K. Hokao, M. Tahara, Culture & Education, Saga University, Saga, Japan

Japan’s “marginal villages” are villages in which older adults that are 65 years old or older account for more than half of the residents, and where collective functions are on the decline. As of April 2012 they numbered 10,091 villages of the total number of villages to 15.5%. These villages are distributed throughout rural districts, with the older adult...
living in them receiving health and social services by long-term care insurance. We have conducted disaster prevention questionnaire survey for 4209 general support centers throughout the country. Most of the staffs had a disaster prevention awareness that was “Somewhat high (26.5%)”, which was followed by “Somewhat low (50.3%)”, with the fewest having a “High (6.2%)” awareness. The most common responses taken by the centers that have experienced disasters during emergencies were: “Confirming evacuation routes for afflicted elderly people (81.7%)”, “Health management for victims (74.4%)”, and “Visiting afflicted elderly people at home (64.4%)” in that order, with the average score for disaster prevention awareness being significantly high. In terms of support from the centers during disasters, a large percentage provided direct support to afflicted older adults, and a contact structure has also been set in place for center professional. On the other hand, it was revealed that preparations regarding management agencies for connecting disaster victims with support that are desired by older adults have been lacking. Examples of these include determining information on them who requiring long-term care in rural areas; fire prevention; and various facilities and agencies related to medical care, health, welfare, and so on.

ON MODELING THE RELATIONSHIP BETWEEN SOCIAL CAPITAL AND HEALTH OUTCOMES FOR CHINA’S OLDER ADULTS: A STRUCTURAL EQUATION MODELING APPROACH

H. Luo, X. Pei, Tsinghua University, Beijing, China

The relationship between social capital and physical and mental health has been established mainly through findings from Western countries. Despite its great share of the global population, the effect of social capital on health outcomes in the developing world remains ambiguous and inconclusive. Even fewer studies have been targeted on the aged population in developing countries. In this study, we use data collected from the China General Social Survey (CGSS) 2005 to unveil the relationship between social capital and older adults’ physical and mental health. In addition, we investigate the suitability of current measures of social capital in modern China. The bonding/bridging distinction is adopted to measure social capital. A structural equation modeling approach is used in analyzing the data by taking the measurement errors of social capital into account. The result shows a positive effect of both bonding and bridging social capital. However, only bonding social capital is found to affect older adults’ health significant in urban area while only bridging social capital is significant in rural area. The results also suggest that the commonly used measures for bridging social capital are not suitable for older adults in rural area.

DOES CAREGIVING LOWER INCOME? LATENT TRAJECTORY ANALYSIS OF INCOME PATTERNS AMONG PEOPLE CARING FOR AN AGING PARENT

J.C. Greenfield, Washington University in St. Louis, Saint Louis, Missouri

Informal caregivers are the backbone of the long-term care system in the United States, and reliance on informal care is growing. Unfortunately, not much is known about the financial impacts of the caregiving experience, although some evidence suggests that caregivers who are also employed may experience lost wages, forgone promotions, and other costs as a result of their caregiving responsibilities. To better understand the longitudinal impacts of the caregiving experience, this study uses latent trajectory analysis with data from six waves of the Health and Retirement Study (1998-2008) to examine how caregiving impacts the income trajectories of adults (aged 51-67 at baseline) who care for an aging parent. Findings suggest that while caregiving does not have a negative impact for everyone, it is associated with lower income trajectories for at least 15% of respondents, and has marginal significance for an even larger group. Among those impacted by caregiving, being single, widowed or divorced is negatively associated with income trajectories, and race and education are also significant predictors of membership in this affected group. As expected, intensity and duration of caregiving also negatively impact income. The results suggest that while not everyone who provides care for an aging parent experiences lost income, some do – and, importantly, caregiving may exacerbate financial insecurity among already vulnerable groups. Future policy reforms should prioritize supports for vulnerable caregivers, since they are most likely to suffer long-term, negative financial consequences from their caregiving experience.

GROWING OLDER IN ACADEMIA: FACULTY AND STUDENTS’ PERCEPTION OF AGEISM AND AGING

F.I. Schnell, J. Tahmaseb, Political Science, West Chester University, West Chester University, Pennsylvania

There is ample research demonstrating that prejudicial attitudes and discriminatory practices toward older adults are widespread (e.g., Palmore, 2001; Butler, 1963) and that gender biases can compound ageist treatment. Older women are subject to “double jeopardy” — they are victims of age as well as gender discrimination. The main purpose of this study is to examine attitudes about aging and ageism in an academic environment. It also assesses how respondents evaluate the institution’s responsiveness to ageism. Preliminary results from an on-line survey (N=120) of faculty at a public university suggest that older faculty, especially women, are more likely to feel patronized and excluded by their younger colleagues. This survey data is complemented by a student survey (N=160) assessing students’ attitudes about the value and contributions of older employees and public service personnel. These data suggest that many students perceive age as highly related to productivity, willingness to innovate, and general job performance. In addition to presenting a theoretical framework about ageism in the workplace and an analysis of faculty and students’ perceptions of ageism and attitudes toward older individuals, the study also recommends how institutions can build awareness and advocacy about issues of identity and age. Many academic institutions generally promote diversity; the data provided in this study lend support to the notion that awareness of aging and ageism has to be included in a diversity framework.

WHAT ONLINE INFORMATION THAT CONSUMERS CAN FIND ABOUT THE NURSING HOME COMPARE WEBSITE?

D. Liu1, C. Lu2, A. Guan1, 1. University of Nevada, Las Vegas, Department of Health Care Administration and Policy, Las Vegas, Nevada, 2. University of Pittsburgh, Department of Library and Information Sciences, Pittsburgh, Pennsylvania

Purpose: This study analyzes the state affiliated websites leading to the Medicare’s Nursing Home Compare (NHC) website in order to understand which sites are referring Internet users to NHC. This is significant because, in the Internet age, online resources can be popular when a consumer needs to find a good nursing home. Design and Methods: We performed systematic searches from August 2012 through November 2012 for NHC website using the inlink operator provided by Google supplemented with integrated search box within the studied sites. Searches were accomplished for each state in order to collect information about the inlink and websites that can be used by long-term care consumers. Website information were collected by state and evaluated by four independent coders. Results: Our findings show that all 50 states had a link directing to NHC. It took about 4 to 5 clicks when navigating from their front pages. Only a handful of states have an affiliated website for consumers’ use for finding nursing homes. However, while most sites used NHC as a data source, some either did not provide data source information or used data other than NHC. Implications: The design of the website for long-term care consumers needs to be more user-oriented to allow users searching for information easily.
HELP IN THE REAL WORLD: THE MANY USES OF THE HOSPITAL ELDER LIFE PROGRAM (HELP) WEBSITE

P. Chen1, S.L. Dowal2, E.M. Schmitt2, D. Habtemariam2, T. Hsieh1,2, R.N. Victor2, S.K. Inouye1,2,3
1. Beth Israel Deaconess Medical Center, Boston, Massachusetts, 2. Hebrew SeniorLife, Boston, Massachusetts, 3. Harvard Medical School, Boston, Massachusetts

Delirium, a common condition in older hospitalized patients associated with substantial morbidity, mortality, and healthcare costs, can be successfully prevented by the Hospital Elder Life Program (HELP). In 2011, HELP transitioned to a new web-based model to provide HELP resources, including patient/family resources, resources for healthcare professionals, searchable reference database, and HELP implementation materials. While intended to establish HELP, we hypothesized the materials might have broader applications. We conducted an online survey of website registrants to explore the uses of the resources available on the website, and to evaluate knowledge diffusion related to these resources. Of 102 initial respondents, 72 (71%) completed the survey. Of the 72 sites, 39 (54%) had implemented HELP, 13 (18%) were in the process of implementing HELP, 11 (15%) used for non-HELP delirium prevention programs or guideline development, and 9 (13%) used for other purposes. A total of 54 (75%) HELP and non-HELP sites used the website materials for educational purposes, targeting healthcare professionals, volunteers, patients and families. Some examples of this knowledge diffusion included education of: hospital staff (e.g., new-hire orientation for nurses), community healthcare staff (e.g., home care agencies), pre-professional healthcare students (e.g., community college, summer internships), family caregivers (e.g., Alzheimer’s Support Center), and lay community (e.g., geriatric awareness conference). Our results demonstrate that HELP resources are being utilized for creation of HELP and other delirium prevention programs, as well as being diffused broadly in creative and innovative educational efforts across both professional and lay audiences.

LONELINESS, SOCIAL ISOLATION, AND HYPERTENSION IN LATER LIFE: GENDER DIFFERENCES

C. Coyle, Univ Mass Boston, Boston, Massachusetts

Among older adults, loneliness and isolation have both been shown to predict a multitude of poor health outcomes including high blood pressure, cognition and even mortality. However, these two concepts are rarely studied simultaneously and much less is known about the role of gender differences in these associations. This presentation aims to (a) establish gender differences in the rates of loneliness and isolation; (b) to examine association between isolation, loneliness, and hypertension; and (c) discuss importance of these findings for designing promising intervention strategies. Data from the Leave Behind Questionnaire portion of the 2008 Health and Retirement Study (n=7,057) are used to explore the relationship between social isolation and loneliness, including gender and age differences. Loneliness is measured using the Hughes (2004) 3-item scale (α=.95) which asks about the frequency of which an individual feels ‘left out,’ ‘lacks companionship,’ or ‘feels lonely.’ Social isolation is measured using a 14-item scale (α=.70) which includes items such as the frequency of with friends, family and children, participation in group activities, and volunteering. Hypertension was measured using both a self-reported measure of high blood pressure and physical measure of blood pressure. Results establish the importance of gender in shaping loneliness, social isolation, and the relationship between them. For example, loneliness and isolation were significantly but weakly correlated with one another (r=0.19). Further, results from this study support the relationship between these two concepts, isolation and loneliness, and the risk for hypertension among older adults.

SOCIAL INTEGRATION INTO SENIOR HOUSING AND ASSOCIATED WELL-BEING

J. Carroll, S. Qualls, University of Colorado at Colorado Springs, Colorado Springs, Colorado

The present study assessed the social integration of residents of independent senior housing as predictors of social support and loneliness. The rate of incorporation of fellow residents into the network was of particular interest. Antonucci’s concentric circle task assessed social network membership during the first (Time 1) and second (Time2) years within senior housing. Consistent with previous literature (Kahn & Antonucci, 1980), the inner circle contained mostly family (71.67%) and the outer circle had a mixture of family (36.99%) and friends (55.02%) at Time1. Both circles remained stable in total size over time, but the inner circle was unexpectedly significantly larger than the outer circle at both Time1 (Mean Difference = 6.00, p < .001) and Time2 (Mean Difference = 6.71, p = .002). Over time, younger-old adults (ages 63 to 83) decreased the average size of their inner circle (12.18 to 9.65) while the oldest-old (ages 84+) increased the inner circle (8.59 to 14.06). Both the inner and outer circles evidenced the inclusion of fellow residents from Time1 to Time2, but the outer circle evidenced significantly steeper increases than the inner circle (interaction, F(1, 33) = 4.27, p = .047, wp2 = .12, MSE = .91). Perceived social support and loneliness were stable over time but were not predicted by social network changes. Results suggest well-being may be differently predicted between age groups. The young-old may be more receptive of new relationships, while the oldest-old may benefit more from building inner network relationships.

SESSION 310 (POSTER)

POLICY AND EVALUATION STUDIES

EXAMINING THE ROLE OF DEMAND FOR PRESCRIPTION DRUGS ON MEDICARE PART D TAKE-UP USING A DYNAMIC APPROACH

J. Kim, Northeastern Illinois University, Chicago, Illinois

This study examines participation in the Medicare Part D program, and specifically, the factors that influence take-up of Part D benefits among Medicare beneficiaries. Prior research on means-tested income maintenance programs identifies the expected benefit level along with informational reasons, difficulty in the application process, and stigma as the primary explanations for take-up (or lack thereof) in public assistance programs. Framed around this theoretical framework, this research hypothesizes that the take-up decision in Part D’s “managed competition” policy context is driven primarily by demand for prescription drugs, but that this driving force is tempered by various costs associated with participation in the program. The research relies on event history analysis of data from the Health and Retirement Study spanning the years 2006 through 2010 to estimate a six-year take-up rate and to investigate the dynamic effects of medication demand on the eventual take-up decision. The study incorporates contemporaneous demand, lagged demand, and twice-lagged demand variables to distinguish the dynamic effects of persistent demand from that of recent demand on the take-up decision. Life table analysis yields a cumulative, six-year take-up rate of 49.5% for standalone Part D. Meanwhile, hazard models reveal that the effects of contemporaneous demand and persistent demand work in opposite directions. Namely, contemporaneous demand for prescription drugs increases the likelihood of Part D take-up while persistent demand decreases the likelihood of Part D take-up. The results indicate that outreach efforts should be directed to promoting take-up among newly eligible individuals to facilitate access to prescription drugs.

INTERACTIVE PERSONAL EMERGENCY RESPONSE SYSTEM: ADOPTION IN A COLEMAN MODEL CARE TRANSITIONS PROGRAM

1. Hyde, 1. Gerontology Institute, University of Massachusetts Boston, Boston, Massachusetts, 2. Ivy Hall Senior Living, Boston, Massachusetts

Most Personal Emergency Response Systems (PERs) are, as their name suggests, designed to respond to the needs of an older or disabled person in an emergency. As such, when a user activates the system a
likely result is the dispatching of an emergency medical transport team and a visit to the emergency room. As part of a wider effort to discourage unnecessary emergency room use, a new type of PERS that has interactive capability has been developed. This study collected data on twenty consecutive older people who were enrolled in a Coleman model program offered by the VNA of South Eastern Connecticut, designed to prevent unnecessary rehospitalizations. These individuals were offered the use of a PERS device that also had a one-button call feature whereby they could access a nurse 24-hours a day who knew them or at minimum had access to their medical records and could answer questions and help coordinate medications, doctors visits and other health-related issues. The pilot study assessed the usability and acceptability of this new device among a population of seniors who had recently been discharged from a hospital. The study collected data on usage, consumer and staff satisfaction and rates of emergency room usage and rehospitalization.

PROCESSES THROUGH WHICH OLDER ADULTS BECOME INVOLVED WITH NORC SUPPORTIVE SERVICE PROGRAMS
J. Fedor, E.A. Greenfield, Rutgers University, New Brunswick, New Jersey

Natural Occurring Retirement Community Supportive Service Programs (NORC programs) are community-level initiatives that join older adults and diverse stakeholders within a residential area with a dense concentration of older adults to make localities more supportive of aging in place. When conceptualized as an intervention, NORC programs are complex, especially given the voluntary nature by which older adults do or do not become involved with them. Recognizing this complexity, this study aimed to describe processes leading to engagement as well as non-engagement in NORC programs. Qualitative interviews were conducted with approximately 40 older adults with diverse levels of involvement residing across multiple NORC communities around New York City. Results revealed that respondents’ initial involvement with NORC services and programs occurred (a) informally, through “word of mouth” of current NORC participants or staff; (b) reactively, through a critical event that necessitated the assistance of concrete services; (c) during a major life transition, such as widowhood or retirement, that increased the respondents’ need for socialization; and (d) through a relationship that already existed with a NORC staff person. Furthermore, categories of respondents’ non-involvement included (a) the personal disposition of the respondent as not interested in participation; (b) having a negative experience with NORC participants or staff; (c) receiving services and programs as only serving the frail or sick seniors; and (d) being unaware of what NORC is. Implications from this study can inform how NORC services are created and delivered, generate ideas encouraging engagement in later life, and guide future evaluation research.

THEY ARE NOT ALONE, THE STATE PROTECTS THEM: THE ROLE OF STATE POLICY IN MARGINALIZING ELDERS
S.K. Narayanan, School of Social Work, University of Michigan, Ann Arbor, Michigan

Purpose: Pension 65 is a social pension and social service delivery program that provides medical attention and economic support to Peru’s elderly population, with specific focus on indigenous populations. This paper asks how consistent is the State’s construction of old age with the realities of elder life in Peruvian indigenous communities. Research Design and Method: This case study triangulates analytic methods that combine textual and content analysis of all promotional materials from Pension 65, which include brochures, special spreads in the national newspaper, and promotional videos. Analysis of these documents is compared with ethnographic literature on indigenous life in the Andes that provide a comparison of different social and state constructions and meanings of elder life. Findings: My analysis provides three main find-

ings. First is the dichotomization of elderly life as being marginal, separate, and distinct from the rest of social life in Andean communities. Second, the state creates a different reality of old age that differs significantly from traditional views of old age. And third, the state through their promotional discourses marginalizes the indigenous elderly population. Utilizing a critical gerontological theoretical lens, the indigenous elder is semiotically erased as a member of larger social systems, and becomes a symbol of the marginalized individual alone in poverty with only the state for support. Implications: Analysis of the policies surrounding the creation of Pension 65 needs to impact practice where service providers should be cognizant of how these programs could disrupt traditional familial systems within the region.

THE IMPACT OF EMPLOYMENT AND ECONOMIC STATUS ON QUALITY OF LIFE AMONG OLDER KOREAN IMMIGRANTS

BACKGROUND: This study aims to investigate the determinants of quality of life and describe their association with employment and economic status among older Korean immigrants. METHODS: A cross-sectional study of 215 older Korean immigrants (aged 65 years and older) was conducted in Los Angeles County. A hierarchical regression model was employed with quality of life as a dependent variable. Independent variables included in the first step are demographic variables such as age, gender, marital status, and education, and in the second step are economic related variables including employment status and self-rated economic status. RESULTS: After controlling for the effects of demographic variables, a robust hierarchical regression model indicated that employment and self-rated economic status were positively associated with quality of life. Also, the interaction between employment and self-rated economic status was significantly associated with higher levels of quality of life: older Korean immigrants who were employed and had higher levels of self-rated economic status exhibited higher levels of quality of life compared to those with no jobs and lower levels of self-rated economic status. IMPLICATIONS: This population-based study provides an empirical evidence that age, education, employment and self-rated health status are directly associated with quality of life of older Korean immigrants.

MONEY Follows THE PERSON: LESSONS FROM ONE STATE’S STUDY OF CASES THAT CLOSE WITHOUT SUCCESSFUL TRANSITION
K. Ruiz1, N. Shugrue1, D. Lambert1, J. Robison1, 1. University of Connecticut Center on Aging, Farmington, Connecticut, 2. Connecticut Department of Social Services, Hartford, Connecticut

The Money Follows the Person Rebalancing Demonstration (MFP), a multi-year, 47-grantee program, funded by the Centers for Medicare and Medicaid Services, helps states shift Medicaid long term support and services from a historically institutional orientation to greater use of home and community-based services. Participating states set benchmark goals for transitioning people out of institutions. Since 2009, Connecticut has successfully transitioned over 1400 people from nursing homes and other institutions to home and community-based settings, but as in all states, not every person who expresses a desire to return to the community successfully transitions. In an effort to understand and remove barriers to transition, Connecticut initiated a comprehensive study of cases that closed without transition during 2012. Findings indicate that common reasons coded for lack of transition were: person...
changed his/her mind (27%), withdrawal at the request of the conservator/guardian (16%), person declined assessment or did not agree with program requirements (12%), and excess physical or mental health needs (11%). Further in-depth review of case notes and care plans for individuals in those closure categories revealed common characteristics of persons who did not transition, and themes that may inform program managers of ways to improve program process and services to overcome barriers to transition. These include: effective communication with family members and conservator/guardians to allay fears of consumer safety, respite opportunities for those taking on informal care responsibilities, development of options for 24/7 care or supervision, and alternatives for management of formal caregivers when the person is unable to do so.

FROM RESEARCH TO POLICY: GETTING YOUR WORK IN THE HANDS OF DECISION-MAKERS IN THE AGE OF SOCIAL MEDIA

T.L. McMullen1, K. Fitzgerald1, K. Niles-Yokum2, J. Gerontology-Doctoral Program, University of Maryland, Baltimore and Baltimore County, Baltimore, Maryland, 2. York College of Pennsylvania, York, Pennsylvania, 3. Western Kentucky University, Bowling Green, Kentucky

As gerontology programs and researchers fight for funding and facilitated opportunities, a reliance on the need for advocacy, research, and evaluation becomes salient. One goal of gerontology research is to influence public policy and to aid the policymaker in the understanding of evidence-based research. However, academics are often at odds as to how to translate their research to the decision-maker. Differences in language, values, roles and responsibilities, use of social media, and communication may create rifts between academics and rule makers. The interface between the academic and the rule-maker may be messy and difficult to maneuver. Rule-making is a complex process, and at times, becoming an agenda item may seem hopeless. However, policy makers do want to hear about your research as these legislators rely on the most timely and effective research to help guide their decision-making. This qualitative study provided an opportunity to obtain insight from academics, scholars, and experts, exploring how decisions are made to determine the usefulness of aging-related research in policy decisions. Domains that provided guidance for our research included relevant research topics and identifying who decides what is relevant; how to become involved in the policy process; the usefulness of social media; and how aging issues can become a key agenda issue. This qualitative study also explored the perceptions of academics and policymakers as to how academics can become a more significant part of the policy process, in general. The interesting similarities and surprising differences between those involved in day-to-day policy decisions and academics are discussed.

FACTORS ASSOCIATED WITH FALLS RESULTING IN INJURY AMONG RESIDENTS IN RESIDENTIAL CARE FACILITIES IN THE US

S.D. Towne1, Z. Chen2, J. Gerontology-Doctoral Program, University of South Carolina, COLUMBIA, South Carolina, 2. South Carolina Rural Health Research Center, University of South Carolina, COLUMBIA, South Carolina

Objective: We conducted a cross-sectional analysis of a nationally representable sample of Residential Care Facilities (RCFs) to ascertain whether differences across race were present for having a fall that resulted in an injury (hip-fracture or other). Methods: We used the 2010 National Survey of Residential Care Facilities Resident public use file. Dependent Variable: In the past 12 months or time since the resident moved to the RCF, did they have a fall that resulted in any injury or not. Independent Variable: Race (Hispanic, White non-Hispanic (NH), NH Black, NH Asian, NH Other). The study population included 727,367 residents in RCFs. The adjusted analysis included residents general, age, education (high school/less versus some college/more), previous residential status (private residence, another RCF, retirement community, nursing home or other), and facility’s size (number of beds), ownership (for-profit/non-profit), and chain-affiliation. Chi Square was used in bivariate analysis & Logistic Regression in adjusted analysis. Results: Overall, 15% of residents in RCFs experienced a fall resulting in an injury. Rates of falls were different across race (p=.0005). Adjusted analysis: Factors associated with falls included facility size (large vs. extra-large, OR=1.4, 1.1-1.8), previous residence (retirement community vs. private residence, OR=1.5, 1.04-2.1). Factors associated with a lower likelihood in the odds of falls included race (NH Black vs. NH White residents, OR=.5, 0.2-0.9), facility size (small vs. extra-large, OR=.7, 0.5-0.95), gender (male, OR=.7, 0.6-0.8). Conclusions: Understanding factors related to falls in RCFs may prove useful in identifying successful falls prevention interventions for residents of RCFs.

OUTCOME OF AN IN-HOME INTEGRATED SUBSTANCE MISUSE AND MENTAL HEALTH TREATMENT FOR OLDER ADULTS: A PILOT STUDY

R.L. Cooper, S.M. Cummings, College of Social Work, University of Tennessee, Nashville, Tennessee

The number of older adults experiencing alcohol abuse and related consequences is expected to double to five million by 2020 (Gfroerer, Penne, Pemberton, & Folsom, 2003). It is estimated that one in four older adults use psychotropic drugs with abuse potential and that non-medical use of such drugs will increase from the current 911,000 to 2.7 million by 2020 (Simoni-Wastila, & Yang 2006; Collier, Compton, Gfroerer & Condon, 2006). The number of older adults in need of alcohol and drug abuse treatment is expected to more than double from 1.7 million in 2001 to 4.4 million in 2020 (Bartles, Blow, Brockman & Van Citters, 2005). The Older Adult Healthy Living Program (HeLP) is an in-home/office screening, brief intervention, and referral intervention that increases service use, and reduces addiction and mental health symptoms through age-specific Motivational Interviewing (MI) and Cognitive Behavioral Therapy (CBT) program. Participants in this pilot study include 93 public housing residents, 65% were male, 70% were African American with the remainder Caucasian. Of the participants screened for the study 17 participants screened positive for alcohol problems, and 5 indicated prescription drug misuse. Reduction in the mean number of days drinking were significant (p = .02) and change in the Current Opioid Misuse Measure (COMM) was also significant (p =.04). Findings from this study indicate the HeLP intervention is promising in treating older adults with substance abuse with co-occurring mental illness. Future studies will seek to replicate HeLP on a larger scale with a control group condition.

EXAMINING RACIAL-ETHNIC AND GENDER DISPARITIES IN POVERTY AMONG THE ELDERLY USING A DYNAMIC APPROACH

J. Kim, Northeastern Illinois University, Chicago, Illinois

In recent years, absolute poverty among the general population in the U.S. has climbed steadily from 12.1% in 2002 to 15.0% in 2011 according to Current Population Survey estimates. Meanwhile, absolute poverty among those 65 years and over has fallen from 10.4% to 8.7% in the same time span. Part of the illusion of improving economic circumstances among the elderly stems from the public dissemination of statistics that rely on repeated cross-sections of poverty data. As such, this study draws a sample of individuals age 65 and older from the 2002 through the 2010 waves of the Health and Retirement Study and tracks their income trajectories over a ten-year observation window to examine the long-term risk of falling into poverty upon retirement and the extent to which these patterns vary along racial-ethnic and gender lines. Life table analysis reveals a cumulative, sample poverty rate of 22.2% among elderly individuals over the ten-year observation window, and also finds that the risk of poverty is higher among Hispanic elderly indi-
Prescription drugs are increasingly important in older adults' treatment regimen. However, costs associated with the Medicare Part D coverage gap can inhibit medication use. While the Affordable Care Act (ACA) gradually reduces beneficiary cost-sharing requirements in the gap through 2020, it is not clear how this provision will affect medication access and adherence. This exploratory study examined problems associated with the coverage gap and implications of the ACA provision. Data were collected from 22 enrollees over the age of 50 in Medicare Part D plans who experienced the gap. Qualitative, semi-structured interviews were utilized to examine problems faced by enrollees and how the ACA gap closure provision influences medication access. Data were analyzed using NVivo. Results indicate that access and adherence vary, and are affected by the coverage gap. The most common themes suggesting reasons for nonadherence are drug cost, number and type of prescribed medications, and the enrollee's gender, income, and health status. Medication samples and prescription assistance programs are frequently utilized to avoid or delay the coverage gap, and are critical factors in maintaining compliance. Though the ACA provision decreases out-of-pocket expenditures, premiums and cost sharing continue to be problematic and can subsequently impact adherence. Moreover, the increasing cost of medications acts as a barrier to access. These results extend previous research indicating that the coverage gap is problematic for older adults. Further, findings suggest that while the ACA reduces expenditures, the remaining costs can present economic burdens that lead to medication rationing for some Medicare beneficiaries.

THE IMPACT OF PRESCRIPTION DRUG COVERAGE ON MEDICATION USE FOR DEPRESSION AMONG THE ELDERLY: EVIDENCE FROM A NATIONALLY REPRESENTATIVE SURVEY

E. Kalay1, A. Akincigil1, K.A. Zurlo2, S. Crystal1, 1. Institute for Health, Rutgers University, New Brunswick, New Jersey, 2. Rutgers University School of Social Work, New Brunswick, New Jersey

Medicare provides health insurance for most of the elderly in the United States including coverage for prescription drugs. We investigated how variations in cost sharing policies in Medicare prescription drug plans impact the use of medications for depression among the elderly living with depression. Depression is a highly debilitating condition that reduces the quality of life and is associated with negative health outcomes. Antidepressants are often used as the first line of treatment for depression, yet many older Americans do not receive adequate treatment because of racial/ethnic disparities in access to treatment and care. Using data from the Medicare Current Beneficiary Survey from year 2007, we found that even after the implementation of the Medicare Part D prescription drug program in 2006, there continues to be a great variation in cost sharing for prescription drugs for elderly Medicare beneficiaries. The generosity of the prescription drug coverage had a positive and significant effect on the use of antidepressant among depressed elderly (marginal effect=0.35, p<0.001). These results provide a partial answer to the puzzling question of why many people with depression are undertreated and medication adherence is low for the antidepressants that are proven to be efficacious in treating depression.

CANADA’S COMPASSIONATE CARE BENEFIT: IS IT AN ADEQUATE PUBLIC HEALTH RESPONSE TO ADDRESSING THE ISSUE OF CAREGIVER BURDEN IN END-OF-LIFE CARE?

A. Williams1, J. Eby1, V. Crooks2, K.I. Stajduhar3, M. Geisbrecht2, M. Vuksan1, R. Cohen1, K. Brazil1, 1. McMaster University, Hamilton, Ontario, Canada, 2. Simon Fraser University, Burnaby, British Columbia, Canada, 3. University of Victoria, Victoria, British Columbia, Canada, 4. McGill University, Montreal, Quebec, Canada, 5. Queen’s College, Belfast, Ireland

An increasingly significant public health issue in Canada, and elsewhere throughout the developed world, pertains to the provision of adequate palliative/end-of-life (P/EOL) care. Informal caregivers who take on the responsibility of providing P/EOL care often experience negative physical, mental, emotional, social and economic consequences. In this paper, we specifically examine how Canada’s Compassionate Care Benefit (CCB) - a contributory benefits social program aimed at informal P/EOL caregivers - operates as a public health response in sustaining informal caregivers providing P/EOL care, and whether or not it adequately addresses known aspects of caregiver burden that are addressed within the population health promotion (PHP) model. As part of a national evaluation of Canada’s Compassionate Care Benefit, 57 telephone interviews were conducted with Canadian informal P/EOL caregivers in 5 different provinces, pertaining to the strengths and weaknesses of the CCB and the general caregiving experience. Informal caregivers spoke to several of the determinants of health outlined in the PHP model that are implicated in their burden experience: gender, income and social status, working conditions, health and social services, social support network, and personal health practices and coping strategies. They recognized the need for improving the CCB to better address these determinants.

SUSTAINABLE DEVELOPMENT FOR AN AGING SOCIETY: NEW GUIDING PRINCIPLES FOR RESEARCH, POLICY, AND PRACTICE

A. DeLaTorre, Institute on Aging, Portland State University, Portland, Oregon

This paper presents findings from a qualitative dissertation that examined the case of sustainable, affordable housing developed for low-income adults aged 55 and older. Interviews with 31 key informants were conducted to understand the meaning of sustainable development for an aging society, how and why sustainable, affordable housing for older adults has been developed, and policies that have affected the availability and appropriateness of such housing. Findings suggest that introducing the topic of aging into the discourse of sustainable development will lead to a more robust meaning of the concept, which can aid future research, policy, and practice. Additionally, the findings from the study identified a need for sustainable development practices to pay attention to social equity and the equitable distribution of affordable housing for older adults. This paper offers a new definition of sustainable development, along with 10 guiding principles of sustainable development for an aging society.
ranging from informal to formal. Using the 2008 wave of the Health and Retirement Study, this research analyzed data from respondents who were 65 years and older and who were enrolled in a Medicare Part D plan (N=3,040). The aim of this research was to examine whether the enrollment choice, time spent choosing a plan, and type of informational resource used had an effect on Medicare Part D beneficiaries’ plan satisfaction. Preliminary results using multinomial logistic regression revealed that Medicare Part D beneficiaries who were automatically enrolled in their Medicare Part D plan and those who spent little time with plan selection were significantly more satisfied than those who had some input in plan choice and spent some time with plan selection. However, there was no significant difference in the level of Part D plan satisfaction based upon the type of informational resource used. These preliminary results suggest that Medicare Part D beneficiaries are the most satisfied with their plan when the decision-making process is the simplest, especially when the choice of a plan is made for them automatically. There does not seem to be a benefit to using one informational resource over another in terms of ultimate Part D plan satisfaction.

SESSION 315 (SYMPOSIUM)

TRANSLATING RECENT, TRANSFORMATIONAL ADVANCES IN THE BASIC BIOLOGY OF AGING INTO CLINICAL APPLICATION: OPPORTUNITIES AND CHALLENGES

Chair: J.L. Kirkland, Robert and Arlene Kogod Center on Aging, Mayo Clinic, Rochester, Minnesota
Co-Chair: R.I. Shorr, University of Florida, Gainesville, Florida

Implications and approaches for translating interventions that extend healthspan and delay age-related chronic diseases and disabilities as a group in experimental animals, into clinical applications will be discussed. The resultant longevity dividend if achieved could have profound clinical, economic, and social implications.

USING BIOLOGY TO DESIGN NEW TREATMENTS FOR AGING RELATED CONDITIONS

J. Walston, John Hopkins, Baltimore, Maryland

Rapid advances in the understanding of aging-related changes in biology and physiology have paralleled the rapid growth in populations of older adults and aging-related conditions such as sarcopenia, frailty, and functional decline. Improved understanding in the biological pathways that activate inflammatory pathways and the renin angiotensin system and of age-related changes in autophagy and mitochondrial function have also helped to identify important links between these changes and the development of several aging-related chronic disease states. In this session, the speaker will first detail some of the most clinically relevant age-related biological changes identified to date in these biological and physiological systems, and then discuss the potential to target populations of older adults with short term interventions such as anti-inflammatory agents or angiotensin receptor blockers, among others in order to alter trajectory of aging related conditions such as frailty and sarcopenia and to alleviate symptoms such as fatigue and weakness.

TRANSLATING AGING BIOLOGY TO CLINICAL APPLICATIONS – THE NIA/NIH PERSPECTIVE

M. Bernard, National Institute on Aging, Bethesda, Maryland

There have been a number of recent discoveries, supported largely by NIA’s Division of Aging Biology (DAB), that demonstrate the potential to lengthen not only life but also health span. These findings can potentially be translated to the clinical arena through properly trained scientists and configured clinical trials. Our Intervention Testing Program and efforts in coordination with FDA and other agencies to develop acceptable markers for frailty, and universal outcomes for subjects with multiple co-morbidities should help with translation of basic findings to the bedside and beyond. Additionally, the trans-NIH Geroscience Interest Group and the National Center for Advancement of Translational Science (NCATS) are potential means of augmenting efforts that have heretofore been supported almost solely by NIA. Constrained resources, both in appropriately trained personnel and support for clinical studies, continue to be a challenge. However, there are opportunities as a result of collaborative efforts at leveraging initiatives.

DESIGNING CLINICAL TRIALS TO EVALUATE NEW TREATMENTS TO IMPROVE PHYSICAL FUNCTION: TWENTY-YEARS OF LESSONS LEARNED

S.B. Kritchevsky, M.E. Miller, Sticht Center on Aging, Wake Forest School of Medicine, Winston-Salem, North Carolina

Caloric restriction and exercise have been used in animal models to identify molecular targets that might affect aging. Testing new compounds in human clinical trials is the final translational step. While the optimal outcomes are unclear, mobility function (e.g. gait speed) is very likely to be included as it declines with age, predicts mortality and disability and is a determinant of quality of life in its own right. The Wake Forest Older Americans Independence Center has over twenty-years of experience with trials of caloric restriction and exercise interventions to improve mobility function in the setting of a variety of comorbidities including heart failure, COPD, diabetes, and osteoarthritis. This experience can be used to guide the design of trials of novel compounds with respect to: entry criteria, specific outcomes, and sample size requirements. The issue of whether to test new compounds together with exercise or caloric restriction will also be discussed.

CHALLENGES AND OPPORTUNITIES FOR DEVELOPING INTERVENTIONS

J.L. Kirkland, Robert and Arlene Kogod Center on Aging, Mayo Clinic, Rochester, Minnesota

Interventions that extend healthspan or delay age-related chronic diseases in animals are potentially translatable into humans. Translating these findings to humans will require a great deal of work beyond the usual steps in research and drug development. Options for developing a path from bench to bedside for interventions that target fundamental aging processes will be reviewed.

SESSION 320 (SYMPOSIUM)

AGING IN PRISON: QUALITATIVE AND MIXED-METHODS INVESTIGATIONS OF INCARCEERATED WOMEN

Chair: R.S. Hanks, Sociology, Anthropology and Social Work, University of South Alabama, Mobile, Alabama
Discussant: R. Aday, Middle Tennessee State University, Murfreesboro, Tennessee

The three papers included in this symposium present data from survey research and/or narrative interviews with women in jail or prison. The paper by Hanks & Carr draws on feminist and life course literature to explain how women in jail construct their own stories of entry into crime and personal histories of life in and out of jail. The Toomey, Aday & Cován paper explores depression among elderly female inmates, providing suggestions for policy. The Maschi paper uses mixed methods to examine stress and coping among women in the prison environment. Taken as a whole, the papers in this symposium present a picture of women from the point of first offense (not consistently during youth) into later life in prison. During Q&A, participants will have the chance to discuss in depth the age, gender, and methodological issues identified by each study.

102
GENDER COMPARISONS IN CRIMINAL JUSTICE PATHWAYS, WELL-BEING AND COPING AMONG OLDER ADULTS IN PRISON: A MIXED METHODS EXPLORATION
T.M. Maschi, Graduate School of Social Service, Fordham University, New York, New Jersey

The intersection of gender, age, and criminal justice involvement has been minimally explored among older adults in prison. This mixed methods study explores how gender affects the pathways to prison, coping and health and well-being in prison among older adults. This cross-sectional mailed survey study of 677 older adults in prison uses a battery of standardized instruments and a series of open-ended questions. Results indicated that older women compared to their male counterparts in prison were more likely to report higher levels of histories of sexual abuse and adverse later life health and mental health outcomes, and lower levels of resilient coping. Results of a grounded theory analysis of qualitative findings found both older women and men reported common processes of life course trauma and stress, racial and gender discrimination prior to and during prison. These findings suggest that gender responsive strategies are needed to address the needs of older adults in the criminal justice system.

WHAT DO YOU WANT ME TO SAY? USING NARRATIVE INTERVIEWS AND VISUAL PROBES TO EMPOWER WOMEN IN JAIL TO TELL THEIR OWN STORIES OF CRIME OVER THE LIFE COURSE
R.S. Hanks, N.T. Carr, Sociology, Anthropology and Social Work, University of South Alabama, Mobile, Alabama

This paper reports results of a grounded theory analysis of data from 30 narrative interviews with women who were incarcerated in the city jail in a mid-sized southern city. Each interview was conducted by a team of two interviewers. Interviews began, “Tell us about yourself.” Most interviewees responded, “What do you want me to say?” or “What do you want to know?” Two visual probes were used to orient women toward presenting their life histories. The paper describes the use of these probes. Each interview ended with the question, “What do you think people should know about you?” Researchers observed that women were empowered by the interview and usually ended the narrative with some expression of self-affirmation. The analysis presented in this paper explores the narrative as a pathway that encourages women to tell their stories. The process and observations are situated in the context of age and gender.

DEPRESSION FACTORS AMONG FEMALE LIFERS AGE FIFTY AND ABOVE
B.M. Toomey¹, R. Aday², E. Covan¹, 1. University of North Carolina - Wilmington, Wilmington, North Carolina, 2. Middle Tennessee State University, Murfreesboro, Tennessee

While the general American population is aging many forget that the prison population is also growing older. The elderly, female inmate is especially disregarded. The current mixed-methods study, updates earlier research by Ronald Aday. Survey questions assess activity levels, mental health, and correctional policy. Individual interviews, loosely based on the short Geriatric Depression Scale with fifty elderly inmates from the Coastal State Women’s Prison, in Savannah, Georgia, supplement the survey data. The analysis of narrative interviews suggests that a history of trauma leads to greater depression within the correctional facility. Also, the lack of activities geared towards an older population may cause further boredom, thus leading to greater depression. The authors provide insight into the antecedents of depression among elderly female inmates as well as suggestions regarding administrative policies to benefit this population.

SESSION 325 (SYMPOSIUM)

ANXIETY TREATMENT INNOVATIONS TO ADVANCE OPTIMAL AGING OF UNDERSERVED POPULATIONS
Chair: M.A. Stanley, Baylor College of Medicine, Houston, Texas, Houston VA Health Services Research and Development Center of Excellence, Michael E. DeBakey VA Medical Center, Houston, Texas, VA South Central Mental Illness Research, Education and Clinical Center, Houston, Texas
Co-Chair: N.L. Wilson, Baylor College of Medicine, Houston, Texas
Discusser: M.E. Kunik, Baylor College of Medicine, Houston, Texas

Late-life anxiety is highly prevalent (3% to 38% depending on setting) with significant costs, including increased morbidity and mortality. Co-occurrence of anxiety and depression exacerbates personal and societal costs, including lower response to treatments and increased suicidal ideation. Research with older adults suggests they are susceptible to and fear side-effects of pharmacotherapy, and many prefer psychosocial treatment. Psychosocial interventions for late-life anxiety show positive outcomes; however, compared with younger adults, older adults have higher attrition rates and weaker effects. Furthermore, the reach of research has not extended beyond primary care settings or included diverse populations. Psychosocial interventions reported in this symposium represent promising new strategies to extend reach, facilitate engagement, and improve outcomes among underserved groups of older adults with anxiety. Four presentations will describe three clinical trials. The first highlights modifications of a cognitive behavioral therapy intervention to enhance sustainability (modular treatment, telephone delivery, use of nonexpert providers). Outcome data from 223 primary care patients with generalized anxiety disorder showed comparable outcomes achieved by PhD. experts and BA-level providers compared with usual care. The second highlights training for the BA-level providers, with several dimensions of integrity ratings reported. The third describes the community-academic partnership and recruitment activities of a person-centered intervention (Calmer Life) delivered by trained community counselors in four underserved minority neighborhoods. The fourth examines responses of 10 homebound veterans and their homecare medical team to a brief, modular, telephone-delivered intervention (VA-HELPS) with skills addressing anxiety and depression. Both Calmer Life and VA-HELPS allow use of religious/spiritual beliefs.

VA-HELPS: A BRIEF INTERVENTION FOR HOME-BOUND VETERANS WITH ANXIETY AND/OR DEPRESSIVE SYMPTOMS
M.A. Stanley¹, 2, J. Cummings², 2, M. Armento¹, 2, M.E. Kunik¹, 2, J. Cully¹, 2, N.L. Wilson¹, 2, S. Shrestha¹, 2, 1. Houston VA Health Services Research and Development Center of Excellence, Michael E. DeBakey VA Medical Center, Houston, Texas, 2. Baylor College of Medicine, Houston, Texas, 3. VA South Central Mental Illness Research, Education and Clinical Center, Houston, Texas, 4. Department of Psychology, University of St. Thomas, Houston, Texas

Cognitive-behavioral therapy (CBT) is effective for anxiety and depression among older adults, but barriers limit reach and engagement, particularly for older, medically compromised, home-bound adults. VA-HELPS is a brief, modular, skills-based intervention that accommodates the needs of older Veterans who are unable to travel to the medical facility due to distance or physical limitations. All sessions occur via telephone, and flexibility in treatment content allows attention to anxiety and/or depressive symptoms and the option to incorporate religious/spiritual beliefs and practices. An open trial of VA-HELPS is in progress. Twelve patients have been referred by VA providers, three have been included, and two are in treatment. We will present data on 10 participants with attention to changes in severity of worry, anxiety, and depressive symptoms, as well as insomnia and health-related quality of life.
Qualitative data from patients and providers regarding benefits, barriers, and facilitators of the intervention will be presented.

**ENHANCING OUTCOMES AND TRANSLATIONAL VALUE OF TREATMENT OF LATE LIFE GAD IN PRIMARY CARE**

J. Calleo, A. Bush, C. Kraus-Schuman, J. Culity, M.E. Kunik, N.L. Wilson, M.A. Stanley, I. Michael E. DeBakey VAMC, Houston, Texas. 2. Baylor College of Medicine, Houston, Texas. 3. Houston VA Health Service and Research Center, Houston, Texas.

Primary care providers often encounter older adults seeking help for anxiety. Although cognitive behavior therapy (CBT) is effective in older adults, effects are not as large as those among younger adults, and many elements of care (e.g., in-person sessions, expert providers) restrict sustainability. This study tested a modified version of CBT and implementation procedures to enhance sustainability in primary care. Telephone-based delivery was used to provide and review treatment skills. Additionally, treatment effectiveness was examined when care was delivered by Ph.D. or Bachelor (B.A. with no prior mental health experience)-level providers. Older primary care patients (n = 223) with principal or co-principal GAD were randomized to CBT (Ph.D. or B.A.) or usual care (UC). Participants who completed treatment delivered by either a Ph.D. or B.A. level provider had greater improvements in GAD symptoms (GADSS), anxiety (SIGH-A, STAI-Trail) and depression symptoms (PHQ-8) compared to participants who received UC.

**TRAINING NON-EXPERT PROVIDERS TO CONDUCT CBT FOR OLDER ADULTS WITH GENERALIZED ANXIETY DISORDER**

M.E. Dozier, C. Kraus-Schuman, N.L. Wilson, J. Calleo, A. Bush, M.A. Stanley, M.E. Kunik, I. Department of Psychiatry and Behavioral Sciences, Baylor College of Medicine, Houston, Texas. 2. Houston VA HSR&D Center of Excellence, Michael E. DeBakey VA Medical Center, Houston, Texas. 3. South Central MIRECC, Houston, Texas.

As the population of America continues to age, there is an increased need for cost-effective mental health care for older adults. One method of extending the current mental health care resources is to utilize non-expert or “paraprofessional” mental health care providers. The current study examined the validity of training procedures for BA-level providers conducting cognitive behavioral therapy for older adults with generalized anxiety disorder, relative to clinical psychology PhD-level providers. Independent treatment integrity raters (TIRs) evaluated BA-level providers to have high adherence and competence, and, in 50% of cases, TIRs guessed that BA-level providers were PhD-level providers. There were no significant differences in patient perceptions of their clinicians, measured by expectancy ratings following the initial treatment session and an exit interview following the treatment phase of the program which queried satisfaction with treatment and perceived clinician expertise. Various treatment characteristics of the different provider groups were also considered.

**CALMER LIFE: A CULTURALLY TAILORED ANXIETY TREATMENT TARGETED AT UNDERSERVED, MOSTLY AFRICAN AMERICAN COMMUNITIES**

S. Shrestha, P. Wagenet, J. Cummings, M. Armento, M.E. Kunik, G. Evans, M.A. Stanley, N.L. Wilson, I. Houston VA Health Services Research and Development Center of Excellence, Michael E. DeBakey VA Medical Center, Houston, Texas. 2. Baylor College of Medicine, Houston, Texas. 3. VA South Central Mental Illness Research, Education and Clinical Center, Houston, Texas. 4. University of St. Thomas, Houston, Texas.

New treatment models and additional research are needed to expand the reach of mental health care to underserved communities and minority elders. The Calmer Life program is a randomized controlled trial of a skills-based, person-centered intervention for late-life anxiety delivered by trained community counselors to older adults who live, work, worship or receive services in four underserved, mostly minority neighborhoods. Treatment is modular and culturally tailored with an option to integrate religion/spirituality. This presentation will outline the process of developing and working within a community-academic partnership. It will also report on recruitment efforts including community presentations to consumers and leaders at aging agencies, community centers, senior housing, and churches. Engagement of consumers and the use of audiovisual materials in outreach events will be highlighted. To date, 54 potential participants have completed a phone screen, 18 completed initial assessment, and 11 (8 African Americans) have been included in the study.

**SESSION 330 (SYMPOSIUM)**

**COGNITIVE PLASTICITY IN REAL-LIFE INTERVENTIONS**

Chair: J. Oltmanns, Jacobs Center on Lifelong Learning, Jacobs University Bremen, Bremen, Germany
Co-Chair: U.M. Staudinger, Jacobs Center on Lifelong Learning, Jacobs University Bremen, Bremen, Germany
Discussant: S.L. Willis, The Pennsylvania State University, Department of Human Development and Family Studies, University Park, 16802, Pennsylvania

Research on cognitive functioning has a long tradition in the aging literature. A tremendous number of laboratory studies has demonstrated impressive plasticity of cognitive functioning well into old age. However, it is still debated whether similar effects hold true for real-life settings such as an active lifestyle. Past research on the disuse hypothesis consistently provided optimistic but mainly correlational results. Therefore, the aim of this symposium is to bring together outstanding researchers that have studied the effect of cognitively stimulating activities in real-life settings by using an experimental or quasi-experimental approach and employing a variety of activity contexts. Elizabeth Stine-Morrow is going to present results from the “Senior Odyssey” study, an interesting field experiment that offered social opportunities for intellectual challenge in a team-based problem solving program. Sara Haber will talk about her work in the context of the “Synapse” project in which retirees learned a cognitively demanding, novel leisure activity for 15 hours per week over 14 weeks. Ross Andel will present findings from the “SWEOLD” study. He investigated the unique and cumulative effects of occupational complexity and leisure activities on cognitive functioning in old age. In a similar vein, Jan Oltmanns demonstrates that repeated job-task changes are positively related with various indicators of adult cognitive performance. In order to discuss and evaluate the findings from these four different real-life intervention studies, Sherry Willis, as a longstanding expert in the field of cognitive training, will be invited as special guest and discussant.

**EASYDAY ENGAGEMENT AS SOURCE OF COGNITIVE VITALITY? LESSONS LEARNED FROM THE SENIOR ODYSSEY PROJECT**

Senior Odyssey is a program of activity engagement that offers opportunities for intellectual challenge in a social context. Core elements include creativity in ill-defined problem solving, choice of activities, team-based collaboration, competition, and play. In a parametric experimental design, the effects of engaging in Senior Odyssey were contrasted with the effects of (a) a training program in reasoning that incrementally adapted in difficulty with increasing skill and (b) a waitlist control. Odyssey participants showed selective increases in divergent thinking, an ability exercised throughout the program in the absence of training, suggesting that engagement in everyday activities can support cognitive growth. Contrary to the substantive complexity hypothesis, however, we did not find broad transfer to core capacities. Rea-
soning training produced the expected robust effects in improved reasoning. Importantly, individual differences that predicted gain differed for the engagement and training interventions. We contrast engagement and training as distinctive paths to cognitive optimization.

LEARNING NOVEL AND DEMANDING LEISURE ACTIVITIES ENHANCE THE AGING BRAIN: EVIDENCE FROM THE SYNAPSE PROJECT
S. Haber, I. McDonough, G. Bischof, D. Park, Center for Vital Longevity, UT Dallas, Dallas, Texas

A lifestyle intervention was implemented in older adults. Participants learned a cognitively demanding, novel leisure activity for 15 hours/week over 14 weeks. Control groups experienced no new learning and had an equivalent time commitment. All participants completed a semantic classification task before and after the intervention while in an fMRI scanner. The novel-learning group evidenced increased neural recruitment in new brain regions (e.g., medial temporal lobes) that positively correlated with both improvement on a semantic memory retrieval task (verbal fluency) and time committed to the program. Importantly, for the novel-learning group only, the relationship between time committed to the program and cognitive improvement was mediated by changes in neural-recruitment. This study provides the first known evidence of the specific brain mechanisms that impact cognitive functioning as a result of implementing a lifestyle change and identifies learning new, demanding leisure activities as an effective way to enhance brain functioning.

THE ROLE OF MIDLIFE OCCUPATIONAL COMPLEXITY AND LEISURE TIME ACTIVITY IN COGNITIVE PERFORMANCE LATER IN LIFE
R. Andel1, I. Kåreholt2, 1. University of South Florida, Tampa, Florida, 2. Karolinska Institutet, Stockholm, Sweden

The goal was to examine the interplay of occupational and leisure time engagement at midlife and its relation to cognitive health in older adulthood in 805 members of the SWEOLD, a Swedish nationally representative sample, with information about occupation and midlife leisure activity participation from 1968, and cognitive assessment administered in-person in 1992 and 2002. The combination of high (above-median) leisure activity/high work complexity was consistently associated with better cognition in advanced old age controlling for age, sex, education, income and year of cognitive testing. High work engagement was not associated with better cognition when combined with low leisure activity, whereas high overall leisure activity was associated with better cognition when combined with high work engagement. The framework includes environmental features, individual factors, user tools and technology, and individual-environment interaction that facilitate community wayfinding. The presenters will introduce a cross-disciplinary conceptual framework on wayfinding building on established person-environmental models, summarize key findings from a review of literature on community wayfinding, share results from a project examining community wayfinding in older adults, explore the emerging role of technology, and then highlight next steps for research, practice and policy. This work underscores the need for increased attention to the distinctive challenges in older adult wayfinding, especially given our rapidly aging and functionally diverse population. Papers in order of presentation are: (1) A conceptual framework for community wayfinding (2) Cross-disciplinary research perspectives on community wayfinding, (3) Community wayfinding in older adults: Findings from the Chicago wayfinding assessment project, (4) Tools and technologies in facilitating community wayfinding: Opportunities and challenges, (5) Community wayfinding: Pathways for public health policy and practice.

JOBLINK-RELATED TASK CHANGES AS FACILITATORS OF COGNITIVE DEVELOPMENT
J. Ottmanns, B. Godde, A. Winneke, U.M. Staudinger, Jacobs Center on Lifelong Learning, Jacobs University Bremen, Bremen, Germany

Despite age-related decline in some facets, cognitive functioning retains the potential for enhancement throughout the lifespan. Characteristics of the work environment such as job complexity have been positively related to adult cognition (Schooler, 2006). The effect of repeated job-related task changes (→ task mobility), as another kind of cognitive stimulation, however, has not yet been studied. Out of 3,500 blue-collar workers from a production company in northern Germany who had been full-time employed with that company over the last 16 years, 170 persons returned a screening questionnaire. This allowed us to identify 20 pairs of participants who differed in task mobility (high/low) but were optimally matched for age, high school grades, adolescent leisure time activity and job complexity. Using a quasi-experimental design, these two groups completed various tests related to cognitive function-
CROSS-DISCIPLINARY RESEARCH PERSPECTIVES ON COMMUNITY WAYFINDING AND OLDER ADULTS

This presentation by the CDC Healthy Aging Research Network provides a review of the existing literature on community wayfinding from the relevant fields of cognitive psychology, architecture, urban planning, and engineering, ascertaining key lines of investigation, evidence and evidence gaps, and implications for public health gerontology. To date, community wayfinding has received little attention in public health gerontology, despite its relevance to neighborhood walkability, community engagement, pedestrian and motor vehicle safety, access to services such as healthcare, and other aspects of aging in place. The review covers environmental features (e.g., natural landmarks or distinctive design elements), individual factors (e.g., age, cognitive function, or travel purpose), user tools (e.g., mobility aids or mobile interactive devices), and individual-environment interactions that facilitate community wayfinding. Particular attention is directed to wayfinding in special needs populations including older adults with functional limitations.

COMMUNITY WAYFINDING IN OLDER ADULTS: FINDINGS FROM THE CHICAGO WAYFINDING ASSESSMENT PROJECT

Limited research about older adults’ community wayfinding suggests greater challenge with age and decreased cognitive functioning. Given the growth in the older adult population, we need to understand features that enhance or inhibit wayfinding, to enhance mobility and community engagement. This CDC Healthy Aging Research Network study of 35 short-term (n=14) and long-term (n=21) residents (5 and 6, respectively, cognitively limited) in an ethnically diverse Chicago neighborhood identified enhancing and inhibiting wayfinding factors. Data collection included a structured interview (e.g., demographics, function, wayfinding self-efficacy); responses to wayfinding strategies questions including map-drawing; and an origin-to-destination “task walk” with researchers along a prescribed path. Researchers had previously audited the path to identify wayfinding aids and cues. Results from descriptive and content analyses found older adults’ navigation primarily reliant on landmarks; street signs, addresses, and building numbers; and information from others. We will discuss differences in wayfinding strategies and implications for subsequent research.

TECHNOLOGY IN COMMUNITY WAYFINDING: OLDER ADULTS AND PEOPLE WITH DISABILITIES

Community wayfinding (CWF) is critical for maintaining mobility among older adults. Our purpose is to discuss the role of user tools and technologies (e.g., smartphones, compasses, maps, and written directions) in facilitating CWF in older adults and people with mobility disabilities. We report the results of a review and synthesis of the literature on user tools and technologies. We propose new research directions, including the need to better understand the use of tools in everyday settings among diverse populations. We summarize opportunities and challenges, such as barriers and the equitable distribution of these technologies in underserved populations. Without a consideration of these barriers, CWF innovations, no matter how efficacious and effective, may only serve to aggravate health and functional disparities by race, ethnicity, and region in aging populations.

COMMUNITY WAYFINDING: PATHWAYS FOR POLICY AND PRACTICE

Ease of wayfinding in the community facilitates walking and wheeling, promoting use of public transit, and reducing air pollution and risk of pedestrian and motor vehicle injury. While communities invest in wayfinding, their focus is most often on signage and branding, emphasizing commercial interests, entertainment, or tourism rather than broader public health goals. Standards and practice guidelines are limited, especially with regard to pedestrian wayfinding, and there is wide variation in community practices. In recent years, the concept of legible cities has prompted greater attention to the infrastructure and information systems that facilitate wayfinding. This presentation by the CDC-Healthy Aging Research Network and partners derives from a cross-sector survey and assessment of wayfinding practice and policy, highlighting best practices and exemplary initiatives, and sharing consensus recommendations of a multi-disciplinary panel regarding priorities to improve wayfinding in US communities.

SESSION 340 (SYMPOSIUM)
CONCEPTUALISATION, MEASUREMENT AND DETERMINANTS OF FRAILTY
Chair: J. Nazroo, University of Manchester, Manchester, United Kingdom

This symposium focuses on the conceptualisation of frailty, its operationalisation in empirical research, and understanding the genetic, psychological and social determinants of frailty. Proposed contributions in this symposium are: 1. Measuring frailty: A comparison of Fried’s frailty phenotype and Rockwood’s frailty index using the English Longitudinal Study of Ageing (ELSA) Prof. Dr. James Nazroo In this empirical contribution, the conceptual background of frailty is discussed in conjunction with the two main approaches to its measurement. 2. Genetic underpinning of frailty: An examination of candidate genes in relation to cortisol and apoptosis pathways Dr. Kris Mekli Key in uncovering the genetic determinants of frailty is discovering the biological pathways through which genes affect frailty, of which this paper will examine the two main hypothesized ones. 3. Socioeconomic and gender inequalities in trajectories of frailty: findings from a growth modelling approach Dr. Alan Marshall This paper examines the evolution of frailty in a cohort over a period of 10 years, and illustrates that multiple trajectories are possible, but depend strongly on social background and gender. 4. Can frail elderly people be happy? An investigation of the relation between frailty and subjective wellbeing using a structural equation model Dr. Bram Vanhoutte How does frailty, in large reflecting aspects of physical health, relate to mental health and subjective wellbeing?
CAN FRAIL ELDERLY PEOPLE BE HAPPY? AN INVESTIGATION OF THE RELATION BETWEEN FRAILTY AND SUBJECTIVE WELLBEING USING A STRUCTURAL EQUATION MODEL

B. Vanhoutte, ccsr - social sciences, university of manchester, Manchester, United Kingdom

Subjective wellbeing is strongly influenced by physical health, and high wellbeing sometimes is seen as factor of resilience. By examining the influence of frailty on several aspects of wellbeing, such as satisfaction with life, depressive symptoms and eudemonic wellbeing, while at the same time controlling for social background, both direct and indirect influences of frailty on subjective wellbeing can emerge. We will use information from the English Longitudinal Survey of Ageing (ELSA) in a structural equation modelling (SEM) framework, which allows us to draw both cross-sectional and longitudinal conclusions on the relation between physical and mental wellbeing.

GENETICS OF FRAILTY: EXAMINATION OF CANDIDATE GENES RELATED TO CORTISOL AND INFLAMMATION PATHWAYS

K. Mekli1, N. Pendleton2, J. Nazroo1, 1. CCSR University of Manchester, Manchester, United Kingdom, 2. IBBMH University of Manchester, Manchester, United Kingdom

Introduction The mechanistic pathophysiological pathways of frailty are not known but the cortisol pathway and heightened chronic systemic inflammation are thought to be major contributors. Method We chose 87 genes involved in cholesterol transport, cortisol metabolism and inflammation, analysed with linear regression against the Frailty Phenotype (Fried et al. J Gerontol 2001), using only age and sex as covariates in a population-based sample of 4000 individuals. Results The strongest signals were observed in the Protein Tyrosine Phosphatase, receptor type, J (PTPRJ) gene (rs2047812, uncorrected p value=0.00065, \[\beta=0.065\]) and in the promotoric region of the Tumor necrosis factor-\(\alpha\) (TNF\(\alpha\)) gene (rs1800629, uncorrected p value= 0.002, \[\beta=0.057\]). None of these associations were supported following correction for multiple testing. Conclusion Our results provide some evidence for the involvement of the inflammatory pathway in frailty, although using more informed analysis tools with more comprehensive coverage of this area of the genome may be warranted.

MEASURING FRAILTY: A COMPARISON OF FRIED’S FRAILTY PHENOTYPE AND ROCKWOOD’S FRAILTY INDEX USING THE ENGLISH LONGITUDINAL STUDY OF AGEING (ELSA)

J. Nazroo, A. Marshall, University of Manchester, Manchester, United Kingdom

This paper addresses the uncertainty around how frailty should be measured by comparing the Fried and Rockwood frailty assessment measures using data from the English Longitudinal study of Ageing (ELSA). The frailty index developed by Rockwood is based on the proportion of the ‘deficits’ that an individual has experienced. The Fried approach categories individuals into states of ‘robust’, ‘pre-frail’ and ‘frail’ based on the presence of three or more frailty indicators: unintentional weight loss, slow walking speed, subjective exhaustion, low grip strength and low levels of physical activity. We evaluate the success of each frailty measure in predicting death and moves to a care home, using Cox Hazard models and Receiver Operating Curves. Attendees will gain an understanding of how the Rockwood and Fried frailty assessment measures can be operationalized in ELSA and the relative success of each frailty measures in predicting important adverse outcomes.

Socioeconomic and gender inequalities in trajectories of frailty: findings from a growth modelling approach

A. Marshall, CCSR, University of Manchester, Manchester, United Kingdom

This paper considers how trajectories of frailty at the older ages differ according to wealth and gender. Growth curve models are used to capture trajectories of frailty (Rockwood frailty index) by single year of age over 5 waves (8 year period) of the English Longitudinal Study of Ageing. The analysis is stratified by gender and wealth. Levels of frailty are considerably higher for the poorest compared to the richest older people, especially for those under the age of 60. These inequalities are stark; a poor 70 year old has a very similar trajectory of frailty to a rich 80 year old. Women become increasingly frail compared to men with increasing age and there are very different patterns of wealth inequality in frailty trajectories by gender. The paper considers the drivers of these inequalities and the implications for policymakers and clinicians.

SESSION 345 (SYMPOSIUM)

CONTEXTUAL EFFECTS ON INDIVIDUAL DEVELOPMENT ACROSS ADULTHOOD AND OLD AGE

Chair: N. Vogel, Humboldt University, Berlin, Germany, German Institute for Economic Research, Berlin, Germany
Co-Chair: D. Gerstorf, Humboldt University, Berlin, Germany
Discussant: J. Jackson, University of Michigan, Ann Arbor, Michigan

Lifespan and life course perspectives highlight how individual development is embedded within context. Contextual factors can both support and constrain processes of adaptation and regulation, particularly when individual resources are scarce. This symposium brings together four papers that highlight how multiple levels of context, from the macro-system to meso-system, shape individual development in different phases of adult development. Vogel et al. use longitudinal reports of life satisfaction from the German Socio-Economic Panel Study to examine whether and how people living and dying in East Germany vs. West Germany experienced the last years of life differently. Mendes de Leon et al. examine with a large sample of older adults whether differences in neighborhood-level social status exist, how those differences can be measured, and how they relate to survival and changes in physical function. The discussion by James S. Jackson integrates the four papers, highlights their theoretical and methodological contributions, and considers challenges and opportunities of research linking socio-structural characteristics and individual-level outcomes.

DIFFERENCES BETWEEN EAST AND WEST GERMANY IN LATE-LIFE TRAJECTORIES OF LIFE SATISFACTION

N. Vogel1 2, D. Gerstorf2 3, N. Ram1, J. Göbel2, J. Schupp3, G.G. Wagner1 2, 1. Humboldt University, Berlin, Germany, 2. German Institute for Economic Research, Berlin, Germany, 3. Pennsylvania State University, State College, Pennsylvania

Lifespan and life course perspectives highlight the contextual embedding of individual development. This paper examines whether and how people living and dying in East Germany vs. West Germany experienced the last years of life differently. Using annual reports of life satisfaction collected over more than 20 years after German Reunification in 1990 from 4,517 now deceased participants in the German Socio-Economic Panel Study (SOEP) (NW est= 3,471, NE ast= 1,046),

66th Annual Scientific Meeting

107

Downloaded from https://academic.oup.com/gerontologist/article-abstract/53/S1/NP/563183 by guest on 30 April 2018
single- and multi-phase analyses revealed that East Germans, on average, reported lower life satisfaction across the last 15 years of life than their West German peers, and entered the terminal phase of precipitous decline in life satisfaction almost a year earlier after controlling for key individual factors. The results support long-standing notions that macro-context shapes individual development.

SOCIO-ECONOMIC RESOURCES, RISK ASSESSMENTS AND SOCIAL CONTEXTS IN LATER LIFE – ON THE INTERACTION OF MICRO AND MESO LEVELS IN A DYNAMIC PERSPECTIVE
A. Motel-Klingebiel1,2, J. Simonson1, 1. German Centre of Gerontology (DZA), Berlin, Berlin, Germany, 2. National Institute for the Study of Ageing and Later Life (NISAL), Linköping University, Norrköping, Sweden

Older people’s living standards in Europe are higher than ever before and poverty risks are lower than in other age groups. Nevertheless, data demonstrate increasing inequalities and a growth in concerns about future living standards. The presentation faces this development and takes into account individual and socio-environmental dynamics. It contributes to a wider perception of the interaction between resources, their assessment and social change. Analyses are driven by hypotheses regarding the effects of social structure, cohort change and regional differentiation, which are mainly supported. The examination applies structure equation modelling with longitudinal (autoregressive) cross-lagged models to understand the dynamics on the two levels. Data come from the German Ageing Survey (DEAS) (2008-2011). Analyses show that resources and concerns for living standards as well as their development over time are unevenly distributed and that there are strong context effects of regional economic structures on individual living situations and assessments.

LOCALIZED CLUSTERING OF OBESITY IN COMMUNITY DWELLING OLDER ADULTS: A SPATIAL ANALYSIS

Knowledge of the spatial distribution of obesity for the older population can inform research on neighborhood contextual factors associated with this public health problem. Hypotheses about the relationship between neighborhood-level characteristics and obesity were tested adjusting for individual-level characteristics. Data derived from a random-digit-dial sample of 5,688 community-dwelling adults aged 50-74 residing in 1,644 census tracts in New Jersey. Global and local spatial statistics explored patterns of geographic clustering of obesity (BMI >= 30). Geographically weighted regression modeled associations between obesity clusters and population density, walkability and percent impoverished cover along with individual exercise participation. Significant spatial clustering of obesity by census tract was detected. Differential associations with neighborhood and individual level characteristics are described. Understanding the spatial distribution of obesity in the older population illuminates the role of neighborhood contextual factors and may assist public health planners to address the rise in obesity.

NEIGHBORHOOD-LEVEL SOCIAL STATUS AND CHANGE IN PHYSICAL FUNCTION AND MORTALITY
C. Mendes de Leon1, J. Kelley-Moore2, K.B. Rajan3, D.A. Evans1, 1. University of Michigan School of Public Health, Ann Arbor, Michigan, 2. Case Western Reserve University, Cleveland, Ohio, 3. Rush University Medical Center, Chicago, Illinois

Much of what we know about the social gradients in health has focused on overall socio-economic status. Disadvantage in terms of educational attainment, income or wealth is consistently associated with worse health outcomes in many different populations. Much less is known about the degree to which status differences that operate in smaller-scale social environments such as school or neighborhood affect health and well-being. Using data from a study of older adults (N ~ 5,000), we examine survival and changes in physical function in relation to neighborhood-level social status, defined by rankings based on income and social reputation. After adjusting for relevant confounders, income-based higher neighborhood-level social status was significantly associated with smaller declines in physical function and lower mortality risk (p’s < .001). Similar results were obtained for the social reputation-based marker of social status. Status differences in the local social environment may have long-term health consequences for older adults.

THE ART OF DYING WELL
M. Carløe, 1. La Trobe University, Melbourne, Victoria, Australia, 2. Austin Health, Melbourne, Victoria, Australia

This presentation will use the contemporary literature on hospital environments and dying in institutional settings to explore ways the arts can create a safe and nurturing space for people to explore their fears and achieve a “good death” as defined by each individual patient. The presentation will suggest ways to bridge feelings of being isolated and frightened when facing imminent death and loss in a sterile hospital environment, and will discuss strategies to facilitate feelings of familiarity, trust and connectedness at a time when people are at their most vulnerable.

SESSION 350 (SYMPOSIUM)

DISASTERS AND LONG-TERM RECOVERY: PREDICTORS OF PSYCHOSOCIAL WELL-BEING IN LATE LIFE
Chair: K.E. Cherry, Louisiana State University, Baton Rouge, Louisiana

Natural disasters bring catastrophic destruction with loss of homes and property. For the survivors, interpersonal distress and threats to psychological well-being are common in the wake of a natural disaster. Resilience refers to one’s ability to “bounce back” or respond positively to adversity. Many studies have examined post-disaster threats to health and well-being for directly affected individuals during the immediate impact period. However, fewer studies have addressed long-term disaster resilience and recovery in the years after a destructive environmental event. In this symposium, post-disaster resilience and long-term recovery in younger, middle-aged, and older adults will be examined. Four papers will be presented that include behavioral data collected with samples of survivors who experienced three different environmental events, namely, the 2011 tornados in Joplin, MO, the 2007 wildfires in San Diego County, CA, and the 2005 Hurricanes Katrina and Rita in South Louisiana. Long-term threats to health and psychological well-being in younger, middle-aged and older survivors will be covered. Psychosocial predictors of resilience and mental health including depression, anxiety and post-traumatic stress disorder, will be explored. Qualitative analyses of narrative text on potential positive outcomes after disaster will be presented. Taken together, these papers will provide new behavioral evidence concerning psychological and social factors that may lessen vulnerability and promote resilience in the years that follow a natural disaster. Implications for long-term post-disaster recovery will be discussed.

RELIGIOSITY AND PSYCHOLOGICAL WELL-BEING SIX YEARS AFTER THE 2005 HURRICANES KATRINA AND RITA
K.E. Cherry1, L. Marks1, L.A. Sampson2, S. Gales3, P.F. Nezat3, K. Holland1, B. Lyon1, 1. Louisiana State University, Baton Rouge, Louisiana, 2. Columbia University, New York, New York, 3. Louisiana State University Health Sciences Center, New Orleans, Louisiana

Ample experimental evidence documents threats to psychological well-being for survivors of natural disasters in the immediate impact...
PERCEIVED POSITIVE OUTCOMES IN DISASTER SURVIVORS AFTER THE 2005 HURRICANES KATRINA AND RITA
T.G. Hatch, Y. Lu, L. Marks, K.E. Cherry, K.L. Kytola, T.J. Johnson, S.K. Ballard, B. Pinkston, Louisiana State University, Baton Rouge, Louisiana

Hurricanes Katrina and Rita caused a catastrophic amount of damage and destruction to neighborhoods, communities, and businesses along the U.S. Gulf Coast in 2005. This study is part of a larger research program on long-term post-disaster resilience in former and current residents of two coastal parishes in South Louisiana. All participants experienced significant property damage and lengthy displacement in 2005. Narrative data based on verbal responses to an open-ended question on perceived silver linings and positive outcomes associated with the storms were examined. Content analysis yielded three emergent themes: the importance of family and relationships; detachment from physical objects with a greater appreciation for non-material possessions; and a new lifestyle in a new community. These data indicate that traumatic life changing events may lead to positive outcomes for some people. Discussion will focus on post-disaster personal growth, which may help individuals cope with their losses after a destructive hurricane.

PREDICTORS OF MENTAL HEALTH AFTER A DISASTER: A STUDY OF OLDER ADULTS FOUR YEARS AFTER THE 2007 SAN DIEGO COUNTY WILDFIRES
J. Phillips, A. Cruz, S. Cuadra, D. Martinez, M. Perdomo, California State University San Marcos, San Marcos, California

Little research has explored the long-term impact of wildfires on the mental health of community-residing adults. In October 2007, wildfires engulfed northern San Diego County in California. These fires burned approximately 210,000 acres and destroyed over 1200 homes. This study was designed to explore psychosocial factors including age, severity of exposure to the wildfires, and different types of social support on the mental health of these wildfire survivors four years after this event. All participants were residents of this area in 2007. They were men and women, primarily white, married, aged 50-94. Analyses revealed that depressive symptomatology differed among age groups but no age group had high levels of depressive symptoms. Severity of exposure was related to received social support, but not high levels of depressive symptoms. These data imply that these wildfire survivors exhibited well-being. Discussion will focus on implications of the psychosocial factors for long-term recovery.

A LONGITUDINAL ASSESSMENT OF RESILIENCE: AN INVESTIGATION OF PHYSICAL AND PSYCHOSOCIAL PREDICTORS AMONG 2011 JOPLIN TORNADO SURVIVORS
J. Silva Brown, Drury, Springfield, Missouri

On May 22nd, 2011, an EF-5 tornado struck the town of Joplin, MO. This storm subsequently created a long-term mental stressor that challenged the resiliency of those who resided in the affected area. Therefore, the continued investigation of the characteristics that foster post-disaster resilience is essential for community recovery. Participants for this study resided within a 15-mile radius of Joplin, MO. All completed a battery of instruments designed to test physical and mental health, social support, and post-storm resilience. Participants were assessed three (N = 87) and twelve-months post-storm (N = 44). It was hypothesized that social support satisfaction, self-reported physical health, and mental health indicators would significantly predict self-reported resilience. Linear regression analyses support the aforementioned hypotheses. Discussion will focus on ways to reduce suffering amongst those who have been impacted by a natural disaster.
CONVERSATIONS ABOUT ADVANCE PLANNING TOWARDS END-OF-LIFE: EXPERIENCES OF JAPANESE FAMILIES
S. Izumi1, M. Tanimoto2, C. Sakurai3, 1. School of Nursing, Oregon Health & Science University, Portland, Oregon, 2. Chiba University, Chiba, Chiba, Japan

The purpose of this study was to explore experiences and perceptions about advance care planning of Japanese family members caring for older adults. Qualitative interviews were conducted in Japan with 24 family members (10 spouses, 14 adult children: age range 50-87). Although family members wanted the older adult to live long, they acknowledged that there would be a time when sustaining life could be impossible or burdensome and should then be let go. Many participants expressed that they had no idea how a decline in physical condition would occur; therefore, no concrete advance care planning about healthcare were made or discussed with the older adult. Family members thought asking direct questions to the older adult about his/her end of life was harsh. Instead, many family members try to grasp the older adult’s values and preferences from everyday conversation and observation to assume what end-of-life care they would wish for.

WHAT ARE THE ADVANCE CARE PLANNING EXPERIENCES OF PERSONS WITH MILD COGNITIVE IMPAIRMENT?

Persons diagnosed with mild cognitive impairment (MCI) face an increased possibility of developing dementia at some point in the future, but may retain decision making capability for a window of time, and thus the opportunity to participate in advance care planning (ACP). This study explored the ACP experiences of persons with MCI and their spouses’ understanding of ACP. A convenience sample of 10 individuals with MCI and their spouses (N=20) were interviewed. Using a grounded theory qualitative analysis, four themes were identified: 1) decreased awareness regarding ACP from individuals with MCI versus a heightened awareness for the spouse; 2) the preference for comfort care measures only; 3) preferences for future end of life healthcare decisions largely influenced by previous end of life experiences; and 4) lack of discussion of end of life healthcare decisions related to dementia and/or artificial nutrition and hydration by physicians or other healthcare providers.

THE IMPORTANCE OF FAMILY RELATIONSHIPS ON THE DECISION TO ENROLL IN HOSPICE CARE
C.L. Wallace, G. Adorno, School of Social Work, University of Texas at Arlington, Fort Worth, Texas

Patients and families coping with a terminal illness are faced with a number of decisions over the course of their disease. The decision for hospice care is often one of the most difficult. Understanding barriers to hospice care is an important consideration for helping families access care at the end-of-life. Through the use of qualitative interviews, this study explored the process of how and when patients and families decided to begin hospice care and how family relationships and communication play a role within that process. Researchers used grounded theory methods to analyze data from 25 semi-structured interviews. Findings suggest that families are more likely to engage in early use of hospice services when a family member or close friend introduces hospice as an option and serves as an advocate for it. Results also provide implications for health practitioners on the importance of early discussions and education about hospice care.

SESSION 360 (SYMPOSIUM)

FROM POPULATION BASED TO INTERVENTION RESEARCH: MAXIMIZING EVIDENCE FOR AGING IN PLACE INTERVENTIONS
Chair: S. Iwarsson, Health Sciences, Lund University, Lund, Sweden Co-Chair: L.N. Gillin, Johns Hopkins University School of Nursing Center for Innovative Care in Aging, Baltimore, Maryland
Discussant: L.N. Gillin, Johns Hopkins University School of Nursing Center for Innovative Care in Aging, Baltimore, Maryland

The aim of this symposium is to examine studies on home environments and their importance for healthy ageing from which to advance interventions that are grounded in the empirical literature and have potential for implementation in varied health systems and practices globally. The starting point for this symposium is the empirical knowledge gained from the ENABLE-AGE Project and the experiences from intervention studies accomplished in the U.S. context. A hallmark of ENABLE-AGE is the richness of variables covering objective and perceived aspects of housing, with a longitudinal design applying mixed-method approaches, including survey as well as in-depth studies. Similarly, in the U.S., progress has been made linking housing to daily function and understanding underlying neuropsychological mechanisms of aging in place interventions. Based on this empirical record, it should be possible to improve care and housing for older people through the introduction of evidence-based practices, services and products, but uptake and implementation of research findings in practice settings is challenging and slow. Many practice-based development projects have been initiated to improve care and housing for older people, but many have failed and the majority is not sustainable. During the latest decade, promising development has been seen regarding the development of models and frameworks for implementing evidence-based practices. This symposium examines the empirical evidence from population-based studies, emerging understandings from intervention research, and implementation models to derive recommendations for linking the research record to the next generation of aging in place interventions.

HOME AND HEALTHY AGING IN VERY OLD AGE: CORE FINDINGS OF THE ENABLE-AGE PROJECT
F. Oswald1, H. Wahl1, S. Tomson2, O.K. Schilling2, D. Naumann2, M. Haak3, S. Iwarsson4, 1. Interdisciplinary Ageing Research, Faculty of Educational Sciences, Goethe University Frankfurt, Frankfurt, Germany, 2. Department of Psychological Aging Research, Institute of Psychology, Heidelberg University, Heidelberg, Germany, 3. Department of Rehabilitation, Riga Stradins University, Riga, Latvia, 4. Centre for Quality in Care, Berlin, Germany, 5. Centre for Ageing and Supportive Environments (CASE), Lund University, Lund, Sweden

Based on previous studies, accomplished by the investigators of the ENABLE-AGE consortium, this presentation is a synthesis of core findings on links between housing and healthy aging. Data were collected with 1,918 single-living community-dwelling individuals 75-89 years-old, in five European urban regions. The aim is to present a comprehensive compilation of quantitative and qualitative data from cross-sectional and follow-up analyses on relationships between processes of housing and healthy aging outcomes. Findings from quantitative survey analyses show strong links between housing and health indicators as well as predictive effects of objective and perceived housing processes on independence and well-being over time across national samples. Comprehensively, findings from qualitative in-depth analyses help to further deepen the insight into e.g., patterns of community participation in very old age as well as patterns of perceived quality of life. The findings could be used to inform intervention strategies in the field of aging in place.
THE POTENTIAL IMPACT ON HEALTH-RELATED OUTCOMES OF IMPLEMENTING HOUSING ACCESSIBILITY POLICY CHANGES

B. Slag1, C. Chiatto1, F. Oswald1, R. Kaspar1, S. Schmidt1, 1. Health Sciences, Lund University, Lund, Sweden, 2. National Institute of Health and Science on Aging, Ancona, Italy, 3. Goethe University, Frankfurt am Main, Germany

The physical housing environment is important to facilitate activities of daily living (ADL) for older people. An obstructing environment may lead to ADL dependence and thus increase the need of home services, which is individually restricting and a growing societal burden. We will present mathematical simulations of policy changes with regard to housing accessibility that estimate the potential impact on ADL, usage of home services and related costs. We adapted health impact assessment (HIA) methods that consider the best available empirical evidence, and utilized published results from the ENABLE-AGE and other scientific studies to generate the simulations. The simulations predicted that new policies that reduce potentially obstructing housing features would improve ADL performance among older people and reduce the need for home services. Our findings suggest that a policy change can contribute to positive effects with regard to ADL independence among older people and to a reduction of societal burden.

RESIDENTIAL CHOICES IN VERY OLD AGE: A SYNTHESIS OF QUANTITATIVE AND QUALITATIVE FINDINGS

M. Granbom1, C. Löfqvist1, I. Himmelsbach2, M. Haak1, F. Oswald2, S. Iwarsson1, 1. Dept of Health Sciences, CASE, Lund University, Lund, Sweden, 2. Goethe University, Frankfurt, Germany

Based on data from three studies on the Swedish and German subsamples of the ENABLE-AGE Project, the aim of this contribution is to present a synthesis of empirical findings regarding moves, predictors for relocation and the reasoning on where to grow old among very old people. The original studies were based on quantitative (N=384) and qualitative (N=80) longitudinal data. At baseline, the participants were 80-89 years old, living alone in ordinary housing. After four years 18% had moved. Cox regression models showed dependence in cleaning, perceived functional independence, and living in a one-family house to predict moves to ordinary housing. Qualitative analyses revealed that ambivalence between moving and aging in place arose along with increasing problems in everyday life. Over time, practicalities and trivialities of everyday life added up to a decision-base for residential choices. The findings have practical implications for relocation counseling and societal planning targeting very old people.

NEUROBIOLOGICAL PROCESSES IN THE DAILY HOME ENVIRONMENT: IMPLICATIONS FOR AGING IN PLACE INTERVENTIONS

N. Hodgson, L.N. Gitlin, Johns Hopkins University, Baltimore, Maryland

Moving ‘aging-in-place’ intervention development to the next stage requires novel ways of approaching role of biologic factors to inform the relationships among the brain, behavior, function and the environment in the context of everyday life. In this critical review we provide an update on how the daily profiles of neurobiological processes are predictive of individual risk for frailty and institutionalization. We next present an organizing framework of biological sensitivity to context. Within this framework daily life experiences are understood to shape the neurobiological regulatory response systems to meet daily environmental demands. We suggest pathways through which environmental factors affects stress physiology to motivate the development of future interventions. We propose new directions for intervention development that are informed by recent evidence regarding the circadian expression of neurobiological contributions to regulatory response systems that may establish the point in which delivering interventions are most highly effective.

SESSION 365 (SYMPOSIUM)

SECRETS OF LIVING LONG AND PROSPERING AMONG THE OLDEST-OLD

Chair: J. Cho, Scott & White Healthcare, Temple, Texas, Texas A&M Health Science Center, College Station, Texas
Discussant: C.M. Aldwin, Oregon State University, Corvallis, Oregon

The aspiration for longevity and healthy aging has been desired for all ages and in all counties. Developments in medicine have led to lower mortality rates and demographic changes such as increased life expectancy have stimulated growing proportions of extremely old adults (i.e., centenarians). The purpose of this symposium is to explore various aspects of well-being and functioning among centenarians with four studies. The four studies will discuss various comparisons such as cultural, regional, gender, and age differences in extreme late life. da Rosa and colleagues examine cross-national comparisons in mental health between U.S. and Japanese centenarians using the Georgia and Tokyo Centenarian Studies. They show differences in the role of demographic factors, personality, and life events on mental health between two culturally different groups. Heinz and colleagues compare lifestyle characteristics of centenarians from two regions, Georgia and Iowa. Their findings indicate centenarians from each state have unique engaged lifestyle characteristics. Cho and colleagues investigate differences of age, gender, and interaction between age and gender in multiple dimensions of functioning using the Georgia Centenarian Study. They address age and gender related investigations of functioning among oldest-old adults. The discussion by Bishop and colleagues focuses on the role of religiosity on life satisfaction among Oklahoma centenarians. They also draw attention to significant interaction effects between social support and religious beliefs on life satisfaction. After attending this symposium, participants will understand multi-dimensions of well-being among oldest-old adults and learn about unique and complex factors among the long-lived.

PERSONALITY AND LIFE EVENTS AS PREDICTORS OF MENTAL AND COGNITIVE HEALTH OF U.S. AND JAPANESE CENTENARIANS

G.D. da Rosa1, P. Martin1, Y. Gondo2, N. Hirose3, H. Inagaki4, L. Poon5, 1. Iowa State University, Ames, Iowa, 2. Osaka University, Osaka, Japan, 3. Keio University School of Medicine, Tokyo, Japan, 4. Tokyo Metropolitan Institute of Gerontology, Tokyo, Japan, 5. University of Georgia, Athens, Georgia

This study investigates the effect of personality and life events on mental and cognitive health. A population-based sample of 239 U.S. centenarians from the Georgia Centenarians Study and 304 Japanese centenarians from the Tokyo Centenarian Study were assessed. We assessed demographic mean differences between mental and cognitive health in U.S. and Japanese centenarians. Structural equation models were computed for each culture testing for effects of personality and life events (i.e., marriage and historical events) on mental and cognitive health. Results from structural equation modeling indicated that centenarians with a resilient personality had better mental health in both samples. No significant mediating and moderating effects of personality were found in either sample. Japanese centenarians who reported marriage as the most important event had better mental health and those reporting historical events had poor mental health. It’s important to further investigate the role that resilient personality has in affecting important life outcomes.
EXPLORATORY FINDINGS OF ENGAGED LIFE STYLES AMONG IOWA AND GEORGIA CENTENARIANS

Latent class analysis was used to classify groups of centenarians residing in Georgia and Iowa based on engaged lifestyle characteristics. Previous research has noted that engaged lifestyles can have protective effects against cognitive impairment in late life. This analysis included 101 centenarians from Georgia and 118 centenarians from Iowa. Six engaged lifestyle questions (e.g., volunteering) were used to classify individuals into groups. Two unique classes were identified in each state. A cross-tabulation analysis revealed regional profiles that were significantly different from one another ($\chi^2 = 36.02, p < .001$). There were two unique engaged lifestyle classes in both Iowa and Georgia that were different from one another. Some of the unique class characteristics indicate Georgia centenarians were more likely to have learned a foreign language, whereas Iowa centenarians appeared more likely to have given a public lecture. These findings may be due to regional differences in engagement for Iowa and Georgia centenarians.

AGE AND GENDER DIFFERENCES IN MULTIDIMENSIONAL FUNCTIONING: FINDINGS FROM THE GEORGIA CENTENARIAN STUDY

J. Cho, P. Martin, M.G. Ory, M. MacDonald, L. Poon, J. Scott & White Healthcare, Temple, Texas, 2. Texas A&M Health Science Center; College Station, Texas, 3. Iowa State University, Ames, Iowa, 4. Kansas State University, Manhattan, Kansas, 5. University of Georgia, Athens, Georgia

This study examined group differences (i.e., age, gender, and age*gender) in seven areas of functioning from the Duke Older Americans Resources and Services. Participants included 371 community-dwelling octogenarians and centenarians of Phase I and III of the Georgia Centenarian Study. Analysis of variance (ANOVA) was employed to compare seven measures: social resources, perceived economic status, life satisfaction, fatigue, self-rated health (SRH), instrumental activity of daily living (IADL), and activity of daily living (ADL). Results indicated that significant age differences in social resources, fatigue, SRH, IADL, and ADL; significant gender differences in life satisfaction, fatigue, SRH, IADL, and ADL; and significant interaction effects (age*gender) in social resources, life satisfaction, fatigue, SRH, IADL, and ADL. Although women are more likely to have achieved exceptional longevity than men, this study suggests that more complex associations between age and gender exist in various dimensions of functioning among oldest-old adults.

RELIGIOSITY AS A SOURCE OF WELL-BEING AMONG CENTENARIANS RESIDING IN OKLAHOMA

A. Bishop, K. Randall, J. Human Development and Family Science Department, Oklahoma State University, Stillwater, Oklahoma, 2. Bradley University, Peoria, Illinois

The purpose of this investigation was to examine the association between religious beliefs and life satisfaction among centenarians. Data originated from a pilot study of N = 154 community-dwelling centenarians (M=101; SD=1.71) residing in Oklahoma. Hierarchical regression analyses, controlling for age, sex, education, and race, was used. Depressive affect ($\beta = -.48$, $p < .001$) and social provisions ($\beta = .18$, $p = .017$) emerged as significant predictors of life satisfaction. Greater depressive affect appears to directly decrease life satisfaction among long-lived persons, whereas greater social support directly increases satisfaction in life. Overall, the complete model explained 41% of the variance ($F(9,140) = 10.91, p < .001$). Multiplicative effects were further examined. Only the interaction between social support and religious beliefs (SPXRB) was significant ($p = .043$). It appears centenarians use religious beliefs as a proxy relative to the associated influence of social support on life satisfaction.

SESSION 370 (SYMPOSIUM)

WALKING TOWARDS OPTIMAL AGING THROUGH RESEARCH: INTERDISCIPLINARY AND INTERNATIONAL PERSPECTIVES

Chair: N. Notthoff, Department of Psychology, Stanford, Stanford, California

A growing number of studies highlight the importance of physical activity for healthy aging. Walking is a particularly good form of physical activity. It can be performed at varying intensity levels, alone or in a group, and is inexpensive and convenient. Even those with physical or cognitive limitations can participate in walking programs. Reports document the effectiveness of walking as a way to maintain physical and cognitive health for relatively healthy older adults, as a preventative measure (e.g., cardiovascular disease, fall prevention), as a useful therapeutic measure (e.g., sleep disturbances), and for rehabilitation purposes (e.g., after a stroke). The objective of this symposium is to provide an overview of research on walking. We first introduce definitions of walking. Subsequently, we cover environmental and person-specific factors that influence mobility in older adults, review some health benefits older adults can obtain from walking immediately and in the long run, and learn how even older adults with dementia can participate in and benefit from walking. We conclude by discussing interventions to encourage walking in older adults that take into account age-related motivational changes. The symposium provides an interdisciplinary and international view on research on walking. Researchers in the fields of Exercise Science, Medicine, and Psychology from Europe and the United States will present a selection of findings. The goal of the symposium is to foster a discussion and encourage collaboration between researchers from different disciplines aimed at further understanding the benefits of walking for healthy aging and effective interventions targeting older adults.

DEFINING WALKING, GAIT, AND MOBILITY: STEPPING FORWARD IN EFFECTIVE INTERDISCIPLINARY IMPLEMENTATION

E. Freiberger, Institute for Biomedicine of Aging, University Erlangen-Nürnberg, Nurnberg, Germany

Maintaining the health and independence of older adults is an important issue. Physical activity, particularly walking, is a crucial component for achieving this goal, as documented by a vast body of research. The constructs or definitions of the terms pose a barrier for an interdisciplinary approach to implementing effective intervention programs. Physical activity is used as an umbrella term with the term exercise included under other constructs. Walking is among most recommendations for physical activity made with regards to positive effects on health outcomes. Walking can be viewed both as a leisure time physical activity as well as structured, planned exercise with progressive intensity levels targeting at-risk older adults. The presentation will deal with different constructs on walking, mobility, and gait. The presentation is enclosed in a symposium investigating walking in older adults.

OUT-OF-HOME BEHAVIOR, ENVIRONMENTAL MASTERY AND AFFECT: THE MODERATING ROLE OF COGNITIVE STATUS

M. Wettstein, H. Wahl, N. Shoval, G. Auslander, F. Oswald, J. Heinik, Department for Psychological Aging Research, Heidelberg University, Heidelberg, Germany, 2. Hebrew University, Jerusalem, Israel, 3. Goethe University, Frankfurt, Germany, 4. Margoletz Psychogeriatric Center, Ichilov Hospital and Sackler Faculty of Medicine, Tel Aviv, Israel

Relationships between out-of-home behavior, environmental mastery, and affect might depend on the fit between the complexity of the out-of-home behavior domain considered and an individual’s cogni-
PERFORMANCE IN PATIENTS WITH DEMENTIA

achieved changes or even improved further at follow-up measurements. Results: After 6-MTI, positive with controls, crossover-phase with intervention by control group and strength training. The design was a randomized-controlled crossover

Methods: The 6-MTI consisted of daily walking and twice-a-week month multimodal training intervention (6-MTI) on functional fitness

ity, functional dependence and use of healthcare resources. The purpose of this study was to assess the immediate and long-term effects of a 6-month multimodal training intervention (6-MTI) on functional fitness (FF), body composition (BC) and cardiac metabolic risk factors (CMRF).

Background: Training interventions, including walking, are of special interest for older individuals, because of their high rate of disability, functional dependence and use of healthcare resources. The purpose of this study was to assess the immediate and long-term effects of a 6-month multimodal training intervention (6-MTI) on functional fitness (FF), body composition (BC) and cardiac metabolic risk factors (CMRF).

The 6-MTI consisted of daily walking and twice-a-week strength training. The design was a randomized-controlled crossover with four 6-month phases: Baseline assessment, intervention compared with controls, crossover-phase with intervention by control group and an additional 6-month follow-up. Results: After 6-MTI, positive improvement was seen in FF, BC and CMRF. Males and females retained achieved changes or even improved further at follow-up measurements. Conclusions: 6-MTI is feasible and beneficial in older populations as an integral part of prevention and management chronic age related disorders.

EFFECT OF A STANDARDISED TRAINING ON GAIT PERFORMANCE IN PATIENTS WITH DEMENTIA

Walking represents the key motor performance for autonomy, quality of life and risk of falling. In this RCT we determined the effect of an intensive, dementia adjusted training program on gait performances in geriatric patients post ward rehabilitation with diagnostically confirmed mild to moderate dementia (n=49). Patients in the intervention Group (IG) were trained by a standardized progressive resistance and functional training 2 times a week for 3 month. The control group (CG) received a non specific physical training while seated 2 times a week for 3 month. The control group (CG) received a non specific physical training while seated 2 times a week for 3 month. Gait performance was objectively measured by an electronic gateway (GAIT RITE). We discuss significant overall training effects (max gait speed: p=0.001, cadence: p=0.002, stride length: 0.008, double support: p=0.001, single support: p=0.030) except for heel base support: p=n.s. and effects sizes (range: 0.098 to 0.292) with respect to gait performance as well as gait security and predictors of training success.

KEEP WALKING: FACTORS INFLUENCING THE ADHERENCE TO WALKING RECOMMENDATIONS

Walking promotes physical, cognitive, and psychological health. Many people, especially older adults, walk less than the recommended amounts. Findings from psychology (socioemotional selectivity theory) and behavioral economics suggest that perceived time horizons and temporal discounting influence goals and behavior. We examined how these concepts related to time influence walking and adherence to messages promoting it. Participants (n=113 younger adults 18-35 years (M=26.12) and n=112 older adults 65-89 years (M=74.42)) were informed about short-term or long-term benefits of walking or negative consequences of not walking. Walking was measured with pedometers. We discuss how time horizons and temporal discounting (assessed with questionnaires) influence walking and responses to messages promoting it. For example, higher value placed on immediate rewards was related to greater increases in walking in response to information emphasizing short-term benefits, r=0.42, p=0.003. Consideration of perceptions of the future and temporal discounting can inform intervention designs.

SESSION 375 (PAPER)

CROSS-CULTURAL STUDIES

PSYCHOSOCIAL DETERMINANTS OF SUCCESSFUL AGING IN ELDERLY COMMUNITY RESIDENTS: PERSPECTIVES FROM ISRAEL

BACKGROUND. Given advances in longevity, maintaining a high quality of life in old age is a major public health challenge in developed and aging nations. Declines in health and functioning and the dependency that follows are among the major concerns of elderly persons, their families and aging societies. METHODS. This presentation will discuss findings from an in-home questionnaire administered to an Israeli sample of 1,098 community-dwelling persons aged 75 and older, cognitively and functionally competent, living independently. Sample was randomly selected from the municipality records of three Israeli cities – Tel Aviv, Haifa, and Beer Sheva. RESULTS. Over a third of the participants reported health declines in the past year. Increased difficulty performing ADLs and IADLs was also noted, along with a greater reliance on assistance. Hierarchical regression documented that lifestyle characteristics, personal resources, coping and health/functioning history explained 60.8% of the variance in participants’ scores on the summary measure of morale. However, results of the same model run for the morale dimension subscales suggest both common and unique correlates of each dimension and variation with regard to overall explanatory power (ranging from 41.5% for Agitation to 52.9% for Attitude toward Aging). The analysis also indicated that some of the factors impacting one dimension of morale had little or no impact on other dimensions. CONCLUSION. The multidimensional nature of morale, as suggested by these analyses, has ramifications for the design of psychosocial interventions that would facilitate quality of life while living with declines in health and functioning in advanced age.

HAPPINESS IN MARRIED OLDER ADULTS: IS THERE A CULTURAL DIVIDE IN DEFINITION OR IMPORTANCE?

Happiness is a key variable in aging studies. However, the concept of happiness may not the same across cultural groups. This cross-sectional study of 8974 participants in the Health and Retirement Study examines whether health and spousal happiness predict self-reported happiness of married older adults. The results of a hierarchical logistic regression show that in the full model for the full sample, the variables that best predict happiness are spousal happiness, followed by self-reported health. However, when the sample is decomposed by race/ethnicity and gender, the picture changes. For white non-Hispanic respondents, these two variables remain the most important predictors. For
black non-Hispanic men, spousal happiness is a significant negative predictor of happiness; age is the only significant positive predictor for this subsample. The only significant predictor of happiness for black non-Hispanic women is self-reported health; spousal happiness is not a significant predictor of happiness for these women. Finally, spousal happiness does not predict happiness for either Hispanic men or women. The largest significant predictor of happiness for Hispanic men is self-reported health, and the largest significant predictor for Hispanic women is spousal health. For all Hispanics, the number of marriages is a significant negative predictor of happiness. Overall, Hispanic respondents were significantly least likely of any of the three cultural subsamples to report happiness. These results suggest that there may be substantial cultural differences in definitions of or value placed on happiness and should be examined in more depth.

ON CONTEXTUALIZING HEALTH APPRAISAL AMONG OLDER ADULTS IN INDIA: EXAMINATION OF GENDER AND EDUCATIONAL DIFFERENCES

T. Bhatta, N. Lekhak, E. Kahana, Sociology, Case Western Reserve University, Cleveland Heights, Ohio

Drawing from emerging evidence on within nation population group differences in health appraisals in later life, this study examines gender and educational differences in health appraisal among older adults in India. Women’s subordinate status in the Indian patriarchal social system exposes them to health experiences potentially different from men. Similarly, due to a lack of access to health care, individuals with more limited education are also likely to appraise health differently than their better educated counterparts. Such structural positioning could influence the way people conceptualize health, resulting in differential health appraisal. Based on the first wave (2007-2010) of Study on Global Ageing and Adult Health (SAGE), this study utilizes ordinal logistic regression modeling to investigate the influence of gender and educational status on health appraisal among adults aged 50 years and older in India. Vignettes administered to a randomly selected group of individuals provide a frame of reference for better understanding of health appraisals. Findings of this study reveal significant gender and education differences in assessment of functional limitations. Notably, both women and higher educated older adults provided similar appraisals on vignettes administered to assess health. Depending on the type of vignettes, both groups reported either a higher or lower functional limitation severity. Vignettes displaying limitations in vigorous activities generally elicited lower appraisal of functional limitation severity from both groups. The differential health appraisal indicates potential under or overestimation of group level health differences, which could be responsible for inconsistent findings in health disparities research observed in developing nations.

HOW HEALTH CONDITIONS TRANSLATE INTO SELF ASSESSMENTS: A COMPARATIVE STUDY OF OLDER ADULTS ACROSS EUROPE

M. Hardy, F. Acciai, A.M. Reyes, Sociology, Pennsylvania State University, University Park, Pennsylvania

Self-assessed health measures are frequently available in large national surveys and provide one method of comparing health across time and place, since they consistently predict various health outcomes. Even so, group comparisons of these summary measures confound differences in underlying health status with how people scale their health relative to a limited number of response categories. We use data on those aged 50 and older living in Austria, Germany, Sweden, Netherlands, Spain, Italy, France, Denmark, and Greece from the Survey of Health, Aging, and Retirement in Europe (SHARE) to examine framing effects and country differences in self-reported health (SRH). We then assess the persistence of these differences as we control for population heterogeneity in SES, demographic characteristics, and three categories of health and cognition measures: performance-based; self-reports; and self-assessments. SHARE also includes a randomized design feature that allows us to evaluate how the heightened salience of specific health conditions frames SRH. We estimate a series of generalized logit models with partial proportionality, beginning with a baseline estimate of country differences in SRH. We find evidence that prefacing the request for self-assessed health with a rehearsal of specific conditions is associated with more positive SRH; that semantic skills related to language and numeracy also are associated with ‘better’ health assessments; that the full range of indicators for clinically diagnosed and experiential dimensions of health are uniquely reflected in SRH; and that country differences in SRH persist, but some of these differences are non-proportional.

SESSION 380 (PAPER)

FAMILY CAREGIVING: PSYCHOLOGICAL FACTORS

HOW DO CAREGIVER RELATIONSHIP CLOSERNESS AND COPING STRATEGIES AFFECT THE COSTS OF DEMENTIA CARE?

1. County Dementia Progression Study (DPS). Measures for dementia progression and the care environment were collected annually. Caregiver relationship-closeness and coping were assessed with the Noe...
importance of caregiver burden, depression, and uplifts among spouses and adult-children

M.Y. Savundranayagam1, R. Montgomery2, 1. School of Health Studies, Western University, London, Ontario, Canada, 2. University of Wisconsin-Milwaukee, Milwaukee, Wisconsin

The caregiving career begins within the context of an established familial relationship identity between a caregiver and family member with a chronic illness. Caregiver identity theory suggests as the career progresses, individuals incorporate more of the caregiver role into their relationship identity. Using relationship identity to measure the phases of the caregiving career, this study investigated whether experiences of burden, depression, and uplifts differed across the caregiving career and between spouse (N = 264) and adult-child (N = 229) caregivers. Statistical tests using multivariate analyses of variance revealed interactions between relationship to care-recipient and caregiving phase for burden and depression, and main effects of caregiver relationship and caregiving phase for uplifts. Spouse caregivers experienced the greatest burden and depression when their relationship identity was comprised of the caregiver role primarily. Adult-child caregivers, however, experienced the most burden and depression when the familial and caregiver roles equally comprised their relationship identity. The largest differences in caregiver outcomes between spouses and adult-children occurred in the earliest phase of the caregiving career, where the relationship identity was comprised of familial role primarily. While adult-child experienced similar levels of uplifts across the caregiving career, spouses experienced lower levels of uplifts when their relationship identity incorporated more of the caregiver role. Findings are discussed in terms of the differential needs of spouses and adult-children across the caregiving career.

Caregiver quality of life: The differential importance of caregiver burden

N.L. Chappell, C. Dujela, A. Smith, Centre on Aging, Un. of Victoria, Victoria, British Columbia, Canada

While much is known about burden among caregivers to those with dementia, less attention has focused on its relevance for quality of life, differentiating between spouses and adult children caregivers, men and women. This paper seeks to unpack for whom and under what circumstances burden within the caregiving relationship is related to quality of life. A sample of over 900 caregivers in British Columbia Canada were interviewed face-to-face for on average an hour and a half concerning many aspects of the relationship. Using multivariate path analyses, among the entire sample, whether the caregiver is a spouse or child, male or female is unrelated to the burden they experience. Rather, prior relationship, amount of caregiving and health of the caregiver are the significant predictors. However, prior relationship with and health of the care recipient are significant for spousal caregiver burden, but not child burden. Burden, furthermore, is not related to self-esteem but is the major predictor of satisfaction with self, among both spouse and child caregivers, men and women. Spouses though are distinctive in the salience of their prior relationship with the care recipient for their current quality of life. In terms of satisfaction, it matters for women whether they are the wife or daughter; for men, it does not matter whether they are the husband or son (relation matters for women but not men when it comes to their satisfaction).

Disruptive behaviors and anxiety in dementia caregiving: Multiple mediation of rumination, experiential avoidance and pleasant events

R. Romero-Moreno1, A. Losada2, M. Marquez Gonzalez2, B. Mausbach3, V. Fernandez-Fernandez3, C. Nogales-Gonzalez3, I. Lopez4, 1. Universidad Rey Juan Carlos, Madrid, Spain, 2. Universidad Autonoma de Madrid, Madrid, Madrid, Spain, 3. Universidad de California San Diego, San Diego, California, 4. Universidad San Pablo CEU, Madrid, Madrid, Spain

Introduction Care-recipients’ disruptive behaviors are one of the main causes of distress (anxiety) for dementia family caregivers. However, the mechanisms through which this relationship occurs remain unclear. The purpose of this study was to analyze a model aimed to explain how caregiver’s stressors (frequency of behavioral problems) are related to anxiety, analyzing specifically if this link was mediated by three simultaneous coping variables: rumination, experiential avoidance, and frequency of pleasant events. Method and results The sample consisted of 202 family caregivers. Individual face-to-face assessments were done. In order to test the multiple mediators model, the bias corrected and accelerated bootstrapping method was used. Results showed that higher levels of stressors significantly predict anxiety (B = .37; p < .01). Greater stressors significantly predict higher levels of rumination (B = .16; p < .01) and experiential avoidance (B = .28; p < .01). The assessed coping variables significantly mediated the link between stressors and anxiety. The specific indirect effect through the use of experiential avoidance was significantly larger than the effect through frequency of pleasant events. The explained variance for the final model was 48.53%. Effect sizes (K2) of the mediator variables were 0.09 for rumination, 0.07 for the use of avoidance coping, and 0.031 for frequency of pleasant events. Discussion The results suggest that there are multiple pathways through which stressors may be related to increased anxiety. Training caregivers in strategies for increasing acceptance and behavioral activation may buffer the impact that stressors have on anxiety.

Attentional correlates of general and caregiving-related experiential avoidance in dementia caregivers

M. Marquez-Gonzalez1, A. Losada2, I. Cabrera Lafuente3, B.G. Knight1, V. Fernandez-Fernandez2, R. Romero-Moreno2, 1. Universidad Autonoma, Madrid, Spain, 2. Universidad Rey Juan Carlos, Madrid, Spain, 3. Universidad Antonio de Nebrija, Madrid, Spain, 4. University of Southern California, Madrid, Spain

Experiential avoidance has been found to be associated with dementia caregivers emotional distress. The attentional correlates of experiential avoidance have not yet been explored, even when their detection would contribute significantly to support the construct validity of this variable. This study analyzes the presence of attentional biases in dementia caregivers, using a dot-probe task with pictures varying in valence (threatening, positive and neutral), content (general vs. related to caregiving) and time of exposure (100 ms vs. 500 ms). 105 dementia family caregivers performed the dot-probe task and completed measures of generic experiential avoidance (EA) and caregiving-related experiential avoidance (CR-EA). Several bias scores were calculated from...
response times to probes, both globally (across time exposure conditions) and for the 100/500 ms conditions separately: General-Threat bias (GT), General-Positive bias (GP), Caregiving-Related-Threat Bias (CRT), Caregiving-Related-Positive bias (CRP). Also, general biases were calculated, independently from content, for each time exposure (T100/T500, P100/P500). Only CR-EA, but not EA, was significantly associated with attentional biases. Correlation analyses revealed that CREA was related with avoidant CRT biases (CRT global: r = -0.24; p<0.05; CR at 100 ms: r = -0.21; p<0.05), and with vigilant P100 biases (r = 0.33; p<0.01). Paired samples t-tests revealed that two of these biases (CRT100 bias (-24.5; t=-22.69; p<0.01) and P100 bias (9.39; t=2.36; p<0.05)) significantly differed from 0. The identification of a pattern of attentional avoidance of general and caregiving-related threat in high CR-EA caregivers represents a strong empirical argument supporting the construct validity of this variable.

SESSION 385 (PAPER)

LONG-TERM CARE: STAFF ISSUES

EXPLORING NURSING ASSISTANT PERCEPTIONS OF THE QUALITY IMPROVEMENT PROCESS IN NURSING HOMES

As a part of ongoing efforts to improve nursing home (NH) quality, policymakers increasingly promote quality improvement (QI) initiatives. Although nursing assistants (NA) provide the majority of care in NHs and are centrally involved in implementing QI interventions, little is known about their perceptions of the QI process. Within the evaluation of the Minnesota NH Performance-Based Incentive Payment Program (PIPP), semi-structured interviews were conducted with 43 NAs who participated in QI projects at 23 NHs. Projects focused on various clinical and quality of life domains and facilities differed in terms of size, geographic location, profit/nonprofit status, and stand-alone or chain/collaborative affiliation. Interviews explored staff perceptions of the QI process, including challenges, facilitators and positive outcomes. Interviews were transcribed and analyzed using inductive category development. NAs described their important role in engaging residents in potentially beneficial activities, communicating subtle changes in residents’ conditions to nurses, and contributing to a team environment. NAs indicated that training and their established relationships with residents facilitated success. Challenges included increased workload, communication across staff roles and shifts, and adjusting to changes in routines. When asked about positive outcomes, NAs focused on individual resident successes, having more time or more interaction with residents, experiencing improvements in the work environment, having increased awareness of resident conditions, and being listened to by other staff. Results of this study suggest that meaningful involvement of direct care staff in QI activities may provide an important way of not only strengthening QI interventions, but also improving resident outcomes and staff satisfaction.

FORMAL CAREGIVERS’ EXPOSURE TO DEMENTIA-RELATED AGGRESSIVE BEHAVIORS IN JAPAN

H. Hirata, T. Harvath, L. Miller, G. McKenzie, School of Nursing, Oregon Health & Science University, Portland, Oregon

Background: Aggressive behaviors (ABs) related to dementia among older adults have been associated with increased occupational stress among formal caregivers (FCs) in the US and other western countries and may contribute to staff turnover. However, few studies related to this issue have been done in Japan, where caregiver reaction to aggressive behaviors might be different because of cultural and customary differences in how care is provided for older adults. Purpose: The purpose of this research is to examine the relationship between FC exposure to dementia-related aggressive behavior and their occupational stress, job burnout, and intention to resign. Methods: This research is a descriptive, correlational study using cross-sectional design. Data were collected from care workers (n = 106) who were working in the special care units for residents with dementia in eight nursing homes in the western areas of Japan. Findings: There were significant relationships between the frequency of ABs and occupational stress caused by ABs (r = 0.45, p < 0.001) and job burnout (r = 0.25, p < 0.01), and occupational stress and job burnout (r = 0.34, p < 0.001). There were not significant relationships between intention to resign and the frequency of ABs, occupational stress by ABs, and job burnout. Discussion: Although FC exposure to dementia-related AB was not correlated with intention to resign, ABs were significantly correlated with occupational stress and job burnout. These findings illuminate the importance of interventions for FCs’ occupational stress of ABs.

DO YOU SEE ME? NURSING HOME SOCIAL WORKER KNOWLEDGE OF DEPRESSIVE SYMPTOMS AMONG RESIDENTS

K. Cassie, College of Social Work, Univ of Tennessee-EPS, Nashville, Tennessee

Depression is characterized by psychological conditions (such as feelings of worthlessness, recurrent thoughts of death, loss of pleasure in life, etc.) and it has been linked to increased rates of cognitive and functional declines, malnutrition, suicidal ideations, hospitalizations, falls, mortality and longer admissions. Yet misdiagnosis (both over and under diagnosis) of depression among the elderly in nursing homes appears to be pervasive according to recent research. Social workers in long-term care facilities are often responsible for completing biopsychosocial assessments of residents, including assessments of depressive symptoms. This exploratory study assessed social worker knowledge of depression among a sample of 152 nursing home social workers in a single southeastern state. Depressive knowledge was measured using the Late Life Depression Quiz. Findings suggest short-comings in social worker knowledge related to aging norms, elder suicide, the diagnostic complexity of depression and the autonomy of the severely depressed. Furthermore, those who earned more continuing education hours over the past 12 months were more likely to have higher levels of knowledge related to late life depression (r=.245, n=122, p=.006). With the introduction of new assessment instruments within the Minimum Data Set, we are making strides toward improving our recognition of depressive symptoms among residents, but this is no substitute for social worker knowledge of late life depression. These findings corroborate similar research and are cause for action by practitioners and researchers in order to create environments for optimal aging in long-term care facilities. Suggestions for practitioners and researchers will conclude this presentation.

PREDICTORS OF ROLE OVERLOAD AMONG DIRECT CARE WORKERS IN ASSISTED LIVING FACILITIES FOR OLDER ADULTS

R.J. Chao, Social Work, University of South Carolina, Columbia, South Carolina

Emerged in late 1980s, assisted living (AL) has experienced the fastest growth among residential long-term care models in the United States. Typically serving older adults who can no longer live independently, but do not need nursing home care, assisted living combines housing, personal supportive services, and health care. The bulk of care is shouldered by direct care workers (DCWs). These workers experience high levels of role overload in addition to low pay, low benefits, and lack of advancement opportunities. Defined as the extent to which role performance is affected by inadequate time and/or resources, role
overload of DCWs has been identified as a key predictor of their job turnover. Nevertheless, little is known about the factors contributing to DCWs’ role overload in the context of AL. Based on an integrated model of role overload, this study intends to bridge such gap. The study uses data from the pre-intervention survey (N = 984 DCWs in 108 AL facilities) of the Worker Education, Training, and Assistance (WETA) Program in Wisconsin. Multivariate regression analysis show that DCWs’ role overload is positively related to (a) staff shortage, (b) conflicting demands from job and personal life, and (c) length of working at current position; and negatively related to (d) knowing one’s duties before work and (e) receiving recognition for one’s work. Age, gender, ethnicnicity, education, facility proprietary status (for profit vs. non-profit), hourly pay, benefits, and having a second job have no effects in the same analysis. Theoretical, policy, and practice implications are discussed.

BEHAVIORAL ENGAGEMENT OF DIRECT CARE WORKERS: EXAMINING A KEY DETERMINANT TO IMPROVING EMPLOYEE OUTCOMES
D. McCaughey, K. Wu, G. McGahan, C. Baumgardner, HPA, Penn State University, State College, Pennsylvania

Background: Poor employee outcomes and high turnover have been shown to result in low levels of employee engagement at work. According to Macey and Schneider’s (2008) framework, behavioral engagement is a core factor of employee engagement. We posit behavioral engagement is reflective of both the individual and leadership in the workplace. This study seeks to determine how leadership contributes to direct care worker (DCW) engagement and the relationship between employee engagement and outcomes. Methods: Using data from the 2007 National Home Health Aide Survey and the 2004 National Nursing Assistant Survey, factor analysis and hierarchical linear regression was used to develop a behavioral engagement scale and to examine the relationships between employee engagement and outcomes for the DCW and organization. Findings: The findings support the validity of the proposed behavioral engagement scale in both datasets (α = .76). Behavioral engagement is positively associated with job satisfaction (Home Health Aide (HHA) β = .47; Nursing Assistant (NA) β = .38, p-value < .001) and negatively associated with turnover intentions (HHA, β = -.36; NA, β = -.29 p-value < .001). Behavioral engagement is positively associated with DCW willingness to recommend their organization as place to seek care (HHA, β = .34; NA, β = .45, p-value < .001) and as a place to work (HHA, β = .33; NA, β = .51, p-value < .001). Conclusions: Supervisors and senior management have a direct influence on engagement; positive managerial actions result in increased DCW behavioral engagement. The proposed behavioral engagement scale offers LTC organizations an innovative tool which can be used to measure and improve the working environment of DCWs.

SESSION 390 (SYMPOSIUM)

ASSESSING THE “PHYSICAL CLIFF” WITH OBJECTIVE ACTIVITY ASSESSMENT: FINDINGS FROM THE BLSA
J.A. Schrack1,2, V. Zipunnikov1, J. Goldsmith3, J. Bai1, E.M. Simonsick1, C. Crainicaneau1, L. Ferrucci1, Johns Hopkins School of Public Health, Baltimore, Maryland. 2. National Institute on Aging, Baltimore, Maryland. 3. Columbia University School of Public Health, New York, New York

In spite of strong evidence that physical activity has beneficial effects on health and can attenuate age-related functional decline, accurate information on free-living activity habits of older adults is scarce. We modeled the association between free-living activity counts and age using cumulative activity count methodology in 611 BLSA participants (50% male, mean age 67, range 32-93) adjusted for sex, BMI, employment, and comorbid conditions. Minute-by-minute analyses of the data demonstrated that daily physical activity is 1.3% lower for each one-year increase in age, with a different circadian pattern in older compared to younger individuals (p<0.01). Independent of age, poor lower extremity performance, non-working status, and higher BMI were independently associated with less physical activity (p<0.001). Use of accelerometers to characterize daily activity patterns provides accurate and detailed information, particularly at low levels of activity, which are essential for understanding activity patterns and their impact in older persons.

ACTIGRAPHY MEASURES OF FATIGUE: DURATION, INTENSITY, AND FREQUENCY ANALYSIS OF ACTIVITY IN THE BLSA
V. Zipunnikov, J.A. Schrack, C. Crainicaneau, L. Ferrucci, Biostatistics, Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland

Increasing fatigue and activity reduction are common complaints among older adults. We conducted a comprehensive analysis of the relationship between age and free-living activity duration and intensity in 631 participants of the BLSA. Using empirical measures to summarize duration, intensity, and frequency of activity bouts as well as activity/inactivity fragmentation, we explored the most common patterns of activity in four data-driven age strata. We found that: 1) after peaking near 12pm, circadian activity rhythm rapidly declined in participants older than 68 years old; 2) although the number of activity bouts stayed approximately constant during a day the activity intensity declined rapidly in afternoon with increasing age; 3) older adults expended the majority of their energy during morning hours. These findings support a fatigue-related reduction in both activity amount and intensity with age, and indicate an intrinsic mechanism may contribute to the commonly observed age-related reduction in activity.
OBJECTIVELY MEASURE LIFE-SPACE IN OLDER ADULTS USING GLOBAL POSITIONING SYSTEMS (GPS) DATA TO
CHAIR, WALKING, STANDING, AND LAYING ON/STANDING UP FROM A BED USING
TIAL PROBLEMS. I WILL ALSO DISCUSS A SET OF OBJECTIVE AND DETAILED
SUCH PREDICTION ALGORITHMS IN THE APPLICATION TO OBSERVATIONAL STUDIES
ABILITY TO GATHER SPATIAL-TEMPORAL DATA. WE COLLECTED GPS DATA OVER 5
HOURS, 78 INTERVIEWS, AND DOCUMENT ANALYSIS. RESULTS: PRACTICAL ACCESS
THE INFLUENCE OF ORGANIZATIONAL SYSTEMS ON
INFORMATION EXCHANGE IN LONG-TERM CARE FACILITIES: AN INSTITUTIONAL ETHNOGRAPHY
S. Caspar1, P.A. Ratner1, A. Phinney1, K. MacKinnon2, D. O’Connor1, 1. University of British Columbia, Vancouver, British Columbia, Canada, 2. University of Victoria, Victoria, British Columbia, Canada
Purpose: Effective information exchange and collaboration among healthcare team members is essential for high quality of care in long-term care (LTC) settings. Methods: An institutional ethnography was conducted to derive data from three LTC facilities and included 83 participant observation hours, 78 interviews, and document analysis. Results: Practical access to institutional texts containing individualized care-related information (e.g., assessments, care plans, progress notes) was dependent on job classification. Regulated healthcare professionals (e.g., RNs) frequently accessed these texts to exchange information. Front-line care aides lacked practical access to these texts and primarily received and shared information orally. Consequently, microsystems of care, based on these distinct information exchange formats, emerged. The organizational systems in the facilities studied mandated the written exchange of information and did not formally support an oral exchange. Implications: Organizational initiatives aimed at building positive work-place relationships are needed to support information exchange within and between these microsystems of care.

ESTIMATING ENERGY EXPENDITURE FROM HEART RATE AND ACTIVITY COUNTS: A BAYESIAN APPROACH
J. Goldsmith1, J.A. Schrack1, V. Zipunnikov2, L. Ferrucci1, C. Crainiceanu1, 1. Columbia University, New York, New York, 2. Johns Hopkins University, Baltimore, Maryland, 3. NIA, Baltimore, Maryland
Wearable devices promise to revolutionize the estimation of energy expenditure at the subject level by providing continuous collection of movement and heart rate data. Several challenges currently prevent accurate estimation, including the effect of heterogeneity in relationship between heart rate and energy expenditure and the unclear relationship between activity and heart rate data. In this work we seek to combine in-lab calibration data with free-living activity and heart rate data collected as part of the Baltimore Longitudinal Study on Aging to flexibly derive subject-level energy expenditure relationships and estimates. Both data sources contribute to identifying the threshold between inactivity and activity, as well as to estimating the relationship between heart rate and energy. Crucially, this approach incorporates subject-specific features to generate personalized estimates of energy expenditure: preliminary results indicate that neglecting subject heterogeneity can lead to over- or under-estimation of total daily energy expenditure by more than 500 calories.

SESSION 395 (SYMPOSIUM)
BUILDING CAPACITY FOR HIGH QUALITY LONG-TERM CARE: USING SYSTEMS-LEVEL FRAMEWORKS
Chair: M.E. Dellefield, Research, VASDHS, San Diego, California
Co-Chair: K. Corazzini, Research, VASDHS, San Diego, California
Discussant: R.A. Anderson, Research, VASDHS, San Diego, California
The IOM (2002; 2013) has consistently called for attention to improving the microsystems of care that shape quality of care; DOD/AHRQ Initiatives such as TeamSTEPPS® long-term care suggest improving quality requires improving collaboration (2013) within and across microsystems. In nursing homes, microsystems may be made up of subgroups of nurse aides, nurses, and residents. In home health care, microsystems may include the elderly patient, home care aide, family member, and nurse. Such microsystems emerge within the context of a larger macrosystem, whether as a standalone nursing home or home health care agency or part of a multi-state corporate entity. These microsystems are complex adaptive systems (CAS), embedded within larger CAS; they may form and reform as they adapt to the demands of the elderly individual’s needs and the work environment. As a result, structured team processes with formal boundaries may oppose and impede the dynamics that allow effective microsystems to emerge. The purpose of this symposium is to describe key factors that facilitate or impede the capacity for high-quality long-term care within and between these microsystems. We examine how nursing home staff quality of interactions and licensure mix affect care outcomes of these microsystems, the microsystems of consumers of home health care who successfully remain at home, and how macro-system factors including support for nursing home administrators and overall staff education levels affect quality. This symposium highlights how building the capacity for high-quality long-term care requires advancing the empirical basis of a systems-level framework of how care emerges across an organization.

THE INFLUENCE OF ORGANIZATIONAL SYSTEMS ON INFORMATION EXCHANGE IN LONG-TERM CARE FACILITIES: AN INSTITUTIONAL ETHNOGRAPHY
S. Caspar1, P.A. Ratner1, A. Phinney1, K. MacKinnon2, D. O’Connor1, 1. University of British Columbia, Vancouver, British Columbia, Canada, 2. University of Victoria, Victoria, British Columbia, Canada
Purpose: Effective information exchange and collaboration among healthcare team members is essential for high quality of care in long-term care (LTC) settings. Methods: An institutional ethnography was conducted to derive data from three LTC facilities and included 83 participant observation hours, 78 interviews, and document analysis. Results: Practical access to institutional texts containing individualized care-related information (e.g., assessments, care plans, progress notes) was dependent on job classification. Regulated healthcare professionals (e.g., RNs) frequently accessed these texts to exchange information. Front-line care aides lacked practical access to these texts and primarily received and shared information orally. Consequently, microsystems of care, based on these distinct information exchange formats, emerged. The organizational systems in the facilities studied mandated the written exchange of information and did not formally support an oral exchange. Implications: Organizational initiatives aimed at building positive work-place relationships are needed to support information exchange within and between these microsystems of care.

NURSING HOME NURSES’ EDUCATION AND RESIDENT OUTCOMES
M.J. Dyck, M. Kim, K. Berliner, L.A. Bonney, Mennonite College of Nursing, Illinois State University, Normal, Illinois
The education of RNs in nursing homes is lower than in any other practice setting in the United States. The research question was: Does the educational level of nursing home nurses impact the capacity for high quality care in nursing home systems? The sample was a stratified random sample of free-standing nursing homes based on the CMS over-
A SYSTEMS ANALYSIS OF THE FACTORS THAT CONTRIBUTE TO THE NURSING HOME ADMINISTRATORS

Registered Nurse Directors of Nursing (DONs) serve in professional nursing management roles in nursing homes; as such, DON strategies to facilitate nursing staff care directly affect the capacity of clinical microsystems for high quality care. The purpose of this study was to describe strategies used by DONs to facilitate microsystem performance and the co-occurrence of such strategies with Centers for Medicare and Medicaid Services (CMS) quality measures. An embedded, mixed-methods study design (Creswell & Plano Clark 2011) of DONs (N=51) in two states was used to describe patterns of strategies used to facilitate nursing assessment, care planning, supervision and delegation, and the explanations and expected outcomes of those strategies. Qualitative data were mixed with quantitative data of CMS quality measures. Results indicate specific patterns of strategies co-occur with better quality in the context of DONs who explained their strategies as facilitating higher capacity clinical microsystems and who tracked microsystem outcomes.

MANAGING COMPLEX SYSTEMS TO MAINTAIN INDEPENDENCE: THE PERSPECTIVE OF HOME CARE CONSUMERS

K. Kietzman1,2, S. Wallace1,2, J. Torroella1, C. Chang1,2, A. Choi3, M. Mendez-Luck1, A. Benjamin4,1. 1. UCLA Center for Health Policy Research, Los Angeles, California, 2. UCLA Fielding School of Public Health, Los Angeles, California, 3. California State University, Dominguez Hills, Los Angeles, California, 4. Oregon State University, Corvallis, Oregon, 5. UCLA Luskin School of Public Affairs, Los Angeles, California

Accounting for the perspective of consumers is essential in efforts to improve quality and advance more person-centered systems of care.

The HOME study conducted in-depth interviews with more than three dozen older adult “dual-eligibles” in California (i.e., those insured by both Medicare and MediCal) to document how they manage a fragmented network of health and social care to continue to live independently at home. These data reveal that most consumers depend on the successful interaction of both formal (e.g., health care and social services) and informal (e.g., unpaid family) systems of care to effectively meet their basic needs. As California finalizes an initiative to transition “dual-eligibles” into managed care, the consumer perspective represented in the HOME study will be especially useful for gauging the early effects of this transition to a new system of care, and identifying both improvements and gaps that may still need to be addressed.

EVIDENCE-BASED FALL PREVENTION FOR PHYSICAL THERAPIST: THE REACH, IMPLEMENTATION AND EVALUATION OF AN ONLINE TRAINING PROGRAM ON PHYSICAL THERAPY PRACTICE

T. Shubert1,2, C.B. Clarke1, S.A. Bomberger2, M.L. Smith3,4, M.G. Ory4. 1. UNC Center for Aging and Health, Chapel Hill, North Carolina, 2. UNC School of Public Health, Chapel Hill, North Carolina, 3. University of Georgia, Athens, Georgia, 4. Texas A&M, College Station, Texas

The Otago Exercise Program is an evidence-based fall prevention program delivered by physical therapist in 6 visits over a one year...
period. Developed in New Zealand, few physical therapists in the United States have knowledge of the program. Through a partnership with the CDC and the Carolina Geriatric Education Center, an online training program was developed and deployed to have the greatest reach and implementation of the program. The CDC-funded Policies, Partners, and Programs for Fall Prevention evaluated the impact of the online training on implementation of the Otago program. This presentation will: 1) Present perceived and actual barriers and facilitators towards implementation; 2) Present preliminary outcome data of patients receiving Otago; 3) Discuss the complexities of implementing an evidence-based fall prevention program within the current healthcare system.

**FALL PREVENTION IN CLINICAL SETTINGS: THE IMPLEMENTATION AND EVALUATION OF THE STEADI TOOL KIT**

M.L. Smith1,2, R.J. Schuster1, C.O. Cherry1, M.G. Ory2, 1. College of Public Health, The University of Georgia, Athens, Georgia, 2. Texas A&M Health Science Center, College Station, Texas

This presentation will highlight the implementation and preliminary evaluation of the STopping Elderly Accidents, Deaths, and Injuries (STEADI) tool kit, a new resource developed by the Centers for Disease Control and Prevention (CDC) to improve fall risk screening, treatment, and referral practices in primary care settings. Specifically, this presentation will: (1) outline the overall rationale and components included in the STEADI tool kit; (2) describe the implementation of the Clinician Engagement and Education (CEE) Sessions used to prompt healthcare providers to make microsystem changes in their group practices; (3) describe the design, elements, and infrastructure being used to evaluate STEADI; and (4) discuss successes, challenges, and general lessons learned about implementation and evaluation during the pilot phase. This presentation will also identify resources healthcare professionals can use when implementing STEADI in primary care settings to reduce falls-risk among their at-risk geriatric patients.

**DEVELOPING, IMPLEMENTING, AND DISSEMINATING A FALLS PREVENTION CURRICULUM FOR COMMUNITY HEALTH WORKERS**

M.G. Ory1, J. St. John1, C.E. Beaudoin1, T. Shubert2, C. Rosemond2, D. Howell1, M.L. Smith1, 1. Health Promotion and Community Health Sciences, Texas A&M Health Science Center, College Station, Texas, 2. University of North Carolina, Chapel Hill, North Carolina, 3. Texas A&M University, College Station, Texas, 4. University of Georgia, Athens, Georgia

The Policies, Programs, and Partners for Fall Prevention (PPPFP) study incorporates multi-level intervention approaches to address fall prevention using several dissemination research methodologies—including training Community Health Workers (CHWs)/Promotores to deliver fall prevention messages. The purpose of this presentation is to discuss the development, implementation, and dissemination of the falls prevention CHW curriculum. Utilizing best practice models for training CHWs, adult learning theory, and message tailoring, the PPPFP study team developed a CHW curriculum on fall prevention. CHWs receiving the training use the information to connect at-risk seniors to medical services and evidence-based community fall prevention programs. The curriculum was first offered online in Texas—providing CEUs as part of the state CHW recertification process. Then the curriculum was adapted and disseminated to North Carolina for in-person training. This CHW-tailored curriculum has vast implications to reach larger proportions of high-risk seniors outside of healthcare settings through message tailoring.

**STATE-BASED FALL PREVENTION COALITIONS: POLICIES IMPLEMENTED, BARRIERS ENCOUNTERED, SUCCESSFUL STRATEGIES**

The National Council on Aging released the State Policy Toolkit for Advancing Falls Prevention in late 2012. The toolkit provides evidence-based guidance and resources for state and local fall prevention coalitions to have the greatest impact on change. However, little is known about the current policy efforts being done by state-based fall prevention coalitions. As a component of a CDC-sponsored “Policies, Programs, and Partners for Fall Prevention” grant, 35 states with active fall prevention coalitions were surveyed concurrent with the toolkit release in 2012 to document fall prevention strategies, policies, and regulations implemented to advance fall prevention; identify facilitators and barriers; and document general coalition practices and procedures. This presentation will: (1) highlight results of the state falls prevention coalition policy survey; and (2) identify successful strategies employed to advance falls prevention policies.

**SESSION 405 (SYMPOSIUM)**

**DECREASING BEHAVIORAL SYMPTOMS WHILE OPTIMIZING FUNCTION IN LONG TERM CARE RESIDENTS WITH MODERATE TO SEVERE COGNITIVE IMPAIRMENT**

Chair: E. Galik, School of Nursing, University of Maryland, Baltimore, Maryland
Co-Chair: B. Resnick, School of Nursing, University of Maryland, Baltimore, Maryland
Discussant: M. Bolz, New York University, New York, New York

Half of all nursing home (NH) and assisted living (AL) residents in the United States have moderate to severe dementia and are functionally disabled. Unfortunately, these individuals have limited opportunities to engage in functional and physical activities due to custodial care practices that focus on task completion and policies that restrict mobility for fear of falls. In a vicious cycle, this restriction results in unintended functional decline and places residents at increased risk of pain, falls, hospitalizations and death. These residents may also have related behavioral symptoms, such as agitation and resistance to care. It is during care interactions that behavioral symptoms are most commonly exhibited. This resistance discourages staff from engaging residents in functional activities and adds to functional decline. While some non-pharmacological interventions successfully address behavioral symptoms, they tend to focus on sedentary and soothing activities, such as massage, reminiscence, and relaxing music. Unfortunately, these interventions ignore function and in some cases propagate deconditioning and disuse. Alternatively, Function Focused Care is a theoretically based way to provide care in which caregivers teach, cue, model, and assist residents to perform functional tasks and engage in physical activity. This symposium will discuss the functional and behavioral outcomes of the Function Focused Care study for NH residents with dementia; compare the use of antipsychotic medication in AL and NH settings; present an innovative approach to addressing behavioral symptoms while optimizing function in this population; and present a case study of a successful method to decrease antipsychotic use at the site level.
CASE EXAMPLE OF A SITE BASED APPROACH TO DECREASE INAPPROPRIATE ANTIPSYCHOTIC USE IN NURSING HOMES
K. Wolfe, E. Galik, B. Resnick, School of Nursing, University of Maryland, Baltimore, Maryland

Antipsychotic medications are widely used in long-term care settings to treat behavioral and psychiatric symptoms of dementia and there is limited support as to their effectiveness and safety. The purpose of this quality improvement project was to demonstrate an effective way to decrease inappropriate use of antipsychotics in nursing home settings. Inappropriate use was defined as prescribing practices that did not comply with Centers for Medicare and Medicaid Services guidelines. An initial assessment of antipsychotic drug use was done using the American Medical Director’s Association Checklist and the information was provided back to the staff and education provided relevant to findings. The baseline prescribing rate for antipsychotic medications was 20%. Non-pharmacologic interventions were documented by the activities personnel, but nursing staff did not document any behaviors or interventions attempted. Outcomes and a dissemination plan will be provided for how this approach can be used in any nursing home.

SESSION 410 (SYMPOSIUM)

SUCCESSFUL AGING: SUCCESSFUL FOR WHOM?
Chair: L.R. Phillips, Nursing, UCLA, Los Angeles, California
Discussant: L.R. Phillips, Nursing, UCLA, Los Angeles, California

Many of the current definitions of successful aging are derived from Rowe and Kahn whose criteria are most applicable to non-Latino White Americans. These criteria emphasize physical health and strength. The degree to which these criteria are well-suited to describing successful aging among individuals in ethnically and racially diverse groups is uncertain. It could even be argued that setting these criteria as the standard for successful aging, invalidates the aging experiences of individuals who belong to groups that experience the bulk of chronic disease burden such as those in ethnically and racially diverse groups. The purpose of this symposium is to explore alternate criteria of successful aging that might be more relevant to diverse groups of older adults, particularly those with chronic illnesses. The first paper will present a concept analysis and currently accepted criteria for successful aging. The second paper will consider factors that influence successful aging in older African Americans and will suggest criteria that may be more appropriate for the group. The third paper will focus specifically on socioeconomic factors that may influence successful aging through their impact on mental health. The fourth paper will consider successful aging among African American caregivers who are experiencing post-caregiving transitions following the death of their loved one. The final paper will explore parameters of successful aging among Latinos based on group perceptions. The goal is begin to define parameters of successful aging that may be more universally applicable.

UNSUCCESSFUL AGING IN MINORITY GROUPS AS A SELF-FULFILLING PROPHECY?
S. Cobb, UCLA, Los Angeles, California

In our aging society, having strong and positive mental health can help assure successful aging. However, minority populations are plagued with messages and adversities that may damage and influence their mental health. There is an emergent need for research on the social and behavioral factors that influence mental health and impede successful aging for minority elders. This presentation will survey the literature and expose challenges that may influence the mental health of diverse populations.
SUCCESSFUL AGING: AFRICAN AMERICAN POST-CAREGIVERS EXPERIENCING POST-CAREGIVING TRANSITIONS
E. Ume1,2, B.C. Evans2, 1. School of Nursing, Charles R. Drew University of Medicine and Science, Los Angeles, California, 2. Arizona State University, Phoenix, California

The period of post-caregiving is a critical, though often ignored phase of caregiving. Few caregiving studies specifically focus on the experiences of African American post-caregivers (AAPCGs) or ways the caregiving experience is related to successful aging. This study of 40 AAPCGs whose caregiving role terminated with the death of their loved ones explored post-caregiving experiences of AAPCGs. This paper will present findings about facilitators to healthy post-caregiving transitions (PCT) and their relationship to successful aging. In general, AAPCGs utilized spiritual and other coping strategies, engaging in life balance activities, enjoying family time through reminiscence, visiting the cemetery and adjusting personal beliefs about the loss of their loved one in their transitions. Other facilitators included: AAPCGs’ satisfaction with care provided, feeling appreciated; fulfilling the wishes and legacies of deceased loved ones. Consideration will be given how the PCT can be used to develop criteria for successful aging among AAPCGs.

SUCCESSFUL AGING—WHAT IS IT AND WHO DOES IT DEFINE? A CONCEPT ANALYSIS
M. Wargo-Sugleris, University of California Los Angeles, Los Angeles, California

The concept of successful aging is widely defined by Rowe and Kahn’s definition based on the MacArthur Study and includes three factors: optimal physical and cognitive functioning, absence of disability and disease, and engagement with life. These factors have been used primarily to describe adults between the ages of 65-95 in retirement and primarily “elderly males” (1; 2). Although the concept of successful aging is used in occupational and gerontological journals, there is no agreed common or standard definition for defining successful aging (1; 2; 3). This paper will be a concept analysis of the term “successful aging” as it applies to people as they enter “successful aging”, men and women. The paper will lay the foundation for an exploration of the concept of successful aging as it applied to ethnically and racially diverse groups. References 1. Rowe & Kahn, 1997 2. Tate, Lah, & Cuddy, 2003 3. Depp & Jeste, 2009

PHYSICAL FUNCTION: A PARAMETER OF SUCCESSFUL AGING FOR LATINOS?
G. Flores, Nursing, University of California, Los Angeles, Los Angeles, California

Current definitions to successful aging include physical function as a criterion, without considering to what extent physical function fits the perception of successful aging among Latino older adults. To promote successful aging among Latino older adults, understanding the perceptions of successful aging among this population and how physical function fits with their perceptions is essential. Understanding such perceptions will help validate the aging experience of Latino older adults, and stimulate new approaches to culturally-sensitive research focused on successful aging. The purpose of this presentation is to explore current literature that aims at understanding the perception of physical function as a criterion of successful aging among Latino older adults, in an effort to stimulate culturally-sensitive definitions of successful aging. Consideration will be given to how successful aging among Latino older adults is defined in the literature, and how cultural nuances of successful aging are conceptualized in the literature.

SESSION 415 (PAPER)

BIOLOGY AND GENETICS

AGING, LATENT VIRAL INFECTION, AND RADIATION EXPOSURE
J.L. Pugh, M. Smithey, J. Nikolich-Zugich, Genetics IDP, Immunobiology, University of Arizona, Tucson, Arizona

Susceptibility to infectious disease increases with age, making it one of the leading causes of death in people over 65. The immune aging process may be accelerated by the presence of life-long latent infections, such as cytomegalovirus, that put a constant burden on the immune system. Theories of biological aging also suggest that immune cells may have defective functions in old age because of a lifetime of self-renewal, and DNA damage related senescence, among other factors. Sub-lethal whole-body irradiation results in dose-dependent death of immune cells throughout the body, forcing some peripheral self-renewal of surviving immune cells. We exposed mice to various sub-lethal irradiation doses (0Gy – 4Gy) in youth, and followed them for life. Some mice were also given life-long murine cytomegalovirus (MCMV) to reflect the most common latent virus in human populations. At the end of life, mice were vaccinated against, and then infected with, West Nile Virus (WNV). Our results show that a single sub-lethal radiation exposure in youth, in the context of latent MCMV infection, results in a unique immune cell population distribution, and ultimately decreased vaccine efficacy.
Implications to the fields of radiobiology, immune aging, and vaccine development will be discussed.

ROLE OF CD4+ T CELLS IN AGE-RELATED DEFECTS IN IMMUNITY

Aging results in an incompletely understood state of immune deficiency called immunosenescence. T-cells are known to play a fundamental role in directing and regulating human immunity. Models utilizing West Nile Virus (WNV) and Listeria monocytogenes (Lm) have clearly defined defects in old CD8+ T cells that directly contribute to increased susceptibility in elderly. Specifically, aged CD8+ T cells have a reduced pathogen-specific precursor frequency, the magnitude of the response to an infection is reduced, and the resultant effector cells have reduced effector functions. However, the contribution of CD4+ T cells to immunosenescence is not well understood. We hypothesize that aging results in a reduced frequency of CD4+ T cells specific for, and capable of responding to, WNV. To enumerate CD4+ WNV-specific T-cells, we have engineered an I-Ab class II MHC tetramer presenting the immunodominant CD4 WNV epitope, E641-655. This technical advance has allowed us to perform the first studies aimed at carefully evaluating the frequency of precursor and responding antigen-specific CD4+ T cells in old and adult mice in responses to WNV. Interestingly, the precursor frequency of E641-1Ab specific CD4+ T cells was found to be higher in old mice as compared to adult mice. Also, as compared to adult, old mice have reduced number of E641-1Ab specific CD4+ T cells in the brain on day 10 post-WNV infection despite having equivalent numbers in the blood and spleen. These studies demonstrate that CD4+ T cells do not conform to the current understanding of immunosenescence measured in CD8+ T cells.

STRESS RESPONSIVE BIOCHEMICAL ANABOLIC/CATABOLIC IMBALANCE AND TELOMERE LENGTH IN OLDER ADULTS
S. Vasunilashorn1, A.A. Cohen2, 1. Population Studies, Princeton University, Princeton, New Jersey, 2. University of Sherbrooke, Sherbrooke, Quebec, Canada

A growing body of research has documented the relationship between chronic psychological stress and telomere length. The mechanisms that link stress and telomere length, however, are not well understood. Studies have reported that chronic stress shifts the balance of hormones to low levels of anabolic and high levels of catabolic hormones. This suggests one possible biochemical mechanism by which stress accelerates telomere shortening, which is considered an indicator of cellular senescence. To examine the interplay between biochemical factors related to stress arousal and cellular aging, we investigate the association between anabolic/catabolic (A/C) imbalance and telomere length in the Social Environment and Biomarkers of Aging Study (SEBAS) in Taiwan. SEBAS participants age 54 and older with values for two anabolic hormones (serum dehydroepiandrosterone sulfate [DHEAS] and insulin growth factor [IGF]-1), four catabolic hormones (cortisol, epinephrine, norepinephrine, and interleukin-6 [IL-6]), and leukocyte telomere length were examined. We found that IL-6 was the only individual biochemical associated with shortened telomere length (z0.88). Neither of the two A/C ratios (DHEAS/cortisol nor IGF-1/cortisol) was associated with telomere length; however, a high A/C imbalance summary score was associated with a greater odds of having a short relative to a long telomere length (odds ratio 1.19, 95% CI 1.05-1.35). These results indicate that A/C imbalance, defined by at-risk levels of several anabolic and catabolic biochemical factors, may be one mechanism through which psychological stress is associated with leukocyte telomere length and possibly to cellular senescence.

APOLIPOPROTEIN E ALLELE AND HEARING LOSS IN OLDER ADULTS
D.J. Mener1, J. Betz2,3, K. Yaffe4,5, T. Harris6, E. Helzner7, E.S. Strotmeyer8, E.M. Simonsick9, F.R. Lin1,2,3, 1. Department of Otolaryngology-Head & Neck Surgery, Johns Hopkins School of Medicine, Baltimore, Maryland, 2. Department of Epidemiology, Johns Hopkins School of Medicine and Bloomberg School of Public Health, Baltimore, Maryland, 3. Center on Aging and Health, Johns Hopkins Medical Institutions, Baltimore, Maryland, 4. Departments of Psychiatry and Neurology, University of California, San Francisco, San Francisco, California, 5. Departments of Epidemiology and Biostatistics, University of California, San Francisco, San Francisco, California, 6. Laboratory of Epidemiology, Demography, and Biometry, National Institute on Aging, Bethesda, Maryland, 7. Departments of Epidemiology and Biostatistics, State University of New York Downstate Medical Center, Brooklyn, New York, 8. Intramural Research Program, National Institute on Aging, Bethesda, Maryland, 9. University of Pittsburgh, Center for Aging & Population Health, Pittsburgh, Pennsylvania

Background: Prior studies have reported conflicting results of the association between apolipoprotein E4 (APOE4) allele status and hearing loss in older adults. Methods: We studied 1833 men and women (mean age 77.4) enrolled in the Health, Aging and Body Composition study, a prospective observational study begun in 1997-98. Participants were categorized by the number of APOE4 alleles in their genotype. Hearing was measured with an audiometer in a sound attenuating booth. Using multiple linear regression we assessed the association between APOE4 status and speech frequency pure tone average (PTA, 0.5 kHz-4 kHz) hearing in the better ear. Hearing thresholds were modeled using profile analysis with an unstructured covariance matrix in each pure tone frequency (0.5 kHz-8 kHz) by APOE4 status. Models were adjusted for demographic and cardiovascular risk factors. Results: Compared to participants with zero APOE4 alleles, participants with two (-4.26 dB, p=0.11) or one (-0.85 dB, p=0.22) allele did not differ in speech PTA. Participants with two alleles had better hearing thresholds at 1.0 kHz (-8.48 dB, p < 0.05) and 2.0 kHz and those with one allele had better thresholds at 4.0 kHz (-2.45 dB, p < 0.05) and 8.0 kHz (<2.98 kHz, p < 0.01) than participants with zero alleles. There was neither consistent nor overlapping frequency specific hearing threshold differences for participants with one or two compared to zero APOE4 alleles. Conclusion: After adjustment for multiple comparisons, APOE4 allele status was not independently associated with hearing loss in older adults.

IDE (RS6583817) AND PULSE PRESSURE AFFECT EXECUTIVE FUNCTION LEVEL AND CHANGE IN OLDER ADULTS
G. McFall, S.A. Wiebe, D. Vergote, J. Jhamandas, D. Westaway, R.A. Dixon, Univ of Alberta, Edmonton, Alberta, Canada

Introduction: Using new data from the Victoria Longitudinal Study we examine two modifiable (pulse pressure [PP], body mass index [BMI]) and one non-modifiable (Insulin Degrading Enzyme [IDE] polymorphism, rs6583817) factors associated with differential change in executive function performance over three waves (~8-9 years). Method: Baseline participants were n=613 women and men (M age=71 years) with genotype data. Analyses consisted of: (a) confirmatory factor analysis establishing a single latent EF factor consisting of two inhibition and two switching indicators, (b) latent growth curve modeling (Mplus 6.0) over a 40-year age band of aging (ages 53-95), and (c) path analysis investigating effects of IDE (G=protective factor), PP, and BMI. Initial results: First, results indicated significant differences in initial level of EF (1.19, p<.01), significant intravidual change (p<.01), and significant interindividal differences in intravidual change (0.002, p<.001). Second, PP was more comprehensively associated with EF.
than was BMI. Specifically, older adults with normal baseline PP performed better on EF at age 75 (centering age) and showed significantly lower rate of decline (slope=-.004) than those with higher PP (slope=-.008). The IDE G+ group had better EF at age 75 (intercept=-.210) and lower rate of EF decline (slope=-.009) than the G- group (intercept = -.113, slope = -.023). Third, initial interaction analyses (PPxIDE) showed that PP effects were diminished, but that the interaction affected both level of EF and change in EF. Conclusion: The protection effect associated with IDE (rs6583817) is moderated by PP, confirming the importance of blood pressure regulation in older adulthood.

SESSION 420 (PAPER)

NURSING

HOW NURSING ASSISTANTS' PERCEPTIONS OF BARRIERS TO WALKING OLDER HOSPITALIZED ADULTS DIFFER FROM OTHER STAFF

C. Bianchi, N.M. Watson, School of Nursing, University of Rochester, Rochester, New York

The purpose of this study was to identify staff perceptions of professional, institutional, patient and family related barriers to walking hospitalized older adults. More than half of hospitalized older adults lose function by the second day of hospitalization as a result of decreased mobility. A survey for hospital staff providers (MDs, NPs, PAs), nursing staff (RNs/LPNs), therapists (PTs/OTs), and nursing assistants (NAs) was developed to identify perceived barriers that interfere with walking hospitalized older adults. Strong psychometrics were established for the survey. It was administered to staff in one acute care hospital via email. Responses were anonymous. A 30% response rate was obtained (n=175/580). Significant differences in staff beliefs about barriers related to patients and families and professional and institutional issues were found. Significantly more nursing assistants (NAs) - the staff providing the most direct care - believed patients want to walk (p=0.035) and families want them walked (p=0.006) in contrast to other staff. This finding suggests that reluctance of patients and their families to walking while hospitalized may not actually be a barrier to walking if NAs' perceptions are correct. Further, significantly more nurses (p=0.049) and NAs (p=0.010) believed walking is a priority for NAs where other staff did not. Thus failure of NAs to walk patients may not be due to NAs failure to recognize the importance of their role in walking patients but instead due to other institutional or professional barriers. These barriers might include inadequate NA staffing (73%) or lack of understanding of ambulation orders (p=0.009; p=0.001).

AWARENESS OF AND ATTITUDES TOWARD ADVANCE DIRECTIVE PLANNING AMONG GERONTOLOGICAL SOCIAL WORKERS IN SOUTH KOREA

S. Kwon, Georgia State University, Atlanta, Georgia

Ethical issues around the provision of life-sustaining treatment to terminally ill patients at the end of life have been the subject of sharp debate in Korean society. In response to this legally as well as morally complex subject, the importance of advance directives designed to ensure patients' wishes and preserve their autonomy in end-of-life (EOL) care decisions has been highlighted, and the utilization of such advance directives through discussion and documentation of individuals preferences with a legal statement has been encouraged. Designed for descriptive and explanatory purposes, this study explores their awareness and attitudes of gerontology social workers in regard to EOL care planning and advance directives, and their degree of willingness to deal with this issue in social work practice settings. Structured questionnaires using the Scale of End-of-Life Planning (SELP) were completed by gerontological/geriatric social workers (N=246) in a metropolitan area of South Korea. The results of the study indicate that 73.2% of the participants were not aware of advance directives, while 22.4% indicated they were moderately aware and 4.5% stated that they were highly knowledgeable. Regarding their awareness of the medical technologies used to assist patients in the final stages of life, 89.8%, 75.2%, 79.7%, and 74% of the respondents stated that they were knowledgeable about cardiopulmonary resuscitation, mechanical ventilation, dialysis, and tube feeding, respectively. Analysis of this study shows that participants emphasize individuals' rights to make their own decisions in respect of EOL care and generally have a positive attitude to EOL care planning to ensure patient wishes and preferences (M=49.89, SD=4.70). However, only half of the participants indicate that they are strongly willing to handle EOL care planning or advance directives in their practice settings, while 40 percent are unsure of them. These findings highlight the lack of awareness of advance directives and suggest the need to do a broad campaign to increase not only affiliated professional but also public awareness.

LISTENING TO THE NURSE PAYS OFF: AN INTEGRATED NURSE HEALTHLINE PROGRAM WAS ASSOCIATED WITH SIGNIFICANT COST SAVINGS

Objective: To estimate the relations between adherence with nurse recommendations about where to seek care and expenditures for health-care services received by callers to a Nurse HealthLine triage program designed for callers 65 years of age or older with Medicare supplement coverage. Methods: Healthcare utilization and claims data from 152,855 calls into the Nurse HealthLine for the three year period encompassing 2009 to 2011 were included. Callers who followed the nurse recommendations about where to seek care were classified as adherent, while those who did not were classified as non-adherent. Program-related savings were estimated by comparing the difference in downstream healthcare expenditures between adherent and non-adherent callers, after using multivariate modeling to adjust for case mix differences between these groups. Results: Forty-two percent of callers were redirected to a higher level of care (e.g. emergency room versus urgent care), 44% to same level of care, and 13% to a lower level of care, indicating the program focused on directing members to the appropriate level of care. Analyses showed that the program was associated with significant savings of $33.4 million over the three year period (p<0.05), with about 90% attributable to Medicare, 8% to the supplement plan, and 2% to callers. Conclusions: This is the first known Nurse HealthLine triage program designed solely for Medicare beneficiaries with supplemental coverage. The program generated statistically significant (p=0.05) savings, resulting in positive return on investment of $1.37, indicating that for every dollar spent on the program, $1.37 was saved over the three year period.

DEVELOPING ADVANCED PRACTICE NURSES INTERVENTIONS FOR THE POPULATION 80 YEARS AND OLDER

L. Imhof, R. Naef, H. Petry, R. Mahner-Imhof, Institute of Nursing, Zurich University of Applied Sciences, Winterthur, Switzerland

Individually tailored Advanced Practice Nursing interventions have been shown to be highly beneficial for better health outcomes. In RCT's, requiring control and standardization of the intervention, tailoring poses a challenge. Tailoring the interventions for an RCT, required a decision about the comprehensive assessment of the life situation, alignment to principles of patient-centered interventions and categorizing of the nurses’ activities. Therefore, in order to develop a RCT testing a home visit program in people at age 80 years and older in Switzerland, a literature review and focus groups with experts have been conducted. The literature was analyzed for relevant topics to be assessed in the oldest
old. Additionally, underlying principles of effective interventions were investigated and activities of nurses were identified. A comprehensive geriatric assessment, intervention pathways and nursing activities’ categorization were developed and discussed with clinical and research experts as well as people over 80 years. The comprehensive geriatric assessment included a health status appraisal and was enlarged by social and environmental aspects. Patient- and family-centered care, self-care promotion, empowerment and partnership were defined as the leading principles. The Advanced Practice Nurses’ activities were categorized as targeting patients-education, training new skill in participants, providing hand-on-care, and reassessing and evaluating goal achievement. The intervention was tested in a RCT (n=461) with people 80 years and older. Within this RCT, the three elements allowed a individually tailored APN interventions and led to low attrition rates and significantly improved health outcomes.

UNDERSTANDING JOB SATISFACTION AMONG MEDICAID HOME CARE WORKERS
V. Phillips1, A. Hunsaker2, K. Zhang1, 1. Health Policy and Management, Rollins School of Public Health of Emory University, Atlanta, Georgia, 2. School of Social Work, University of Pittsburgh, Pittsburgh, Pennsylvania

Home care workers play a critical role in caring for frail elderly people. This workforce exhibits high rates of job turnover, which negatively affect client satisfaction, quality of care, and incentives for provider-sponsored training. Agencies currently report aide shortages across settings and concern about future labor supply. Increasing job satisfaction is one way to reduce turnover, increase quality, and promote workforce stability. Using the Job Diagnostic Survey (JDS), this paper assesses job satisfaction among aides working in the Georgia Medicaid home and community-based services program. The JDS provides an overall satisfaction score and scores on five subscales: job growth, job security, compensation, supervision, and co-workers. Aides in three regions completed survey rounds over a three year period to generate a panel dataset comprised of over 1700 aides. Select sample characteristics are: 64% African American; 95% female; and 37% completed high school only. Seventy-two percent were certified nursing assistants. The mean number of clients cared for weekly was 4.4. The aides worked an average of 27 hours per week per agency and 26% also held non-agency jobs. We used a generalized linear mixed model, accounting for clustered ordinal data, for analysis. Being older, working more weekly agency hours, and having only a high school education significantly increased overall satisfaction, while working in a personal care home/assisted living facility or being African American decreased it. Results for the subscales, comparisons with national JDS norms, and policy implications will be discussed.

SESSION 425 (SYMPOSIUM)

EVALUATING THE QUALITY OF NURSING HOME CARE: A REVIEW OF SOME RECENT CMS INITIATIVES

Evaluating the quality of nursing home care requires a range of methods, including a review of recent CMS initiatives. The Nursing Home Compare Five-Star Quality Rating System, the Nursing Home Value Based Purchasing Program (NHVBP), as assessment of the status of Quality Assurance and Performance Improvement (QAPI) programs in nursing homes, and the newly enhanced Nursing Home Compare Website.

EVALUATION OF THE NURSING HOME COMPARE WEBSITE: USER ASSESSMENT OF RECENT WEBSITE ENHANCEMENTS
A.S. Edwards1, E. Rosenzweig2, A. Muma1, 1. US Health, Abt Associates Inc., Durham, North Carolina, 2. Bentley University, Waltham, Massachusetts

Initially designed in 1998, the Nursing Home Compare (NHC) website underwent significant changes in 2011 to improve user experience. Through usability tests, focus groups, and a web-based survey, user satisfaction with NHC, usefulness of the information presented and usability of the tool were assessed. The web-based survey revealed a wide range of users from researchers and health care providers to consumers seeking nursing home care for themselves or on behalf of others. In three rounds of consumer testing, participants were consistently impressed with the breadth of information available for nursing homes. Most users were able to articulate the main purpose of NHC and the Five-Star Quality Rating System, and found the rating system to be helpful in searching for and comparing nursing homes. Health care providers found the website to be a motivation for quality improvement and a useful resource for comparing their performance to that of other nursing homes.

IMPLEMENTATION OF NURSING HOME VALUE BASED PURCHASING DEMONSTRATION – YEAR TWO EXPERIENCE

Under the Nursing Home Value Based Purchasing (NHVBP) Demonstration, the Centers for Medicare & Medicaid Services assesses the performance of nursing homes based on a set of performance measures and makes performance payments to those nursing homes that achieve a higher performance or improvement over time based on these measures. The demonstration includes 171 nursing homes from 3 States (Arizona, New York, Wisconsin). Comparison groups were selected based on random assignment (New York) or propensity score matching (Arizona and Wisconsin). In all three States, staffing levels were higher in Year 1 than in the baseline, with average nursing hours per resident day increasing from 3.5 to 3.58 in Arizona, from 3.62 to 3.7 in New York, and from 3.55 to 3.8 hours in Wisconsin. In Arizona and Wisconsin, the demonstration was associated with lower rates of potentially avoidable hospitalizations in Year 1 but not in Year 2.

NURSING HOME COMPARE: THE FIRST FOUR YEARS OF THE FIVE-STAR QUALITY RATING SYSTEM

In December 2008, the Centers for Medicare & Medicaid Services enhanced its Nursing Home Compare website to include “star” ratings for each US nursing home, measuring multiple dimensions of quality including outcomes of health inspection surveys, staffing levels, and performance on selected quality measures. The rating system has now been in place for over four years, and over this period, we have examined trends in the ratings each year and across years. Specifically, we examined stability and longitudinal changes in the underlying components of the rating system, and compared the results of each individual year, noting significant changes among the years. Trends show that since the inception of the rating system, there has been a significant increase in the number of 5-star nursing homes and a corresponding decrease in the number of 1-star nursing homes, with the most significant change being in the quality measure component of the rating system.
THE STATUS OF QAPI IN NURSING HOMES: RESULTS OF BASELINE DATA COLLECTION USING THE NURSING HOME QUALITY IMPROVEMENT QUESTIONNAIRE

The Nursing Home Quality Improvement Questionnaire was fielded to collect standardized information on (1) current quality assurance and performance improvement (QAPI) activities in nursing homes; (2) challenges providers face in conducting quality improvement activities; and (3) areas where technical assistance might be beneficial. Of the 2,990 respondents who completed the questionnaire, the majority indicated that their facility had a written QAPI plan, they use some form of data to evaluate their performance, and they use a systematic approach to determine when an in-depth analysis is needed to fully understand the underlying causes of a problem. Having adequate time to complete quality improvement activities was rated by respondents as the greatest barrier confronting them. The second largest barrier was finding staff with quality improvement skills. Respondents indicated that the most beneficial types of technical assistance would include training on critical thinking skills and training on quality improvement concepts and methods.

SESSION 430 (SYMPOSIUM)

EXPANDING SERVICES AND SUPPORTS TO CAREGIVERS OF INJURED VETERANS

Chair: C. Gruman, The Lewin Group, Falls Church, Virginia
Co-Chair: L. Alecxih, The Lewin Group, Falls Church, Virginia
Discussant: K. Greenlee, Administration for Community Living, Washington, District of Columbia

The Caregivers and Veterans Omnibus Health Services Act of 2010 (P.L. 111-163), marked a new era in the delivery of services for Caregivers of Veterans. The VA’s Caregiver Support Program (CSP) provides comprehensive assistance to qualified Caregivers including: a monthly stipend, health care benefits, enhanced respite care, mental health services, travel, lodging and per diem benefits, education and training, education and resources through a Caregiver website, and information and referral assistance through the Caregiver Support Line. Since inception in May 2011 through FY12, 6,606 Caregivers received a stipend and nearly 7,500 Caregivers received education and training; the Caregiver Support Line received over 50K calls and 1,690 Caregivers, without access to health insurance, were enrolled into The Civilian Health and Medical Program of the Department of Veterans Affairs, (CHAMPVA). This symposium examines how VA’s transformation through P.L. 111-163 empowers Caregivers of Veterans with severe physical and psychological injuries sustained since September 11, 2001. The first two sessions present the challenges, successes and policy implications since implementation of CSP. Preliminary evaluation results demonstrate Primary Family Caregivers experienced a significant drop in Caregiver burden while Veterans experienced a significant 30% drop in inpatient utilization and 4.6% increase in outpatient utilization. The second two sessions outline VA’s new respite care program, known as Veteran-Directed Respite (VDR). VDR offers Veterans a flexible budget, expands access and offers choice and control in respite care delivery. VDR offers a promising respite alternative to post 9/11 Veterans that do not fit the traditional model of respite care services.

SESSION 3: THE VETERAN-DIRECTED HCBS PROGRAM AND REBALANCING VA’S LONG-TERM CARE

In 2008, ACL and VA collaborated to develop Veteran-Directed Home and Community Based Services (VD-HCBS) that gives Veterans choice and control over their long term care. Veterans manage a capped budget and decide for themselves, or with their designated representative, what mix of goods and services will meet their needs. Veterans are also able to hire and supervise their own workers and purchase services needed to live independently in the community. Since 2008, 42 VAMCs and 100 ADRCs partnered to offer VD-HCBS in 25 states. 1,500 Veterans received VD-HCBS to date, allowing them to safely remain in their homes avoiding hospital admission or nursing home placement. Veterans report being highly satisfied with the program and that without VD-HCBS, they would be at risk for permanent placement in a nursing home. Presenters will discuss how VD-HCBS embraces VA’s philosophy of rebalancing long-term care and expanding alternative options for delivering HCBS to Veterans.

SESSION 4: EXPANDING VETERAN-DIRECTED RESPITE (VDR) TO CAREGIVERS ENROLLED IN VA’S CSP

Findings from an evaluation of VA’s CSP report that although Caregivers may require respite services, VA’s traditional delivery of respite care does not support their individual needs or the needs of the post 9/11 Veteran population served by the program. As a result, VA is looking to develop an innovative approach to providing respite care to the Caregiver population enrolled in CSP. The result is the Veteran Directed Respite Program (VDR). VDR provides Veterans with a flexible budget that can be used to hire their own workers to provide respite care. During this session, presenters from ACL and VA will discuss how they plan to capitalize on the success of the Veteran-Directed Home and Community Based Services Program to operationalize the Veteran Directed Respite Program and how this new program will fill an unmet need to Caregivers enrolled in VA’s Caregiver Support Program.

SESSION 1: IMPLEMENTATION OF VA’S CAREGIVER SUPPORT PROGRAM (CSP)

L. Taylor, J. Henius, M. Kabat, U.S. Department of Veterans Affairs, Washington, District of Columbia

During this session, presenters will discuss implementation from a policy perspective of CSP. As a result of fast-paced implementation to meet statutory requirements, VA had to within a year: develop the systems, tools and processes to systematically assess over 10,000 applications from Caregivers for eligibility and enrollment; hire and train over 150 Caregiver Support Coordinators; and, handle and track over 50,000 phone calls to the Caregiver Support Line. Presenters from VA will discuss how implementation was managed at the federal level as well as the challenges and successes that have arisen along the way. For example, presenters will detail how VA adapted from offering CSP through Veterans Health Administration as opposed to Veterans Benefits Administration, where most other VA compensation-type programs are organizationally aligned.

SESSION 2: RESULTS AND FINDINGS FROM AN EVALUATION OF VA’S CSP

L. Taylor, J. Henius, M. Kabat, U.S. Department of Veterans Affairs, Washington, District of Columbia

Presenters from VA will discuss findings from a comprehensive evaluation of CSP implementation. Part of this session will focus on findings that deal with how local Caregiver Support Coordinators and large health care systems integrated CSP into their operations as well as the challenges and opportunities that resulted. For example, how did VA develop an inter-disciplinary team that could effectively and efficiently assess the physical and mental needs of Veterans and abilities of the Caregiver? Additionally, the presenters will discuss findings that outline how Veterans and Caregivers are directly benefiting from participation in CSP. For example, initial results have indicated that in 6 months...
The clinical practice guideline issued by the American and British Geriatrics Societies was incorporated into a 24-hour interprofessional training curriculum to promote the adoption of evidence-based practice projects to reduce falls in a range of settings that include long term care, hospitals (including emergency department), and community clinics. GECs working in the area of Falls prevention were funded to better equip the health professions’ workforce (multiple disciplines included medicine, nursing, physical therapy, social work) to implement Falls risk assessments to reduce future falls occurrences. Participating GECs have adopted multi-factor screenings (evidence-based practice) as measurable outcomes occurring in partner clinical sites. As such, the practice itself has morphed to these unique organizations with varying stakeholder and political interests. The targeted practice has evolved since 2011 within situational parameters, which has led to systemic changes at both the educational and organizational levels. Methods and measures to collect practice data vary across the GECs based upon organizational constraints. In addition to planned outcomes (some of which are reported to funder), several unintended effects (educational, practice, and contextual) will illustrate the need for organizational (long term care, emergency room) adaptation to evidence-based practice over time and vice versa. Presentations will highlight evaluation perspectives (utilization-focused, change theory) conducive to such projects in that they prioritize stakeholder input, organizational change, or the need to measure unintended effects. The challenges in upholding stakeholder interests in similar projects as organizational changes occur are discussed as they may undergird the sustainability of practices (and related education) shown to improve health status and/or reduce costs in the research base.

INTERPROFESSIONAL TRAINING TO ADDRESS FALLS ASSESSMENT AND MANAGEMENT
C.L. Goode, J.H. Mathews, E.F. Ansello, Virginia Geriatric Education Center, Richmond, Virginia

The clinical practice guideline issued by the American and British Geriatrics Societies was incorporated into a 24-hour interprofessional training curriculum to promote the adoption of evidence-based practices and improve team care processes among health professionals at a Program of All-Inclusive Care for the Elderly. Medical chart audits (N = 133) to document practice change, indicated that physical therapists significantly increased documentation of post-fall risk assessments (34.6%, p < 0.005), as well as the causes (54.6%, p < 0.005) and circumstances of falls (46.23%, p < 0.0001). Unanticipated results related to improved falls reporting procedures, the development of a site-specific falls prevention program, and better coordinated team care through early, proactive actions. This presentation will outline how the Utilization-Focused Evaluation approach was used to ensure that stakeholder interests were an inherent aspect of the evaluation design. It will also detail the hypothetical structure, process, and outcome contextual considerations mapped during evaluation planning.

EVIDENCE-BASED FALLS TRAINING IN AN ACUTE CARE SETTING: RECIPROCAL INFLUENCE OF CONTEXT AND PROGRAM
C.P. Carrico, C. McKibbin, Wyoming GEC, Laramie, Wyoming

There are high costs involved with falls in health care settings. In addition to monetary costs, there is a burden of human suffering among patients and caregivers when falls occur. Evidence shows that an inter-disciplinary and multifaceted approach to falls prevention that targets multiple risk factors is more likely to reduce falls than a single-measure. To assist a falls-reduction initiative in a regional medical center, the Wyoming Geriatric Education Center implemented a two-phased, multifactorial falls assessment training. In phase one, over 600 nurses, technicians, physical therapists, and other disciplines were trained in the Greensboro Falls curriculum. Evaluation revealed a high level of training satisfaction, improvements in knowledge, intent to change practice, and actual practice change across disciplines. Contextual factors directed training focus changes for phase 2 that then targeted one unit. Outcomes assessed using chart audits will be reviewed as will the contextual factors that determined training direction and success.

ORGANIZATIONAL CHANGES FROM FALLS TRAINING IN AN EMERGENCY DEPARTMENT: FACILITATING EVIDENCE BASED PRACTICE AMONG HEALTH PROFESSIONALS
J.A. Metcalf, Maine GEC, Portland, Maine

The University of New England Maine Geriatric Education Center has developed a training program for rural emergency department health professionals and includes development, implementation and evaluation of an evidenced based practice for improving the quality of falls care for older adults utilizing 12 validated quality indicators. The updated quality indicators from those developed in the Assessing Care of Vulnerable Elders (ACOVE) have provided the direction for the project. (Chang JT, Ganz DA, Quality indicators for falls and mobility problems in vulnerable elders. J Am Geriatr Soc 2007; 55:327-334). This program provides an overview of planning, training and evaluation occurring in years 1-3 of this HRSA funded 5 year grant cycle. The presentation will also discuss how movement toward change requires attention to the need to adapt expectations to context as illustrated by lessons learned, successes and unintended effects.

FALLS IN LONG TERM CARE
J. Marks, Johns Hopkins University, Baltimore, Maryland

EBP related to falls in long term care continues to be a challenge to health care professionals working in this setting. Literature review addresses multi-factorial assessment for falls including: history of falls, vitamin D supplementation, medication review, gait and balance assessment, visual assessment, and orthostatic blood pressures. Strong recommendations for evidence based interventions seem to be limited for long term care settings, this session will address the importance of an educational component for staff addressing the multi-factorial assessment including technique for measurement of orthostatic blood pressures. The impact of adapting evidence based practice into this simple process and the implications to interventions will be discussed.

SESSION 440 (PAPER)

BEHAVIORS AND ATTITUDES AMONG OLDER WORKERS AND RETIREES FROM A CITIZENSHIP PERSPECTIVE
P.H. Jensen, Aalborg University, Aalborg, Denmark

This paper analyzes causes and effects of early exit/retirement. A distinction is made between older adults subject to voluntary and involuntary retirement, and focus is on how the experience of retirement...
affects the life conditions of retirees from a citizenship perspective. The analysis is based on a survey conducted among 1,700 Danish early retirees 60-64 years of age. All retirees are enrolled in a retirement scheme allowing older adults to retire +59 years of age. Citizenship is the key dependent variable and citizenship is about equality of status. Marshall (1950) has paraphrased citizenship as “equal social worth”, referring to that people have a sense of belonging to a collectivity or community so that citizens can meet as equals. A central dimension of citizenship deals with the manner in which citizens orient themselves towards the political system; whether citizens have access to a consumer life-style; how the individual citizen socially is related to other citizens, and citizens identity and own role perception. Loss of citizenship — epitomized as economic, social and political marginalization — is associated with low levels of self-esteem. The paper shows that the cause for early exit/retirement has a massive effect on the life conditions of the retirees. The paper shows that voluntary retirees are well integrated into consumer lifestyles as well as social and political communities, whereas involuntary retirees to a large extent are exposed to the risk of ending up in poverty, social and political isolation, as well as low levels of self-esteem.

THE ROLE OF DEBT IN BABY BOOMER’S RETIREMENT PROSPECTS

S. Neufeld, Wayne State University, Detroit, Michigan

Problem: American middleclass households face historic financial erosion due to depressed housing markets and incomes and continuing high unemployment rates. For the baby boomer cohort now nearing retirement age, these conditions have reduced the capacity to accumulate the wealth necessary to maintain standards of living in retirement. In addition, their debt levels remain at near historic highs, yet scant attention has been paid to whether this debt can be offset by existing assets or whether income generated by accumulated wealth can service this debt were baby boomers to retire on time lines expectable by previous generations. Methods: Data is drawn from the 1989 to 2010 Survey of Consumer Finances and the 2010 Health and Retirement Study. Measures included real estate, financial and pension assets including Social Security, consumer and housing-related debt. Findings: Analyses revealed: (1) Amount of debt carried into retirement has been steadily increasing since 1989. (2) Debt levels of baby boomer households are larger than other age groups, and they will carry more debt into retirement than any previous cohort. (3) Middle income (2nd to 4th quintiles) boomer households are most likely to face reduced standards of living in retirement and will have the most difficulty in servicing their debts. Discussion: The housing collapse and the Great Recession devastated the wealth of many baby boomer households, yet high levels of debt remain. This debt will reduce the retirement lifestyles of many boomer households, particularly middle income households, which highlights the erosion of the middle class in American society.

RACIAL/ETHNIC INEQUALITY AMONG OLDER WORKERS: FOCUSING ON WHITES, BLACKS, AND LATINOS WITH THE CUMULATIVE ADVANTAGE/DISADVANTAGE FRAMEWORK

E. Choi, F. Tang, V. Copeland, School of Social Work, University of Pittsburgh, Pittsburgh, Pennsylvania

Although minority workers may face retirement differently from Whites, our knowledge of older minority workers is fragmentary because of the limited theories and methodologies that are used in existing studies. This study aims to examine what contributes to older minorities’ labor market participation and whether these factors differ from those of older Whites. Cumulative advantage/disadvantage (CAD) theory provides the conceptual framework, emphasizing the process by which the social system generates inequality and how unfavorable positions in early life influence the accumulation of disadvantages in later age. Using the 2004 and 2008 Health and Retirement Study datasets, this study uses the work status (working or retired) of individuals age 65+ as the outcome. Based on the CAD framework, the variables of interest include financial status, health, education, and career patterns (employment stability and job types). Using a Probit approach, racially separate analyses are used to compare the factors across Whites, Blacks, and Latinos. The results show stark differences in the factors by race. While older Whites tend to stay in the labor market when they have better health, are relatively young, and value work more highly. However, Blacks are found to work even in poor health because of greater financial need. Also, older Latino workers seem to experience double barriers of age and race at work. Congruent with CAD theory, older people’s labor market participation does not simply result from individual preference per se but from social structures, which reflect underlying racial inequality within older workers. Policy implications are discussed.

FINANCIAL CAPACITY, ASSET OWNERSHIP, AND ACCESS TO CREDIT AMONG LOW-INCOME OLDER ASIAN IMMIGRANTS

Y. Nam, E. Lee, J. Huang, J. Kim, 1. University at Buffalo, Buffalo, New York, 2. National Asian Pacific Center on Aging, Seattle, Washington, 3. Saint Louis University, St. Louis, Missouri

Background: Older Asian immigrants are growing but vulnerable population, especially those who came to the U.S. at the late stages of their lives. Despite their economic vulnerability, we know little about long-term economic security issues among older Asian Immigrants, especially those related to financial capacity and asset ownership. This study examined financial conditions among low-income older Asian immigrants. Method: This study used new survey data collected from low-income older Asian immigrants in a supported employment program (N = 150). This study employed various indicators of financial conditions, including financial knowledge scale, saving regularly or not, and ownership of long-term savings. We compared old-age immigrants who came to the U.S. at the late stage of their lives with young-age immigrants to determine the roles of acculturation. This study uses logit, ordered-logit and negative binomial regressions. Results: Analysis results demonstrated that older Asian immigrants are financially vulnerable. Their level of financial knowledge is low: average number of correct answer to three basic financial knowledge questions is one. A small percentage of respondents regularly save (20%). A low proportion own long-term savings (about 30%) and homes (20%). Regression analyses indicated that old-age immigrants’ financial-management skills, knowledge of social programs, and ownership rates of bank accounts, long-term savings, and vehicles are significantly lower than those of young-age immigrants with comparable demographic and household characteristics. Findings suggest a positive role of acculturation Conclusions: The results indicate precarious financial situations among low-income Asian immigrants and call for active interventions for this population, especially old-age immigrants.

SESSION 445 (PAPER)

CIVIC ENGAGEMENT, ACTIVITY PROFILES AND USING TECHNOLOGY IN RESEARCH: FINDINGS AND ETHICAL ISSUES

VIRTUAL SOCIAL SPACES IN RURAL PLACES: LINKING OLDER PEOPLE TO COMMUNITY THROUGH NEW TECHNOLOGIES

H.R. Feist, K.L. McDougall, Australian Population and Migration Research Centre, University of Adelaide, Adelaide, South Australia, Australia

Older people choosing to age-in-place in rural areas want to remain connected to their social and support networks, no matter where those connections are located. Enabling and supporting older rural people to utilise new technologies can strengthen their connections to social net-
works, community information, and to services. This paper discusses the results of a three-year research project that explored connection to personal networks and the wider community for older Australians in rural locations through the use of new technologies. The ‘Linking Rural Older People to Community’ project involved a survey (n=858) and follow-up interviews (n=201) with people aged 55+ years living in the Murraylands region of South Australia. A 12 month pilot study followed with a subset of 47 study participants providing them with their choice of a laptop computer or Apple iPad®, 3G internet and self-directed tuition. Results suggest that new technologies combined with reliable internet connections and supportive tuition enhanced community connectedness, increased access to community information and improved social networks; in particular communication with dispersed family ties.

DEDUCTIVE DISCLOSURE AND CONFIDENTIALITY IN ACCESSIBLE DIGITAL MEDIA

R. Hrybyk, J.K. Eckert, M.C. Nemec, E.G. Roth, Center for Aging Studies, UMBC, Baltimore, Maryland

How can qualitative researchers use digital media and the internet to disseminate findings while preserving the confidentiality of respondents? The convention of confidentiality in qualitative research allows for modifications to raw data to describe findings without revealing the participants’ identities. However, unique elements of the narrative may inadvertently lead to the deductive discovery of the protected identity. Publishing research findings on the internet increases the possibility that a site or an individual will be recognized and this poses ethical questions relating to confidentiality. Digital stories link images to the spoken word in a compelling manner and increase the potential for practical application of research findings. The web offers opportunities to share knowledge gained in publicly funded research with a wider audience, but respondents must be protected from potential embarrassment – or worse – while the integrity of the research process is preserved. This paper will present and discuss a case study, a five minute digital story, to illustrate issues of research integrity, informed consent, and confidentiality in the digital context. Ethnographic data for this presentation are drawn from a five-year NIA-funded qualitative study, “Stigma and the Cultural Context of Residential Setting for the Elderly.” After attending this presentation, attendees will have a better understanding of ethical challenges qualitative researchers face in the information age.

“IT’S FUN DOING SOMETHING MEANINGFUL”: CIVIC ENGAGEMENT OF OLDER ADULTS THROUGH THE HEALTHY COMMUNITIES THROUGH HEALTHY FOOD PROGRAM IN NEW YORK CITY

INTRODUCTION – Healthy Communities through Healthy Food (HCF) was a multi-year multi-site program in New York City to increase the civic engagement of older adults. Older adults were encouraged to take leadership roles in community gardens, farmers markets, a produce buyers club, cooking demonstrations and educational activities. Prior to HCF, older community members were not often seen as leaders in food access. METHODS: An evaluation of HCF was conducted from 2010 to 2012. Surveys were completed by 148 participants; three focus groups were held (28 participants), and in-depth qualitative interviews were conducted with 12 participants and 11 stakeholders. RESULTS: Survey results suggest that main motivators for HCF involvement were improvement in health and wellbeing (50%), learning new skills (35%), and feeling connected to their community (34%). Qualitative findings regarding motivation were consistent: One participant noted: “This is my hobby. [I ask myself] what can I do to improve the quality of food to the people around me?” A second said: “It gave me an opportunity to express myself, to get close to people, to teach people how to eat.” Nearly half of those surveyed considered themselves to be a leader or have interest in leadership, however focus group participants indicated that they were more interested in being role models or mentors rather than “leaders,” and preferred decisions be made by consensus approach. DISCUSSION: The HCF program attracted participants to civic engagement activities, largely due to its focus (i.e. improved access to healthy food) for individuals involved and the broader community.

SESSION 450 (POSTER)

BIOMETRICS AND GENETICS

NONINVASIVE BRAIN STIMULATION ALTERS CNS ACTIVITY AND IMPROVES BALANCE IN OLDER ADULTS

B. Manor, Y. Zhou, Y. Hao, A. Pascual-Leone, J. Zhang, 1. Harvard Medical School, Boston, Massachusetts, 2. Beth Israel Deaconess Medical Center, Boston, Massachusetts, 3. Peking University, Beijing, China

Introduction: Balance is regulated by a complex system including numerous brain networks and cognitive functions. Noninvasive transcranial direct current stimulation (tDCS) modulates brain activity and induces acute improvements in cognitive and sensorimotor function. The purpose of this study was to determine the acute effects of tDCS on standing balance, as well as brain perfusion, in older adults. Methods: Ten healthy older adults were recruited. On Visits 1 and 2, subjects completed balance assessments immediately before and after 20min of either real or sham (i.e., control) tDCS targeting cognitive brain regions. Balance was assessed by measuring standing postural sway with eyes-open, eyes-closed, and while performing a cognitive task. On Visits 3 and 4, arterial spin labeling MRI was used to quantify resting-state brain perfusion, before and after real or sham tDCS as described.
Reduced gait velocity is associated with both physical disability and cognitive impairment. Vascular disease and vascular risk factors have been associated with reduced gait velocity. Small vessel cerebrovascular disease resulting from chronic ischemia has been hypothesized to underlie these associations. However, the mechanisms linking vascular disease to gait have not been clearly described. We assessed the relation of cerebral perfusion measured by Transcranial Doppler ultrasound (TCD) to gait velocity in the Einstein Aging Study (EAS) community-based cohort. Analyses include 98 non-demented EAS participants (mean age 80.6; 46 % female) who underwent TCD and quantitative gait assessments at their annual visit. TCD was used to assess mean flow velocity (MFV) (cm/sec) in the middle (MCA), anterior (ACA), and posterior (PCA) cerebral arteries. Gait velocity (cm/sec) was measured using a computerized walkway (GAITRite, CIR systems). Linear regression was used to assess the relation between gait velocity and MFV, adjusting for demographics and comorbidities. In linear regression analyses adjusted for age, sex and education, ACA and MCA MFV’s were positively associated with gait velocity (p < 0.01), while PCA MFV was not. The positive associations with ACA and MCA MFV persisted after additional adjustment for history of cardiovascular disease, diabetes and hypertension (p < 0.03). Blood flow velocities in the cerebral arteries that perfuse motor cortex (MCA and ACA) were positively associated with gait velocity. This supports the hypothesis that preserved cerebral perfusion is an important factor in gait. Whether impaired perfusion (as in chronic ischemia) predicts gait impairment requires longitudinal study.

EFFECTS OF ENDOCRINE DISRUPTORS ON AGING IN WISTAR RATS

T. Shinkai, K. Fukui, Shibaura Institute of Technology, Saitama, Japan

Tetrachlorodibenzodioxin (TCDD) and bisphenol A (BPA) represent a family of ubiquitous environmental pollutants and are well known as environmental endocrine disruptors and they change multiple endocrine systems in the living body. Moreover, it has been reported that exposure to the chemicals causes oxidative stress in a variety of animal models and there is a suggestive consideration that they may have influence on aging. In order to investigate the lifespan associated with the endocrine disruptors, we gave a single subcutaneous injection of TCDD (100μg/kg body weight) and BPA (100μg/kg body weight) to pregnant Wistar rats on gestational day 19 and studied effects of a relatively low dose of the chemicals on mortality, body weight and morphological changes in male and female offspring. The mean lifespan of the non-treated animals were 27.1±4.7 months in male and 30.8±5.2 months in female. The lifespan and the body weight decreased in TCDD treated rats. Furthermore, exposure of low dose of TCDD increased apoptotic cells in the rat brains. These results indicate that TCDD which was transferred into the offspring through the placenta and the mammary gland caused the lifespan-shortening. On the other hand the changes of lifespan were not recognized between BPA treated rats and controls. But hypothyroidism was observed in BPA treated animals. It indicates that BPA was also transferred from the mother into the offspring. Our finding suggests that the endocrine disruptors may induce modulation of homeostatic functions and cause a change in aging.

PROTEIN SYNTHESIS AND CELLULAR PROLIFERATION IN MODELS OF SLOWED AGING

The disposable soma theory of aging describes resource allocation between growth, somatic maintenance and reproduction. We hypothesized that in models of slowed aging, there would be more energetic resources allocated to somatic maintenance and less toward growth. We used nutritional (caloric restriction (CR)), pharmaceutical (rapamycin fed (Rap)), genetic (Snell Dwarf), and epigenetic (crowded litter (CL)) mouse models of slowed aging. In these animals we measured protein synthesis (mixed tissue and mitochondrial) and cellular proliferation in multiple tissues (liver, heart, and skeletal muscle) by the incorporation of deuterium oxide (D2O) into protein or DNA. In general, mixed protein synthesis rates were maintained or decreased, the rates of mitochondrial protein synthesis were preferentially maintained, and the rates of cellular proliferation were decreased. A notable exception was the CL model in which both protein synthesis and cellular proliferation were increased. Our data represent the first attempt to characterize aspects of growth and somatic maintenance in multiple models of slowed aging. In conclusion, there is an increased investment in somatic maintenance in most models of slowed aging indicated by maintained protein synthesis and decreased proliferation. CL animals are a notable exception and deserve further investigation.

CHANGES IN IGF-I AND ITS BINDING PROTEINS ARE ASSOCIATED WITH DIABETES IN OLDER ADULTS

IGF-I has structural homology with insulin and both promote glucose uptake. (Jacob, 1989). IGF-I is bound to six binding proteins in circulation. Little is known about long-term changes in IGF-I and IGF-BPs in normoglycemic subjects who later develop IGT, IFG, or diabetes. Participants were 897 adults aged ≥ 77 years (16% black, 62% women) enrolled in the CHS All Stars cohort study. Plasma levels of IGF-I, IGFBP-1, and IGFBP-3 were assessed and ADA criteria for IGT, IFG, and diabetes were used to classify participants using data from baseline (1996-1997) and 9-year follow-up visits (2005-2006). At baseline, mean age was 76.3 years (SD=3.6) and 166 (18.5%) had diabetes. During follow up, mean IGF-I and IGFBP-3 levels decreased while IGFBP-1 levels increased for all groups. The greatest change in protein levels occurred in those with diabetes at baseline (9-year changes: -9.3% for IGF-I, 59.7% for IGFBP-1, -13.4% for IGFBP-3); the smallestest in individuals who remained normoglycemic at follow-up visits (9-year changes, p-value for comparison to diabetes group: -3.7% for IGF-I, p<0.01, 25.6% for IGFBP-1, p<0.001, -6.4% for IGFBP-3, p<0.001); and intermediate changes, which were significantly different from the diabetes group, occurred in those who were normoglycemic at baseline but developed IFG at follow-up. Our results suggest that changes in IGF proteins vary with worsening glycaemia. Older adults with diabetes exhibit changes in IGF proteins that may put them at greater risk for diseases associated with the IGF-axis.
DURING AGING DIFFERENT AFFECTS ON IMMUNE PROTECTION

Support a role for glucagon in liver regeneration that is the diminishment

1.4. The binding kinetics differ between groups. Thus, our study may

operated animals. Following partial hepatectomy the binding increased

protein in the young controls with similar values in the aged and sham

animals and following partial hepatectomy. Iodinated glucagon binding

lated rat liver plasma membranes obtained from young and aged ani-

tors and cytokines plays an important role in hepatocyte regeneration.

Evidence suggests that a complex balance of peptide growth factors and cytokines plays an important role in hepatocyte regeneration. To evaluate a possible role for glucagon we studied its binding to isolated rat liver plasma membranes obtained from young and aged animals and following partial hepatectomy. Iodinated glucagon binding was measured after incubation of plasma membrane aliquots in 0.1M Tris-HCl buffer, pH 7.4, at 37 degrees C, and separation of bound from free by centrifugation of the aliquots in 20 fold excess of ice cold buffer at 12,600g. Glucagon binding was calculated at 7~ 0.5 fmol/100 mcg protein in the young controls with similar values in the aged and sham operated animals. Following partial hepatectomy the binding increased in the young to 10.2 ~ 1.2, 12.8 ~ 1.2 and 22 ~ 2.4 fmol/100 mcg protein at 4,8 and 24 hours, respectively. In the old the binding was similar at 4 and 8, but significantly lower at 24 hours, calculated at 14.2 ~ 1.4. The binding kinetics differ between groups. Thus, our study may support a role for glucagon in liver regeneration that is the diminishing with aging.

CALORIE RESTRICTION AND RAPAMYCIN HAVE DIFFERENT EFFECTS ON IMMUNE PROTECTION DURING AGING

E.L. Goldberg1,2, M. Smither,1 J. Uhrlaub1, J. Nikolich-Zugich1,2, J. Uhrlaub1, J. Nikolich-Zugich1,2, J. Department of Immunobiology and Arizona Center of Aging, University of Arizona, Tucson, Arizona, 2. Department of Nutritional Sciences, University of Arizona, Tucson, Arizona

Despite advances in healthcare, infectious disease remains a leading cause of death in the elderly. This becomes especially important to consider when studying lifespan-extending interventions. Two natural interventions have been shown to extend lifespan in mammals: calorie restriction (CR) and prolonged rapamycin (rapa) treatment. Both of these interventions are proposed to function by decreasing mTOR signaling, thereby decreasing cellular metabolism. However, mounting an immune response against acute infection requires an enormous metabolic investment that is likely to be altered by CR or rapa, potentially exacerbating the age-related decline in functional immunity. Therefore, we tested the impact of CR and rapa treatments on survival and antigen-specific immune responses in 18 month old C57BL/6 mice infected with West Nile Virus. We found that CR and rapa have differing effects on immune response, although both groups exhibited decreased survival after acute infection. We conclude that metabolic interventions that extend lifespan may come at the cost of immune protection during aging. Careful consideration must be taken when evaluating lifespan extension, to take into the account the Healthspan.

AGING EXACERBATES OBESITY-INDUCED CEREBROMICROVASCULAR INJURY AND COGNITIVE DECLINE IN MICE

Z. Tucek, P. Toth, D. Sosnowska, T. Gautam, W.E. Somtag, Z. Ungvari, A. Ciszak, Reynolds Oklahoma Center on Aging, Donald W. Reynolds Department of Geriatric Medicine, University of Oklahoma Health Sciences Center, Oklahoma City, Oklahoma

Obesity in the elderly promotes the development of vascular cognitive impairment, which develops in the absence of Alzheimer-type senile plaques as a result of cerebromicrovascular alterations. To elucidate the mechanisms by which aging exacerbates the deleterious cerebrovascular effects of obesity, young (7 mo) and aged (24 mo) C57BL/6 mice were fed a high fat diet for 5 months. Compared to young obese mice, aged obese mice exhibited impaired pressure-induced myogenic constriction and flow-induced constrictive of middle cerebral arteries, disruption of the blood-brain barrier, hippocampal microvascular rarefaction, microglia activation, up-regulated hippocampal expression of pro-inflammatory cytokines and chemokines and impaired performance in tests relevant for hippocampally -dependent tasks of learning and memory. Taken together, aging exacerbates obesity-induced cerebromicrovascular injury and neuroinflammation, which likely promote the development of vascular cognitive impairment in aged obese individuals.

HEALTHSPAN TRAJECTORIES DIFFER FROM LIFESPAN TRAJECTORIES

B. Newell1,2, D. Kitzenberg1, L. Beverly1, J. Cypser1,2, K. Karubus1, P. Tedesco1,2, L. Gentile1, T. Johnson1,2, J. Integrative Physiology, University of Colorado, Boulder, Colorado, 2. Institute of Behavioral Genetics, Boulder, Colorado

In the nematode C. elegans genetic mutations decrease mortality and extend lifespan, but their effect on functional decline has not been as widely studied. We have developed methods for assessing healthspan, which is the period of life with minimal functional loss. We have assessed three alterations in locomotion. We find that longevity mutations typically promote better healthspan outcomes. There is an overall correlation between longer lifespans and longer periods of health in the insulin/insulin-like-growth factor signaling pathway. However, not all longevity-promoting mutations show extended healthspans. Health declines differently depending on the assessment used. In addition to highlighting the genetic influence on health and life outcomes, these methods will contribute to identifying candidate genes and pathways that mediate healthspan extension in mammals. Supported by the Glenn Foundation and gifts from the Son2 Foundation.

A MULTI-ORGANISM APPROACH TO SELECTING STRONG CANDIDATES FOR MAMMALIAN LONGEVITY GENES

G.L. Suphin1, S. Bean1, M. Kaeblerie2, R. Korstanje1, J. The Jackson Laboratory, Bar Harbor, Maine, 2. University of Washington, Seattle, Washington

The search for genetic factors involved in aging has identified hundreds of genes for which altered expression is capable of increasing life span in one or more model organisms. As the first pharmacological agents targeting these genes begin to be translated into clinical trials for treatment of age-associated disease, it will be useful to prioritize potential clinical targets from the growing list of candidate aging factors that are likely to influence longevity in mammals. We have devised a candidate-gene approach to combine recent genomic methods in mammals with the powerful genetic tools available in invertebrates to identify evolutionarily conserved longevity genes with a high likelihood of impacting mammalian aging. An initial list of longevity-associated genes was selected based on a meta-analysis of human and mouse genome-wide association studies. Orthologs of each gene were then selected in both Caenorhabditis elegans and Saccharomyces cerevisiae. A screen is currently underway to determine whether RNAi knockdown or deletion of each ortholog increases life span in worms or replicative life span in yeast. In cases where life span extension is observed, knockdown of the ortholog will be combined with knockdown of genes in commonly studied aging pathways to look for epistatic interaction. Interesting candidates will be carried forward for longevity studies in mice. Here we provide a detailed description of our screening strategy and report preliminary results.

SARCOPENIA AND AGED SKELETAL MUSCLE HYPERTROPHY ARE INDEPENDENT OF LIFELONG SATELLITE-CELL DEPLETION

J.D. Lee, J. Mula, C. Fry, T. Kirby, J. Beggs, M. Campbell, J. McCarthy, C.A. Peterson, Rehabilitation Sciences, University of Kentucky, Lexington, Kentucky

Aging is associated with the loss of muscle stem cells, satellite cells, a process assumed to contribute to sarcopenia. However, no definitive evidence exists showing that satellite cells are necessary for muscle
maintenance or adaptation with age. To directly address these issues, we developed the Pax7-DTA mouse that allows conditional and specific deletion of Pax7+ satellite cells with tamoxifen administration. Four month old mice were treated with tamoxifen or vehicle and allowed to recover for one (young) or 20 (old) months, followed by synergist ablation (SA; two weeks of overload) or sham surgery. Tamoxifen-treated muscles showed >90% satellite cell depletion after 1 month and no recovery after 20 months, such that the aged mice lived the majority of their lives with a significantly reduced satellite cell pool. With age, vehicle-treated muscles demonstrated an expected reduction (-52%) in Pax7+ satellite cells. Further, an age-associated loss of muscle mass and attenuated muscle hypertrophy in response to overload was observed in 24 month old mice; however, either was not affected by lifelong satellite cell depletion. During overload in old mice, tamoxifen prevented myonuclear accretion and the appearance of small, regenerating myofibers, but did not influence overall muscle hypertrophy. These data provide convincing evidence that loss of satellite cells does not exacerbate sarcopenia, nor are satellite cells required for myofiber hypertrophy even in old age. Thus, satellite cell loss does not play a causal role in sarcopenia or in diminished muscle adaptability observed with age.

LOSARTAN IMPROVES EXERCISE TOLERANCE IN A FRAIL MOUSE MODEL

C. Lin1,2, H. Yang1, T.N. Burks1, P.M. Abadir1, J.D. Walston1, J. Johns Hopkins University, Baltimore, Maryland, 2. Chang-Gung Memorial Hospital, Taoyuan, Taiwan

Frailty is an important geriatric syndrome. Interleukin-10 knockout (IL-10 k.o.) mice are utilized to study the biological basis of frailty. Losartan is known to improve skeletal muscle healing and decrease disuse atrophy in older mice. We hypothesized that blocking angiotensin II type I receptor with Losartan would improve exercise tolerance and strength in treated compared to untreated older frail mice. Twenty IL-10 k.o. mice aged 72 wks were equally divided into control group or treated with Losartan (0.9g/L) for 20 wks. Weight, physical activity, grip strength, and time to exhaustion on treadmill were measured monthly. Time on treadmill in treated IL-10 k.o. mice increased 29.2% and decreased 6.6% in the control group over the same period (p<0.059). Grip strength, weight, and physical activity showed no change over this 20 week period. Our study suggests that blocking renin-angiotensin system with losartan in frail older mice may improve activity tolerance. This result, along with prior studies showing protection against disuse atrophy and improved mitochondrial function in older mice, provides important rationale for further study of losartan in the treatment of frailty.

AGE-RELATED CHANGES TO THE INTRINSIC DEATH PATHWAY IN LIVERS OF FISCHER 344 RATS

Concord Hospital, Sydney, New South Wales, Australia, 6. National Institute of Ageing, National Institute of Health, Sydney, New South Wales, Australia

Aging is associated with increased hepatic apoptosis. Apoptosis is tightly regulated by the mitochondrial intrinsic death pathway. Following cell death stimulation, pro-apoptotic (BID, BAX) and anti-apoptotic (Bcl-2, Bcl-Xl) proteins translocate into the mitochondrial membrane where this pivotal balance determines apoptosis. We aimed to characterize age-related changes in hepatic expression of proteins involved in the intrinsic cell death pathway and apoptosis. Young adult (6x1 months) and old (26x2 months) male Fisher 344 rats were injected i.p. with saline (Young n=9, Old n=9) (control group of a larger study) 4 hours before euthanasia. Samples of perfused liver were snap frozen for subsequent immunoblot analysis of BAX, BID, Bel-XI and Bel-2 expression in the mitochondria and cytosol, VDAC- 1 in the mitochondria and Cytochrome C, Caspase-3 in cytosol. In the cytosol, expression of BID, truncated BID (tBID), BAX and Bel-Xl were decreased in old rats compared to young (p<0.05). No change with age was observed in cytosolic expression of Bel-2. Compared to young, in old age mitochondrial BID, tBID and VDAC-1 expression significantly decreased (p<0.05), while Bcl-2 trended to decrease and BAX and Bcl-XL did not change. Consistent with our finding of increased apoptosis via Caspase-3 activation, the ratio of mitochondrial BAX to Bcl2, an indicator of pro-apoptosis stimulation, trended to increase in old age (p<0.07). However surprisingly, the intermediate mitochondrial apoptotic signal, cytochrome C was similar in both ages in the cytosol. Preliminary results suggest dysregulation and less cytosolic reserve of apoptotic protein in the hepatic intrinsic death pathway in old age.

PROTEOMIC ANALYSIS OF CELLULAR SENESCENCE AND THE SENESCENCE-ASSOCIATED SECRETORY PHENOTYPE (SASP) IN HUMAN PREADIPOCYTES

Y. Zhu, T. Tchkonia, M.B. Stout, N. Giorgadze, S. Dasari, H. Bergen, J.L. Kirkland, Mayo Clinic, Rochester, Minnesota

Advanced age is associated with fat tissue loss, chronic inflammation, and metabolic dysfunction. Senescent preadipocytes and endothelial cells accumulate in fat with aging and obesity and may affect tissue structure and function through factors they secrete. To study the fundamental mechanisms that drive cellular senescence and characterize the SASP, quiescent (early passage) and senescent (late passage) cells were analyzed using a label-free quantitative proteomics approach. Proteins were analyzed by nano-LC-MS/MS. Pathway analysis was conducted using Ingenuity. 130 proteins were found to be differentially secreted by pre-senescent vs. senescent preadipocytes. Among these proteins, pro-inflammatory proteins were highly secreted from senescent preadipocytes, including IL6, MCP-1, TGF-β, PAPP-A, and others, which likely contribute to the chronic inflammation associated with adipose tissue dysfunction. Furthermore, TGF-β signaling was highly activated and Wnt signaling was down-regulated. This suggests that the SASP inhibits preadipocyte differentiation into fat cells, contributing to fat loss with aging. Combining secretome and cell lysate data, protein translation was found to be the most activated process during cellular senescence. Phospho-mTOR and its downstream target, phospho-S6K1, were further analyzed by Western-blot, confirming that activated protein synthesis could contribute to the consequences of cellular senescence.

P49/STRAP REGULATES CELL MORPHOLOGY THROUGH BRIDGING SRF-RELATED AND BUD22-RELATED SIGNALING PATHWAYS

X. Zhang1,2, G. Azhar1,3, S.C. Rogers1,2, J.Y. Wei1,2, I. Geriatics, University of Arkansas for Med Sciences, Little Rock, Arkansas, 2. Central Arkansas Veterans Healthcare System, Little Rock, Arkansas

Objective: SRF is a major transcription factor which plays a significant role during cardiac development, maturation and adult aging. P49/STRAP (SRFBP1) is a SRF-binding protein that forms a protein complex with SRF, myocardin and Nkx2.5 thereby modulating the transcriptional regulation of cardiac genes. P49/STRAP mRNA is increased with advancing age in both human and mouse, however, its role in gene expression and cell morphology remains to be determined. Methods: Results: We used H9C2 and C2C12 cell lines. We found that the endogenous p49/strap protein is concentrated in the nucleus, but also widely distributed within the cells and showed proximity to the actin fiber. After treatment with p49/strap adenovirus, the actin filaments appeared disorganized, stained weakly and the cells were also smaller in size vs. control cells. Microarray analysis revealed that 32 genes were differentially expressed with 1.4-fold change in p49/strap treated vs. control groups. 5 genes were upregulated: while 27 genes, including...
RAGE, were significantly down-regulated after p49/strap adenovirus treatment. Bioinformatic analysis indicated that p49/strap protein is a member of BUD22 family that regulates yeast budding and cell polarity during growth. Conclusion: p49/strap is a SRF binding protein and also a BUD22 family member. Therefore, p49/strap may serve as a bridge that links two signaling pathways: the SRF-related pathway in transcriptional regulation of cytoskeletal genes, and the BUD22-related pathway that regulates cell size, morphology and growth. The increased expression of p49/strap that is observed in aged hearts may mediate cell growth and morphology in cellular senescence and hence impact organismal aging.

SENEGENT CELLS COMPROMISE FAT TISSUE FUNCTIONS
M. Xu, Y. Zhu, T. Pirskhalava, N. Giorgadze, D. Baker, J. van Deursen, T. Tchkonia, J.L. Kirkland, Mayo Clinic, Rochester, Minnesota

Introduction: Senescent cells with essentially irreversible loss of replicative potential accumulate in tissues with aging. Cellular senescence is associated with a pro-inflammatory senescence-associated secretory phenotype. We tested the hypotheses that senescent preadipocytes accumulate with aging, contribute to age-related inhibition of adipogenesis and fat tissue inflammation, and whether eliminating them restores fat tissue function. Methods: Senescent cell abundance was determined by senescence-associated beta-galactosidase assay and p16ink4A mRNA. Human preadipocytes were X-irradiated to induce senescence. Non-irradiated preadipocytes were stained with DiI and co-cultured with control or irradiated preadipocytes. Preadipocytes were also cultured in conditioned media (CM) from control or irradiated preadipocytes mixed 1:1 with differentiation medium. Fifteen days later, the percent of differentiated target cells was determined. Macrophage migration in response to CM was assayed. INK-ATTAC transgenic mice with a p16ink4A prokeratin fragment and FKBPs/caspase-8 (ATTAC) were bred with BubR1 hypomorphic mice, which have accelerated age-related subcutaneous fat loss. Senescent cells are specifically eliminated from these mice by administering AP20187. Results: Senescent cells increased in fat tissues with aging and obesity. The percent of differentiated Dil-labeled preadipocytes was lower following exposure to senescent than control cells. Differentiation was also impaired by CM from senescent preadipocytes. Macrophage migration was greater in response to senescent preadipocytes. Subcutaneous fat tissue loss was partially reversed by clearing senescent cells from INK-ATTAC;BubR1H/H mice with AP20187. Conclusion: We found senescence-mediated age-related subcutaneous fat tissue loss was partially reversed by clearing senescent cells from INK-ATTAC;BubR1H/H mice with AP20187. Conclusion: We found senescence-mediated age-related subcutaneous fat tissue loss was partially reversed by clearing senescent cells from INK-ATTAC;BubR1H/H mice with AP20187. Results:

DIFFERENTIAL AND SYNERGISTIC EFFECTS OF TNF-α AND IFN-γ ON HUMAN PREADIPOCYTE SENESCENCE
R. Kandhaya Pillai, T. Tchkonia, Y. Zhu, N. Giorgadze, A. Palmer, T. Pirskhalava, J.L. Kirkland, Internal Medicine, Mayo Clinic, Rochester, Minnesota

Cellular senescence plays a dynamic role in stress response and aging processes of complex organisms by limiting the proliferative capacity of damaged cells. Continuous presence of low-grade circulating cytokines leads to chronic activation of the immune system and contributes to age-related pathologies and adipose tissue dysfunction. The role of inflammation and inflammatory mediators in adipose tissue senescence remains elusive. We investigated the chronic effects of the pro-inflammatory cytokines, TNF-α and IFN-γ, on preadipocytes isolated from human subcutaneous adipose tissue. Long term exposure to TNF-α, IFN-γ, or their combination had differential effects on preadipocyte proliferation. TNF-α treatment increased proliferation, while IFN-γ decreased the proliferation compared to control. In contrast to TNF-α alone, the combination of both TNF-α and IFN-γ drastically decreased proliferation and induced growth arrest. Unlike TNF-α alone, the combination significantly increased SA-β gal activity, p21, and p16, but decreased expression of novel genes that are required for cell cycle regulation. Interestingly, the combination of IFN-γ plus TNF-α synergistically induced prolonged activation of JAK/STAT and mTOR signaling pathways. Our results suggest that synergistic action of TNF-α and IFN-γ acts as a molecular switch and plays an important role in tightly regulating the senescence program.

GENETIC ANALYSIS OF BEHAVIOR AND COGNITIVE DECLINE IN AGING DIVERSITY OUTFBRED MICE
L.C. Anderson, C. Acklin, E.J. Chester, Chester Lab, The Jackson Laboratory, Bar Harbor, Maine

The Diversity Outbred (DO) mouse population is a new genetic population with high recombinational precision, genetic polymorphism and phenotypic diversity. In a cross-sectional study of these mice at three different age points we aim to correlate age related cognitive impairments to mechanistic neurological and affective measures. We will also map the genetic sources of variation in cognitive decline among individuals and relate them to general mechanisms of senescence. Using high-throughput healthspan phenotyping, mice are characterized for physiological and behavioral endpoints. The behavioral assay is conducted at three time points (6, 12, and 18 months of age) and consists of the Open Field Activity and Anxiety, Novel Object Exploration and Recognition, T-Maze Spontaneous Alternation, Tail Suspension Test (TST), and Rotarod acquisition and performance. Following completion of all physiological and behavioral testing, brains are dissected and hippocampal CA1 neurons are labeled for quantification of dendrite length and spine density. Results from these behavioral assays reflect measureable age related behavioral change in the DO population. The TST is a depression-related measure and quantifies affective changes. Males exhibit increased immobility with age on the TST. Social isolation may account for this effect. In the T-maze the total number of arm transition choices is higher for young mice even after accounting for...
anxiety (time in center zone) and activity level (total distance traveled). In this highly diverse population, measures of age related decline are consistent with previous findings and will be amenable to genetic dissection. Supported by AG038070-03

MITOCHONDRIAL DNA DELETION MUTATION ACCUMULATION IS DRIVEN BY A FEED FORWARD LOOP A. Herbst, D. McKenzie, J. Aiken, University Of Alberta, Edmonton, Alberta, Canada

Aged muscles contain intracellular expansions of somatically derived clonal mitochondrial DNA deletion mutations. At high abundance, these mutations disrupt the expression of mitochondrially-encoded protein subunits of the electron transport chain resulting in respiration deficient muscle fiber segments. These fiber segments atrophy and break contributing to the loss of muscle mass that occurs with age. To understand the nuclear response to these mitochondrial mutations, we combined the selectivity of micro-dissection with gene expression analysis and detected a program of mitochondrial biogenesis. We hypothesized that this program was promoting mtDNA deletion mutation accumulation, non-adaptively responding to the cellular insult in a feed forward loop. We tested this hypothesis by treating aged rats with compounds that stimulated mitochondrial biogenesis. This treatment increased muscle mitochondrial genome copy number and increased the abundance of muscle fibers containing mitochondrial DNA deletion mutations. We conclude that in electron transport system abnormal muscle fiber segments, a vicious cycle of metabolic insufficiency and non-compensatory mitochondrial biogenesis drive mtDNA deletion mutation accumulation.

APPEARANCE OF AXONAL DEGENERATION IN MOUSE HIPPOCAMPAL NEURONS CAUSED BY OXIDATIVE STRESS AND AGING K. Fukui, T. Shinkai, S. Urano, Shibaura-Institute of Technology, Saitama, Japan

Reactive oxygen species attack several living tissues and increase the risk of development and progression of serious disease. Our group is continuing to study about the relationship between age-related oxidative damage and neurodegenerative disorders. Previously, we found that treatment with low concentration of hydrogen peroxide induced axonal and dendrite degeneration, but not cell death, in granule cells. In this study, we found axonal degeneration in hippocampal CA1 region of normal old mice using immunohistochemical assay. Furthermore, the expression of collapsin response mediator protein (CRMP)-2, which plays a crucial role in the maintenance of axonal condition, were significantly decreased in hippocampus of normal old mice than that of normal ones. In addition, the appearance of microtubule associated protein (MAP)-light chain 3 (LC3), a major index of autophagy, was significantly changed. These results indicate that axonal degeneration is induced in living tissues, but not cultured cells, and that changes in CRMP-2 and MAP-LC3 may underlie oxidative stress-related axonal degeneration.

SESSION 455 (POSTER)

COGNITION: HEALTH AND INTERVENTIONS

INTERACTIVE VIDEO GAMING AND HEALTH EDUCATION IN OLDER ADULTS WITH MCI: A FEASIBILITY STUDY

T. Hughes, J.D. Flatt, M.A. Buters, M. Ganguli, University of Pittsburgh, Pittsburgh, Pennsylvania

Study: The purpose of this study was to evaluate the feasibility and potential efficacy of interactive video gaming and health education to improve cognitive functioning in older adults with mild cognitive impairment (MCI). Methods: Twenty older adults with neuropsychologically defined MCI (mean age 77.4 [SD 5.8] years, 70% female, mean education 13.48 [SD 2.14] years) from the Monongahela-Youthigheney Health Aging Team (MYHAT) study were randomized to one of two group-based programs, interactive video gaming or health education, for 90 minutes each week for 24 weeks. Assessments were conducted before and after the intervention period and 6 months later. The primary outcomes were related to study feasibility. We also explored the effect of the interventions on neuropsychological performance using the computerized assessment of mild cognitive impairment (CAMCI). Results: All 20 participants completed the intervention, with 18 attending 21/24 sessions. Overall satisfaction with the programs was rated as “very good” by 80% of participants. Neither of the group-based programs had statistically significant improvements in cognitive functioning. However, gains in global cognitive function were observed in 7/9 participants, and maintained over time in 4 participants, in the interactive video game group. In the health education group, 4/10 participants had gains in global cognitive function that were maintained over time, and an additional 3 participants had delayed gains in performance. Conclusions: Our results suggest that both intervention programs were feasible for those with MCI. Significance: Gains in cognitive function in both programs provide preliminary support for a larger trial in individuals with MCI.

WHO ARE WE MISSING IN BEHAVIORAL INTERVENTION TRIALS? RECRUITMENT RESULTS FROM A PILOT STUDY

T. Hughes, M. Ganguli, University of Pittsburgh, Pittsburgh, Pennsylvania

Study: Better characterization of those recruited for randomized controlled trials may enhance their design and influence their interpretation. The objective of this study is to describe the characteristics of participants by their level of interest in a behavioral intervention program for cognitive health in late life. Methods: Participants were 1,240 (mean age 80.32 years) members of a population-based cohort study of mild cognitive impairment (aka MYHAT study). Participants were asked whether or not they would be interested in participating in a program to evaluate the potential health benefits of interactive video gaming and health education. Comparisons between those responding “no” vs. “maybe/yes” were made on a variety of demographic, health, and lifestyle measures assessed in the MYHAT study. Results: Among the participants surveyed, 835 (67.23%), 258 (20.77%), and 147 (11.84%) responded that they were not, maybe, or definitely interested in the program, respectively. Those who not interested were more likely to be older, male, White, retired/unemployed, cognitively impaired, less engaged in activities; and to live with others, rate their overall health and memory as poor/fair; and have an IADL impairment and an uncorrected hearing problem compared to those who responded “maybe/yes”. Common barriers to participation were time availability, lack of interest, and health concerns. Conclusions: Those not interested in participating in behavioral interventions differ on important characteristics compared to those who are interested. Considering these differences has implications for recruiting specific target groups as well as a representative sample for whom the results of intervention trials can be generalized.

COMPARISON OF IN-PERSON VERSUS TELEPHONE ADMINISTRATION OF MMSE IN THE UAB STUDY OF AGING

R.E. Kennedy1, C. Williams1, M. Crowe2, P. Sawyer1, R.M. Allman1, 1. Gerontology, University of Alabama at Birmingham, Birmingham, Alabama, 2. University of Alabama at Birmingham - Psychology, Birmingham, Alabama

Background: The Mini-Mental State Exam (MMSE) is a widely used, brief cognitive assessment, but items requiring in-person administration limit its use in epidemiological studies. Telephone versions of the MMSE (MMSET) have been developed but validation studies are lim-
CARDDIOVASCULAR AND CNS MEDICATIONS’ INFLUENCE ON MMSE TRAJECTORIES FOR MEXICAN-ORIGIN MEN AND WOMEN

G.I. Caskie1, J. Margrett2, 1. Education and Human Services, Lehigh Univ, Bethlehem, Pennsylvania, 2. Iowa State University, Ames, Iowa

Although some cognitive decline in old age may be normative (Schie, 1996), usage of certain prescription medications by elders can also be related to cognitive changes. Given the linkages of cognitive decline to poorer functional outcomes (Sampel-Ternent et al., 2008), mental health outcomes (Reyes-Ortiz et al., 2008), and physical health (Insel et al., 2005), understanding how prescription medication use relates to cognitive change in older adults is vital; in this study, cardiovascular and central nervous system (CNS) medications are examined. Further, because Latino/a individuals may be at greater risk for development of dementia as compared to Whites (Rose, 2005), the current study examines trajectories of performance on the MMSE over 5 waves covering 11 years for a representative sample of older men (n=1243) and women (n=1708) of Mexican-origin. A multi-group latent growth model, covarying age, education, self-rated health, and use of CNS and cardiovascular medications, had good fit (CFI=0.977, TLI=0.944, RMSEA=0.028). Mean MMSE at baseline was estimated to be 24.29 for men and 24.17 for women, with a significant, average rate of decline for women (-0.47) and men (-0.54). MMSE declined more slowly between the first two waves, more quickly between the second and fifth waves, for women than men. Taking cardiovascular medications predicted higher baseline MMSE for both men and women; however, taking CNS medications predicted higher baseline MMSE only for men. Taking cardiovascular, but not CNS, medications predicted slower rate of MMSE decline for men; neither medication type was related to MMSE decline for women.

STRESSFUL EXPERIENCES, SOCIAL SUPPORT, AND GENETIC VULNERABILITY IN COGNITIVE FUNCTION: FINDINGS FROM THE WISCONSIN REGISTRY FOR ALZHEIMER’S PREVENTION (WRAP)

M. Zulsdorff1, C.D. Engelman1, E. Friedman1, R. Koscik2, E. Jonaitis2, A. LaRue2, M.A. Sager2, 1. Population Health Sciences, University of Wisconsin School of Medicine and Public Health, Madison, Wisconsin, 2. University of Wisconsin School of Medicine and Public Health - Wisconsin Alzheimer’s Institute, Madison, Wisconsin, 3. Purdue University - Human Development and Family Studies, West Lafayette, Indiana

Objective: Cognitive aging is influenced by a complex set of variables. We examined relationships between stressful events, social support, APOE ε4 status, and cognitive function in middle-aged adults with a family history of Alzheimer’s disease enrolled in the Wisconsin Registry for Alzheimer’s Prevention (WRAP). Method: Participants completed neuropsychological tests and psychosocial questionnaires. Outcomes included cognitive factor scores: speed and flexibility (SF), verbal learning and memory (VLM), and working memory (WM). Key predictors included standardized index scores for stressful events and social support. Multiple regression test were used for each predictor variable, adjusting for demographic factors and number of APOE ε4 alleles. In secondary analyses, measures of health and lifestyle were added to models and relationships were re-examined. Finally, interactions between psychosocial variables themselves and APOE ε4 status were assessed. Results: Mean (sd) age was 56.7 (6.5) years (n=623). Primary analyses showed relationships which were significant at the p<.05 level between SF and stress (beta=-.117) and between SF and social support (beta=.106) but not between VLM or WM and stress or support. Secondary analyses indicated that relationships remained significant after accounting for health and lifestyle factors. In interaction models, a significant, negative interaction between social support and number of APOE ε4 alleles was seen (beta=-.118). Conclusion: As the population ages, the need to identify modifiable risk factors for cognitive decline intensifies. Findings suggest that psychosocial factors may influence cognitive function, and that this influence varies according to cognitive domain as well as by presence of specific genetic risk factors.

DAYTIME SLEEP IS ASSOCIATED WITH 6-MONTH CHANGE IN COGNITIVE FUNCTIONING IN AT-RISK OLDER ADULTS

J.M. Dzierezwski1, C. Fung1, S. Joulidian2, C. Alessi2, M. Irwin1, H.L. Martin1, 1. University of California, Los Angeles, Los Angeles, California, 2. V A Greater Los Angeles Healthcare System, Los Angeles, California

Introduction: The longitudinal association between sleep and cognitive function was understudied and not well understood, especially in late-life. Examination of the association between potentially modifiable risk factors, like sleep, and cognitive change in at-risk older adults.
C-reactive protein (CRP), a biomarker of inflammation produced by the liver, has been established as an indicator of overall, and particularly cardiovascular, health. CRP may also be associated with an increased risk of dementia and cognitive dysfunction, but findings have been inconsistent. We examined CRP levels in relation to cognitive performance across six cognitive domains (executive function, verbal memory, non-verbal memory, language, working memory, and visuospatial skills) in adults with MMSE scores ≥ 24. Serum CRP levels were obtained from fasting blood samples collected during morning visits and analyzed using high-sensitivity turbidimetric immunoassay. Participants underwent a neuropsychological evaluation at the Memory Clinic at Charles University in Prague, Czech Republic (mean age=66.5, 43% female, and mean education=14.3 years, N=118). Linear regressions controlling for age, sex, and education were used to estimate the associations between each cognitive domain and CRP. Higher levels of CRP were associated with worse performance on executive function tests (Trail Making Test Part B and Controlled Oral Word Association; β=−0.171; p=0.048) and with worse language performance (Boston Naming Test; β=−0.209; p=0.039). Associations with other cognitive domains were not significant. High levels of CRP may be a marker of poor executive function and language performance in otherwise normally cognitively functioning adults. Particularly the association between high CRP levels and poor executive function may have implications for subsequent cognitive impairment. Research on the association between CRP levels and cognitive aging may help in uncovering the role of cardiovascular health in cognitive dysfunction.

The moderating effects of stress on the association between the apolipoprotein E ε4 allele and cognitive decline

J. Sheffler, N. Sachs-Ericsson, Clinical Psychology, Florida State University, Tallahassee, Florida

As the population ages, the prevalence of dementia is becoming an escalating health problem with rates even higher for African American’s than Whites. The APOE ε4 allele is the strongest known genetic predictors of dementia – though not all who have the gene develop dementia. Previous research has suggested that there may be environmental influences that effect the expression of the gene. This study investigated how stressful life events influence the relationship between the APOE ε4 allele and cognitive decline and how this relationship may differ by race in an epidemiological sample (EPSE; N = 1,847) of older adults. We predicted that stressful life events would have a greater influence on cognitive decline among those with the APOE ε4 allele than those without the allele, and that this effect would be greater for African Americans than Whites. Cognitive functioning and its covariates were assessed over three year period. Using hierarchical regression, and after controlling for the main effects the APOE ε4 allele, stress and race, we found that the interaction of the allele and stressful life events predicted cognitive decline by (F<sub>9,1841</sub> = 6.523, p=0.011). We also found that the interaction of race and stressful life events predicted cognitive decline (F<sub>9,1841</sub> = 6.785, p=0.009). Finding indicate that African Americans may be more susceptible to the negative effects of stress in late life. Additionally, individuals with at least one APOE ε4 allele have an increased risk of developing cognitive decline when exposed to stressful life events.

Are lipoproteins associated with cognitive performance?

M. Chami-Ketterl, R. Andel, O. Lerch, J. Laczó, J. Horňíček. School of Aging Studies, University of South Florida, Tampa, Florida; 1. School of Aging Studies, University of South Florida, Tampa, Florida; 2. Charles University, Prague, Czech Republic; 3. International Clinic Research Center, St. Anne’s University Hospital, Brno, Czech Republic

There is evidence indicating that lipid levels may be associated with cognitive function, particularly among women. We aimed to examine low density lipoprotein (LDL), triglycerides, high density lipoprotein (HDL), and HDL/LDL ratio in relation to cognitive performance, measured with six well-established domains (verbal memory, non-verbal...
As part of another study, 19 participants age 65 years and older completed a battery of measures that included memory (Auditory Verbal Learning Test, AVLRT), psychomotor speed (WAIS 4th ed. Coding subtest), and executive skills (Tower of London, TOL). Participants also completed assessments of memory complaints, self-efficacy, and use of mnemonic techniques as well as a depression scale (Center for Epidemiological Studies Depression scale, CES-D). We hypothesized that depression would have a direct effect on memory as well as an indirect effect via self-efficacy. A path analytic model investigated relations among variables with a bootstrapping procedure. Results showed that executive function (TOL) and psychomotor speed were directly related to memory (AVLRT; \(z = 2.90, p = 0.004\) and \(z = 3.47, p < 0.001\)) as were memory complaints and techniques. Depression was not directly related to memory (\(z = -0.45, p = 0.65\)) and its indirect effect via self-efficacy was also nonsignificant (standardized direct effect = 0.08, \(p = 0.27\)). Follow-up exploratory analyses took note of the impact of depression on executive function (TOL; \(z = 1.77, p = 0.08\)) and evaluated the indirect effect of depression on verbal memory via this path. Depression had a significant indirect effect on verbal memory via executive function (standardized direct effect = -0.17, \(p = 0.03\)). Results are thus not consistent with an impact of depression on memory self-efficacy but suggest that it may be related via decreased executive functions.

**COMBINED EFFECT OF EXERCISE AND COGNITIVE TRAINING ON DUAL-TASK PERFORMANCES**

1. Institut universitaire de gériatrie de Montréal, Montréal, Québec, Canada. 2. Université du Québec à Montréal, Montréal, Quebec, Canada. 3. Université de Montréal, Montréal, Quebec, Canada.

**Introduction:** Both computerized cognitive training and aerobic physical exercise lead to improvement on various cognitive measures (Lussier, Gagnon Bherer, 2012; Langlois, Minh Vu, Chassé, Dupuis, Kergoat & Bherer, 2012). However, few studies have examined the combined effect of both interventions. **Methods:** Eighty-one subjects completed 75% of both their respective physical and cognitive training programs (aerobic/dual-task training: \(n = 25\), aerobic/placebo stimulation: \(n = 20\), stretching/dual-task training: \(n = 21\), stretching/placebo stimulation: \(n = 14\)). Programs effectiveness was compared based on improvement on a transfer dual-tasks condition that was not used in the dual-task training. **Results:** While all programs induce similar benefits on
single-task and single-mixed trials, participants who received the dual-task training improved to a greater extent on the dual-mixed trials, F(1,79)=7.06, p=.010, η²=0.082. The type of physical training (aerobic or stretching) had no significant effect on this improvement. **Conclusion:** While stretching and aerobic physical training had similar impact on a measure of divided attention, dual-task training proved to be significantly more effective than placebo stimulation.

**FOUR-YEAR CHANGE IN COGNITIVE PERFORMANCE FOR INDIVIDUALS OVER 50 WITH AND WITHOUT CHRONIC PAIN**

L. Zettel-Watson, B. Follick, J. Katschke, J. Melendez, D. Rutledge, C. Jones, B.J. Cherry, California State University, Fullerton, Fullerton, California

Several research studies document cognitive performance differences between older adults with and without chronic pain conditions, but few studies have investigated these changes over time. Seventy-three adults over the age of 50 (81% female) were tested four years apart on measures of executive function (Stroop, Digit Span Forward and Backward, Trails A and B), verbal fluency (naming animals), processing speed (Digit Symbol Substitution), and problem solving (Everyday Problems Test). Forty-four participants were healthy older adults (Mage = 71.7 years) and 29 were individuals with a diagnosis of fibromyalgia (FM) (Mage = 63.0 years), a chronic pain condition. Although the primary symptom of fibromyalgia is chronic pain, fatigue and cognitive complaints also are commonly reported. Paired samples t-tests revealed that most people saw a significant decline in scores between 2008 and 2012 on most variables. Using regression analyses and controlling for age, gender, and education, those with FM did not differ from those without FM in terms of cognitive changes over the 4 year period.

Although the FM individuals continued to perform at a lower level in some domains, they do not appear to be declining at a faster rate than the healthy controls. However, in the present study, the rate of decline for FM participants was similar to healthy older adults who were 8 to 10 years older, supporting previous studies that have concluded that patterns of cognitive performance in individuals with FM present like accelerated aging.

**ESTIMATING THE LIFE-EXPECTANCY WITH AND WITHOUT COGNITIVE DECLINE IN BRAZIL**

F. Andrade¹, L.P. Corona², Y. Duarte², M. Lebrão², L. Zettel-Watson, B. Follick, J. Katschke, J. Melendez, D. Rutledge, C. Jones, B.J. Cherry, California State University, Fullerton, Fullerton, California

Objectives: Estimate life expectancy with and without cognitive decline in a sample of older adults in São Paulo-Brazil. Methods: Data from two waves of SABE (Health, Well-being and Aging) study conducted in São Paulo-Brazil were used in the analyses. In 2000, 2,143 people aged ≥ 60 years-old were interviewed. In 2006, 1,115 of the participants from the first wave were re-interviewed, 649 have died and 379 were lost to follow up. A modified version of the mini-mental state examination (MMSE) was used to screen elderly with possible cognitive decline. Interpolation of Markov Chains method was used to estimate the life expectancy with and without cognitive decline. Results: In 2000, 13.2% of the older adults were classified as having cognitive decline. At age 60, men expect to live 14.6 years (s.d. 0.6) without cognitive decline and 2.0 years (s.d. 0.3) with cognitive decline; among women these numbers are 18.4 years (s.d. 0.6) and 3.2 years (sd. 0.3), respectively. At age 90, men expect to live 4.2 years (s.d. 0.4) without cognitive decline and 2.4 (s.d. 0.3) with cognitive decline; among women these numbers are 5.7 (s.d. 0.5) and 3.6 (s.d. 0.4), respectively. Women expect to spend a larger number and proportion of remaining years with cognitive decline than men Conclusions: With increases in life expectancy, cognitive decline has emerged as a major health problem threatening the wellbeing of older adults. In Brazil, women face a longer number of years with cognitive impairment, which is due to their longer life expectancy.

**THE EFFECT OF SENSORY IMPAIRMENT ON COGNITIVE AND FUNCTIONAL ABILITY IN CENTENARIANS**

A.A. Rahman-Filipiak¹, J.L. Woodard¹, L. Miller², A. Davey³, P. Martin⁴, L. Poon⁴, 1. Wayne State University, Detroit, Michigan, 2. University of Georgia, Athens, Georgia, 3. Temple University, Ambler, Pennsylvania, 4. Iowa State University, Ames, Iowa

Two theories have been proposed to explain age-related covariation of cognitive and sensory functions: The Common Cause hypothesis and the Sensory Deprivation hypothesis. We hypothesized that the Common Cause hypothesis better accounted for this age-related covariation. We examined associations between sensory functioning, cognitive functioning, functional status, and motor functioning in a sample of centenarians (N = 244) from the Georgia Centenarian Study to test this hypothesis. Special attention was given to cross-sensory-modality associations. Hierarchical regressions were also utilized to determine whether inclusion of either objectively-measured or self-reported sensory functioning or motor functioning predictors accounted for additional variance in late-life outcomes, beyond demographic factors alone. Although age and education were important predictors of late-life cognitive and functional outcomes, sensory functions accounted for a significant proportion of variance in several late-life outcomes. In particular, objectively-measured hearing ability consistently predicted variance in cognitive and functional abilities. Furthermore, grip strength and hand-tapping ability were significant predictors of late-life outcomes. The results of the current study provide strong evidence for the Common Cause hypothesis of cognitive aging.

**PERCEIVED COGNITIVE IMPAIRMENT IN AFRICAN AMERICAN ELDERS: HEALTH AND IADL FUNCTIONAL IMPAIRMENTS**

P.A. Lichtenberg, L.J. Ficker, C. Lyons, M. Hanna, Wayne State University Institute of Gerontology, Detroit, Michigan

Although the CDC began to assess Perceived Cognitive Impairment in 2009, there has been no in-depth study of how a perceived decline in thinking or memory skills may be reflected in the health and lifestyle of an independent community-dwelling older person. Among urban-dwelling older African Americans, who are at elevated risk for cognitive impairment and dementia, we know even less regarding the interaction of these risk factors. Five hundred one African American elders (n = 501) between the ages of 55 and 95 with an average age of 70.73 years (SD = 8.6 years) participated in telephone interviews. Approximately one-third of the elders endorsed that their memory, thinking skills, or ability to reason was worse than a year ago (n = 150; 29.9%) and only 25% of this group (n = 38) reported that this cognitive impairment impacted IADL functioning in their daily lives and/or warranted a consultation with their doctor. Bivariate and logistic regression analyses indicated that perceived cognitive impairment was associated with increased health problems, mobility limitations, depressed mood, and lower social functioning. Elders who reported that cognitive problems impacted their daily functioning of IADLs (e.g., shopping, paying bills, driving) reported the greatest health and mental health challenges. Perceived Cognitive Impairment is an important health variable with implications for an older adults’ overall health, mental health, mobility, and social functioning.

**DEMOGRAPHIC AND CROSS-CULTURAL PERSPECTIVES**

AFRICAN AMERICAN UTILIZATION OF HEALTHCARE BY REGION SOCIALIZED: A LIFE COURSE PERSPECTIVE

C. Koehn³, A. Bardo¹, J. Brown¹, S.M. Lynch³, 1. Miami University, Oxford, Ohio, 2. Princeton, Princeton, New Jersey

Previous literature suggests that Blacks utilize healthcare less than whites depending on the geographic region in which they currently
OLDER IMMIGRANTS AND VOLATILITY IN HEALTH INSURANCE TRAJECTORIES IN LATER LIFE
A.M. Reyes, M. Hardy, Sociology, Pennsylvania State University, University Park, Pennsylvania

Health disparities between immigrants and native-born occur at both older and younger ages. While having health insurance is often thought to improve access to better health care, the nature of insurance coverage may vary considerably across groups and may change for individuals over time. Although the 65-and-older age group is largely covered by Medicare, those aged 50-64 are more vulnerable to losing coverage, which may translate into less consistent care. We use the 2001, 2004, and 2008 cohorts from the Survey of Income and Program Participation (SIPP) to identify trajectories of health insurance transitions among the 50 and older. Health insurance is classified into seven categories: private, Medicare, Medicaid, none, private/Medicare, Medicaid/Medicare, and combinations of the three. Using latent class analysis, we stratify by age (50-59, 60-69, 70+) because of measurement invariance. We find considerable variability in HI trajectories, and preliminary results indicate that health care utilization varies significantly by childhood region when controlling for SES, age, and cohort. The post-1950 cohort is more likely to utilize health care than the pre-1950 cohort, and regional variation is significant only when measured at time of socialization—compared to present region.

ACTIVE LIFE EXPECTANCY OF OLDER ADULTS IN SINGAPORE BY SEX AND SOCIO-ECONOMIC STATUS
A. Chan1, R. Malhotra1, D.B. Matchar1, Y. Sato2,3, I. Duke-NUS Graduate Medical School, Singapore, Singapore, Singapore, 2. National University of Singapore, Singapore, Singapore, Singapore, 3. Nihon University, Tokyo, Tokyo, Japan

While overall and sex-specific active life expectancy (ALE) estimates for older adults in Singapore, a rapidly ageing Asian nation, are available, they are based on cross-sectional data. Further, they are not socio-economic status (SES)-specific. Using data from two waves (2009 and 2011-12) of a nationally representative longitudinal survey (N, Wave 1=5000) we estimate disability and mortality transitions among community-dwelling Singaporeans aged >60 years and compute ALE by sex and SES. Disability (inactive state) was defined as a limitation in at least one of 6 ADLs and 7 IADLs. Education (Low [<Primary]/High [>Primary]) was considered a SES indicator. A multistate life table method was employed using an interpolated Markov chain approach. Sex and education affected the transition from an active to inactive state (disability incidence), being significantly higher for females (vs. males) at all ages and for those with low (vs. high) education till age 88. Other health transitions, including to mortality, were not associated with sex or education. While women, relative to men, had higher life expectancy at age 60 (25.7 [23.8,27.5] vs. 21.6 [20.1,23.1]), they spent a greater proportion of years (29.9% vs. 12.4%) in an inactive state. Those with low, vs. high, education not only had lower life expectancy at age 60 (22.5 [21.1,23.9] vs. 28.5 [25.0,32.0]) but also spent a greater proportion of years (24.1% versus 17.8%) in an inactive state. Differences in disability transitions and ALE by sex and SES among older adults in Singapore are mostly similar to those observed in Western societies.

THE IMPACT OF WORK HOURS ON HAPPINESS OVER THE LIFE SPAN IN JAPAN, SOUTH KOREA, TAIWAN, AND CHINA

Work is a critical part of the life course and most commonly examined in relation to income and retirement in previous research. Particularly, work hours have received growing attention as a significant predictor of subjective quality of life such as happiness. Although employed people are generally happier than those unemployed, the findings depend on geographic locations. For example, influenced by the “busy ethic,” Americans believe that working longer hours leads to greater happiness, unlike Europeans who tend to be more leisure-oriented. However, little is known about the association between work hours and happiness in East Asia as the majority of research has been done in North America and Europe. Given the rapidly aging societies in East Asia, the impact of work hours on happiness over the life span is a critical research area. Data come from the 2010 East Asian Social Survey, an internationally representative dataset of adults in Japan, South Korea, Taiwan, and others.
Mainland China. Partial proportional odds ordinal logistic regression was used to model happiness as a function of work hours, age, and other covariates. Results show that work hours were negatively associated with happiness only in Japan and Taiwan. At the same time, age was negatively associated with happiness in all four nations. Our follow-up analyses suggested that working longer hours may have increasingly negative effects on happiness in accordance with aging. Detailed discussions regarding identified between-nation differences (e.g. stage of economic development, socio-cultural norms, work ethics) and implications for possible policy change are provided.

**SATISFACTION WITH SOCIAL CARE: COMPARING THE VIEWS OF SOUTH ASIAN AND WHITE SERVICE USERS IN ENGLAND**

R. Willis, M. Evandrou, P. Khambhaita, P. Pathak. University of Southampton, Southampton, United Kingdom

In Britain, national surveys indicate that black and minority ethnic (BME) respondents report lower levels of satisfaction with social care services when compared with white respondents. Examining the reasons for such differences is a necessary step in improving the provision of services for BME users. As also found in the US population, double jeopardy makes this issue particularly important; there may be a greater need for social services among certain minority groups due to higher levels of ill health and disability. This paper reports on in-depth interviews with South Asian and white British users of social services, and with social care practitioners such as occupational therapists and social workers. The aim of the interviews was to compare the reasons for low or high satisfaction among the two ethnic groups. Shared sources of dissatisfaction among the Asian and white participants included interpersonal problems with staff members, and difficulties in accessing the services. A distinct concern identified among the Asian participants was personal problems with staff members, and difficulties in accessing the services.

**EXAMINATION OF IMPORTANT LIFE EXPERIENCES OF THE OLDEST-OLD: CROSS-CULTURAL COMPARISONS OF U.S. AND JAPANESE CENTENARIANS**

The purpose of this study was to compare the most important life events reported by U.S. and Japanese centenarians. This study included a population-based sample of 239 U.S. centenarians from the Georgia Centenarian Study and 304 Japanese centenarians from the Tokyo Centenarian Study. Two open-ended life events questions were categorized and grouped into different life event domains. Several cross-tabulations were computed to investigate culture and gender differences in most important life event domains. Next, four configurational frequency analyses were conducted using Neuroticism, Extraversion, and the first most important life event domain. Path model analyses for each group demonstrated adequate fit. Among Hispanics, IRFA had the strongest association with dementia severity ratings, measured by the Clinical Dementia Rating (CDR) scale, across a sample of 444 Hispanic and 11,081 NHW outpatients. Covariates included patients' psychiatric symptoms (IRNS) in clinicians' dementia severity ratings, measured by the Clinical Dementia Rating (CDR) scale, across a sample of 444 Hispanic and 11,081 NHW outpatients.

**THE GERONTOLOGICAL SOCIETY OF AMERICA**

140
AGE HERE, BUT NOT THERE: WITHIN-CULTURE VARIABILITY IN WHY WE REMEMBER THE PERSONAL PAST

N. Alea1, S. Ali1, S. Black2, 1. Behavioural Sciences, University of the West Indies, St. Augustine, St. Augustine, Trinidad and Tobago, 2. University of Florida, Gainesville, Florida

Humans are embedded in culture as they draw on autobiographical memory to meet environmental demands (Bluck, Alea, & Demiray, 2010). The study examined cultural (American, Trinidadian) differences in the functions of autobiographical remembering by assessing person-level predictors, including age, education, health, and personality. Three autobiographical memory functions, self-continuity, social-bonding, and directing-behavior (Bluck & Alea, 2011), were examined in young and old American (n = 179; young M = 19.32, old M = 72.69) and Trinidadian adults (n = 150; young M = 25.99, old M = 63.24). No between-culture differences emerged in the functions of autobiographical memory, though within-culture variability was evident for both age and personality. For Americans, age was the strongest predictor of using memories to maintain self-continuity (β = .26) and to direct-behavior (β = .23); older Americans less often used memory to meet these needs than younger Americans. Age was not a predictor of memory function for Trinidadians. Personality traits (e.g., extraversion β = .21, agreeableness β = .16, conscientiousness β = .20) predicted using memories for social-bonding in Americans, but predicted using memories for self-continuity (e.g., neuroticism β = .23) and directing-behavior functions (e.g., neuroticism β = .20, openness β = .24) for Trinidadians.

The discussion focuses on how within-culture environmental demands interact with age and personality to shape people’s use of memory. After attending this session, participants will be able to identify person-level predictors of how memory is used to meet adaptive needs in daily life in two cultures.

IMPACT OF MORTALITY SELECTION ON AGING COHORTS

Background. Systematic gradual changes in composition of aging cohorts that occur as a result of selective mortality processes are important to all gerontological research. Objective. We demonstrate the extent of changes in the distribution of important cohort characteristics that arise purely as a result of selective mortality. Methods. We use data on health, wealth, education, and other covariates from two cohorts (the AHEAD cohort, born 1900-23 and the HRS cohort, born 1931-41) included in the Health and Retirement Survey, a nationally representative 20-year panel study of older Americans (N=14,466). We calculate sample statistics for the surviving cohort at each wave. Repeatedly using only baseline information for these calculations so that no changes occur at the individual level (what changes is the set of surviving respondents at each wave), we can observe the impact of mortality selection on the cohort characteristics. Results. We find substantial changes in the distribution of all examined characteristics across nine survey waves. For instance, the number of chronic conditions declines from 1.5 to 1 in the AHEAD cohort; the decline is steep enough that a crossover is observed between the older AHEAD and the younger HRS cohort. Discussion. The mortality selection process changes the composition of older cohorts substantially. We discuss and illustrate factors that impact the pace of changes over time. Researchers focusing on elderly need to be aware of the extent of the selection and interpret their conclusions accordingly.

CORRELATES OF SUBJECTIVE HEALTH IN OLDER HISPANIC AMERICANS AND ADULTS IN VIETNAM: A CROSS-NATIONAL STUDY

H. Nguyen1, C. Hoang2, N. Ngo3, S.H. Zarit4, 1. Wake Forest School of Medicine, Winston-Salem, North Carolina, 2. Da Nang University of Medical Technology and Pharmacy, Da Nang, Viet Nam, 3. Day Tan University, Da Nang, Viet Nam, 4. Pennsylvania State University, State College, Pennsylvania

Numerous studies have documented the predictive significance of SRH for a number of health outcomes, including social–psychological well-being, health care consumption, morbidity, and mortality. SRH is generally associated with three broad categories of physical illness burden, functional disability, and mental health. Though some knowledge is established, it is unclear whether there are different determinants in different racial/ethnic groups. The goal of this study was to delineate the determinants of SRH in older Hispanic Americans and Vietnamese adults. We investigated the association between sociodemographic factors (age, gender, marital status, education, employment, and material hardship), health indicators (comorbidity, depression, and cognitive function), functional limitation, and objective physical performance (grip strength and lower-extremity performance) and SRH. This study included 300 individuals from the Hispanic Aging Survey (HAS; mean age = 67.6) and 600 participants from the Vietnam Aging Survey (VAS; mean age = 70.3). SRH was measured with a single item that asked people to rate their health on a 5-point scale from “excellent” to “poor.” Separate multivariate regressions were run for HAS and VAS samples. SRH was not associated with age and education in older Vietnamese adults; it was associated with material hardship, comorbidity, depression, cognitive function, functional limitation, and lower-extremity performance. These results were different from findings in Hispanic adults, where SRH was only associated with age, education, comorbidity, and depression. For Vietnamese adults, self-reports of poor health become more closely related to current symptoms and functional problems. The area of how people view their own health warrants further examination.
DIFFERENTIAL EFFECTS OF LIVING ARRANGEMENTS ON OLDER ADULTS’ PSYCHOLOGICAL WELL-BEING BY GENDER
C. Henning-Smith, Division of Health Policy and Management, University of Minnesota, Minneapolis, Minnesota

Objectives: 1. How does gender affect the relationship between living arrangements and psychological well-being? 2. Are these relationships mediated by demographics, health status, or region? Methods: Data come from the Integrated Health Interview Series. The sample consists of non-institutionalized individuals age 65 and older (n=4,903). Psychological well-being is measured by self-rated quality of life (QOL) and the Kessler-6 measure of psychological distress. Living arrangements is a three-category variable: living alone, living with a spouse, or living with others. Nested multivariate models were calculated to predict QOL and psychological distress, with subgroup analyses performed separately by gender. Results: 36% of men lived alone, 46% lived with a spouse, and 17% lived with others (vs. 57%, 24%, and 19% of women, p<0.001). With gender as the only predictor, both women and men had lower odds of better QOL when living alone or with others (as compared to living with spouse). After including covariates, the effect of both types of living arrangements persisted for women (OR=.59 and .58, respectively, p<0.01). For men, living with others became non-significant but living alone remained a significant negative predictor of QOL (OR=.53, p<0.01). The relationship between living arrangements and psychological distress was mediated by demographic characteristics for both genders. Discussion: Programs and policies should pay particular attention to the differential effects of living arrangements by gender. Interventions to improve psychological well-being for older adults living alone or with others may include increasing the availability of home- and community-based services, financial support, and access to social support networks.

SESSION 465 (POSTER)

EDUCATIONAL ISSUES

TEACHING ABOUT OPTIMAL AGING IN THE ONLINE CLASSROOM: DEPLOYING FEMINIST PEDAGOGY
B. McCann, V.Q. Glass, Gerontology, University of Louisiana Monroe, Monroe, Louisiana, 2. Virginia Tech, Blacksburg, Virginia

With competition from online universities, and decreasing public funds at state institutions, more and more programs are turning to the virtual classroom, reflecting a major wave of change in gerontological education. As educators adapt to this new mode of instruction they may try to retain as much of their teaching philosophy as possible in what may seem like an inflexible environment. Teachers influenced by feminist methods, in particular, may feel that the online classroom is incompatible with a philosophy that focuses on students' embodied experience. This presentation will reveal concrete ways in which we have deployed feminist-inspired pedagogical practices in online gerontology and human development classrooms. Successful practices include a) building a collaborative environment through discussion board techniques, b) raising awareness about issues related to optimal aging via real and virtual “field trips,” c) sharing power via required drafts of major written assignments, and d) critical thinking assignments that ask students to critically reflect on current gerontological research. Finally we will discuss some common issues associated with feminist inspired course policies (such as a very flexible late policy), and tailoring courses to specific student populations. The presentation will be supplemented with initial findings from a larger study on feminist pedagogy and online education (N = 39). As a summary, we will discuss implications for feminist gerontology and the gerontological classroom.

GIVING LEARNING A HAND: ASSESSING EXPERIENTIAL ACTIVITIES FOR THE GERONTOLOGICAL CLASSROOM
R.J. Karasik, P.A. Greenberg, H. Nordell, E.T. Peterson, P. Woischke, Gerontology, St. Cloud State University, St. Cloud, Minnesota

Considerable attention has been given in gerontology and geriatrics to experiential activities outside of the classroom (e.g., community-based research, field experiences, internships, service-learning, site visits, volunteering). Less attention has focused on hands on experiences that take place within the classroom setting. While the pedagogical approach of using hands on experiences to teach about human physiology has a long tradition in medical education, the adaptation of this practice to gerontology is relatively new (Alt-peter & Marshall, 2003). The use of simulations and other hands on tools has been shown to not only enhance students’ knowledge, but also their overall empathy for older adults (Eymard, Crawford & Keller, 2010; Henry, Ozier & Johnson, 2011). The following reports on the development and implementation of a series of in-class experiences in three areas: (a) simulation of normal and pathological processes of aging; (b) health prevention activities (e.g., screenings and exercise); and (c) assistive and adaptive technology using universal design. To assess their effectiveness, pre/post surveys (N=162) were gathered from undergraduate and graduate gerontology students regarding their learning styles and the impact of these hands on classroom activities. Initial findings revealed a strong preference for traditional modes of learning (e.g. lecture, video). A second trend, however, showed over half of the students (n = 92, 56.8%) also preferred hands on learning experiences. Student response to the hands on modules was overwhelmingly positive. These findings support the importance of incorporating a variety of teaching approaches, including hands on to enhance the gerontological classroom.

THE RHETORIC OF CLAIMS-MAKING: THE CASE OF CHOLINESTERASE INHIBITORS
A. Smith, O. Guerra, 1. Department of Sociology, University of Victoria, Victoria, British Columbia, Canada, 2. Centre on Aging, University of Victoria, Victoria, British Columbia, Canada

Cholinesterase inhibitors (ChEIs) are a first-line group of medications which are widely prescribed to treat the symptoms of mild to moderate Alzheimer disease (AD). ChEIs have been extensively promoted in pharmaceutical advertising since their introduction in the 1990s. This could explain, in part, the commercial success of these medications despite the modest effects demonstrated in clinical trials. Little is known about how pharmaceutical advertising in medical journals represents the symptoms of AD and the benefits of ChEIs. To address this gap in knowledge, we present findings based on a survey of 350 issues of the Canadian Medical Association Journal that resulted in the identification of 19 separate Aricept® ads printed 97 times. From the online pharmaceutical advertisement database AdPharm.net, we identified 11 more Aricept® ads appearing in medical journals from 2004-2011. Using semiotic analysis, we systematically coded the ads for visual elements and themes of medication benefit as reflected in the maintenance or enhancement of spousal, intergenerational and filial relationships. Specifically, the analysis revealed how the ads translated clinical trial results into dramatic everyday-life scenarios of benefit whereby the AD sufferer’s regained the ability to assume familiar roles and partake in valued social relationships. The ads deployed powerful emotional visual and linguistic imagery suggestive of exaggerated therapeutic efficacy and the promise of an improved future. This study critically articulates the discursive dimensions of pharmaceutical advertising and provides insights into the role of drug companies in the construction of AD as an imminently treatable disease.
ATTITUDES TOWARD OLDER ADULTS AND ATTITUDES VALIDATION OF A SCALE TO MEASURE STUDENTS’ locations. The Collaborative also successfully engaged faculty thousands of miles apart to develop, maintain, and expand a virtual learning program. Evaluations indicate that using multiple technologies allows frequent contact among Collaborative leaders and Scholars and troubleshoot the logistics of launching and maintaining a complex distance-learning program. The current research examines the educational needs of those currently working with older adults and explores the core competencies for Interprofessional Collaborative Practice and the Partnership for Health & Aging Geriatric Competencies. Scholars participate in 40 hours of mandatory core content delivered by webinar; engage in self-directed learning; participate in formal and informal mentoring sessions, and complete a capstone project on curriculum development or quality improvement. The benefits and challenges in developing, implementing, monitoring and evaluating a collaborative interprofessional faculty development program in geriatrics are discussed. Year 1 served as a pilot, allowing us to develop and test the competency-based, interprofessional curriculum designed for adult learners; experiment with varied technologies for delivering content, making it dynamic and interactive; collect data on learners’ perceptions of improvements needed in teaching and application to practice based on program content; and troubleshoot the logistics of launching and maintaining a complex distance-learning program. Evaluations indicate that using multiple technologies allows frequent contact among Collaborative leaders and Scholars and mentors, enabling faculty representing different disciplines and located thousands of miles apart to develop, maintain, and expand a virtual learning community. The Collaborative also successfully engaged faculty learners who are even more diverse in their disciplines and geographic locations.

VALIDATION OF A SCALE TO MEASURE STUDENTS’ ATTITUDES TOWARD OLDER ADULTS AND ATTITUDES TOWARD THE AGING PROCESS

Measuring learning outcomes has become standard procedure in most college classrooms. Gerontological educators often seek to address and challenge students’ attitudes toward older adults and the aging process using classroom activities; therefore simple and practical measures of attitude are needed to evaluate effectiveness of such activities. This study was designed to psychometrically test two visual analog scales (VASs) to assess 1) attitudes toward older adults and 2) attitudes toward the aging process. Content validity was established by a panel of six content experts and 30 undergraduate students. A sample of 190 undergraduate students was then recruited to assess test-retest reliability and concurrent validity. All participants completed the two VASs, the Anxiety about Aging Scale, and the Fraboni Scale of Ageism. The current study provided a foundation for informed debate on design, benefits, and costs of adopting an RFP model. The RFP literature highlighted seven archetypal RFP models, including within-organization rotation, client-based rotation, and time-sensitive rotation, e.g., term-based and summer rotations. Themes of benefits among RFP models included the following (compared with traditional placements): richer diversity of perceived learning and skills building; broader understanding of organizational systems; and enhanced, student self-confidence and self-efficacy. The review of literature also gleaned a number of themes relative to risks of RFP implementation, including learning fragmentation; increased demand of administrative and supervisory time and resources; and elevated student anxiety. The current study further offered strategies identified in literature for minimizing potential risks with RFP models, along with discussion of supplemental programmatic supports to maximize successful, rotation-based field placements in gerontological settings.

EDUCATIONAL NEEDS AND CORE COMPETENCIES FOR PROFESSIONALS IN GERONTOLOGY: WHAT SHOULD WE DO NEXT?

D.J. Van Dussen, S.M. Leson, Sociology, Anthropology, and Gerontology, Youngstown State University, Youngstown, Ohio

According to the Institute of Medicine, significant shortages of workers educated in gerontology are expected over the next decades (2001). Subsequently, many current employees have little or no Gerontological education but do seek more (Van Dussen and Leson, 2010). The current research examines the educational needs of those currently working with older adults and explores the core competencies that will be needed including understanding of geographical diversity and policy and disease related topics as identified by respondents (n=766) of a statewide sample of professionals in Ohio. Of the 766 respondents, 57.9% had no formal training in gerontology/geriatrics. The most common respondents were dietetics professionals (41.4%), administrators (16.2%), private practice medical (13.3%), and a remaining mix of professionals in the health professions, social work, and public and private organizations. The respondents, from both urban and rural settings, indicated a variety of desired educational topics including mental health issues, nutrition, end of life, and medications. Professionals reported the most preferred educational delivery methods were web based and interactive distance learning leading to a certificate or degree. Addi...
OLD VS. YOUNG: UNDERSTANDING MEDIA PORTRAYALS OF ELDER FRAUD
E.O. Burgess1, J.L. Atkinson2, B.S. Blackwell1, 1. Gerontology Institute, Georgia State University, Atlanta, Georgia, 2. Georgia State University - Communication Department, Atlanta, Georgia, 3. Georgia State University - Criminal Justice and Criminology Department, Atlanta, Georgia

Although financial abuse of older adults or elder fraud has received national attention over the past decade, how these issues are portrayed has received little scholarly attention. Existing research finds that media framing of aging issues shapes peoples’ understanding of the topic, particularly when they have no personal experience. This study examines how elder fraud is defined in newspapers, how ages of participants (i.e., both victim and perpetrator) are framed, and what constructs are important in elder fraud reporting. Using a Lexis-Nexis search across 25 years of articles from the top 5 circulating US newspapers (New York Times, Washington Post, USA Today, Los Angeles Times, and the Wall Street Journal), 104 distinct news articles on elder fraud were identified. Content analysis coding via QDA Miner, combined with human coding, enabled accurate identification of the victims’ and offenders’ backgrounds (race, gender, age) and the language used to describe victims, crimes, and offenders. Types of elder fraud varied from stealing checks to granting titles to homes or cars to having other financial assets taken. On average, victims were older than perpetrators. In several cases, fraud was “the old against the older.” In general, “old” (victim) was tied to other conditions of vulnerability (e.g., widowhood and blindness); while “young” (perpetrator) was frequently associated with greed. Moreover, analysis revealed that the framing of familial relationships complicated by age stereotypes. This study has important implications for the future framing of research on societal perceptions of aging and elder fraud.

ENHANCING CARE OF SENIORS: IMPACT OF A LIVING CLASSROOM ON THE EDUCATION OF CARE AIDES
V.M. Boscart1,2, L. McCleary1, P. Stolte3, 1. Research, Conestoga College, Kitchener, Ontario, Canada, 2. Schlegel Research Institute of Aging, Kitchener, Ontario, Canada, 3. Brock University, St-Catherine, Ontario, Canada, 4. University of Waterloo, Waterloo, Ontario, Canada

Enhanced care and quality of life for seniors requires change in many areas, including gerontology education for health care professionals; practice development and skills enhancement for those working with seniors; and knowledge translation research that is relevant for seniors care. When these elements occur independently of each other, as they often do, there are serious disconnects between what is going on in practice, education, and research. To overcome this silo approach to practice development in Long-Term Care (LTC) and improve access for students, Conestoga College (Kitchener, Canada), the University of Waterloo-Schlegel Research Institute for Aging (Waterloo, Canada), and Schlegel Villages (Guelph, Canada) created a collaborative partnership model. This paper will present the integration and evaluation of “Living Classrooms” in nursing and care aides’ education to enhance knowledge solutions and training grounds for students while practicing learning in place and living learning. Findings of this 2-year descriptive evaluative study have significant implications for career attractiveness of LTC, recruitment and retention issues, interprofessional collaboration education and resident-centred learning; and the promotion of LTC as a professional learning and mentoring environment.

SESSION 470 (POSTER)
END-OF-LIFE STUDIES

PALLIATIVE CARE FOR OLDER ADULTS: A SYSTEMATIC REVIEW OF U.S. MEDICAL SCHOOLS
E. Sikorska-Simmons, M.E. Ingram, University of Central Florida, Orlando, Florida

Palliative care has been recognized as an important treatment option for patients with life-limiting illnesses. With its emphasis on pain management, symptom control, and psychosocial support, palliative care can improve the quality of life for patients and reduce the cost of medical services. Traditionally, palliative care has been oncology-based; however, with the aging population, the awareness that it should also address the needs of older people with advanced nonmalignant diseases is expanding. The manner in which medical schools incorporate such training into their programs has not been explored. This study systematically examined the extent to which palliative care (especially, geriatric palliative care) is included in medical school education in the United States. All 141 schools (as listed by AAMC) were selected. Web-based and manual searches of school catalogs and other relevant materials were conducted. Of these 141 schools, 25% had an academic or clinical unit devoted to teaching and providing consultations in palliative medicine, 36% offered ACGME accredited fellowships in hospice and palliative medicine, and very few offered training in geriatric palliative medicine. The contents of these programs were examined according to: 1) disease specific aspects of palliative medicine, 2) symptom control, and 3) psychosocial and ethical issues. Overall, this review suggests that a dearth of adequate training in palliative medicine exists, especially when it comes to the management of nonmalignant illnesses that cause death among older people (e.g., heart disease, stroke, and neurodegenerative diseases). Delivering high quality palliative care to the rapidly growing older population remains a major challenge.

MAINTAINING MOTIVATION OF HOSPICE WORKERS: BURNOUT, SECONDARY TRAUMA, AND JOB SATISFACTION
S.H. Jones, Social Work, Texas State University, San Marcos, Texas

Approximately 44.6% of U.S. deaths in 2011 occurred under hospice care. Workers delivering this care are expert guides through physical, emotional, and spiritual changes at life’s end. Research shows rewards and stresses in this work, with 30% turnover. Recent economic and regulatory pressures potentially threaten time spent in quality direct care, often the greatest source of fulfillment. Studies of coping strategies recommend teaching workers individualized self-care, but research in this area is in early stages. A longitudinal, interventional study of the effect of self-care planning on hospice workers’ burnout, secondary trauma, and job satisfaction was conducted with a convenience sample of 172 direct care workers in 16 hospices of varying sizes located in 14 states. Pretest data suggest that while most hospice workers were managing well, a segment of the sample was not. One third scored in the high range on the key indicator of burnout, and on a Likert scale measure of intent to leave the job (1-10, 1 = lowest), 20.4% reported a score of five or higher. Mean ratings on identical Likert scale measures of perceived support were 7.4 for team, 6.9 for supervisory, and 6.2 for organizational support. Secondary trauma scores were primarily low (55.8%) or average (43%). Quantitative results indicated that organizational factors, including hospice size and perceptions of team, supervisory, and organizational support, were significantly related to burnout, secondary trauma, and intent to leave. Qualitative data support these findings. Implications include suggestions for attending to factors that provide support to hospice workers.
PERCEIVED ILLNESS BURDEN AND ITS ASSOCIATED CORRELATES: A MEASURE OF OBJECTIVE AND SUBJECTIVE HEALTH CONSEQUENCE AT THE END OF LIFE
S. Bodnar-Deren, 1. Sociology, Virginia Commonwealth University, Richmond, Virginia, 2. Mount Sinai School of Medicine, New York, New York

Objective. I used data from the New Jersey End-of-Life (NJEOL) study (N=293) (2006-2008), an ethnically-diverse sample of non-institutionalized older adults (≥ age 55) to investigate perceived illness burden (PIB) and its correlates. PIB is a measure of patient appraisals that captures both functional limitations and perceived burden to the self and others. Two questions guide the analysis: Do the objective indicators of physical health align with subjective perceptions of being a burden? If there is no agreement between the objective and subjective, are there specific characteristics of individuals for whom there is not alignment? Methods. Post-hoc comparisons between PIB categories (high-disability/high-burden; high-disability/low-burden; low-disability/high-burden; low-disability/low-burden) were conducted using analysis of variance (ANOVA). Multinomial logistic regression was used to examine the correlates of PIB. Results. Of the sample, 28% of respondents were in the high-disability/high-burden category, 18% in the high-disability/low-burden category, 12% in the low-disability/high-burden category, and 41% in the low-disability/low-burden category. Race/ethnicity, age, number of children, income, number of health conditions, and level of depressive symptoms were all significant correlates of PIB category. Discussion. An understanding of how perceived illness burden works for patients may lead to end-of-life discussions and interventions that better meet the needs and goals of patients.

CURRENT TRENDS IN END OF LIFE CARE FOR OLDER ADULTS WITH ADVANCED DEMENTIA IN NURSING HOMES: A LITERATURE REVIEW
H. Kim, 1. University of Pennsylvania School of Nursing, Philadelphia, Pennsylvania

Background: A large number of older adults with advanced dementia reside and die in nursing homes (NHs) with poor end-of-life (EOL) care. There is, however, little information that addresses the current trends in EOL-care research for NH residents with advanced dementia. Objective: The purpose of this literature review was to understand the current trends in research regarding EOL care for older adults with advanced dementia in NHs. Methods: A literature review was performed using electronic databases – PubMed, CINAHL, and Cochrane – from January 2000 to December 2012, and using MeSH terms – “end of life care”, “palliative care”, “dementia”, and “nursing homes”. Findings: Five common themes in research regarding EOL care for older adults with advanced dementia in NHs were found: (a) current situations of EOL care in NHs, (b) factors and barriers related to good EOL care, (c) outcome measures to evaluate EOL care, (d) single or multi-component palliative care programs, and (e) international collaborative works. Conclusions: Quality EOL care for this population has mainly been explored. Future intervention studies to improve EOL care in NH residents with advanced dementia, longitudinal studies to evaluate the effectiveness of palliative care interventions, disparities in EOL care, and studies focusing on cost-effectiveness and regulatory perspective to promote practice of EOL care in this population are required. Implications: This literature review gives an overall picture and future directions of EOL-care research in older adults with advanced dementia in NHs.

IT’S NOT A MATTER OF HOW MUCH TIME REMAINS: CENTENARIANS AND THEIR VIEWS ON LIFE’S END
K.M. Boch1, C. Rott1, K. Boerner2, D.S. Jopp3, 1. Institut für Gerontology, Heidelberg, Germany, 2. Jewish Home Lifecare/Mount Sinai School of Medicine, New York, 3. Fordham University, New York, New York

How individuals cope with the prospect of their own death is a very personal process that is also shaped by cultural traditions. The purpose of this study was to explore the views on lifes end of individuals who have lived an exceptionally long life and are per definition close to death. In the population-based Second Heidelberg Centenarian Study, 74 individuals who were exactly 100 years old and cognitively intact enough to participate in an in-depth interview, were asked a series of questions related to death, dying, preparations for life’s end, and life after death. In addition, mental and physical health outcomes were assessed. Findings revealed that only one participant perceived life’s end as threatening, and only 22% of participant expressed a longing for death. Although most participants were afflicted with a variety of physical ailments, neither frequency nor intensity of reported pain were related to longing for death. However, participants with higher levels of depression and poorer perceived health were significantly more likely to express a longing for death. Findings demonstrate that longing for death is not a common experience among very old individuals. Instead, the predominant picture appears to be a persistent strong will to live. Findings further suggest that among those who do wish to die, this desire emerges when a person’s psychological strengths are exhausted, rather than stemming from poor physical health.

OLDER AFRICAN AMERICANS’ PERCEPTIONS OF THE CONGRUENCE BETWEEN CULTURAL PREFERENCES FOR CARE AT THE END OF LIFE AND HOSPICE SERVICES RECEIVED
H. Noh, 1. The University of Alabama School of Social Work, Tuscaloosa, Alabama

The existence of racial disparities in the use of hospice care is widely recognized. Possible barriers to African Americans’ enrollment in hospice care include those that are cultural and value-based in nature. Though previous studies provide insight into what cultural preferences, if not accommodated by hospice care providers, might prevent this group from receiving such service, little has examined this from older terminally ill African Americans who were receiving hospice care at the time of the studies. To further explore what cultural and value-based preferences they have and how well these preferences were respected by hospice providers, in-depth, face-to-face, audiotaped interviews were conducted using a semi-structured survey with 28 older African American hospice patients. Data from the transcripts were analyzed using content analysis. Congruence between the patients’ preferences and values were seen in the themes of dying at home, independent decision-making, autonomy in daily life, unwillingness to be a burden, social support, and respectful and caring attitude from healthcare providers. Some respondents expressed dissatisfaction with the level of open communication with health care providers and dependability of hospice services provided. Interdisciplinary team meetings could serve as a forum for discussion of values important at the end of life and how to translate this into respectful care. A focus on respecting the preferences and values of older terminally ill African Americans may enhance the experience of dying with hospice services for these individuals and their family members.

THE ROLE OF RELIGIOSITY/SPIRITUALITY IN END-OF-LIFE CARE: PERSPECTIVES OF HOMELESS OLDER ADULTS
E. Ko1, H. Nelson-Becker2, 1. San Diego State University, San Diego, California, 2. Loyola University Chicago, Chicago, Illinois

This study explored the role of religiosity/spirituality on perceptions and choices about end-of-life care among homeless older adults as part of a larger study. Beliefs about and attachment to God (Cicirelli, 2004; Kirkpatrick, 1998, 2005) may correlate with ideas about dying and advance care planning. A qualitative study using in-depth individual interviews was conducted with 21 residents at the Transitional Housing Program (THP) in a large city in Southern California. Individual interviews were audio-taped and transcribed. The majority of the participants (n=18) were male and the mean age was 65 years old. About
71% of the participants (n=15) had ever lived on the street prior to moving to the transitional housing. Almost half (n=10; 47.6%) reported no family/relatives whom they could contact at least once a month. The four main themes included: 1) God will prevent a medical crisis during the end-of-life phase; 2) God sustains when social support is absent; 3) Trust in God protects against death anxiety; and 4) Religious teachings provide hope in an afterlife. Many participants viewed death as inevitable, but belief in God provided strength to endure. Religiosity offered guidance during the end-of-life stage. Faith in God may be an important coping mechanism for death-related fear in this homeless transient older population. Implications suggest that the role of religion be considered in developing end-of-life care plans with homeless older adults.

SESSION 475 (POSTER)

FAMILY & INTERGENERATIONAL RELATIONS

DUMELA MMA: NEEDS AND PERSPECTIVES OF SOUTH AFRICAN GRANNIES RAISING GRANDCHILDREN
M.L. Dolbin-MacNab1, S.E. Jarrott1, L. Moore1, M. DeChavonnes Vrugt2, M. Erasmus3, 1. Human Development, Virginia Tech, Blacksburg, Virginia, 2. North-West University - Mafikeng, Mafikeng, South Africa

In South Africa, the HIV/AIDS epidemic, unemployment, and other sociocultural issues have resulted in a substantial portion of grandmothers or “grannies” assuming primary responsibility for raising multiple grandchildren and great-grandchildren. Despite the fact that the number of South African grandparents raising grandchildren is among the highest in the world, little is known about their experiences and about how they manage their caregiving responsibilities. Using qualitative interview data, which was gathered and analyzed in collaboration with South African faculty and students, this study examined 75 South African grannies’ needs and how their caregiving responsibilities had impacted their lives and those of their grandchildren. Results of a thematic analysis indicate that grannies have a variety of needs related to parenting and finances. Managing grandchild behavior problems and adolescence was a challenge, as was facilitating grandchildren’s education. Financial difficulties made it difficult for grannies to afford basic necessities and care for themselves. Grannies reported positive and negative impacts of raising their grandchildren. Positive impacts included the relationship with the grandchild and improved psychological well-being. Negative impacts included financial difficulties, health problems, relational problems within the extended family system, and psychological distress. Generally, grannies perceived that the caregiving arrangement had positively impacted their grandchildren via providing them with a better life and a supportive family environment—though grannies raised concerns about the negative impact of living with limited resources and the challenges associated with the changed grandparent-grandchild relationship. The findings provide valuable direction for future research and intervention with South African grannies raising grandchildren.

THE GOOD GRANDPARENT: PERSPECTIVES OF YOUNG ADULTS
E.E. MaloneBeach, M. Hakoyama, Human Development and Family Studies, Central Michigan University, Mount Pleasant, Michigan

Approximately 80% of older adults are grandparents, many of whom proactively involve themselves in their grandchildren’s lives. While they may strive to be good grandparents, it is not entirely clear which of multiple common and changing grandparental roles, contribute to grandchildren’s perspectives of good grandparenthood. The current study is based on a survey of adult grandchildren (N = 470 undergraduates), who identified characteristics of the good grandmother and grandfather and evaluated their grandparent’s role performance. We examined grandparental roles to explain variances in grandchildren’s views of good grandparenthood. Regression analysis revealed that grandparents who were performing as disciplinarian, friend, advisor, and supporter explained 32.2% of the variance in grandchildren’s perspectives of their grandparents’ grandparenting quality. All of these roles but disciplinarian were positively associated with perceived grandparenting quality. Further, when controlling for gender, among granddaughters, the roles of disciplinarian, friend and supporter explained 34.6% of the variance. Among grandsons, the roles of advisor and supporter explained 25.2% of the variance in their ratings of grandparents’ grandparenting quality. These results indicate that grandchildren have gender-related differences in expectations for grandparental roles. Future research is needed to examine a) the extent to which grandparents adapt their role performance to the gender of their grandchildren; b) congruence between grandparents and grandchildren’s ideas of good grandparenting role performance; c) the match between grandchildren’s expectations and their evaluations of their grandparents’ role performance in relation to expectations for becoming a grandparent.

THE EFFECTS OF SPOUSAL ILLNESS ON SELF-RATED HEALTH IN OLDER PEOPLE: DO THEIR INFORMAL NETWORKS MAKE A DIFFERENCE?
T. Saito-Kokusho1, T. Waku1, I. Kai1, 1. National Center for Geriatrics and Gerontology, Oho, Japan, 2. Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland, 3. University of Tokyo, Tokyo, Japan

Older adults are more likely than younger people to experience serious illness, in either themselves or their partners. However, the effects of spousal illness or hospitalization on older people’s health are still unclear, particularly in non-Western countries. Thus, we examined the effect of spousal illness on self-rated health in older adults, focusing on informal networks as a moderator. Participants were selected from a two-year longitudinal survey conducted in Fukui Prefecture of Japan, who responded to both initial (T1) and follow-up (T2) surveys and lived with their spouse at T1. Self-rated health was assessed with a single 5-point item, while spousal illness was assessed by experiences of spousal illness or hospitalization in the previous year. Informal networks were assessed by whether they had children living within 30 minutes of them and whether they met friends every week. Of 1914 participants, 52.9% were men, the mean age was 73.1 years, and 15.2% had experienced recent spousal illness or hospitalization. Spousal illness had a marginal negative effect on self-rated health (p = .069), after adjusting for informal networks and other covariates. However, the interaction effect of spousal illness and having children close was significant (p = .035), indicating that the health of people not close to their children was more affected by spousal illness. The effect of spousal illness on physical health in older adults might not be very serious; however, it could be a greater risk for older people who have no children living close to them.

EXAMINING SIMILARITIES IN LIFE SATISFACTION WITHIN AND BETWEEN COUPLES OVER TIME
H.M. Schade1, F.J. Infurna2, D. Gerstorf2, C. Hoppmann1, 1. Developmental Psychology, Humboldt University Berlin, Berlin, Germany, 2. German Institute for Economic Research (DIW Berlin), Berlin, Germany, 3. University of British Columbia, Vancouver, British Columbia, Canada

Research based on between-couple perspectives indicates that spouses share similarities in a range of psychosocial characteristics. The present study adds to this literature by examining spousal similarities in life satisfaction and its time-related change from both between-couple and within-couple perspectives. To examine this, we applied latent growth models to longitudinal data (22 annual waves) from 3,257 adult couples in the German Socio-Economic Panel (SOEP; age at baseline: Mwives = 43 years, Mhusbands = 46 years). At the between-couple level, spouses showed considerable similarities in both levels of and rates of change in life satisfaction. For example, men reporting high life...
PATTERNS OF SUPPORT EXCHANGES BETWEEN MIDDLE-AGED ADULTS AND THEIR AGING PARENTS

K. Kim1, S.H. Zari2, K.S. Birditt3, K. Fingerman1, 1. The University of Texas, Austin, Texas, 2. The Pennsylvania State University, University Park, Pennsylvania, 3. University of Michigan, Ann Arbor, Michigan

Research on intergenerational support has examined only one direction of support, focusing on support given to aging parents. However, given that help and assistance from aging parents can still be important for middle-aged children’s lives, it is necessary to consider both support given and received to describe fully the pattern of intergenerational exchanges in adult families. This study investigates how middle-aged adults (aged 40–60) exchange support with their aging parents (aged 57–96), and factors predicting the patterns of support exchanges (e.g., individual needs/resources and beliefs, family characteristics, and relationship quality). Using 862 parent–child dyads nested within 629 families, we applied a latent profile analysis to ten support indicators that adult offspring reported (five types of support given to and received from each parent). Four latent patterns were identified: (1) “high exchanges” (11.7%) (2) “high non-tangible support exchanges” (26.3%), (3) “moderate non-tangible support exchanges” (42.1%), and (4) “low exchanges” (19.9%). Multilevel logistic regressions revealed that after controlling for individual needs/resources and geographic distance, middle-aged adults who are in minority status are more likely to belong to a high exchange pattern with the highest levels of practical and financial support provided to parents (Pattern 1). Also, both dimensions of relationship quality with parents (i.e., positive and negative relationships) are positively associated with having high exchange patterns (Pattern 1 and Pattern 2), suggesting that extensive support exchanges with parents may entail ambivalence toward their parents.

AGING AND RESILIENCE: THE ROLE OF FAMILY AND INDIVIDUAL RESILIENCE IN SUCCESSFUL AGING

A. Martin1,2, B. Distelberg3, B. Palmer1,2, D. Jeste1,2, 1. Psychiatry, University of California, San Diego, La Jolla, California, 2. Stein Institute for Research on Aging, La Jolla, California, 3. Loma Linda University, Loma Linda, California

Introduction: Due to the rapidly shifting distribution of older adults and the impact of aging on the family system it is imperative that increased attention is given to geriatric family research. Considering how family resilience relates to multidimensional constructs of aging provides a foundation for understanding the reciprocal effects of aging on the entire system. This research applied a family resilience lens to the study of successful aging across four domains; self-rated success, physical health, psychosocial health, and cognitive health. Methods: A total of 1,006 community-dwelling older adults from the SAGE (Successful Aging Evaluation) study were analyzed using structural equation modeling (SEM) to, first, understand the predictive power of family and individual resilience on outcomes of successful aging, and then, to test the causal effect of family and individual resilience on domains of aging. Resilience was measured with the Family and Individual Resilience Measure (FIRM). Results: Our results showed an indirect effect of individual resilience and direct effect of family resilience on all four domains of successful aging (γd=0.75 SD, df=283): NNI=−0.903, CFI=.915, RMSEA=.044 with a 90% CI between .040 and .048. Path coefficients suggested noteworthy relationships between family and individual resilience and outcome variables of successful aging. Conclusion: This study provides a framework for understanding optimal aging as closely related to both family and individual resilience. The application of family resilience to the study of aging offers valuable information to guide future research, practice, and policy by providing a framework to understand families as they age.

REMAINING SATISFIED WITH LIFE AT 100 AND BEYOND: THE SALIENT IMPACT OF DISTAL LIFE EXPERIENCE AND PROXIMAL PSYCHOSOCIAL RESOURCES

A. Bishop1, B. Brock3, G. Randall3, 1. Human Development and Family Science Department, Oklahoma State University, Stillwater, Oklahoma, 2. Bradley University, Peoria, Oklahoma

Data for this study originated from 154 centenarians residing in Oklahoma. Mplus 7.0 was used to test a hybrid path model involving the influence of manifest distal variables (maternal closeness, paternal closeness, and family financial problems) on life satisfaction through three proximal manifest mediators (social provisions, economic security, and religious activities). The model fit the data well: Satorra-Bentler χ2 (N=149; df=56) = 64.91; p = .13; CFI=.96; RMSEA=.03; 90% CI [0, .06]; SRMR=.04 (using FIML). The association of distal variables on life satisfaction (R2=.37) was completely mediated. Controlling for age, sex, education, neuroticism, and self-reported physical and functional health, significant distal associations were evident relative to reported maternal closeness on social support (γ=.17, t = 2.21), paternal closeness on social support (γ=.14, t = 1.85), and economic security (γ=.21, t = 2.63), and family financial problems on religious activity (γ=.15, t = 1.79). In addition, significant proximal associations on life satisfaction existed for social support (β=.31, t = 3.66), economic security (β=.17, t = 1.93), and religious activity (β=.16, t = 1.96). The total indirect effect of maternal closeness on life satisfaction through the proximal mediators was .05, 95% CI [.04, .40]. Results indicate that maternal closeness has a salient association with social, economic, and religious resources vital to the development of life satisfaction in very old age. Implications of the reported effects are discussed.
HEALTH SHOCKS, WEALTH SHOCKS, AND MARRIAGE AMONG OLDER COHORTS
J. Ward-Batts, Economics; Institute of Gerontology, Wayne State Univ, Detroit, Michigan

I use longitudinal data from the U.S. Health and Retirement Study (HRS) to examine marital formation, dissolution and stability among older cohorts. In particular I address whether and how adverse health and wealth changes affect marital dissolution and marital duration among married couples. There may be causal effects in the opposite direction as well – i.e., marital dissolution may affect health and wealth. Careful use of longitudinal data allows isolation of the causal effects of health and wealth changes on marriage outcomes. Marriage is an important institution for helping to maintain well-being at older ages through risk sharing, mutual care-giving, and social and emotional support, among other mechanisms. If health or wealth shocks negatively impact marriage, then they may negatively impact both short- and long-term well-being through this pathway. If such an effect is significant, then policy measures aimed at preserving marriage in the face of adverse events may be useful.

GRANDMOTHERING AS A PROTECTIVE FACTOR FROM STRESS
J. Coplon, D. Wang, Women’s Studies Research Center, Brandeis University, Waltham, Massachusetts

As the population ages exponentially, there is increasing interest in addressing the unmet needs of the elderly around the world. A unique subgroup of elders are custodial grandparents, those who are the primary caregivers of their grandchildren. In African countries, and in particular Uganda, elderly women face “off-time parenting” of their orphaned grandchildren whose parents have died of AIDS. In our pilot study, we explore the potential protective factor the role of a grandmother has on strengthening a sense of purpose in life and generativity, which lead to their demonstrated resilience. Ten Ugandan elders were recruited by a Non-Governmental Organization, AWOFS (AIDS Widows Orphans Family Support). With the help of an interpreter, the primary author conducted semi-structured interviews. Prompt questions directed conversation towards “appreciative inquiries” on positive aspects of their lives and wisdom to be passed on to future generations. Examples from the ten narratives will be discussed and analyzed. In the six interviews with elder women, the role of grandmothering contributes significantly to the meaning and purpose of their lives, which ultimately drives them to be resourceful and even entrepreneurial. While much research focuses on the added burden of caregiving, we bring attention to the possibility that the rewards of grandmothering may in fact be protective. The interviews were transcribed into first-person narratives, and photographic portraits were also taken. These stories and images have been displayed in public exhibits. In doing so, we aim to give marginalized elders a “voice” and to refute negative stereotypes of elders.

GRANDCHILDREN’S PERCEPTIONS OF THEIR FAMILIES: THE GOOD, THE BAD, AND THE WORRY
C. Musil, C. Warner, J.A. Zauszniewski, P. Thongtarn, V. Toyi, Case Western Reserve University, Cleveland, Ohio

There has been much attention to grandmothers as caregivers to grandchildren, but less consideration to how the grandchildren living in various family structures fare. In this content analysis of open-ended data obtained from grandchildren, we examine how grandchildren perceive their families and what worries them most. The sample included 156 grandchildren (age 8-19) whose grandmothers participated in a longitudinal study of grandchild caregiving and health. The 71 grandchildren raised by grandparents, 27 grandchildren in multi-generational homes, and 58 grandchildren living with parents completed a mailed questionnaire; they were asked to describe the best thing and the worst thing about their family, and what worries them most. Data were analyzed using content analysis, then thematic comparisons were made between grandchildren’s perceptions across the three family structures. There were few group differences between grandchildren’s reports of the best thing about their family, which focused on care and support, or in the worst thing about their family, which primarily focused on family conflicts, although the nature of the conflicts differed by family structure. Grandchildren’s worries showed greater variation between families. Grandchildren living with grandmothers reported concerns about the grandmother’s health and their ability to meet expectations for good behavior, whereas children living only with parents reported more concerns about school and activities. Children in all family structures reported worries about family members dying, although fears of abandonment were more frequent among children raised by grandmothers. These insights into grandchildren’s perceptions suggest a need for strengthening family communication and security, especially in grandparent headed households.

OLDER ADULTS CORESIDENCE WITH DAUGHTERS VERSUS SONS: THE ROLE OF ECONOMIC CONTEXT IN CHINA
M. Sereny, Sociology, Duke University, Durham, North Carolina

In China it is the norm for older adults to co-reside with adult children, traditionally the eldest son. Less commonly studied are those older adults who coreside with adult daughters, even when sons are available. This study examines determinants of coresidence with a daughter versus a son, specifically testing whether social context plays a role. Are older adults who reside in more economically developed communities more likely to live with daughters than those who live in less developed areas, net of individual characteristics? This study tests the modernization hypothesis that a decline in traditional behaviors (such as preferred coresidence with sons versus daughters) is associated with economic development. This is an important topic of study in China where number of children has declined dramatically and future older adults may not have an adult son available for coresidence. This paper utilizes multi-level models with older adults residing in communities defined at the level of prefecture-level city district, county, and county-level city. Individual-level data comes from the 2008 wave of the Chinese Longitudinal Healthy Longevity Survey (CLHLS). The community development indicators come from Chinese Statistical Yearbooks. Community-level measures include average wages, percent of the population that is rural, total population size, GDP per capita, and percentage of people employed in the service industry. Preliminary analysis finds that among older adults with equal numbers of children, those in urban areas are more than twice as likely to coreside with an adult daughter as those in rural areas.

SOCIALIZATION PROCESSES AMONG AFRICAN AMERICAN GRANDPARENTS AND THEIR GRANDCHILDREN

The importance that socialization has for the future of children, and the future of African American communities, is seen as inseparable. This socialization can encompass beliefs of racial socialization, morals, cultural traditions, etc. Racial socialization beliefs of primarily southern African American grandparents raising grandchildren were examined with the expectation that grandparents would not report a high level of belief in the importance of racial socialization as a parenting tool. Ninety-four families with youth aged 10-17 years participated in the study. Ninety-five percent of the parents reported a moderate to high racial socialization belief level. Findings indicate parent racial socialization belief level was not significantly correlated with their age, household income, or level of education; neither parent age nor household income were predictors of parent racial socialization belief levels. Qualitative
findings indicated that African American youth were provided with race-specific messages involving the importance of education, religion/spirituality, and racism. Another sample of 171 midwestern African American grandparents and their young adult grandchildren were examined on the impact the grandparent belief system had on their grandchildren’s beliefs. Interestingly, the greatest impacts of the grandparent belief system on their grandchild’s were in the areas of religion, moral, education, and personal identity beliefs. Grandparents believed they purposefully targeted sharing cultural ways and practices with their grandchildren to foster pride and self-esteem in their grandchildren. Thus, these examples of intergenerational socialization processes may serve to foster resilience and personal pride in youth cared for by African American grandparents.

SESSION 480 (POSTER)

FAMILY CAREGIVING: IMPACT ON SPOUSES AND MARRIAGE

PHYSICAL ILLNESS AS A RISK FACTOR FOR DIVORCE AND SEPARATION AT OLDER AGES

K. Latham1, A. Karraker1, I. Population Studies Center, University of Michigan, Ann Arbor, Michigan, 2. IUPUI, Indianapolis, Indiana

Physical illness and disability are increasingly common experiences as individuals age and may increase divorce or separation risk by operating as stressors on the marital relationship. Using data from the Health and Retirement Study (HRS) (1998-2008), this research explores whether a spouse experiencing onset of a life-threatening chronic disease (i.e., cancer, heart disease, lung disease, or stroke) or disability predicts divorce or separation among married US adults aged 50 and older. To assess risk of divorce/separation, a series of discrete-time event history models with multiple competing events were estimated using multinomial logistic regression. Widowhood and respondent death or attrition were modeled as competing events, as these may all also be related to disease or disability onset. Additionally, gendered interactions were examined to evaluate whether gender moderated the association between spousal onset of disability or chronic disease and divorce/separation. Net of sociodemographic characteristics, the odds of divorce/separation were greater for respondents whose spouse had experienced disability onset (OR=1.858, p=0.0006); however, spousal onset of chronic disease was not significantly associated with risk of divorce/separation. The risk of divorce/separation was moderated by gender for respondents whose spouse experienced chronic disease onset, but this was not the case for disability onset. Female respondents whose husbands had experienced onset of a life-threatening chronic disease were less likely to divorce/separate, relative to male respondents whose wives had experienced life-threatening chronic disease onset (OR=0.4102, p=0.0442). These results suggest that physical illness in the form of chronic disease or disability shape the risk of divorce/separation among older adults.

CROSS-EFFECTS OF DISABILITY AND CAREGIVING ON SPOUSES’ DISTRESS

E.D. Quach, M.E. Szinovacz, F.W. Porell, University of Massachusetts, Boston, Boston, Massachusetts

Guided by the stress process model and the notion of linked lives from the life course perspective, we examined the cross effects of disability and caregiving on depressive symptoms of spouses. Prior studies have documented that illness and disability of one spouse negatively influence this spouse’s psychological well-being as well as that of his or her partner. Building on these findings, we investigated the extent to which disability and caregiving increase distress of both members in a couple, that is, distress resulting from being ill, having an ill spouse, receiving spousal care, and providing spousal care. We also sought to distinguish these cross effects by gender, using gender-specific comparison groups. Our analyses rely on the 2010, 2008, and 2006 waves of the Health and Retirement Study (n=11,031). Using hierarchical linear modeling, we controlled for stable individual differences and couple differences in order to ascertain gender effects. Our results suggest that disability, chronic illness, and self-reported poor health of one spouse is associated with higher depressive symptoms of both the ill spouse and his/her partner, with wives experiencing a more pronounced depressive effect than husbands did. Our results also suggest that receiving care from a spouse may increase depressive symptoms of husbands, whereas wives experience higher depressive symptoms if they are the sole caregivers for their spouses. These results confirm cross-effects of spouses’ illness on each other. They also imply that caregiving and care receiving have divergent effects for husbands and wives.

SPOUSAL CAREGIVING AND ASSOCIATED HEALTH OUTCOMES: FINDINGS FROM THE HEALTH AND RETIREMENT STUDY

K.B. Dassel1, D.C. Car2, 1. Center for Gerontology, Western Kentucky University, Bowling Green, Kentucky, 2. Stanford University, Stanford, California

Numerous studies have identified negative health outcomes associated with spousal caregiving, however, little is known about how care-recipient cognitive status impacts caregiver health outcomes. The current study examines differences in health outcomes between spousal caregivers of persons with compared to those without cognitive impairment. Using Health and Retirement Study data, we examine health differences among surviving spouses of individuals who died between 2000 and 2010 (N=2,382) with and without cognitive impairment. Health is measured based on a change in aggregate health, including chronic diseases, mobility, functional status, depressive symptoms, and subjective health. Among spousal caregivers, who have a mean age of 74.2 years old (S.D.=10.1), and were predominately Caucasian and female (78.0% and 69.8%, respectively), approximately a third (31.9%) experienced a decline in health status in the two years leading up to and just following the death of his/her spouse. Among decedents, 16% had a cognitive impairment diagnosis prior to death. Preliminary results indicate that caring for a cognitively impaired individual has greater health consequences than caring for someone without such a diagnosis. Specifically, caregivers of spouses who were cognitively impaired have 39% higher odds (95% CI [1.08-1.78]) of experiencing a decline in their overall health status compared to caregivers of spouses who were cognitively intact. We discuss the public health implications of these findings in light of projected increases in dementia diagnoses.

GENDER DIFFERENCES IN THE HEALTHY CAREGIVER EFFECT: SPousAL CAREGIVING AND TWO HEALTH BEHAVIOURS

M. Badger, A.V. Wister, B.A. Mitchell, Simon Fraser University, V5A 1S6, British Columbia, Canada

This study aims to examine whether there are gender differences in a ‘healthy caregiver effect’ among spousal caregivers/non-givers by analyzing two health behaviours: physical activity (PASE) and skipping meals. Using data from the 2008-2009 Canadian Community Health Survey, Healthy Aging Module, hierarchical regression analyses were used to investigate the association between spousal caregiving and the two health behaviours among married persons 65+ (N=7,625). The hierarchical models for both dependent variables included: caregiving status, socio-demographic variables, health factors, and psycho-social factors. The analyses were conducted separate for each gender. The full models accounted for similar proportions of explained variance for females (R2 = 0.220, p < 0.001) and males (R2 = 0.21, p < 0.001). Findings supported a positive association between spousal caregiving and physical activity, which was slightly stronger among females (b = 0.22, p < 0.001) than males (b = 0.17, p < 0.001). Logistic regression was used to examine the same hierarchical factors on skipping meals, as one
measure of food insecurity. A statistically significant association emerged between spousal caregiving and skipping meals, but only for men (OR = 1.62, p < 0.01). Controlling for covariates, spousal caregivers regardless of gender have higher levels of physical activity than non-caregiving spouses, lending support to a healthy caregiver effect. However, spousal caregiving men only (versus married non-caregivers) were found to have an increased likelihood for skipping meals. Accordingly, multiple dimensions must be addressed when assessing the healthy caregiver effect.

UNEXPECTEDLY, AND INCONSISTENT WITH MOST PRIOR RESEARCH, THERE WAS NO GIVERS FOR PARENTS AND ADULT CHILDREN ARE ASSOCIATED WITH DEPRESSION.

Data are from the second wave (2004-2006) of the longitudinal National Health, and caregivers' declining physical function may play an essential role in IWDs' nursing home placement. The findings highlight the importance of early interventions on promoting caregivers' physical well-being.

DOES THE MARITAL RELATIONSHIP INFLUENCE THE ASSOCIATION BETWEEN CAREGIVING AND DEPRESSION?

C. Lendved, University of Wisconsin-Milwaukee, Milwaukee, Wisconsin

The connection between caregiving and negative mental health has been extensively researched; however, not all studies report that caregivers suffer the same consequences. Few studies assess the effect of a caregiver's marital quality on the negative outcomes of caregiving, despite research consistently finding that marriage provides a buffer to distress. To address this gap in research, this study utilizes the stress process model to understand how spousal strain influences depression. Logistic regression analyses were conducted to: 1) establish the caregiving and depression relationship; 2) determine if this relationship differs when looking at type of relationship (i.e., spouse vs. child) or weekly time spent in care; and 3) determine whether the presence of spousal strain influences the association between caregiving and depression. Data are from the second wave (2004-2006) of the longitudinal National Survey of Midlife Development in the United States (MIDUS II). Consistent with prior literature, I found that time spent in care and caregivers for parents and adult children are associated with depression. Unexpectedly, and inconsistent with most prior research, there was no association between spousal caregiving and depression. No evidence was found that spousal strain impacted the relationship between caregiving and depression. The lack of buffering effect of spousal strain on the caregiving-depression relationship suggests that marriage may not offer buffering impacts for all married individuals, particularly caregivers. These surprising findings suggest caregiving is not universally detrimental and further exploration should account for various conceptualizations of caregiving (i.e., time spent on care, relationship with care recipient).

SESSION 485 (POSTER)

LONG TERM CARE

RELATIONSHIPS BETWEEN PERCEIVED DECISIONAL CONTROL, RELOCATION TO ASSISTED LIVING, ADJUSTMENT, AND SOC: A MODERATED MEDIATION ANALYSIS

N.G. Regier1, J.K. Frank2, R. Rock3, P.A. Parmelee1, J. Blackburn, J.L. Locher, M. Kilgore1. 1. Psychology, University of Alabama, Tuscaloosa, Alabama. 2. Montgomery County Adult Protective Services, Rockville, Maryland

The decision to transition to long-term care profoundly affects the lives of older adults, yet they often play a limited role in the decision-making process or are excluded altogether. This finding is alarming, as the adverse effects of low perceived control on adjustment to long-term care is well-documented. The present study examined the association of perceived decisional control with older adults' well-being and adjustment to an assisted living facility. These outcomes were then examined within the framework of the well-known and validated metamodel, Selective Optimization with Compensations (SOC; Baltes & Baltes, 1990). Specifically, the current study assessed whether or not the indirect effects (via perceived decisional control) of contributing factors to relocation on measures of adjustment and well-being were impacted when new assisted living residents focused their resources on whatever goals were deemed most important, realistic, and helpful in adapting to the environment. Grounded theory methodology was used to assess for the implementation of SOC-based strategies, and a categorical variable was created identifying the presence or absence of an SOC strategy in the participant's responses. In a sample of 91 newly-transitioned assisted living residents in Maryland and Alabama, results partially support the moderating role of SOC strategies on the strength of indirect effects of several predictor variables (moving for reasons related to safety, caregiver burden, health, and functional independence) on post-relocation outcomes (acceptance of the move, negative affect, depression, and socialization). Overall, SOC adaptations appear to promote adjustment and well-being to relocation at various levels of perceived decisional control.

ESTIMATING NURSING HOME RESIDENTS ELIGIBLE FOR TRANSITION TO HOME AND COMMUNITY-BASED SERVICES

J. Blackburn, J.L. Locher, M. Kilgore, Health Care Organization & Policy, University of Alabama at Birmingham, Birmingham, Alabama

Purpose: We developed an algorithm to estimate the number of older adults receiving long-term care in a nursing home who were potentially eligible to transition to home and community-based services (HCBS). Methods: All Centers for Medicaid and Medicare Services (CMS) certified nursing facilities are required to perform assessments which are contained within the Minimum Data Set. Data from Alabama during the last quarter of 2008 contained 19,195 older adults determined, based on payer type, to be long-term nursing home residents. Each successive specification of potentially transferable residents was based on functional status, level of care, performance on activities for daily living (ADLs), incontinence, behavioral symptoms, and medical condi-
tions requiring skilled nursing care. Results: Common specific conditions requiring institutional care included being bed-ridden, the severity of incontinence and/or demonstrated significant disruptive behavior. Allowing the algorithm definition to vary, between 2,515 (13%) and 5,910 residents (31%) were identified as possibly eligible for HCBS. Conclusions: Most long-term nursing home residents require a level of care that may not be practical to provide in a community setting. However, a substantial number of those with more modest care requirements may be able to transition to the community. The algorithm we present may be adopted by other states and is easily modifiable to estimate different levels of care based on the individual state’s availability of services and preferences.

WHAT DO LONG-TERM CARE STAFF KNOW ABOUT THE DIFFERENCES BETWEEN DEPRESSION AND DEMENTIA? T. Gendron¹, A. Heck², 1. Virginia Commonwealth University, Richmond, Virginia, 2. Piedmont Geriatric Hospital, Burkeville, Virginia

A cross-sectional study of 159 long-term care staff completed a series of questionnaires on knowledge of dementia, knowledge of depression, a series of forced-choice questions on the differentiation between dementia and depression, as well as a demographics questionnaire. Relative to professional staff, paraprofessional staff had lower scores in depression knowledge and differentiation knowledge. Differences in knowledge between staff were based on job type rather than level of education. Dementia training has been a priority recent years, which has sparked a multitude of initiatives and programs geared towards training LTC staff. Our study results indicate that overall, LTC facilities are effective at training staff about dementia. Overall knowledge of dementia was high for both occupation groups and across all levels of education. However, there is a need for increased on the job training regarding depression in older adults; as another interesting finding of this study is the belief by all staff, but particularly paraprofessionals, that depression is a normal part of aging. This highlights the need for increased educational efforts on the importance of detection and treatment of depression. The view of depression as a normal and expected part of aging has major implications for the differentiation between depression and dementia. Misinformation regarding aging, from physical and psychological perspectives, can lead to underrecognition of depression and/or overrecognition of dementia.

IN THE EYES OF THE BEHOLDER: HOARDING IN ASSISTED LIVING

C.R. Bennett, M.C. Nemec, A.D. Peeples, A. Frankowski, University of Maryland, Baltimore County, Baltimore, Maryland

Recognizing hoarding behavior and hoarding practices is critical to understanding overall health and well-being of residents in assisted living (AL). Clinical or diagnostic definitions of hoarding, however, may not align with residents’ experiences in AL. Policy and safety requirements for AL settings can dictate routine cleaning or removal of items from residents’ rooms, but for some ALs then run the risk of residents moving out thus decreasing the bottom line. Importantly, what is the role that autonomy plays in hoarding behavior? Do staff and family members may thereby disenable residents’ autonomy in AL by inhibiting hoarding behaviors and preventing accumulation of hoards at clinical or diagnostic levels? Is the resident’s quality of life affected? To understand the complexity of hoarding in AL, this poster examines: (1) clinical versus popular definitions of hoarding and how these are interpreted and expressed in AL settings; (2) views on hoarding from the perspectives of residents, their family members, managers, housekeepers, and care staff; and (3) related academic research and policy reports. Ethnographic data for this poster are drawn from two multi-year, multisite NIA-funded qualitative studies, “Autonomy in Assisted Living: A Cultural Analysis” and “Stakeholders’ Models of Quality in Assisted Living.” Fieldnotes and interview transcripts from eleven ALs, ranging in size from 16 to 80 residents, were coded and analyzed using Atlas.ti software. This poster concludes with recommendations on how best to address hoarding in AL from four stakeholder groups: AL residents, their family members, staff, and administrators.

PATHWAYS INTO LONG-TERM CARE ACCOMMODATION IN BRITAIN: COMMON ASPECTS, DIFFERENCES AND POLICY IMPLICATIONS

A. Vlachantoni¹,²,³, O. Maslovskaya², M. Evandrou¹,²,³, J.C. Falkingham¹,²,³, 1. Centre for Research on Ageing, University of Southampton, Southampton, United Kingdom, 2. EPSRC Care Life Cycle Programme, University of Southampton, Southampton, United Kingdom, 3. ESRC Centre for Population Change, University of Southampton, Southampton, United Kingdom

Population ageing is a global challenge, and understanding the dynamics of living arrangements in later life and their implications for the design of appropriate housing and long-term care is a critical policy issue. This paper investigates the dynamics of living arrangements amongst people aged 65 years old and over between 1991 and 2008, focusing on two types of accommodation: sheltered accommodation and residential care. The empirical research examines the rates and determinants of moving into sheltered accommodation and institutional care, using all 18 waves of the British Household Panel Survey and a discrete-time logistic regression model in order to model the probability of entering each type of accommodation. The paper shows that the factors associated with each of the two transitions in later life are different; for example age, health and marital status are significant determinants of an older person’s move into residential care, while the move into sheltered accommodation is in addition associated with an older person’s housing tenure and highest educational qualification. Such results indicate that the two kinds of transition may be more prevalent in different stages of the latter part of the life course, and have crucial implications for the design of future social care provision.

RACIAL/ETHNIC DIFFERENCES IN QUALITY OF LIFE FOR NURSING HOME RESIDENTS

T.P. Shippée¹, C. Henning-Smith¹, G. Rhee¹, R.N. Held², R. Kane¹, 1. Health Policy and Management, University of Minnesota, 420 Delaware St. SE, MMC 729, Minnesota, 2. Department of Human Services, Saint Paul, Minnesota

Objective: This project investigates: 1. Are there racial/ethnic differences in nursing home (NH) residents’ quality of life (QOL)? 2. If so, do these differences exist at the resident and/or facility aggregate level? 3) Do these differences persist across domains of QOL? Methods: The setting for this study is Minnesota nursing homes (NHs). Data come from: 1) resident-reported QOL (n=10,929) collected in survey of residents in each NH; 2) Resident clinical data from the Minimum Data Set; and 3) facility-level characteristics from the Minnesota Department of Human Services (n=376). Bivariate and multivariate analyses were conducted to identify differences in QOL by racial/ethnic group, controlling for relevant predictors. Results: Minority NH residents reported lower QOL on seven out of eight QOL domains, compared to White NH residents. In multilevel models, these differences became non-significant after controlling for resident functional and mental health status (except for mealtime enjoyment). At the facility level, being in a facility with a higher percentage of white residents significantly predicted better QOL for all domains but environment, after controlling for other resident and facility covariates. Discussion: Racial/ethnic differences in QOL exist on both individual and aggregate levels. However, individual-level racial/ethnic differences may be mainly explained by health status, pointing to the cumulative disadvantages encountered by minority elders. Proportion of White residents in the facility level remained a significant predictor of QOL, suggesting the importance of
examine structural policies, community factors, and geographic inequality in understanding QOL.

RACE, IMMIGRATION STATUS AND JOB SATISFACTION OF CERTIFIED NURSING ASSISTANTS

K. Zakoszecina1,2, P.A. Parmelee1,2, 1. Center for Mental Health and Aging, Tuscaloosa, Alabama, 2. University of Alabama, Tuscaloosa, Alabama

Certified Nursing Assistants (CNAs) offer up to 90% of direct care to long-term care residents. Unfortunately, CNAs have an extraordinarily high turnover rate that is accompanied by low levels of work satisfaction. Previous, largely qualitative literature has indicated that perceived lack of respect and perceived discrimination drive job satisfaction differently in CNA’s of different race/ethnicity. This present, quantitative study further examines CNA job satisfaction with an emphasis on race, immigration status, dementia training respect, and perceived discrimination. Secondary data analysis of the National Nursing Assistant Survey used information from 3,017 nursing assistants in 1,500 nursing facilities, including data on training, supervision, client relationships, and workplace environment. This study looks at a sample of 2,897 participants, 61.3% are Non-Hispanic Whites (NHWs) and 31.4% are African Americans (AAs); 89% are U.S.-born citizens, 4.2% immigrants, and 6.8% citizens through naturalization. Structural equations path analyses indicated that race predicts job satisfaction, and that both respect and discrimination partially mediate that association. This pattern of findings was consistent across all three citizenship groups. US-born citizens reported the highest levels of discrimination and lowest levels of respect; conversely immigrants reported lowest perceived discrimination and greatest respect. These effects varied with age. Dementia training, hypothesized to moderate these effects as a function of understanding of problem behavior, was not a significant factor. These results highlight the complex nature of CNA job satisfaction in long-term care.

CHANGE IN THE RESIDENT POPULATIONS SERVED BY CANADIAN PRIVATE AND PUBLIC LONG-TERM CARE FACILITIES OVER A FIFTEEN-YEAR PERIOD

C. Lestage1, G. Bravo1, M. Dubois1, N. Dubuc1, L. Demers1, K. Painter1, 1. University of Sherbrooke, Research Centre on Aging, Sherbrooke, Quebec, Canada, 2. National School of public administration, Quebec, Quebec, Canada

In Canada, there are few data on the residents served by the private and public long-term care (LTC) sectors, and none on whether their respective population has changed over time. Such knowledge would help plan services for older adults who can no longer live at home due to increased disabilities. Objectives: To compare 1) the resident populations currently served by private and public LTC facilities and 2) how each population has evolved over time. Methods: The data come from 2 cross-sectional studies conducted in 1995-2000 and 2010-2012. In both studies, we randomly selected care settings in which we randomly selected residents aged 65 and over. In total, 451 residents from 145 settings assessed in 1995-2000 were compared to 329 residents from 102 settings assessed in 2010-2012. Measurements included cognitive and functional disabilities assessed with the Modified Mini-Mental State Examination and Functional Autonomy Measurement System, respectively. Results: In both study periods, older adults housed in the private sector had less cognitive and functional disabilities than those in public facilities (p < 0.001). Between the 2 study periods, the proportion of residents with severe disabilities increased from 68.1% to 77.9% in public facilities while decreasing from 15.9% to 7.4% in their private counterparts. Conclusion: Findings suggest that private facilities care today for less-disabled older adults, leading to public facilities the heavy responsibility of caring for those with more demanding needs.

These trends may impact both LTC sectors’ ability to deliver proper care to their residents.

INNOVATION IN TREATMENT FIDELITY: MEASURING RECEIPT OF TREATMENT USING INDIVIDUALIZED MAPPING

K.A. Porte1, M.B. Aselage1, T.L. Yap1, K. Corazzini1, C. Colon-Emeric1,2, R.A. Anderson1, 1. Research, Duke University School of Nursing, Durham, North Carolina, 2. Durham VA Medical Center, Durham, North Carolina

Measuring treatment fidelity in complex behavioral interventions is necessary to enhance reliability and internal validity. CONNECT is a multi-component intervention aimed at improving communication between nursing home staff to reduce fall rates. In the intervention, the participants learn local interaction strategies that address “connection,” working together; “information exchange,” the flow of new resident information between staff; and “two-eyed seeing,” examining problem situations from different points of view. We developed an innovative strategy for assessing “receipt of treatment” through a process, individualized mapping, facilitated by trained research interventionists to measure adherence and behavior change. To assess participants’ use of local interaction strategies, interventionists first use a facilitated process in which participants evaluate the staff who should be in their network regarding the residents in their care. Using this information, participants draw a relationship map depicting their individual network and the level of interaction needed for each network member (e.g., frequent, infrequent). Over a period of 6 weeks, participants use tear-off sheets to self-report use of local interaction strategies (e.g., connection, information exchange, two-eyed seeing) with the staff on their map. Based on these self-reports, researcher’s create visual feedback reports on the use of local interaction strategies and use this to explore barriers and facilitators to communication between participants and identified members of their network. The individualized mapping process: 1) reinforces participants’ use of new interaction skills, and 2) provides a measure of intervention content mastery and uptake. The individual mapping process may be an effective technique in other complex behavioral interventions.

FACTORS AFFECTING JOB SATISFACTION AMONG HOME HEALTH AIDES

S. Yoon, J. Probst, Health Services Policy and Management, University of South Carolina, Columbia, South Carolina

Background: Home health aides are front-line workers in delivering home health care. Job satisfaction among these important workers has been associated with patient health outcomes and quality of services. Methods: We conducted a cross-sectional study using the 2007 National Home Health Aides Survey, a nationally representative sample of home health aides (n = 3,274). Structural equation modeling was employed to examine the latent relationships between personal backgrounds, organizational factors, job related characteristics, and job satisfaction. Results: Most home health aides were positively satisfied with their jobs. At the personal level, increasing age, being separated/divorced versus other conditions, and personal health were positively associated with satisfaction. Structurally, health insurance and training were positively associated with job satisfaction. Being trusted, having confidence in one’s ability, and supervisor quality were significantly associated with satisfaction. SEM analysis suggested that personal factors were positively associated with satisfaction through latent variables. Conclusions: We emphasize the importance of providing health insurance as an option for workers and providing train-
OPPORTUNITIES FOR RECREATION AND LEISURE IN NURSING HOMES: VARIATIONS ACROSS RURALITY

T. Killian, University of Arkansas, Fayetteville, Arkansas

Older persons’ active engagement in recreation and leisure activities is positively related to well-being, even after they have made the transition to congregate living environments. Although many residents in nursing homes have significant physical and cognitive limitations, continued engagement in diverse occupational, cultural, and physical activities that are appropriate for levels of function is associated with increased well-being. In fact, CMS guidelines require facilities to provide those opportunities, but there are wide variations in the implementation of those guidelines. This study focused on how opportunities for leisure and recreation varied across rurality. Data from the 2004 National Nursing Home Study was used to examine variations in opportunities for recreation and leisure provided to residents. The dependent variables were seven types of opportunities: offsite, evening, weekend, outdoor, gardening, pet therapy, and intergenerational activities. Descriptive analyses found a large majority of nursing homes provided opportunities for residents to engage recreation and leisure. Weighted logistic regression models were then used to examine variations in opportunities across rurality after controlling for covariates that included facility characteristics (for-profit, accreditation, bedsize, and national chain), pay source of residents (percent using Medicare or Medicaid as primary payer source), and staffing (hours-per-patient days of RNs, LPNs, and CNAs). Findings suggested that rural nursing homes were more likely than others to offer activities, especially activities that were off-site or outdoor activities. Many studies have emphasized rural disadvantages in nursing home quality, but this study suggests that this may be an area of advantage for rural nursing homes.

ENHANCING DIRECT CARE WORKERS’ PERCEPTIONS OF CHALLENGING INTERACTIONS WITH RESIDENTS WITH DEMENTIA

C. Coulter, D.M. La Fazia, L. Teri, University of Washington, Seattle, Washington

Purpose: Direct Care Workers (DCW) provide majority of care to residents in Assisted Living (AL), and therefore are ideal agents for improving care and reducing behavioral symptoms of dementia. This study used video vignettes to evaluate the effect of STAR (an evidence-based training program) on DCW perceptions of their interactions with residents with dementia. Methods: 73 AL DCWs completed the STAR training. Participants viewed 4 vignettes of interactions with residents and were asked a series of questions designed to evaluate key goals of the training following each scene at baseline and 6 weeks post intervention. Data was analyzed qualitatively via inductive framework analysis to identify major themes and patterns pre- and post-training. Results: Thus far, 33% of the participant data has been analyzed for key effect indicators. STAR increased recognition of the resident behavior; 66% of participants identified the behavior prior to intervention, and 85% after. Affective outcome recognition improved: initially, 70% recognized a negative outcome, whereas post-training 79% recognized a negative outcome associated to unresolved agitation. Self-efficacy and strategies to improve interactions demonstrated improvement: pre-intervention, 67% verbalized self-efficacy and correctly identified effective strategies; after STAR training 81% verbalized self-efficacy and cited specific strategies to use. Conclusion: STAR successfully targeted multiple key goals of DCW perceptions of interactions with residents with dementia. This method of inductive evaluation of training is a novel approach to intervention measurement and provides unique insights into training impact.

EXPLORING HOW NURSING HOME LEADERS DIFFERENTIATE WORKFORCE DIVERSITY FROM EQUAL EMPLOYMENT OPPORTUNITY/AFFIRMATIVE ACTION PROGRAMS

L.D. Vinson1,2, A. Long-Daniels1, A.M. Ward1, A. Snow1,2, M.R. Crowther1,2, 1. Department of Psychology, The University of Alabama, Tuscaloosa, Alabama, 2. Center for Mental Health and Aging, The University of Alabama, Tuscaloosa, Alabama

Workforce diversity (WD) is defined as the various demographic characteristics that influence workplace approval, performance, liking, and advancement. WD is a philosophical organizational behavior concept, an ideal for organizations to strive toward to improve their patient-centered outcomes. The federal and state workforce discrimination policies and laws, including Equal Employment Opportunity/Affirmative Action (EEO/AA) programs, have a different goal—the protection of vulnerable classes of individuals in the workplace. Previous research suggests employers associate WD with compliance-based strategies, such as EEO/AA. This study examined how nursing home leaders characterize WD. The data for this project came from a survey designed to explore WD management perceptions and practices among nursing home leaders in AL, GA, MS, and TN. When the leaders were asked whether WD was substantially different from EEO/AA programs, 25% indicated Yes, 46% indicated No, and 27% were Uncertain. There were no significant differences between the responses in the current sample compared with a previous study of U.S. employees, $\chi^2 (2, N = 28) = 7.94, p = .019$. Survey responses indicated that the presence of more diversity management practices may influence whether leaders differentiate WD from EEO/AA programs (approaching significance at the .057 level). This study reveals the importance of nursing home leader education to support a better understanding of the WD concept. As the demographics of the workforce continue to evolve, it will become imperative for nursing homes to distinguish between EEO/AA guidelines and WD if leaders wish their facilities to be employers of choice.

THE INFLUENCE OF SOCIAL ENGAGEMENT ON QUALITY OF LIFE FOR OLDER ADULTS LIVING IN SENIOR HOUSING

A.R. Roberts, Mandel School of Applied Social Sciences, Case Western Reserve University, Cleveland, Ohio

Quality of life is a central issue for all older adults, as old age is often a time of increased vulnerability due to losses in health, functioning, and social relationships. Social engagement is a potential adaptation strategy older people may use to maintain or enhance quality of life, conceptualized as providing and receiving social support and participating in formal group activities. This secondary data analysis of the Erickson Life Study (Resnick et al., 2001; 2005), a 5-year study of the physical health and psychosocial functioning older adults from 4 continuing care retirement communities in Maryland and northern Virginia (N=300), examined longitudinal changes in quality of life and explored how the level of social engagement at one year influenced changes in quality of life over time. Measures included the Perceived Quality of Life Scale (Patrick et al., 2001) and the Inventory of Socially Supportive Behaviors (Krause & Markides, 1990). On average, quality of life decreased over time. Results from the latent growth curve model showed that providing social support to others and participating in group activities were associated with better quality of life. These predictors also slowed the rate of decline in quality of life over time. No relationship was found between receiving social support and quality of life. The findings emphasize the influence of social engagement on quality of life over time and demonstrate the importance of older adults providing social support to others and participating in formal group activities to support better quality of life over the long run.
Understanding Falls in Long-Term Care: A Video-Based Case Study Approach

R. Woolrhy, A. Sixsmith, S.N. Robinovitch, H. Chaudhury, F. Feldman, B. Symes, Simon Fraser University, Vancouver, British Columbia, Canada

Falls are the leading cause of injury for residents living in long-term care facilities, representing a significant cost burden and having negative impacts on the independence and autonomy of the older person. Research into the causes of falls in long-term care is limited by inaccurate reporting procedures and a focus on specific intrinsic and extrinsic risk factors. This paper outlines a more holistic approach using video-based case studies to explore the complex nature of falls and the interaction between the contributory factors precipitating a fall. This paper is based on ongoing work from a CIHR-funded research project on the causes and prevention of falls in long-term care facilities in Metro Vancouver, Canada. The methodology utilizes video observations of the faller, stimulated recall interviews and focus groups with care staff alongside resident case-notes. The findings highlight the inter-related contributory factors of falls at the personal (e.g. cognitive status), interpersonal (e.g. social factors) and organisational level (e.g. staffing organisation). This holistic approach to understanding falls provides an opportunity to identify the systemic factors associated with fall incidents in long-term care and a tool for targeted, context-specific intervention. In conclusion, the paper highlights some of the methodological issues related to case study development and the use of video in falls investigations.

Predictors of Inappropriate Sexual Behavior in Nursing Home Residents

P. Bamonti, E.C. Price, L.A. Gerolimatos, J.J. Gregg, B. Edelstein, West Virginia University, Morgantown, West Virginia

Inappropriate sexual behavior (ISB) involves statements, gestures, and physical actions that are sexual in nature and unwanted. ISB is a relatively understudied problem in nursing homes, despite research demonstrating its detrimental effect on residents and professional caregivers. This study examined predictors of ISB among nursing home residents. We hypothesized that residents with a history of ISB would be more likely to be male, have a dementia diagnosis, and poorer executive functioning. Participants were 112 nursing home residents (age: M = 68.3, SD = 11.7; 52.7% male). Medical charts were reviewed for a more likely to be male, have a dementia diagnosis, and poorer executive impairment cut-off of 15. Recommendations for future research will be discussed.

An Iron Cage of Long-Term Care? The Rationalization of Aging

M. Brazda, C.R. Bennett, UMBC. Baltimore, Maryland

Max Weber’s sociological theory centers on the constructs of practical, theoretical, formal, and substantive rationality. This poster examines Weber’s four types of rationalization through the lens of providing long-term care for older adults from independent living (IL) to assisted living (AL). Rationalization influences within society can be seen in these two social institutions that provide the mechanisms necessary to derive economic benefit out of the aging process. This poster discusses formalized rationalization with regard to IL and AL as both provide an efficient and predictable system for dealing with the biopsychosocial fluctuations of aging. Additionally, the transition of an older adult from their home to IL and AL resultant of prompting by one’s family caregiver or responsible party provides the basis for a discussion of substantive rationality. Next, this poster examines theoretical rationality as seen by the ability of IL and AL as social institutions to provide a way to overcome the daily realities of aging while maintaining independence and autonomy. Lastly, this poster examines practical rationality; IL and AL settings provide a pragmatic way to care for older adults while limiting disruption in the lives of one’s family members. This poster posits that this process creates an iron cage of decision making, entrapping an older adult; once locked in, it becomes hard to remove oneself or one’s family member.

Session 490 (Poster)

Mental Health and Aging

Mental Health Literacy and Attitudes About Mental Disorders Among Younger and Older Adults

D.L. Segal, T.L. Bragg, F.L. Coolidge, University of Colorado at Colorado Springs, Colorado Springs, Colorado

Mental health literacy refers to knowledge and beliefs about mental disorders which aid their recognition, management or prevention (Jorm, 2000). Little is known about the mental health literacy of older adults, a population known to under-utilize mental health services. In this study, a new measure of mental health literacy, the Symptoms Identification Scale (SIS), was created to measure knowledge about symptoms of anxiety, depression, mania, and personality disorders based on DSM-IV diagnostic criteria. Younger adults (N = 409; M age = 20.2 years) and older adults (N = 40; M age = 71.6 years) completed the SIS and a measure of attitudes about mental disorders. Internal consistency for SIS scores was high for the Total score (alpha = .86) and adequate for the subscales. Participants were most knowledgeable about symptoms of depression (60% correct) with relatively limited knowledge about personality (34% correct), anxiety disorders (33% correct), and mania (30% correct). Regarding age-differences, two effects approached significance: younger adults had greater knowledge about anxiety disorders (p < .07) whereas older adults had greater knowledge about personality disorders (p < .06). Regarding attitudes, older adults expressed more favorable attitudes about depression (p < .05) and mania (p < .03) than younger adults. Across age groups, women were able to accurately identify more symptoms of depression (p < .01) than men, and women had more favorable attitudes toward anxiety (p < .01) and depression (p < .01) than men. These results show generally poor mental health literacy across age groups, although older adults expressed more positive attitudes about some disorders.

Parental Trauma and Relational Conflicts in Adult Sibling Relationships

I.V. Felsen, Mental Health Counseling, Ferkauf Graduate School of Psychology, Bronx, New York, New York

Severe mutual resentments are often recounted by adult siblings who are children of Holocaust survivors. Conflicts may intensify around the care of ailing and aging parents, adding to the difficulties experienced at this stage of life by both the survivor parent and the adult children. At times such tensions culminate in non-negotiable rifts, especially after the death of the parent. The severing of relationships among siblings leaves them, and subsequently their children, cutoff from extended family relationships. Clinically observed polarized family roles and adaptational styles among adult siblings are described and it is suggested that parental trauma intensifies normative process of identity differentiation among siblings. It is posited that the enactment of trauma-related segregated mental contents through intersubjective experiences in the family system mediates intergenerational transmission.
of particular relational models. Relationship rifts and cutoffs between adult siblings are examined as enactments of such implicit relational models that associated with features of intersubjective communication in trauma survivor families. Relational enactments that perpetuate the legacy of loss and of tears in generational continuity in families with parental traumatic histories need to be understood in the context of the disintegrative impact of trauma on individuals, families and larger groups in order to offer meaningful psycho-social interventions. The late phase of life for the survivor parents is a critical time at which early intersubjective relational family experiences are re-activated for adult siblings. This time offers an opportunity for more complex and more adaptive intra-psychic and interpersonal re-integration to be achieved.

MOTIVATIONAL INTERVIEWSING TO IMPROVE PRESCRIPTION OPIOID ADHERENCE AMONG OLDER ADULTS: A FEASIBILITY STUDY
Y. Chang, School of Nursing, The State University of New York, University at Buffalo, Buffalo, New York

Background: Older adults are frequently prescribed opioids for their chronic non-cancer pain. Non-adherence (misuse or abuse) to prescription opioid can have very detrimental effects on older adults’ health. Motivational interviewing (MI) is a low-intensity and short-duration technique. It focuses on increasing insight and awareness regarding unhealthy behaviors, and motivates at-risk individuals to change their behavior. However, its effect on older adults’ prescription opioid use remains unclear. Purpose: This study will determine the feasibility of recruiting and retaining 30 older adults who misuse prescription opioid to participate in a 4-week, individualized MI, and will examine its effect on prescription opioid adherence. Methods: This ongoing study uses a one-group with pre-post design (baseline, post-treatment, 1, 3, and 6-month follow-up). Participants are recruited from a primary care office and a pain management clinic. The MI manual was developed by three mental health professionals and delivered by two trained therapists. Outcome measures include risk for opioid abuse, substance use, and treatment satisfaction. Results: Fifteen participants have enrolled in this study and completed 3-month follow up. The length of the weekly MI ranged from 5 to 15 minutes. Preliminary findings indicated a significant reduction in the risk of opioid abuse and substance use. Participants reported a great level of satisfaction regarding the usefulness of the MI. Conclusions: The MI demonstrates promising outcomes in improving older adults’ prescription opioid adherence. This study is expected to provide data to design and implement future randomized controlled trials to test the effects of MI in the outpatient setting.

RACIAL DIFFERENCES IN SATISFACTION WITH SOCIAL SUPPORT AMONG DISTRESSED RURAL OLDER ADULTS
A.V. Hyams, E. Wayde, M.R. Crowther, F. Scogin, Psychology, The University of Alabama, Tuscaloosa, Alabama

Objectives: A few studies have shown that satisfaction with social support (SS) is associated with better mental health among African Americans. Satisfaction with SS may be more important to African Americans because of their culture of mutual reliance and the central role of extended family and fictive kin. Scant research has examined racial differences. This study explored whether race moderates the relationship between total satisfaction with SS and psychological distress (PD) among older adults. Methods: Data comes from the Project to Enhance Aged Rural Living (PEARL). Subjects aged 65+ (N=94) completed the SCL-90, a self-reported health item, and a 24-item SS measure. Total satisfaction with SS was calculated from all relevant SS items. A multiple regression was conducted, with covariates health, gender, income, and education entered first, race and satisfaction with SS entered second, and the interaction entered third. Results: There was a significant interaction between satisfaction with SS and race, \( R^2 = .23, F (7, 84) = 3.30, p < .05 \). As satisfaction increased for Caucasians, PD decreased, but African Americans’ PD remained fairly constant regard-
threshold for depression; depression ratings were associated with somatic symptoms and functional impairment. Among participants above threshold, only 5.1% had a psychiatric diagnosis and 62.7% had received psychiatric treatment within the year. Logistic regression analyses of predictors of documented diagnoses of depression or psychiatric treatment revealed that somatic symptoms independently predicted diagnosis (B=−13), whereas syndromal depression (B=−12), mental health functional impairment (B=−0.6) and somatic symptoms (B=−0.7) predicted documented treatment. Overall findings indicate high rates of distress and possibly significant under-treatment among Russian immigrant older adults in primary care, and that those most likely to receive treatment manifested a typical pattern of both syndromal depressive symptoms and functional impairment.

SOCIAL ISOLATION, DEPRESSION AND FUNCTIONAL IMPAIRMENT AMONG RUSSIAN IMMIGRANT OLDER ADULTS
D. Bronshteyn, A. Palma, A. Feyder, R. Zweig, Ferkauf Grad Sch of Psychology, Yeshiva University, Bronx, New York

Russian immigrant older adults have significant difficulty dealing with the immigration process and are vulnerable to adjustment difficulty and psychological distress, including social isolation and depression, but little is known about factors related to the variables that may protect against or contribute to adverse outcomes. This study aimed to examine relationships of social isolation and pet ownership to syndromal and somatic expressions of depression and to mental and physical functional impairment. Russian speaking older adults (N = 175) ranging from 65 to 92 years of age (M = 76.3, SD = 5.76) were recruited from several primary care physician offices. Data were collected via self-report measures. Mental and physical functional impairment (SF12v2), social isolation (LSNS-R), and somatic (PHQ-15) and syndromal (PHQ-9) expressions of depression were assessed. Eighteen percent of the sample endorsed experiencing significant social isolation and 33.9% reported syndromal depression. Socially isolated older adults tended to endorse more syndromal (but not somatic) symptoms of depression then those who were less socially isolated. After adjusting for depressive symptoms, social isolation was independently associated with both greater mental and physical functional impairment, while pet ownership did not play a significant role in this relationship. Overall, findings indicate that Russian immigrant older adults experience considerable social isolation and syndromal depression, and that both factors independently predict both mental and physical functional impairment among Russian older adults who present in primary care.

THE ROLE OF RELIGIOSITY IN MENTAL HEALTH SERVICE UTILIZATION: FINDINGS FROM THE COLLABORATIVE PSYCHIATRIC EPIDEMIOLOGY SURVEYS
K. Ford, G. Kim, University of Alabama, Tuscaloosa, Alabama

Objective: Religion and its many facets may act as predisposing factors by influencing mental health status and providing schema for interpreting mental health issues and the appropriateness of seeking MHS. We aimed to examine the role of religious practices and beliefs in determining older adults’ attitudes toward MHS and on their utilization rates. Methods: Drawn from the Collaborative Psychiatric Epidemiology Surveys (CPES, 2001-2003), 2,405 adults aged 18-87 who had needs for MHS over the past year were included in the analyses. We performed logistic and linear regression analyses to evaluate the relationships between participants’ religious service attendance, the amount of embarrassment they would feel if others knew they were using MHS, and past-year MHS use. Results: Results showed that higher frequency of religious service attendance predicted both greater embarrassment about MHS use (β=0.070, p=0.001), and greater likelihood of past-year MHS use (β=0.155, p=0.000). Older age was significantly associated with more positive attitudes toward MHS (β=0.088, p=0.000), and with greater religious involvement (β=0.150, p=0.000). Conclusions: Regular religious service attendance may provide more access to resources and therefore facilitate MHS use, but religiosity is also associated with greater embarrassment about MHS. Our findings suggest that there is a link between using MHS and feeling embarrassed about doing so. Given that older age was associated with both greater religiosity and less embarrassment about using MHS, the closer examination of this population and their experiences with MHS could help us to balance access to resources with positive attitudes toward those resources.

STRUCTURAL PREDICTORS OF INSTRUMENTAL ACTIVITIES OF DAILY LIVING

Even among older adults living in the community, there is considerable variability in the ability to carry out Instrumental Activities of Daily Living (IADLs). IADLs are higher-level activities essential for independent living and include tasks such as shopping, accounting, food preparation, medication management, and technology use. Studies have consistently linked IADL performance with aging-related declines in executive function, in particular attentional and behavioral control processes, as measured by traditional neuropsychological assessments. Additionally, neuroscience has provided evidence that there are gray matter reductions associated with aging in cortical regions that are believed to underlie executive functioning. However, little research has investigated if brain regions implicated in executive function are associated with actual performance-based IADLs. The present study investigates cortical thickness at regions of interest in the purported frontoparietal executive control network as predictors of performance-based functional outcomes thought to depend on executive regulation. The sample consists of 23 community-dwelling older adults (14 men; Mean age=72.39 years, SD=5.05; Mean education: 15.91 years). Preliminary results indicate that after accounting for demographic variables, cortical thickness in six regions of interest (left frontal, left precuneus, left inferior parietal lobule, right dorsolateral prefrontal cortex, right intraparietal sulcus, and right mideagulate) were significantly predictive of performance on the Timed Observed Tasks of Daily Living, F(6, 16) = 3.364, p = .024, R2 = .558. This research provides an important link between neuroscience and everyday functioning. Implications of these findings will be further discussed.

APPLES TO ORANGES: COMPARISONS TYPES AND PERCEIVED HEALTH OUTCOMES AMONG OLDER ADULTS
K.S. Hurley, SPESES, Ball State University, Muncie, Indiana

Most individuals rely on two types of comparisons, social and temporal. Festinger (1954) proposed that humans have an innate drive to evaluate self-abilities and social comparison theory proposes that individuals seek to gain knowledge about their abilities by looking to similar others for comparison. Alternatively, temporal comparison theory (Albert, 1977) posits that individuals compare their current selves to their past selves to determine improvement or decline in abilities. Research has shown that older individuals utilize more temporal comparisons than younger individuals (Brown & Middendorf, 1996; Suls & Mullen, 1982, 1983-84) in response to increased social and physical limitations. These findings raise questions about the potential relationships between self-evaluative comparison approaches and both mental and physical health. Direction of comparisons (upward versus downward) also contribute to perceptions of physical health and abilities among older adults. This study focused specifically on downward temporal and both upward and downward social comparisons because they appear to result in different outcomes for self-perceptions and psychological well-being among older adults. Independent living adults (N = 257) age 65 to 103 years (M = 82.3, SD = 7.8) completed surveys on comparison types and health perceptions. Correlational findings show...
the use of downward social comparisons (e.g., comparison with peers in poorer health) relate more robustly to positive perceptions of both mental and physical health outcomes than temporal comparisons or upward social comparisons. These results highlight the need for further examination of older adult social contexts for understanding differences in perceived quality of life in older age.

A PREVALENCE STUDY OF SUICIDAL IDEATION AND SUICIDE ATTEMPTS AMONG U.S. CHINESE OLDER ADULTS

E. Chang1, R. Chen1, J. Ng1, J. Ruan1, M.A. Simon2, X. Dong1, 1. Rush Institute for Healthy Aging, Rush University Medical Center, Chicago, Illinois; 2. Northwestern University, Chicago, Illinois

Background: Immigrant older adults are at higher risk of suicidal ideation and suicide attempts due to acculturation stress, physical and mental comorbidities, and unmet social support. Prior data suggests Chinese American older adults had highest rate of completed suicides compared to other U.S. ethnic and racial groups. However, the prevalence of suicidal ideation and suicide attempts remains largely unknown among community-dwelling Chinese older adults. Methods: The cross-sectional study sampled a population of 3,018 Chinese older adults in Chicago. The prevalence of suicide ideation was assessed by PHQ and Geriatric Mental State Examination in an in-home interview format. Results: Among surveyed participants (N=3,018), sixty percent were women. Participants’ age ranged from 60 to 105 years old. The mean age was 73 years old. Fifty-six percent of the participants received a high school education. In total, 3.7% of the participants reported suicidal thoughts in the past year. The prevalence of lifetime suicidal thoughts was 9.4%. As for suicide attempts, 0.2% of the participants have attempted suicide in the preceding year, and 0.9% reported lifetime suicide attempts. Overdose, medication and jumping from heights were most commonly reported suicide plans. In addition, 2% of participants reported knowing a friend, family member or spouse who felt suicidal. Conclusion: The findings suggest suicidal ideation and attempts are alarming in this sample. Rigorous research is needed to identify risk and protective factors of suicidal behaviors. Direct suicide prevention strategies with culturally and linguistically sensitive services are in urgent need.

EARLY REHOSPITALIZATION OF OLDER ADULTS ENROLLED IN FLORIDA’S MEDICAID PROGRAM

M.A. Becker, T. Boaz, M. Sosinski, R. Andel, Aging & Mental Health Disparities, University of South Florida, Tampa, Florida

Introduction: Hospital readmission soon after discharge is costly and a burden on patients and their families. Medicare expenditures alone for these unplanned readmissions are estimated at around $15 billion a year. This study examined patterns and risk factors for rehospitalization (within 30 days of discharge from initial hospitalization) among older Medicaid enrolled Floridians. Methods: We used eight years (FY 2003-11) of Florida Medicaid enrollment, HMO behavioral health encounters, and fee-for-service claims data as well as data obtained from the Florida Center for Health Information Inpatient Hospital Database to identify episodes of hospitalization for all Medicaid-enrolled adults. Sample included all adults 65 years of age or older with an inpatient hospital episode for which they had continuous Medicaid enrollment for at least 180 days prior to and following the episode. We estimated the relative risk of early rehospitalization using Cox proportional hazards regression in SAS procedure PHREG. Results: Having major psychotic disorder, bipolar disorder, and major depressive disorder increased the risk of early rehospitalization by 22%, 18%, and 17%, respectively. Having 2 or more physical health comorbidities increase the risk by 28%. Alcohol and substance abuse increased the risk by 13% and 9%, respectively. The risk was 16% higher in men than women, 10% higher in Blacks compared Whites, and slightly lower for Hispanics and other ethnicities compared to Whites. Conclusion: Mental illness, comorbid medical conditions, substance abuse, male gender, and being Black may be important factors to consider when designing interventions to reduce the occurrence of early rehospitilizations.

CHARACTERISTICS AND CORRELATES OF LATE-LIFE HOARDING: EVALUATION OF AN OLDER ADULT NON-Clinical Sample

It remains unclear whether compulsive hoarding (CH) is a symptom sub-group of obsessive-compulsive disorder (OCD) or a disorder importantly different from OCD. Research on CH is particularly pertinent to older adults as this age group appears to be frequently affected by the disorder. The goal of the present study was to evaluate the relationships between measures of CH, OCD, and stressful life events to elucidate differences and similarities between CH and OCD symptoms in older adults. Participants were 97 older adults (age 65+) evaluated longitudinally and who completed assessments of a wide range of psychological, physical, and cognitive measures as part of a larger study. Correlations, regression analysis, and discriminant function analysis (DFA) were used to examine the relationship between CH measures (OCI-R hoarding scale and the SI-R total) and OCD symptom measures, primarily the non-hoarding subscales of the OCI-R. The associations between indicators of a trauma history and CH and OCD symptom measures were examined to determine if a stronger relationship existed between trauma and CH symptoms. CH measures were more strongly correlated with each other than with non-CH OCD symptom measures. However, concerning the relationships between CH, OCD, and traumatic life events, the observed results varied. CH measures did have a stronger relationship with each other than with other OCD measures. However, CH measures were found to have some moderately strong relationships with measures of negative affect, and very little relationship with measures of stress. Limitations to the current study and further directions for research are suggested.

FAITH HELPS ME THROUGH: RELIGIOUS COPING IN DISASTER SURVIVORS IN THE YEARS AFTER THE 2005 HURRICANES KATRINA AND RITA

Y. Lu, T.G. Hatch, L.D. Marks, K.E. Cherry, K.L. Kyotola, T.J. Johnson, E.T. Allen, T. Benedetto, Louisiana State University, Baton Rouge, Louisiana

In 2005, Hurricane Katrina and Rita brought tremendous loss and destruction to the U. S. Gulf Coast. This study examined the role of religious beliefs and practices in coping with Hurricane Katrina and Rita in the years after the deadly storms. In all, 125 adults from two coastal parishes in South Louisiana participated in the study. All participants experienced significant property damage and lengthy storm-related displacement. Two groups were compared: Group 1 were 62 directly affected persons who relocated to new homes in non-coastal communities (M age = 58.4 years, SD = 17.1 years, age range: 18 to 89 years; 21 males, 41 females). Group 2 were 63 directly affected persons who were displaced, and returned to rebuild and restore their lives in their home communities (M age = 60.7 years, SD = 15.0 years, age range: 20 to 83 years; 26 males, 37 females). Participants’ responses to seven open-ended interview questions were transcribed and narrative texts were content analyzed. This study focuses on two questions concerning whether religious beliefs and practices helped them cope with the storms. Qualitative grounded theory methods were employed to analyze these data. Four emergent themes were identified: 1) Loss, frustration, and challenges; 2) Spiritual beliefs: “He [God] takes care of everything;” 3) Religious practices: “I couldn’t do anything…but I could pray;” 4) Faith community: “church—our safe haven.” These data strongly suggest that religious faith is a critical factor in coping with disaster for some people and contributes to post-disaster resilience.
OLDER ADULTS: AN EXPLORATORY STUDY
LIFE ON PSYCHOLOGICAL SYMPTOMS IN RURAL
Implications for practice and policy will be addressed.

ings suggest that these adult survivors displayed good mental health. to the wildfires was not associated with higher levels of depressive symp-
tomatology than those in their seventies who showed less depressive
rily white and married with an average age of 67.5 years. Analyses
on the degree to which age, sex, and severity of wildfire exposure
fluenced long-term mental health as assessed by the CES-D during
the summer of 2012. The participants were 151 community-residing
adults ranging in age from 50 to 94 years who lived in northern San
Diego County during the 2007 wildfires. The participants were prima-
arily white and married with an average age of 67.5 years. Analyses
revealed a main effect between age and depression. Post-hoc compar-
ismons indicated that those in their sixties showed more depressive symp-
tomatology than those in their seventies who showed less depressive
symptomatology than those in their nineties but none of the depression
mean scores for these age groups indicated high levels of depressive
symptoms. Contrary to what might be expected, severity of exposure
to the wildfires was not associated with higher levels of depressive symp-
toms nor was the sex of the participant a significant factor. These find-
ings suggest that these adult survivors displayed good mental health.
Implications for practice and policy will be addressed.

THE EFFECTS OF SOCIAL SUPPORT AND QUALITY OF LIFE ON PSYCHOLOGICAL SYMPTOMS IN RURAL OLDER ADULTS: AN EXPLORATORY STUDY
M.A. LaRocca, F. Scogin, Clinical Psychology, University of Alabama, Tuscaloosa, Alabama

Empirical studies of the psychological well-being of rural older adults are lacking, and the role of social support and quality of life in this population warrants investigation. The current study extended the findings of Scogin et al. (2007) by exploring the role of social support and quality of life in psychological symptoms in rural older adults. One hundred twenty-one predominantly African American participants, characterized primarily as rural, low resource, and physically frail, were administered the Symptoms Checklist-90-Revised (SCL-90-R; Derogatis, Rickels, & Rock, 1976), Quality of Life Inventory (QOLI; Frisch, 1992), and a composite measure of social support consisting of multiple scales. Outcome measures consisted of the SCL-90-R Positive Symptom Total (PST) and Interpersonal Sensitivity (IS) Scale. Regression analysis revealed that age, race, and sex did not significantly predict either PST or IS scores. However, higher quality of life predicted lower PST score (p < .05), and both higher quality of life and greater social support predicted lower IS score (p < .05). These results suggest that efforts to improve both social networks and basic perceptions of subjective well-being may reduce psychological distress and interpersonal discomfort of underserved older adults in rural communities.

EFFECTS OF SOCIOECONOMIC STATUS ON MENTAL HEALTH: MEDIATING EFFECTS OF RETIREMENT PREPARATION
H. Jun1, S. Oh1, S. Kim1, M. Kim2, H. Lee3, 1. Human Ecology, Yonsei University, Seoul, Republic of Korea, 2. Duke University, Durham, North Carolina

South Korea is the fastest aging society in the world. As the older population rapidly grows up, the researchers have begun to emphasize the quality of life of the elderly. The purpose of this study is to examine the effects of the socioeconomic status on mental health of the eld-erly. In addition, we examined the mediating effects of the retirement preparation on the relationship between the socioeconomic status and the mental health. Data extracted from three waves of the Korean Retirement and Income Study 2009 (KReISP03) were used. The final sample was composed of 4,132 cases aged 65 and older. Three variables, socioeconomic status (education level, income level), the retirement preparation, and mental health (life satisfaction, depression) were analyzed. The results were as follows: First, the education level had a significant effect on the life satisfaction and the retirement preparation fully mediated the relationship between the education level and the life satisfaction. Second, the education level did not have any direct effect on the depression of the elderly, but indirectly influenced the depression via retirement preparation. Third, the income level had negative effects on the depression, and the relationship between the income level and the depression was partially mediated by the retirement preparation. Finally, the income level did not have any direct effect on the life satisfaction of the elderly, but indirectly influenced the life satisfaction.

INCORPORATING RELIGION AND SPIRITUALITY INTO A MANUALIZED CBT INTERVENTION FOR ANXIETY WITH NON-MAINSTREAM SPIRITUAL PARTICIPANTS: A CASE STUDY
K. Ramos1,2, T. Barrera1,2, M.A. Stanley1,2, 1. Baylor College of Medicine, Houston, Texas, 2. Michael E. DeBakey Veterans Affairs Medical Center, Houston, Texas, 3. Educational Psychology, University of Houston, Houston, Texas

Generalized anxiety disorder (GAD) is common in older adults, and cognitive behavior therapy (CBT) has demonstrated positive outcomes. Recent approaches have considered the potential benefit of incorporating religion and spirituality into CBT for late-life GAD with positive effects. The current case study examines the flexibility and utility of a manualized CBT treatment when non-traditional religious and spiritual beliefs and practices (i.e., Unitarian Universalism) are incorporated. Although the model for this treatment allows flexibility with regard to religious and/or spiritual beliefs and behaviors, all pilot work to date has been conducted with participants who describe themselves as Christians. Examples of the intervention’s flexibility to include non-mainstream beliefs across the CBT skills learned are highlighted. Additionally, measures relating to anxiety, depression, worry, and well-being were collected across the 12-week CBT intervention and again at 6-month follow-up to examine symptom reduction. Clinical outcome, implications, and future directions are discussed.

SESSION 495 (POSTER)

NUTRITION AND OBESITY

A MULTIFACTORIAL LIFE COURSE PERSPECTIVE ON CHANGE IN BODY MASS INDEX: A LONGITUDINAL STUDY WITH 65 YEARS OF FOLLOW-UP
A.K. Dahl1,2, C.A. Reynolds3, T. Fall4, P.K. Magnusson1, N.L. Pederson1,5, 1. Department of Medical Epidemiology and Biostatistics, Karolinska Institutet, Stockholm, Sweden, 2. School of Health Sciences, Joenkoping University, Joenkoping, Sweden, 3. University of California - Riverside, Riverside, California, 4. Uppsala University, Uppsala, Sweden, 5. University of Southern California, Los Angeles, California

Background: In elderly populations, body mass index (BMI) rather decrease than increase, but the underlying causes are poorly understood. Hence, we aimed to study the influence of multifactorial causes of change in BMI, across the adult life course. Methods: Totally, 6,130 participants from TwinGene, which had up to 12 BMI assessments, and 536 from the Swedish Adoption/Twin Study of Aging, which had up to 12 BMI assessments, ranging over 65 years were included. The influence of lifestyle factors, cardiometabolic diseases, and an individual obesity
Recent analyses have shown that, in contrast to younger adults (<65), overweight older adults (65+) experience somewhat lower mortality risks than their normal weight peers, while obese older adults have only moderately elevated mortality risks (Flegal et al. 2013, Stommel, 2012). One possible explanation is that, among older adults, a substantial proportion gained weight later in life. To test the effect of early versus late weight gain on the mortality risks associated with current BMI levels among older adults, this analysis employed the linked data from the National Health and Nutrition Examination Survey (NHANES III, 1988-1994) and the National Death Index (NDI, 1988-2006). Based on available survey information, respondents were divided into four standard BMI categories and three weight gain categories: (1) stable between age 65 and time of interview, (2) weight gain starting after 25 but earlier than 10 years before the interview, (3) weight gain within the last 10 years of the NHANES interview. The Cox proportional hazard models employ days to mortality as the main outcome and control variables such as sex, age, race/ethnicity, marital status, household income, smoking status, alcohol consumption, leisure time physical activity. The results show that older Americans, who have been overweight and obese since age 25, do face higher mortality risks than normal weight persons (HRs: 1.36, 2.05; p<0.01). For older individuals who gained weight after age 25 or within the last 10 years of the NHANES interview, there are no elevated mortality risks associated with being overweight or obese.

**LONG-TERM OBESITY AND FUNCTIONAL LIMITATIONS IN OLDER AMERICANS**

Background. Many Americans are becoming obese earlier in their lives, increasing the average number of years lived with obesity. Objective. To determine the impact of long-term obesity independent of current body weight for older adults’ functional limitations. Methods. We analyzed adults aged 60-74 from the U.S. 1999-2010 National Health and Nutrition Examination Survey (NHANES). Respondents were considered functionally limited if they reported difficulty or much difficulty with any of the following 6 tasks such as walking one-fourth mile, walking up 10 steps without resting, stooping/crouching/kneeling, or lifting or carrying 10 lb. Logistic regression models predicted the odds any functional limitation (separately for men and women) based on weight at age 25 and current weight. Results. Men and women who were obese in both periods had higher odds of functional limitations (Male OR 2.20, 95% CI 1.34-3.63, Female OR 1.91, 95%CI 1.09-3.34) compared to those currently obese but not obese at age 25. After adjustment for the severity of current obesity, however, the odds of functional limitations associated with current obesity were similar for those who were obese at 25 compared to normal weight at 25 (Male OR 1.40, 95% CI 0.83-2.35, Female OR 0.98, 95% CI 0.66-2.09). Conclusions. The elevated risk of functional limitations associated with longer-term obesity are primarily due to the risk of more severe obesity later in life among those obese earlier in life, rather than the duration of obesity. Current attained weight rather than duration may be the best reflection of current physiological risk.
REDUCING HUNGER AMONG MEXICAN-ORIGIN SENIORS IN TEXAS BORDER COMMUNITIES
J.R. Sharkey1,2, W.R. Dean1,2, M. Gomez1,2, M. Castillo1,2, E. Munguia1,2, J.R. Sharkey1,2, W.R. Dean1,2, M. Gomez1,2, M. Castillo1,2, E. Munguia1,2, J.R. Sharkey1,2, W.R. Dean1,2, M. Gomez1,2, M. Castillo1,2, E. Munguia1,2

Nutrition-related health conditions disproportionately affect disadvantaged seniors that face increased vulnerability to hunger and poor nutritional health. Mexican-origin older adults face physical, economic, and sociocultural contextual challenges to the accessibility, affordability, adequacy, and appropriateness of food resources on multiple levels: individual and community. In February 2012, seniors were recruited for 14 focus groups (FG) in four geographic areas to understand food acquisition and preparation knowledge and skills, and learning styles. All FG guides were written in an iterative process with team promoters and community partners. All FGs were conducted by a highly trained promoter in Spanish and audio-recorded. A six-stage process was used for audio data transcription and translation in to English. All FG data were organized into segments, read through with themes identified and assigned, and sorting and sifting to identify similar phrases, patterns, themes, and common sequences. Seniors described their experiences and beliefs in discussing the following topics: how they get food to eat at home; experiences when they do not have enough money for food; experiences when they do not have enough food to eat; major concerns; decision-making when confronting competing demands for resources; childhood experiences; planning for meal preparation; source of nutrition information; community resources; and community needs. Seniors will be key in identifying issues regarding food acquisition and food preparation knowledge and skills needed to reduce food insecurity. This will be key for increasing the knowledge and skills of Mexican-origin seniors.

SESSION 500 (POSTER)

PHYSICAL HEALTH: ACTIVITY AND FRAILTY

GENDER DIFFERENCES IN TRAJECTORIES OF PHYSICAL ACTIVITY AMONG OLDER ADULTS WITH DIABETES
S.J. McLaughlin1,2, M. Janevic1, C.M. Connell1, 1. University of Michigan School of Public Health, Ann Arbor, Michigan, 2. Miami University, Oxford, Ohio

For many Americans, diabetes and its complications threaten optimal aging. Although physical activity improves diabetes control and may reduce the risk of complications, few older adults with diabetes engage in regular physical activity. The aims of this research are to investigate the trajectory of physical activity across time in older adults with diabetes and to determine if the observed pattern varies by gender. Using data from the Health and Retirement Study, we utilized hierarchical linear modeling to examine the odds of engaging in moderate or vigorous physical activity between 2004 and 2010 among adults age 65 and over who reported having diabetes in 2004 (n=1,894). At baseline, 45% of older adults reported engaging in moderate or vigorous physical activity at least once a week. Compared to 2004, the odds of engaging in this level of activity were 6% lower in 2006, 20% lower in 2008, and 46% lower in 2010. A smaller percentage of women (39.7%) than men (51.9%) reported engaging in moderate or vigorous physical activity at baseline. Although both men and women experienced a decline in physical activity over time, the decline began earlier for women. While findings suggest that both older men and women with diabetes would benefit from efforts to promote and sustain engagement in physical activity, attention should be directed at understanding the factors responsible for the lower prevalence of physical activity among older women as well as their earlier onset of decline.

AGE, SELECTION, OPTIMIZATION, AND COMPENSATION THEORY, AND SKILLED GOLF PERFORMANCE
B. Hayslip, T.A. Petrie, University of North Texas, Dept. of Psychology, UNT, Denton, TX, Texas

While measures of Selection, Optimization, and Compensation (SOC) as they apply to everyday life exist, little is known about the relevance of SOC to golf, wherein despite physical changes, persons may play well into their 80s. Through a variety of compensatory techniques, they may maintain their skills and enjoyment of the game. The present study tested predictions based upon SOC theory specific to golf in two independent samples (n = 1336, n = 208) of golfers competing in the DuPont World Amateur Golf Championship. A 17-item SOC measure assessed a variety of techniques and strategies that one might use to maintain and/or improve one’s golf skills (e.g., playing game improvement clubs, playing shorter courses, taking lessons, practicing, developing course management skills, being positive about one’s skills, learning to relax/controlling one’s emotions during play; alpha = .81). For both samples, contrary to predictions based upon SOC theory, age was negatively, though weakly related to overall SOC scores (p < .01), and more skilled players were more likely to endorse the importance of using such techniques/strategies for them personally (p < .01). Overall SOC scores to an extent predicted tournament performance, and correlated with independent measures of competitive trait anxiety and both general adaptive and golf-specific skill use. Age and/or skill level effects varied considerably when specific domains of SOC were examined. These findings provide mixed support for SOC theory and also suggest that the use of compensatory strategies to maintain one’s golf skills are dependent on the specificity of such strategies.

MEAN BODY WEIGHT PERCENTAGES TO WEIGHT LIFTED BY GENDER AND AGE FOR COMMUNITY-DWELLING SENIOR ADULTS
K.A. Caillouet, L. Cosio-Lima, P. Schuler, C. Nordin, N. Hoskins, University of West Florida, Pensacola, Florida

PURPOSE: Determining safe initial weight lifting loads for adults over 60 years old can be challenging. Recommendations exist in the literature but not all apply to this specific population. The purpose of this study is to provide a guide of initial weight loads lifted relative to mean body weight percentage by gender and age group for older adults. This guide may be used to establish initial weight loads for this population. METHODS: Community-dwelling older adults (n = 165) were divided by gender and into 3 age categories: 60-69, 70-79, and >80 years. Estimates of initial loads representing approximately 75% of subject’s estimated 1-RM were determined for 15 exercises. Exercises performed included leg press, leg extension, leg curl, lower back extension, hip abduction, hip adduction, compound row, latissimus dorsi pull-down, abdominals, calf raises, triceps push-downs, vertical chest press, bicep curls, lateral and front raises. STATISTICAL ANALYSIS: Mean body weights and mean pounds lifted were calculated for each group and exercise. Mean body weight percentage was divided by mean weight lifted to determine percentage for initial load calculation. RESULTS: Initial loads were determined for 15 exercises for each age and gender category to provide estimation for baseline weight loads. These references will be provided in table format upon acceptance of this abstract. CONCLUSION: Providing percentages of mean weights lifted to mean body weight for age and gender groups in older adults may provide fitness specialists a safe and efficient method to determine initial loads for strength-training programs for this population.
DETERMINANTS OF FRAILTY IN OLDER PEOPLE IN THE COMMUNITY

M.V. Duarte, C. Paúl, UNIFAI – Unit of Investigation and Education on Adults and Elders, UNIFAI – Unit of Investigation and Education on Adults and Elders, 032, Porto, Portugal

Frailty is a geriatric syndrome characterized, according to Fried, by a set of factors of biological/physiological nature. The presence of these indicators makes elders vulnerable to incapacity, falls, hospitalization, institutionalization and death. The present study was developed with a representative sample of 335 community dwelling individuals, living in the north of Portugal (mean age 64.4, sd.), 53.4% women., The Frailty Protocol included: sociodemographic factors; frailty assessment, according to the adjusted Fried criteria, comprised three or more of the following components: 1) unintentional weight loss; 2) weakness, 3) self-reported exhaustion, 4) slow walking speed and 5) low physical activity; functionality; Mini Mental State Examination (MMSE); mood (Geriatric Depression Scale) and relationships. The prevalence of phenotypic frailty was 34.9% (118); 172 (50.9%) participants were considered to be in a pre-frailty stage and only 14.2% (48) was non-frail. Frailty is more present in women (40.9%, 95% IC 33.9- 48.1), in more advanced ages (60.4%, 95% IC 46.9-72.4) and in illiterate people (71.1, 95% IC 55.2-83.0). When adjusted to the multidimensional theoretical model, age is considered as predictor factor (2,1, 95% IC 1.0-4.3), as is depressive symptomatology (3,3, 95% IC 1.3-8.1); Social relations appear as a protector for frailty (0.2, 95% IC 0.1-0.5). We concluded that depressive symptoms are a predictive factor for frailty whereas social relations minimize the risk of frailty. Guidelines for intervention in these fields, to prevent the phenotype of frailty are suggested.

MEASURING FRAILTY: PHENOTYPE CRITERIA VS GRONINGEN FRAILTY INDICATOR (GFI)

M.V. Duarte, C. Paúl, UNIFAI – Unit of Investigation and Education on Adults and Elders, UNIFAI – Unit of Investigation and Education on Adults and Elders, 032, Porto, Portugal

The challenge of measuring frailty in elders is still a live discussion among the scientific community. So, there are several measurement instruments born from distinct conceptual paradigms. This becomes relevant in the need to reach a consensus at the instruments level so that empirical works can be credibly comparable. The present study had a non-random sample of convenience, of 100 individuals that use a social response, of day care centre type in the north region of Portugal. The assessment protocol contemplated 5 criteria of phenotypic frailty (PF) by Fried (unintentional weight loss; weakness, self-reported exhaustion, slow walking speed and low physical activity), as well as a multidimensional measurement - Groningen Frailty Indicator (GFI). The results show a phenotypic frailty (PF) of 57% and a GFI frailty of 55%. As for gender distribution, women are more frail (61,4%) considering the two measurement measures. As for the analysed age groups we can see that in both ways of assessment older people (more 75 years) are more frail (FF= 57%; GFI= 59,7%). The distinction between these two measures is seen in the identification of frailty in younger age stages (50-64 years) in which the PF doesn’t have anyone identified and the GFI shows that 40% of these people are frail. We conclude that both measures reflect the same impact of frailty in elders, nevertheless when the concept is opened to a vision that includes psychosocial indicators; it seems that it is detected in younger ages.

THINKING YOU’RE OLD AND FRAIL: A QUALITATIVE STUDY OF OLDER ADULTS’ BELIEFS REGARDING FRAILTY

K. Warnoth1, M. Tarrant1, I. Lang2, C. Abraham1. 1. University of Exeter Medical School, Exeter, United Kingdom, 2. NHS Devon, Exeter, United Kingdom

Objectives: A qualitative study was conducted because the psychological correlates of becoming frail are largely unexplored. The present study explored older adults’ attitudes towards and experiences of aging and frailty, and how these can influence health and well-being. Methods: Open purposive sampling was conducted by recruiting individuals through different organizations. Twenty-nine residents in South West England, aged over 65, who varied on a frailty index, were asked about experiences of aging and frailty in semi-structured interviews. Transcripts of the interviews were coded and analyzed using Grounded Theory and Thematic approaches to systematically extract recurring accounts and identify common constructs and themes in participants’ responses. This combination allowed detailed, response-driven extraction of participants’ comments as well as facilitating a theory-informed approach to identify important assertions and themes. Results: Identifying as a frail old person was felt by participants to be related to health and participation in an active life. The respondents discussed how feedback from others and comparisons with other older adults informed their self-perceptions and attitudes about old age and frailty. Specifically, being categorized as old and frail was felt to encourage attitudinal and behavioral confirmation of that identity, including a loss of interest in participating in social and physical activities, poor health, stigmatization, and reduced quality of life. Discussion: This qualitative study gives insight into the role of social psychological factors in older adults’ health and activity. The effects of self-perceptions and identification should be considered in further research and health services for older adults.

ENHANCEMOBILITY: A STRUCTURED GROUP EXERCISE PROGRAM FOR INDIVIDUALS WITH COGNITIVE IMPAIRMENT

Background: Exercise and physical activity have been shown to improve strength and mobility, reduce depression, and decrease behavioral disturbances in older adults with cognitive impairment. With progressive cognitive decline, however, such programs are challenging due to reluctance to participate, difficulty learning and remembering to do exercises, safety concerns, and lack of exercise expertise in dementia care providers. EnhanceMobility (EM) is an individualized, small-group exercise program that was designed to overcome these challenges. Methods: Thirty-one residents of four dementia care facilities participated in the study. The activity directors and 2 other staff members from each facility were trained to conduct the EM groups. Resident assessments were conducted at baseline and after 4 months. A single group, pre-post analysis of outcomes, using T-tests and Chi Square analyses evaluated statistical significance of changes. Results: As expected, cognitive functioning declined, with an average 1.88 point decline on the MMSE (p<.01) over 4 months. Despite cognitive decline, functional mobility improved significantly, with a 2.28 improvement on the Physical Functioning Scale (p<.05). Participants also exhibited significantly fewer behavior problems following EM on the RMBPC (<.001), including fewer depressive behaviors (p<.01). Despite improvement in functional mobility and behavioral disturbance, gait speed, Berg Balance Scale and Short Physical Performance Battery showed no change from baseline to 4-month follow up. Conclusions: Results of this investigation contribute to the development of an evidence-based group exercise program for individuals with dementia. Such a program may improve quality of life and reduce costs of care by maintaining mobility and improving behavior and mood.

SEDENTARY TIME IS ASSOCIATED WITH MARKERS OF UNHEALTHY DIET IN OLDER ADULTS

D.E. Rosenberg, N. Gell, D. Arterburn, Group Health Research Institute, Seattle, Washington

Background: Sedentary time (ST) is independently associated with several chronic conditions and mortality. There is evidence that sedentary activities promote increased snacking and macronutrient consumption which partially explains such relationships. Research has not
examined the relationship between diet and ST in older adults. Methods: We used health risk assessment data from 21,759 Medicare beneficiaries (Mean age = 73, 47% male, Mean BMI = 28.1). Self-reported ST was measured with the International Physical Activity Questionnaire and diet quality items (satisfaction with eating habits, daily servings of dairy, high fat food consumption). Charlson comorbidity scores and body mass index (BMI) were extracted from electronic health records. One-way ANCOVA adjusting for age, sex, BMI, and comorbidity were conducted. Results: There was a graded increase in ST among those eating high fat foods: < once/week (291 min), several times/week (310 min), once/day (318 min), and several times/day (344 min) (all p’s < .001). People with no servings of dairy had higher ST (342 min) than those with 1 (312 min), 2 (298 min), 3 (300 min), or 4+ (312 min) servings per day (p’s < .001). People with no interest in changing their diet had higher ST (348 min) than those actively changing their diet (301 min) or who are satisfied with their eating habits (300 min) (p’s < .001). Conclusions: We find preliminary evidence among older adults that poorer diet quality is associated with more ST. Since older adults have high ST, further investigation on relationships between ST, diet, and health outcomes is warranted.

MEDICINE BALL STRENGTH TRAINING FOR SENIOR ADULTS IN RURAL COMMUNITY SETTINGS

L. Traywick, L. Washburn, J. Vincent, L. Copeland, T. Woodson, University of Arkansas Division of Agriculture, Cooperative Extension Service, Little Rock, AR, Arkansas

Despite evidence for the positive health effects of regular physical activity, older adults are the least active group of Americans. Only 13% of older adults report regular strengthening activities. New strategies are needed to increase access to strength training programs for older adults. The use of medicine balls provides a novel approach to involve senior adults in community-based strength training programs. This session will show evidence of effectiveness of a medicine ball strengthening routine conducted in community settings in the rural Arkansas Delta region with older adults. Preliminary results from the Senior Fitness Test (n=53) show 83% of participants increased upper body strength; 75% improved lower body strength; 55% increased upper body flexibility; 58% increased lower body flexibility; 70% improved agility and dynamic balance; and 81% improved aerobic endurance. The Self-Efficacy for Exercise scale showed self-efficacy among participants increased 41% from pre- to post-test in this 12-week program. This approach can be replicated in other community settings.

AGE DIFFERENCES IN THE RELATIONSHIP BETWEEN NAPPING AND SLEEP OUTCOMES

Introduction: Napping may be associated with positive or negative outcomes depending on individual circumstances. Accordingly, the relationship between napping and sleep has proven complex. This study explored the association between napping and sleep in older and younger adults by examining both the day-to-day and overall associations between these variables. Methods: 50 younger (M=19.88, SD=2.76) and 50 older (M=67.81, SD=6.73) adults completed 14-consecutive-day sleep diaries. Sleep variables included number of nighttime awakenings (NWAK), sleep quality rating (SQR), and total time in bed (TIB). Napping variables included mean and daily nap duration, nap number, and time of day naps occurred. Multilevel modeling analyses were used to predict sleep outcomes from daily and overall nap variables. Results: For NWAK and SQR, there was a significant interaction between age group and daily time of day nap occurred, β=−0.52, p<0.01 and β=−0.35, p<0.02, respectively. Evening naps were associated with fewer nighttime awakenings and higher sleep quality ratings in older adults. The opposite pattern was found for younger adults. A significant interaction between daily nap duration and age group, β=0.70, p<0.05, revealed that for older adults, longer daily nap duration was associated with more time spent in bed. For younger adults, longer daily nap duration was associated with less time spent in bed. Conclusions: Daily napping was predictive of sleep outcomes while overall napping was not. As these results show, associations may be masked when only mean values are considered in analyses. Several age differences were found between napping and sleep outcomes. Implications and future research directions will be discussed.

IMPROVING OPTIMAL AGING WITH PHYSICAL ACTIVITY: CHALLENGES IN QUANTIFYING PHYSICAL ACTIVITY WITH TRI-AXIAL ACCELEROMETERS IN A RANDOMIZED CONTROLLED CLINICAL TRIAL FOR OLDER WOMEN

L.L. Leefler1, S.Y. Lensing1, K.K. Gamer1, J. McSweeney1, 1. College of Nursing, University of Arkansas for Medical Sciences, Little Rock, Arkansas, 2. Central Arkansas Veterans Healthcare System, North Little Rock, Arkansas

Purpose: Physically active older women enjoy greater quality and quantity of life, yet their engagement in physical activity is objectively reported at 2%. Quantifying activity is very challenging in older women because of lower rates and speed of movement. Using sensitive tri-axial accelerometers, we discuss modifying thresholds, cut points, and wear-time validation parameters to accurately analyze the activity of older women. Methods: Currently, 22 women > 60 years old were recruited to participate in a RCT of an intervention to increase physical activity. Metabolic Equivalent Tasks (METs), activity minutes, activity bouts, and intensity were measured using standard and our derived age-modified settings. Results: Average wear-time was significantly higher for modified 52% (SD 12) vs. 21% (SD 19) than for standard settings. Nine women (41%) did not meet criteria for usable data (>3 days of 10-hours) using standard settings, reducing the analytic sample to 13; whereas, all women were evaluable with modified settings. Findings of our modified settings were confirmed with individual graph analyses of data. We found significantly lower METS [M (SD)] 1.09 (0.06) vs. 1.12 (0.10) and higher sedentary minutes per day, 674 (114) vs. 473 (66) for the modified vs. standard settings. There were trends for lower average kilocalories per day, higher number of bouts in moderate activity, and minutes/day in light activity for modified settings vs. standard. Conclusions: Findings indicate standard accelerometers settings may not be sensitive enough to accurately detect physical activity of older women. It is critical that standard formulas be modified for typical movement of older adults.

SESSION 505 (POSTER)

DEMENTIA-DELIRIUM

PRESSURE ULCER STAGE AND PAIN IN NURSING HOME RESIDENTS WITH DEMENTIA

There are 1.4 million nursing home (NH) residents in the United States and approximately 24% have pressure ulcers. Pressure ulcers are known to be associated with pain, but pain severity associated with each stage of pressure ulcers is not fully understood. Further, no studies have quantitatively evaluated pressure-ulcer related pain in NH residents with dementia. The purpose of this study was to examine the relationship between pressure ulcer stage and pain severity in NH residents with dementia stratified by three levels of cognitive impairment. Minimum Data Set (MDS) assessments from Florida NH residents (N = 56,577) were used to address this question. Participants had a mean age of 84 years (SD = ± 7 years), and the majority were female (67.7%). Based on MDS-Cognitive Performance Scale ratings, NH residents were categorized into mild, moderate, or severe cognitive impairment groups.

The Gerontological Society of America
For all groups, about 20% had pressure ulcers and 25 – 50% had pain. Across all levels of cognition, those with pressure ulcers were significantly more likely to have severe pain than those without pressure ulcers. NH residents with severe cognitive impairment were rated by staff as having more severe pain compared to residents with mild or moderate cognitive impairment, across all stages of pressure ulcers. Health care providers should carefully assess and manage pain in this highly vulnerable population, especially before and after pressure ulcer treatments.

IMPLEMENTING THE HOSPITAL ELDER LIFE PROGRAM IN A REHABILITATION SETTING – CHALLENGES AND LESSONS LEARNED

N. Pearce\(^1,2\), S. Edgar\(^2\), C. Bradfield\(^2\), M. Krueger\(^1\), 1. Grand River Hospital, Waterloo, Ontario, Canada, 2. University of Waterloo, Waterloo, Ontario, Canada

Introduction: The Hospital Elder Life Program (HELP) is a well-recognized intervention shown to prevent delirium and decline in hospitalized older adults. To date, HELP has been implemented and evaluated in acute care settings only. In this study, HELP was implemented on a 32-bed geriatric rehabilitation unit. Objectives: To evaluate the implementation of HELP in a rehabilitation setting. Method: Prior to implementation, the HELP team reviewed the standard HELP protocol with clinicians on the rehabilitation unit. Minor changes to the protocol were identified as necessary in this setting (e.g., modifying the feeding assistance protocol for congregate dining). During the first month of implementation, the HELP team met weekly to discuss challenges encountered and, based on feedback from patients and the multidisciplinary team, further adjust the protocol to fit within a rehabilitation setting. Results: Some adjustments to the protocol have been required. For instance, patients have not tolerated the standard timing of interventions. The team had been trialing two interventions from 1000 to 1300 and 1600 to 1900. Initial feedback suggests that this change is less fatiguing for patients who are also receiving therapy. Preliminary qualitative results indicate that the program is well received and seen to be of benefit by patients, families, and health care personnel. Conclusions: With minor changes to the standard protocol the HELP program can be successfully implemented into a rehabilitation setting. Further research is needed to determine the effectiveness of the modified program in preventing delirium and reducing functional and cognitive decline in older rehabilitation patients.

ASSESSING COMPETENCY OF PROVIDERS IN A LONG-TERM ACUTE CARE HOSPITAL TO EVALUATE DELIRIUM

R.P. Lopez\(^2\), H.H. O’Connor\(^2\), J.W. Devlin\(^2\), A. White\(^1\), A.J. Guarino\(^1\), 1. MGH Institute of Health Professions, Boston, Massachusetts, 2. New England Sinai Hospital, Stoughton, Massachusetts, 3. Northeastern University, Boston, Massachusetts

There is a paucity of research on competencies of healthcare providers in long-term acute-care hospitals (LTACH) to care for patients with delirium. We used a survey to collect demographic variables, level of training with delirium, frequency in dealing with delirium, and methods of assessing delirium. Delirium knowledge was assessed with a ten-item true/false examination (Cronbach’s alpha .90). Fifty-six surveys were returned. Respondents were mostly female (86.8%) representing 55% (n = 31) reported routinely evaluating for delirium. The majority (55%, n = 31) reported evaluating for delirium and reducing functional and cognitive decline in older adults with dementia, can be vital partners in identifying delirium. The aims of this study were to describe what family caregivers know about delirium and their preferred ways to receive information. Learning what family caregivers know about delirium and preferred ways of receiving information is foundational to designing effective educational interventions and improving health outcomes for older adults with DSD. Method: A cross-sectional design was used and a survey on delirium knowledge was mailed to a sample of 400 family caregivers residing in 26 residential zip codes areas in a Midwest City. The sample was systematically selected from the local Alzheimer’s Association’s list of family caregivers. Results: To date, 72 surveys were returned. Respondents mean age was 62.38 years; 76.4% were White and 79.2% were female. Approximately half of the respondents (52.1%) thought they knew what delirium was, however their recognition of symptoms was incongruent with their reported knowledge and 77.1% desired information about delirium. The most preferred ways of receiving information were via newsletter, in person class and Internet. Conclusions: The findings indicate that family caregivers for older adults with dementia need and desire information about delirium.

VALIDITY AND RELIABILITY OF CLOCK DRAWING TEST FOR ALZHEIMER DEMENTIA USING THE NEW NIA CRITERIA

R. Raju Paul, L.E. Drake, M.A. Nair, K. Kan, J. Rosenbaum, S. Chandrashekar, F. Feijo, A.K. Nair, The Alzheimer Center TheAlzCenter.org, Quincy, Massachusetts

Background: The Clock Drawing test (CDT) is widely used in clinical screening for cognitive impairment. We assessed the accuracy and reliability of Montreal Cognitive Assessment (MOCA) method of scoring CDT to differentiate Alzheimer Dementia as defined by the new NIA criteria (NIA AD) and other subjects attending a memory clinic. Methodology: Cross sectional data of 152 outpatients attending TheAlzCenter.org from January to December 2012 were assessed. Sensitivity, specificity, ROC curves and Cronbach’s Alpha were calculated for cutoff points of 0, 1, 2 and 3 for the MOCA method of scoring CDT. Results: 118 NIA AD patients and 34 NIA AD negatives (29 MCI, 5 memory complaints) were studied. Mean age was 78.5±9.6 (AD 80.3±8.4, MCI 72.2±10.9, p<0.01); 56% were female; 94.7% were white. Mean education was 12 in all groups studied. Mean MoCA CDT score was 1.59±1.03 (AD 1.45±0.99, MCI 2.06±1.04, p<0.01). Using MOCA CDT scoring alone to discriminate diagnostic groups, optimal cutoff point was 2 (83% sensitivity, 44% specificity). Area under the curve by ROC analysis was 0.67 (95% confidence interval 0.77-0.56). Assuming a pretest probability of 0.5, positive predictive value was 2.08, and negative predictive value was −1.16. The MoCA scale was reliable in our
DIFFERENTIAL EFFECTS OF HORMONE THERAPY TYPE AND USE ON COGNITION IN WOMEN AT RISK FOR DEMENTIA

T.E. Woolie, H. Kenna, K. Williams, N. Rasgon, Psychiatry & Behavioral Sciences, Stanford University School of Medicine, Stanford, California

Objective: To evaluate differential cognitive effects of hormone therapy (HT) use and type [17-β estradiol-based (17βE) versus conjugated equine estrogen (CEE)] in postmenopausal women aged 50-65 years at risk for dementia. Method: Women with risk factors for dementia currently on any type of hormone therapy (HT) were recruited from the community. Neuropsychological data was collected at baseline and 2 years after randomization to either continue (HT+, N=28) or discontinue (HT-, N=17) HT use. Results: Women who remained on HT improved in variables of attention and naming whereas women who discontinued HT did not significantly change over time. The significant improvement in naming was driven by women who remained on 17βE; no within group change in naming was seen in women who remained on CEE. The improvement in attention in the HT+ group was not due to specific within group change for either HT type. Both HT+ and HT- groups significantly improved on phonemic (letter) fluency. In the HT+ group, the improvement in phonemic fluency was driven by within group changes for women who remained on CEE; no significant changes were seen on this variable for women who remained on 17βE. No within group differences were seen on phonemic fluency in the HT- group. Cognitive flexibility was improved in both groups who discontinued HT. However, women who discontinued CEE showed a significantly greater improvement compared to women who discontinued 17βE. Conclusion: The differential cognitive effects of hormone use and type may inform treatment protocols for women at risk for dementia.

THE LEVEL AND INFLUENCING FACTORS OF COST OF DEMENTIA IN BEIJING, CHINA

Z. Wang, X. Li, School of Nursing, Peking University, Beijing, China

Objective: With the rapid aging of population, dementia has brought great economic burden on the society. Estimation of costs of dementia can provide basis for rational integration and allocation of social resources. This study aims to investigate the level and influencing factors of cost of dementia in community-dwelling and institutional dementia patients. Methods: Data on the monthly direct and indirect costs of each dementia patient and their caregivers was collected from 87 community-dwelling dementia patients and 75 institutional dementia patients in Beijing, China. The severity of dementia was rated by Global Deterioration Scale (GDS); patients’ ability of daily living was rated by Activity of Daily Living Scale (ADL); behavioral problems were rated by Cohen-Mansfield Agitation Inventory (CMAI). Results: The average total costs per patient per month in the community group were higher than that of the institutional group (969.67 USD versus 857.33 USD, P<0.01). The informal care costs in the community group accounted for 44.6% in the total costs (432.41 USD per patient per month). Regression analysis revealed that complicated by chronic diseases (β=0.281), severity of dementia (β=0.235), agitated behaviors (β=0.227), living at their own homes (β=0.196) were influencing factors of the total costs (R2=0.367, P<0.001). Conclusion: The total costs, especially informal care costs, are higher in community-dwelling dementia patients. The severity of dementia, complicated by chronic diseases, behavioral problems can predict the total costs. The family resources and institutional resources should be integrated based on the severity of dementia and the caring ability of families. [Key Words] Dementia; Costs; Community; Nursing Homes; Influencing factors

DEMENTIA INCIDENCE AND DEMENTIA FREE-LIFE EXPECTANCY IN THE ADULT CHANGES IN THOUGHT STUDY

Background Dementia and Alzheimer Disease (AD) incidence patterns for age ≥ 85 years are unclear. Dementia-free life expectancy calculations have primarily used cross-sectional data. Using a cohort with a substantial number of subjects over 85 years of age, we estimate dementia and AD incidence and dementia-free life expectancy. Method: Using data from the Adult Changes in Thought Study, a population-based cohort of 3605 adults age ≥ 65 years enrolled from 1994-2010 and followed longitudinally, we estimate dementia and AD incidence. We use a three state piecewise homogeneous Markov model to estimate life expectancy and dementia-free life expectancy. Results: Dementia incidence increases through ages 85 – 89 years (74.2 cases per 1000 person-years) and continues for those ≥ 90 years (105 cases per 1000 person-years), with a similar trend for AD. For individuals dementia-free at age 70, dementia-free life expectancy is 84.3 years for men and 85.7 years for women, representing 98.1% of total life expectancy for men and 97.5% for women. On average from ages 70 – 90 years, women can expect to live approximately 1 dementia-free year longer than men of the same age. Those who completed college or more education live approximately 0.5 years longer dementia-free than those with less education. Percentage of life expectancy free of dementia is similar across educational attainment categories. Conclusions: Dementia and AD incidence increase with age. Women and those with higher education have small dementia-free life expectancy advantages.

FOSTERING AUTONOMY THROUGH A COMBINED TRAINING AND SUPPORT PROGRAM IN PATIENT/CAREGIVER DYADS IN MILD TO MODERATE DEMENTIA (DYADEM)

Initial diagnosis of dementia means mostly a severe shock for both patient and partner. Many couples who have to deal for the first time with this subject are asking questions about how to manage the increasing memory loss, loss of independence or how to remain always calm and understanding. But often couples remember other crises they were mastering together and have the wish to accomplish the new challenges together. Previous Interventions usually focussed on either caregiver counselling or patient support/training. Few interventions have specifically targeted interpersonal resources. We offer a socio- and psychotherapeutic support program in a population of community dwelling older adults suffering from mild to moderate dementia and their partners, which is designed to strengthen personal and dyadic coping abilities. The key aim is to help couples to master everyday problems that are connected with the disease and thereby to delay nursing home placement. The study wants to answer the question whether an early intervention in the form of combined training and support for dementia patients and their partners is more effective than standard counselling offers. Participating patient/partner dyads are seen in their own homes for 7 sessions supplemented by 2 telephone sessions. The program contains information about the disease and support facilities, as well as communication training, problem solving, stress management, encouragement of ADL skills etc. Goal criteria such as QoL, autonomy, neuropsychiatric symptoms of dementia, relations quality etc. are assessed before and 4 weeks/ 6 months after the intervention. First study results are presented.
INSTITUTIONALIZATION OF PEOPLE WITH DEMENTIA: CAREGIVER REASONS AND THE SITUATION BEFORE ADMISSION

B. Afram, H. Verbeek, M.H. Bleijlevens, J.P. Hamers, R. Consortium, Maastricht University, Maastricht, Netherlands

Objective: To investigate whether reasons for admission of people with dementia (PwD) to long-term care facilities according to informal caregivers correspond with characteristics prior to admission. Methods: Data were collected at baseline (PwD lived at home) and three months later at follow-up (PwD were institutionalized) in eight European countries. Characteristics prior to admission were assessed at baseline using standardized questionnaires. Reasons for admission were assessed via open-ended questions at follow-up. Bivariate associations were calculated between caregivers’ reasons for admission and scores on corresponding measurement-instruments. Results: Caregivers’ reasons for admission of 113 PwD (39% male; mean age: 83.3 years) were analysed. Both patient-related (e.g. neuropsychiatric symptoms, cognition, care dependency) and caregiver-related reasons (e.g. caregiver burden) were reported. In cases where caregivers reported neuropsychiatric symptoms as a reason for admission, significantly higher scores were found on the corresponding scale compared to cases not reporting neuropsychiatric symptoms (p<0.001). Caregivers mentioning burden scored significantly higher on certain burden (sub-)scales (p<0.01) and average time spent on IADL-care and supervision (p<0.001). Interestingly, in cases where caregivers reported cognition as a reason, PwD scored significantly better on the cognition-scale compared with PwD of caregivers who did not state cognition (p<0.05). No significant differences were found on other (sub-)scales. Conclusion: There is some discrepancy between caregivers’ statements and the pre-admission assessments (standardized questionnaires). The reason for this discrepancy remains unclear. Future studies should investigate whether informal caregivers view or experience the pre-admission situation differently or whether the measures used to determine the pre-admission situation need improvement.

IMPAIRED MOTIVATION CONTRIBUTES TO APATHY IN BEHAVIORAL VARIANT FRONTOTEMPORAL DEGENERATION

Background- The syndrome of apathy, defined as a reduction in self-generated or voluntary behavior, is caused in part by disruption of the frontal-striatal system. Reduced motivation, a common finding in behavioral variant Frontotemporal Degeneration (bvFTD), has been strongly associated with apathy. bvFTD patients have decreased reactivity to both positive (reward) and negative (punishment) signals thereby making goal selection, which is critical to motivation, more difficult. Evidence from healthy subject MRI studies suggests that the ventral medial prefrontal cortex (vmPFC) is important for determining information regarding interpretation of reward and punishment. Aim- To investigate the neural basis of impaired motivation in apathetic persons with bvFTD. Methods- We assessed participants with mild bvFTD (mean MMSE=27.3; n=20) judged apathetic by caregiver report and graphically-matched controls (NC; mean MMSE=29.40; n=15). To quantify apathy objectively, we measured reaction time (RT) to press a button in response to a simple visual stimulus presented on a computer screen (48 trials). To assess motivation, we offered an explicit monetary incentive for responding rapidly (motivation RT), using a point system. Motivation RT was then related to gray matter atrophy using voxel-based morphometry. Results- bvFTD participants were slower on the simple task (bvFTD=946.60ms; NC=582.07ms; p=0.005) and the motivation task (bvFTD=933.32ms; NC=525.05ms; p=0.038). Poor motivation in apathetic bvFTD participants was related to atrophy in the vmPFC and anterior cingulate. Conclusions- Apathetic bvFTD patients have profound difficulty with motivation that contributes to apathy. These findings are related to atrophy in the frontal regions important for reward processing.

PRODUCTIVITY LOSSES DUE TO ALZHEIMER’S DISEASE DEATHS AMONG ADULTS AGED 40-64 YEARS, 1999-2008

K. Moschetti1, N. Barragan2, R. Basurto-Davila3, P.L. Cummings2, F. Sorvillo1,2, T. Kuo2,4, J. Michigan State University, East Lansing, Michigan, 2. Los Angeles County Department of Public Health, Los Angeles, California, 3. UCLA Fielding School of Public Health, Los Angeles, California, 4. David Geffen School of Medicine at UCLA, Los Angeles, California

Background: Although Alzheimer’s disease (AD) most commonly affects adults aged 65 years and older, the prevalence of this disease in younger cohorts is not rare. To date few studies have quantified the burden of AD (mortality and lost productivity) among adults aged 40-64 years. To address this gap in the literature, we examined mortality and lost productivity trends for this age group in the United States, using 1999-2008 U.S. multiple-cause-of-death data. Methods: Number of cases; crude, age-specific, and age-adjusted mortality rates; and AD-related productivity losses were estimated. The disease burden was compared to those of other chronic conditions. Results: From 1999-2008, a total of 7,039 AD-related deaths were identified for the 40-64 age group in the United States. The age-adjusted mortality rate remained relatively static: 0.75 per 100,000 population in 1999 (95% CI: 0.69-0.80) to 0.71 per 100,000 population in 2008 (95% CI: 0.66-0.76). Total productivity losses due to premature death from AD totaled nearly $3.7 billion. Average productivity losses per AD death for the 40-64 age group totaled $522,681, which was nearly 71% of the average productivity loss per death for heart disease ($738,429) and 87% of the average productivity loss per death for prostate cancer ($598,969). Conclusion: Productivity losses and AD-related deaths in the 40-64 age group was not trivial during 1999-2008. Study findings may have policy implications with respect to social services allocation, healthcare planning, caregiving, and end-of-life care for this younger cohort.

A DIMENSIONAL ANALYSIS OF THE CONCEPT OF SUFFERING IN PEOPLE WITH DEMENTIA AT END-OF-LIFE

L. Smith, College of Nursing, Medical University of SC, Vale, North Carolina

Suffering is difficult to assess but particularly so in people with dementia who do not use language purposefully. Hospice and palliative care are frequently withheld from dementia patients until end of life is near. While it is assumed that people with dementia do suffer in the late stages of their disease, this assumption is not clear in the literature. Therefore, the research questions proposed for this analysis include: 1) What are the dimensions of the concept of suffering? and 2) How will knowing the relationships between the dimensions and qualities of the concept ‘suffering’ ensure widespread understanding and applicability in research and practice of suffering in individuals with dementia at end of life? The aims of this paper are to analyze dimensions of the concept of suffering in individuals with dementia at end of life and to establish relationships between these dimensions to improve care at end of life for this population. Caron and Bowers’ method of dimensional analysis as well as the symbolic interactionism theory guided this analysis. Fourteen studies were selected from databases and included in the analysis. The analysis identified four dimensions of suffering (pain, holistic, discomfort, and despair) and two subdimensions (symptoms and communication) and significant meanings and relationships were found among the dimensions. However, these dimensions are not well explored in the literature, hence the need for further research in this area as well as care that is focused on relieving suffering and providing comfort at end of life in individuals with dementia.
THE KOORI GROWING OLD WELL STUDY: HEALTH, AGEING, AND DEMENTIA IN URBAN ABORIGINAL AUSTRALIANS
H.A. Mack1, K. Radford1, S. Chalkley2, B. Draper1, R.G. Cunning1, H. Bennett1, G.A. Brod1,1, 1. Neuroscience Research Australia, Sydney, New South Wales, Australia, 2. Prince of Wales Hospital, Sydney, New South Wales, Australia, 3. School of Medical Sciences, University of New South Wales, Sydney, New South Wales, Australia, 4. Psychiatry, University of New South Wales, Sydney, New South Wales, Australia, 5. Geriatric Medicine, University of New South Wales, Sydney, New South Wales, Australia, 6. School of Public Health, University of Sydney, Sydney, New South Wales, Australia

Objective: The health gap between Aboriginal Australians and the general population has been described as the poorest of Indigenous populations in Western nations. The number of older Aboriginal Australians is increasing rapidly, but not much is known about dementia in this population. This study aimed to determine the prevalence and associations of dementia, along with valid screening tests, in a NSW urban/rural Aboriginal population. Methods: A community census was undertaken of all Aboriginal people aged 60 years and over living in our five partner communities (N=555); followed by a comprehensive survey on health, cognitive function, and life history of participants (N=336 (61%); median age=66 years). Participants scoring below designated cut-offs on three cognitive screening tests and a 20% random sample of those scoring in the normal range, also completed a medical assessment (blind to screening scores), which was the “gold standard” basis for clinical consensus determinations of dementia. Results: The prevalence of dementia was 13.4% (95% CI=10.2-17.5%) with Alzheimer’s dementia the most common (56% of cases), then vascular dementia (23%) and dementia from head trauma (12%). Standardised screenings or a culturally specific tool performed similarly. Associated factors of dementia were investigated including: age, education, stroke, head injury, smoking and alcohol. Conclusions: Dementia prevalence is substantially higher in Aboriginal Australians compared to the general Australian population and many other nations or ethnic groups. There is an immediate need for provision of dementia education and services, as well as a move towards promoting successful ageing, from childhood onwards in this “at risk” population.

EFFICIENT COGNITIVE TESTS Determine TRAJECTORY IN MCI PATIENTS

A Mild Cognitive Impairment study was completed at a clinic where 130 patients were initially enrolled, 78 patients returned for follow-up appointments at 12 months, and 52 patients returned at 24 months after initial intake appointment. A chart review determined if the patients were improving, declining, or there was no change in their status from intake. The change in average scale score for the memory impairment tests and individual cognitive test scores over time was highly related to the classification of patients across the appointments based on repeated measures ANOVA. For the improve group, there were significant increases in the Logical Memory delayed recall (p=0.0042) and Auditory Visual Learning 30min. delayed scores (p=0.0001). Conversely, the Boston Naming Test (BNT) and CLOX2 scores were more indicative of the deteriorating status of the decline group. The CLOX2 scores significantly decreased from intake (p=0.0108) and the BNT scores had a decreasing trend (p=0.0932) for the decline group. Depression was also a contributing factor for declining patients. The non-depressed group had significantly higher BNT at 12 months (p=0.021) and at 24 months (p=0.0205). The BNT scores for the depressed group at 12 months are significantly lower than the scores at intake (p=0.0071) and at 24 months (p=0.02125). This descriptive correlational study confirmed that a limited cognitive battery performed in an outpatient clinic setting can efficiently predict patients who will decline or improve, or will not change. Treatment modalities can be designed based on efficient cognitive testing.

CAREGIVER ACTIVATION FOR DEMENTIA INTERVENTIONS QUESTIONNAIRE: CADI-Q
T. Sadak1, C. Beck2, S. Borson1, 1. University of Washington, Seattle, Washington, 2. University of Arkansas for Medical Sciences, Little Rock, Arkansas

Family caregivers assume increasingly complex roles as they help dementia patients with daily medical and nursing tasks. Clinicians have no formal method or validated tools for assessing and tracking caregiver activation—a process by which caregivers become ready, and then progressively assume, these evolving roles. The goal of this study was to design such an instrument. CADI-Q draws on concepts related to patient activation, and was developed first through qualitative cognitive interviews with 16 expert clinicians representing 6 clinical disciplines, and then with 38 caregivers (mean age 63; 64% women, most Caucasian, caring for patients with moderate to severe dementia). 85% of caregivers described their caregiving stress as moderate to high. Qualitative data were collated to create the final CADI-Q, a 10 item caregiver self-report measure with an interval level, unidimensional Guttman-like structure that assesses five domains: ability to advocate for the individual with dementia; identifying one’s role in provision of care; becoming knowledgeable about loved one’s health problems, treatments and medications; identifying and acting on worrisome, unexpected physical, cognitive, and behavioral changes; and partnering with health care providers. Items and response options were understood and consistently interpreted by caregivers as intended and were reported to be highly relevant. Data will be presented on correlations between CADI-Q and validated measures of similar constructs. The proposed work is significant and innovative because it offers both novel strategies and pathways for re-framing the delivery of clinical care to patients with dementia, formalizing the partnership between caregiver and clinician.

VAN TRANSPORTATION OF PACE PROGRAM MEMBERS WITH BEHAVIORAL DISTURBANCES: ROUTINE REQUIRED FOR SAFETY
J.S. Sefcik, C. Bradway, S.G. Jost, P. Cavcicione, University of Pennsylvania, Philadelphia, Pennsylvania

The Program of All-Inclusive Care for the Elderly (PACE) is a community based long term care model focused on maintaining nursing home eligible older adults safely in the community. Ninety percent of members from one PACE program are transported on vans to the PACE center to receive interdisciplinary care. Conditions which complicate transportation of these members include dementia (57%) and chronic mental illness (5.7%). While the literature includes evidence surrounding the phenomenon of behavioral disturbances, such as persistent vocalizations, physical aggression, and restlessness, among older adults who attend day centers, there is no evidence regarding behavioral disturbances on van transportation for older adults accessing PACE programs. As a first step this qualitative study solicited van assistants’ and drivers’ experiences with transporting members on vans. A convenience sample of 19 van assistants, all Certified Nursing Assistants, and 12 van drivers from one PACE program attended one of four focus groups. Directed content analysis was used to specifically code for facilitators and challenges to safe van transportation. Routine was identified by van assistants and drivers as a major facilitator to achieving safe van transportation. Routine involved 1) maintaining a consistent daily driving route with the same members, 2) knowing each member and their preferences, and 3) facilitating trusting relationships. Any change in the routine created challenges on the vans, including behavioral disturbances such as physical and verbal aggression, impulsivity, and restlessness,
which caused safety concerns. Implications for research and practice will be described.

SESSION 510 (POSTER)

EPIDEMIOLOGY

THE RELATIONSHIP BETWEEN MITOCHONDRIAL ENERGY PRODUCTION AND MOBILITY IN OLDER ADULTS WITH A WIDE RANGE OF FUNCTION

A portion of age-related declines in gait-speed may be attributable to mitochondrial dysfunction. Mitochondria produce over 90% of ATP needed for movement and the capacity for oxidative phosphorylation decreases with age. We examined the association between mitochondrial function and walking performance in older adults. Phosphocreatine (PCR) recovery in the quadriceps was measured following an exercise bout using 31P magnetic resonance spectroscopy and ATPmax (mM ATP/s) was calculated. Participants were from an ancillary to the Lifestyle Interventions and Independence for Elders (LIFE) Study (n=36), which recruited functionally impaired participants (Short Physical Performance Battery (SPPB, 0-12), 7.9±1.2) and also from the Study of Energy and Aging (SEA, n=29), which enrolled higher functioning participants (SPPB, 10.9±1.4). Walking performance was defined as time (s) to walk 400m over level-ground at usual-pace and participants were asked if anything was bothering them upon completion. Participants were aged 77.6±5.3 years, 64.2% female, 67.2% white and SPPB scores ranged from 3-12 (9.2±2.0). In linear regression analyses, walk-time was significantly related to ATPmax in the SEA cohort (β =-209.02, p=0.02), but not in the combined (β =-65.31, p=0.32) nor the LIFE (β = 42.70, p=0.74) cohorts. When we examined those who reported no discomfort at the end of the walk separately, walk-time was significantly related to ATPmax in the combined cohort (β =-160.02, p=0.04) and the relationship in LIFE was β =-127.38, p=0.27. This suggests that oxidative capacity of skeletal muscle mitochondria may limit walking performance in higher functioning older adults and functionally impaired older adults able to walk 400m without experiencing discomfort.

THE DIFFERENTIAL EFFECTS OF MIDLIFE AND LATE LIFE ALCOHOL CONSUMPTION ON COGNITIVE FUNCTIONING AND REGIONAL BRAIN VOLUMES AMONG OLDER ADULTS

B. Downer1, Y. Jiang2, F. Zanjani2, D. Fardo3, 1. Graduate Center for Gerontology, University of Kentucky, Lexington, Kentucky, 2. Department of Behavioral Science, University of Kentucky, Lexington, Kentucky, 3. Department of Biostatistics, University of Kentucky, Lexington, Kentucky

Background: Moderate alcohol consumption is associated with higher cognition among older adults. One hypothesis postulates that alcohol consumption contributes to preserved regional brain volumes, such as the hippocampus and frontal cortex, which are critical brain regions underlying cognitive functioning. Objective: To examine the relationship between midlife (age 35-59) and late life (age > 65) alcohol consumption, regional brain volumes and cognition among older adults using longitudinal data from the Framingham Heart Study. Methods: Alcohol consumption was assessed during eight examinations from 1971-2008. Participants received a neuropsychological battery and MRI of the brain between 1999-2005. Multiple regression analysis was performed to test for associations between alcohol consumption status and both cognition and regional brain volumes. Results: Midlife alcohol consumption was not associated with cognition or regional brain volumes during late life. Light consumption (1-7 drinks/week) during late life was associated with higher mean cognition, compared to abstainers, (P<0.005) and larger frontal cortex volume (P<0.05); moderate consumption (>7-14 drinks/week) was associated with larger hippocampal volume (P<0.01). Neither frontal cortex nor hippocampal volumes were associated with cognitive measures after adjusting for age, education, gender and APOE e4. Younger age, female gender, and education were associated with higher cognition. Discussion: Light to moderate alcohol consumers during late life tend to have higher cognition and larger hippocampal and frontal cortex volumes. To provide appropriate recommendations on alcohol consumption, it is important to understand the effects that alcohol has on the brain and on cognitive reserve, while considering confounding factors such as age, gender and education.

YEARLY TRANSITIONS BETWEEN INDEPENDENCE AND DISABILITY PROFILES IN HEALTHY COMMUNITY-DWELLING ELDERS

M. Raiche1, N. Dubuc1,2, P. Gaudreau4, J.A. Morais3, B. Shatenstein3, H. Payette1,2, 1. Research Centre on Aging, Sherbrooke University Geriatrics Institute, Sherbrooke, Quebec, Canada, 2. Faculty of Medicine and Health Sciences, Université de Sherbrooke, Sherbrooke, Quebec, Canada, 3. Division of Geriatric Medicine, McGill University, Montreal, Quebec, Canada, 4. Centre Hospitalier de l’Université de Montréal Research Center and Department of Medicine, Montreal, Quebec, Canada, 5. Department of Nutrition, Université de Montréal, Montreal, Quebec, Canada

Transitions between clinical disability profiles have been studied, but entry into disability profiles from independence are less known. The objective was to estimate yearly transitions between such states in the NuAge longitudinal study, comprised of mostly independent participants at baseline. Disabilities were evaluated with the 29-item SMAF (Functional autonomy measurement scale) covering five sectors of activity: activities of daily living (ADL), mobility, communication, mental functions, and instrumental ADL (IADL). Persons were then classified into one of the fourteen disability Iso-SMAF Profiles, where the milder ones are IADL profiles 1-2-3. For the purpose of this study, fully independent persons were classified into a reference profile 0 (P-0). The data were analysed using a continuous-time, multi-state Markov model to estimate the matrix of probabilities for transitions into and out of each clinical states. The disability profile was measured 6156 times over 3 years in 1633 participants (mean age 74.4 years [67-84], 52% women). Initial profiles were mainly 0-1-2 (99.8%) and 96.4% of observed transitions occurred between these profiles. Participants in P-1 were as stable (0.72; 95% CI 0.70-0.74) as in P-0 (0.70; 0.64-0.71), but P-2 were more stable (0.76; 0.73-0.78) than P-0. Probabilities of recovery to full independence from P-1/2 were 0.15/0.09 yearly. The mean time spent in a profile was 2.5/2.7/3.4 years for profiles 0/1/2, respectively. Disability is a dynamic process and full recovery can occur. Flexible organisation of services is required to allow interdisciplinary teams to maximise independence and decrease the onset of future disability episodes.

A LIMIT TO FRAILTY IN OLDER JAPANESE-AMERICAN MEN IN RELATION TO MORTALITY

BACKGROUND: The accumulation of deficits Frailty Index (FI) has been found to have a limit of 0.7. The objective of this study is to investigate the FI, its distribution (including to test for a submaximal limit), and its relationship to mortality risk in a cohort of older Japanese-American men followed to near complete (88.8%) mortality. METHODS: Using data from the Honolulu-Asian Aging Study, FI scores were determined for 3651 men, aged 71-93 at baseline (1991-1993). For each individual, FIls were calculated as the ratio of actual to 34 potential health deficits. Frequency distributions were used to evaluate the limit to the
FI. Logistic regression models were used to evaluate the relationship between the FI and mortality. RESULTS: Across all waves, the limit of the FIs ranged from 0.65-0.71. For individuals who were fittest at baseline (FI = 0), the death rate was 0.08 at the second wave (1994-1996), 0.77 by the final wave (2007-2008). For the frailest individuals at baseline (FI = 0.41+), the death rates were 0.55 and 1.00, for Waves 2 and 7. Controlling for age, logistic regression models demonstrated a significant relationship between FIs at each wave and mortality at subsequent waves. CONCLUSIONS: In this sample of older Hawaiian men, the limit to frailty was observed at a FI value of 0.71, confirming a limit to deficit accumulation. Despite considerable numbers who died with each subsequent wave, there was little variance in the distribution of the FI values. Frailty was closely linked to the risk of death.

TRAJECTORIES OF THE FRAMINGHAM GENERAL CARDIOVASCULAR RISK PROFILE IN MIDLIFE AND POOR MOTOR FUNCTION LATER IN LIFE: THE WHITEHALL II STUDY

A. Elbaz1,2, M. Shipley3, H. Nabi1,2, E.J. Brunner1, M. Kivimaki1, A. Singh-Manoux1,2, 1. Inserm U1018 - Centre for research in Epidemiology and Population Health, Villejuif, France, 2. Department of Epidemiology and Public Health, University College London, London, United Kingdom

Vascular risk factors are associated with increased risk of cognitive impairment and dementia, but their association with motor function, another key feature of ageing, has received less research attention. Our objective was to examine the association between trajectories of the Framingham general cardiovascular disease risk score (FRS) over midlife and motor function later in life. A total of 5376 participants of the Whitehall II cohort study (29% women) who had up to four repeat measures of FRS between 1991-1993 (mean age=48.6 years) and 2007-2009 (mean age=65.4 years) and without history of stroke or coronary heart disease in 2007-2009 were included. Motor function was assessed in 2007-2009 through objective tests (walking speed, chair rises, balance, finger tapping, grip strength). We used age- and sex-adjusted linear mixed models. Participants with poorer performances for walking speed, chair rises, and balance in 2007-2009 had higher FRS concurrently and also in 1991-1993, on average 16 years earlier. These associations were robust to adjustment for cognition, socio-economic status, height, and BMI, and not explained by incident mobility limitation prior to motor assessment. No association was found with finger tapping and grip strength. Cardiovascular risk early in midlife is associated with poor motor performances later in life. Vascular risk factors play an important and under-recognized role in motor function, independently of their impact on cognition, and suggest that better control of vascular risk factors in midlife may prevent physical impairment and disability in the elderly.

BODY MASS INDEX, CHANGE IN BODY MASS INDEX, AND MOTOR DECLINE IN OLDER ADULTS

F. Artaud1,2, A. Singh-Manoux1,2,3, A. Dugravot1,2, B. Tavernier4, C. Tsourou4,5, A. Elbaz1,2, 1. INSERM, Centre for research in Epidemiology and Population Health, U1018, Social and occupational determinants of health, Villejuif, France, 2. University of Versailles St-Quentin, UMRS 1018, Versailles, France, 3. Department of Epidemiology and Public Health, University College London, London, United Kingdom, 4. CHU Dijon, Department of Geriatrics, Dijon, France, 5. INSERM U708, Neuroepidemiology, Bordeaux, France, 6. Université Victor Segalen Bordeaux 2, Bordeaux, France

In older people, poor motor performances are associated with adverse health events. Poor motor performances have multiple causes, including high body mass index (BMI). Little is known about BMI change in BMI and motor decline. Our aim was to examine the association between BMI change in BMI, and fast walking speed (WS) decline in older people. Analyses included 4,007 French ≥65y participants from the Dijon centre of the Three-City study (France) followed every ~2y during 10y. Linear mixed models were used (i) to estimate individual slopes of BMI change, and (ii) to study the relationship between baseline BMI, change in BMI, and change in WS over the follow-up (4 measures), adjusted for age, sex, education, and height. At baseline, mean WS was 153cm/s; obese and overweight persons walked slower than normal weight persons. During the follow-up, the average annual decrease in WS was -1.43cm/s/y (95%CI [ -1.71, -1.16]) in the reference group (normal baseline BMI, stable BMI). Obese subjects had faster WS decline (-0.49/cm/s/y [ -0.90, -0.08]). Participants who lost weight had a greater WS decline (-0.82/cm/s/y [-1.17, -0.47]) than participants with stable BMI, while there was no difference for those who gained weight. In older people, obesity is associated with worse motor performances at baseline and with faster motor decline; independently of baseline BMI, weight loss during the follow-up was associated with faster motor decline. WS and BMI decline are indicators of poor health in older persons; our findings underline the importance of repeat BMI and WS assessments in older people.

TRAJECTORIES OF CHANGES IN HEALTH STATUS USING A MULTI-STATE MODEL

F.G. Pena Silva1, E.A. Gahbauer2, T.M. Gill2, A.B. Mitnitski1, 1. Medicine/GMR, Dalhousie University, Halifax, Nova Scotia, Canada, 2. Yale University, New Haven, Connecticut

Background: Changes in health show complex dynamics but can be summarized using a multi-state transition modeling approach. Our objective was to investigate, in people aged 70 years and older, whether changes in frailty status and mortality risk depend on baseline health, using a stochastic model of frailty state transitions. Methods: Secondary analysis of data from the Yale Precipitating Events Project, a cohort study based in New Haven CT, of non-disabled people aged 70+ years (n = 754), assembled in 1998 and reassessed every 18 months. Thirty-six dichotomous variables (deficits) were used to calculate each individual’s health status, combined in a frailty index. Transitions in the number of deficits over each time interval were represented by the Poisson law, with the Poisson mean dependent on the deficit numbers at baseline. Logistic regression was used to estimate mortality parameters over 162 months of follow-up. Results: The model predicts a variety of changes in health status. Over 14 years of follow-up, the slope of the Poisson mean remains unchanged (0.77±0.04) while the intercept (characterizing the transitions of those who had zero deficits at baseline) increases to 8.5. At the same time, the probability of death accelerates. People with zero deficits have a 20% chance of dying during the first 90 months, then slightly accelerates. The FI increased significantly more slowly in longer lived individuals (life-span 90+) compared to the individuals whose life span was below age 90. The model is valuable for estimating how changes in health can influence mortality in older adults.

EXPLORING SUCCESSFUL AGING THROUGH LONG LIVED INDIVIDUALS

The presentation of the first successful aging model (Rowe & Kahn, 1997) started a path of discussion between psychologists, physiologists and sociologists still present nowadays. Centenarian individuals are frequently referred as “successful agers” due to their exceptional capacity of overcoming and adapting major individual and social life constraints. This study is based on the preliminary findings of the Oporto Centenarian Study (PT100) and aims to analyze the appropriateness of main successful aging approaches on a selected sample of 25 centenarians. Participants were interviewed face-to-face, using a biopsychosocial approach, and were asked to fulfill an assessment protocol including questions on social resources, health, functionality and psy-
MEASURING ATTENTION IN VERY OLD ADULTS USING THE TEST OF EVERYDAY ATTENTION

S. G. Leveille1,2,3, D. K. Kiely4, R. N. Jones5,6, M. M. Gagnon7, W. Milberg8, 9, 1. Nursing, CNHS, Univ Mass Boston, Dorchester, Massachusetts, 2. Hebrew SeniorLife, Boston, Massachusetts, 3. Harvard Medical School, Boston, Massachusetts, 4. Veterans Affairs Medical Center, Boston, Massachusetts, 5. Beth Israel Deaconess Medical Center, Boston, Massachusetts

With growing evidence about the role of cognitive function in mobility changes in old age, there is a need for validated measures of attention for use in longitudinal studies of older populations. In the sixth-year follow-up assessment of the MOBILIZE Boston Study, we included the Test of Everyday Attention (TEA), measuring domains of attention switching, and divided, selective and sustained attention. The test has not been validated in persons aged 80 and older. We studied 148 participants aged 80 to 101 using the TEA and a neuropsychological battery that included measures of multiple cognitive domains (Hopkins Verbal Learning Test, MMSE, Trailmaking A and B, word lists, clock-in-a-box). Proportions of participants with missing TEA tests ranged from 10% on selective attention tasks to 26% on the attention switching task. In general, reasons for not completing TEA tests had to do with failure to comprehend test instructions despite repetition and practice. There was substantial variation in demographic and health factors associated with incomplete tests. For example, older age was associated with missingness only in the map search (selective attention). Among participants who completed the TEA, scores on selective attention and attention switching were strongly associated with general cognitive function. However, the divided attention score was not associated with general cognitive measures (MMSE and the clock test), suggesting an independent measure of attention. Adjustment for age and sex did not alter the findings. These results demonstrate the challenges and potential value of the Test of Everyday Attention in studies of very old populations.

IMPACT OF VANTAGE POINT ON THE ASSOCIATION BETWEEN SELF-RATED HEALTH AND MORTALITY

Numerous studies have demonstrated that self-rated health predicts mortality. Most prior research has employed global rather than age-comparative or time-comparative ratings. The goal of this study was to explore how self-rating vantage point affects mortality prediction. Subjects included 137,258 elderly enrolled in Pennsylvania’s Pharmaceutical Assistance Contract for the Elderly Program who completed a mail survey in 2009-2010. Three self-rated health vantage points were used: global, age-comparative (others of same age) and time-comparative (present vs. one year ago). Multivariate Cox proportional-hazards regression was used to predict subsequent mortality over two years, controlling for demographics and medication-based comorbidity. While 73% of respondents reported equal global and age-comparative ratings, age-comparative scores exceeded global for 18% and were worse than global for 8%. Lower ratings from any vantage point increased mortality risk, but results suggest complex associations among the measures. Compared to persons reporting equal global and age-comparative scores, age-comparative scores worsened than global increased risk (HR=1.54, p<.001), while age-comparative ratings exceeding global reduced risk (HR=0.78, p<.001). The impact of age-comparative deviation from global was stronger in younger groups (interaction p<.001). Time-comparative worsening consistently increased mortality (HR=1.32, p<.001), but effects of improvement varied by age (p<.001). Controlling for other factors, improvement was associated with greater mortality for those aged 65-69 (HR=1.53, p<.001), but did not affect risk in either direction among persons over 80. These results suggest that comparative ratings are particularly useful when used alongside global ratings, and that potential age differences in vantage point meaning may have a bearing on mortality prediction.

COGNITIVE IMPAIRMENT, proxy interviews, and inconsistent longitudinal reporting of chronic disease

C.L. Nagel1, A.R. Quinones2,3, J. Liang4, C. Blaum5, C. Cigolle6,7, 1. Oregon Health & Science University School of Nursing, Portland, Oregon, 2. VA Ann Arbor Geriatric Research, Education and Clinical Center (GRECC), Ann Arbor, Michigan

Chronic disease data from longitudinal health interview surveys are frequently used in epidemiologic studies. Yet, these data may be limited by inconsistencies/disputes in self-reporting diseases across waves.
We hypothesized that cognitively impaired respondents and proxy respondents were more likely to provide such discrepant responses. We analyzed waves 1998-2010 of the Health and Retirement Study (HRS), a nationally representative longitudinal health survey. Our sample included adults ≥51 years (n = 25,850). Diseases included hypertension/heart/lung/diabetes/cancer/arthritis/stroke. Cognitive function was determined by a performance-based measure. We used logistic models to investigate the association of cognitive impairment and proxy status with discrepancies in reporting of diseases at each wave. We used follow-up questions about the diseases (e.g., treatment) in a multi-step process to adjudicate inconsistent responses; we then compared prevalence estimates between the original and adjudicated data. 19.0% were cognitively impaired, and 19.8% used a proxy respondent for ≥1 interview wave. Cognitively impaired respondents had greater odds (range: 1.5-2.9, p < 0.01 for each) of providing inconsistent responses for ≥1 disease for all waves; proxy respondents had greater odds (1.3-3.9, p < 0.01 for each) for six of seven waves. Among all respondents, disease prevalence estimates were higher for the adjudicated data (vs. original). These differences in prevalence estimates were greater for both cognitively impaired and proxy respondents (range: 1.0%-8.6%). Inconsistent reporting of diseases across waves of health interview surveys is more likely among cognitively impaired and proxy respondents. Prevalence estimates calculated from these discrepant responses appear to underestimate the burden of disease, with implications for research using these data.

FACILITATION AND ITS ROLE IN SUCCESSFUL RESEARCH IMPLEMENTATION

In the implementation science literature, facilitation has been theorized as a key factor to successful implementation of research into practice. One of the purposes of facilitation is to make change more compatible with existing practice. While others have focused primarily on the attributes or qualities of effective facilitators, attributes of facilitation as an intervention for implementing research into practice has received much less attention. We conducted a scoping review to identify and define attributes of facilitation that are associated with research use among healthcare professionals (e.g., nurses, physicians, allied healthcare providers). We searched nine electronic databases from the healthcare and management literature (Medline, CINAHL, EMBASE, Web of Science, Scopus, Cochrane Library, PsycINFO, ABI Inform, and Business Source Complete). We undertook content and thematic analysis to summarize the data. We used Rogers’ 2003 attributes of an innovation framework (relative advantage, compatibility, complexity, trialability, and observability) to synthesize attributes of facilitation. Of the 14,598 articles identified, 140 were included in the scoping review. From our sample of 140 articles, we included 85 articles from which we identified 14 attributes of facilitation associated with research use. These findings can lay the groundwork for well-designed and evaluated interventions that are relevant to practice contexts. These attributes of facilitation can be used as a framework in future studies to evaluate effectiveness of facilitation interventions.

VERBAL MISTREATMENT IN THE ELDERLY
T. Fulmer, R. Rodgers, A. Pelger. Bouve College of Health Sciences, Northeastern University, Boston, Massachusetts

Elder mistreatment is a potentially fatal geriatric syndrome affecting over 2 million older adults annually in this country, and is expected to rise exponentially with the aging of the population both nationally and globally. Verbal mistreatment has received insufficient attention because of the subjective nature of the phenomenon, difficulty determining lifetime patterns of verbal abuse or new onset verbal abuse, and cultural variations. Here, we present data from an NIA-funded study examining the prevalence of elder mistreatment in primary care clinics, and specifically, we analyzed the association between verbal mistreatment, decreased quality of life and depression. A sample of 142 older adults (40% male) aged 65 years or older (mean (SD) = 74.88 (6.98)) was enrolled from 2 sites: a large urban medical practice and an academic dental practice. Only 33.3% self-identified as White. We used the Conflict Tactic Scale, the SF36 and the CES-D to examine the constructs of verbal mistreatment, quality of life and depression. Thirty-eight percent of the sample reported verbal mistreatment. Controlling for socio-demographic characteristics, verbal mistreatment was a significant predictor of depression (β = -.27, p < .001), and a negative predictor of vitality (β = -.17, p < .05), social functioning (β = -.28, p < .001), mental health (β = -.25, p < .001), and role limitations OR = 3.14, 95% CI [1.36 – 7.23]. The present findings highlight the prevalence of verbal mistreatment in elderly individuals and the negative sequelae associated with this form of elder mistreatment.

ASSOCIATION OF HEARING LOSS WITH PHYSICAL FUNCTIONING IN OLDER ADULTS
D.S. Chen1,2, D.J. Genther1,3, J. Betz2, F.R. Lin1,4, 1. Johns Hopkins University School of Medicine, Baltimore, Maryland, 2. Center on Aging and Health, Johns Hopkins Medical Institutions, Baltimore, Maryland, 3. Department of Otolaryngology-Head and Neck Surgery, Johns Hopkins University School of Medicine, Baltimore, Maryland, 4. Departments of Geriatric Medicine, Mental Health, and Epidemiology, Johns Hopkins University, Baltimore, Maryland

Objective: To determine whether hearing loss is associated with physical functioning in a nationally representative sample of older adults in the U.S. Methods: Multivariate analysis of audiometric exam data and physical functioning questionnaire items from 1669 adults aged ≥70 years who completed audiometric testing in the 2005-2006 and 2009-2010 cycles of the National Health and Nutrition Examination Survey Results: In a model adjusted for age, demographic characteristics, and cardiovascular risk factors, greater hearing loss (per 25 dB) was associated with greater odds of physical disability in activities of daily living (OR 1.44; 95% CI 1.09-1.90), instrumental activities of daily living (OR 1.60; 95% CI 1.19-2.15), leisure and social activities (OR 1.50; 95% CI 1.11-2.04), lower extremity mobility (OR 1.37; 95% CI 1.11-1.70), general physical activity (OR 1.31; 95% CI 1.05-1.63), work limitation (OR 1.38; 95% CI 1.03-1.86), walking limitation (OR 1.62; 95% CI 1.32-1.99), and limitation due to memory or confusion (OR 1.37; 95% CI 1.07-1.76). Hearing loss was not associated with limitations in amount or type of work done (OR 1.24; 95% CI 0.95-1.62). Conclusions: Hearing loss in the U.S. population is independently associated with increased disability and limitations in multiple self-reported categories of physical functioning.

LIFESTYLE FACTORS AND ACTIVE LIFE EXPECTANCY IN THE CARDIOVASCULAR HEALTH STUDY

We aimed to assess the lifestyle factors associated with the observed years of active life (YAL) in the CHS cohort. YAL was defined as the observed years free of any difficulty in ADL. YAL incorporates health as well as survival and is a robust measure of healthy survival. The CHS is a community-based cohort of older adults in the US. Information regarding lifestyle factors and activities of daily living (ADL) was collected for 4,555 CHS participants at the baseline visit. ADL informa-
tion was collected biannually or annually for 18 years. The association between lifestyle factors (alcohol consumption, smoking, physical activity, BMI, social support and social network score) and YAL were assessed using linear regression models. In the socio-demographic model, black race, lower education, lower income and being unmarried were associated with lesser YAL (p values <.01). When lifestyle factors were added, the effect of race (p=.31) and education (p=.02) were attenuated. In the confounder adjusted model, adjusted for self-reported health, chronic diseases, IADL and MMSE scores at baseline, the associations of race and education were further attenuated. In this fully adjusted model, smoking, physical activity, BMI, and social support score were significantly associated with YAL (p values <.01). Multiple lifestyle factors were linked to optimal aging in CHS. The associations of non-modifiable factors such as race and education were mediated through modifiable factors.

DUAL SENSORY-LOSS AND SOCIAL PARTICIPATION IN OLDER EUROPEANS
A. Viljanen1, T. Törmäkangas1, S. Vestergaard2, K. Andersen-Ranberg2, 1. University of Jyväskylä, Gerontology Research Center, Jyväskylä, Finland, 2. University of Southern Denmark, Odense, Denmark

The purpose of the present study was to describe the prevalence of hearing difficulties, vision difficulties and dual sensory difficulties in 11 European countries, and to study whether sensory difficulties are associated with social inactivity in older Europeans. This study is based on the year 2004 data of the Survey of Health, Ageing and Retirement in Europe (SHARE) comprising 27,536 men and women aged 50 years and older. Hearing and vision difficulties, as well as participation in seven different social activities (voluntary work, cared for or provided help to others, attended course, gone to club, taken part in religious or political organization) were assessed using a structured personal interview. Altogether 5.9% of the participants reported both hearing and vision difficulties (dual sensory-loss), 10.2% only vision difficulties, and 13.5% only hearing difficulties. Two thirds of those participants having dual sensory-loss did not participate in any activities (socially inactive) compared to half of those participants who did not report any sensory difficulties. The participants who reported dual sensory-loss had 2.18 (95%CI 1.83-2.59) times higher odds for social inactivity compared to persons without hearing or vision difficulties. In a model adjusted for age, gender, mobility, depression, cognition, education and wealth the corresponding odds ratio was 1.21 (95%CI 1.00-1.47). Sensory difficulties were associated with social inactivity, but the higher likelihood was attenuated by other health and socio-economic indicators. Our results offer suggestive evidence that different preventive and rehabilitative actions targeting to older persons’ sensory functions may enhance their social activity.

SESSION 515 (POSTER)

EXERCISE AND GAIT

METABOLIC RATE OF WALKING IN FATIGUED VS. NON-FATIGUED OLDER ADULTS
C. Scott, M. Lorow, M. Lewis, M. Pahor, T. Manini, University of Florida, Gainesville, FL

Introduction. Older adults who report fatigue, tiredness or exhaustion are at elevated risk for death and functional impairments. This study evaluated the metabolic rate of walking in severely fatigued compared to non-fatigued older adults in an effort to explain fatigue symptoms. Methods. We conducted a case-control study of older adults who had perceived severe fatigue (N=20, 70±4.9 yrs) and controls without fatigue (N = 23; 72±4.6 yrs). Individuals with overt medical conditions (e.g. pulmonary disorders) and other common reasons for fatigue symptoms (e.g. thyroid levels) were excluded from the study. Participants walked on a treadmill at a speed of 40.2 m/min for 5 minutes followed by their preferred walking speed (range: 48 - 83 m/min) for 5 minutes. Gross, mass-specific and mass-specific net metabolic rate of walking. Measures of perceived exertion were also assessed while walking. Results. Net metabolic cost of walking was significantly lower when participants walked at their preferred walking pace (3.8±1.2 vs. 3.3±0.93 J/kg/m/sec, p < 0.001). This finding held true in fatigued and non-fatigued older adults. The net metabolic cost of walking at a standard speed of 40.2 m/min was similar to between individuals with and without fatigue (3.7±0.9 vs. 3.9±1.5 J/kg/m/sec, respectively). No differences were seen at a preferred walking pace (Fatigued: 3.4±0.8 vs. not-fatigued: 3.2±1.1 J/kg/m/sec). Additionally, fatigued participants rated their perceived exertion similar to non-fatigued participants. Conclusions. Metabolic cost of walking in older adults who report severe fatigue was similar to those who do not report fatigue. Reports of fatigue in elders are unlikely to be explained by a higher energy cost of movement.

COMPARISON OF TRADITIONAL AND TASK-SPECIFIC EXERCISE ON GAIT IN THE PRE-CLINICALLY DISABLED

Objective. Compare walking performance following a task-specific exercise (TSE) intervention and a recommended program by the National Institute on Aging (NIA) that includes walking, balance, and resistance exercise in pre-clinically disabled older adults. Methods. Sixty-nine pre-clinically disabled older adults (69.9 ± 8.35 years) were tested. They reported no difficulty performing typical daily tasks, but modified the method or frequency with which daily tasks were executed. Interventions were conducted 2 times per week for 12 weeks. TSE training included rising from a chair and the floor, climbing stairs, and gait challenges (e.g., navigating obstacles). Spatiotemporal gait parameters were recorded with and without shoes under single and dual task (counting backwards by three’s starting from 100, 50, and 25) conditions using an instrumented walkway system (GAITRite® mat). Results. TSE training increased gait velocity and cadence under single (mean change, 6.65 cm/sec [2.00], p = 0.03 and 3.39 steps/min [0.96], p = 0.02, respectively) and dual (mean change, 5.32 cm/sec [2.30], p = .023 and 4.06 steps/min [1.15], p = .01, respectively) task conditions, compared to the NIA program. TSE training increased base of support (mean change, 0.57 cm [0.23], p = 0.03) under dual task conditions, compared to the NIA intervention (mean change, -0.17 cm [0.24]). No significant changes in step variability were observed. Similar results were found with shoes-off conditions. Discussion. TSE training improves gait velocity and cadence significantly more than the current NIA exercise recommendation aimed to prevent physical disability in at risk older adults.

EFFECTS OF RESISTANCE TRAINING ON COGNITIVE FUNCTION AMONG OLDER ADULTS
S. Smith1, B. Hamill1, C. Sodowsky1, M. Powers1, M. Gray2, 1. Kinesiology & Health Studies, University of Central Oklahoma, Edmond, Oklahoma, 2. University of Arkansas, Fayetteville, Arkansas

The purpose of this one-year study was to assess the impact of resistance training protocols on cognitive function among older adults. Participants over the age of 75 years were randomly assigned to a low velocity (LV) or high velocity (HV) resistance training group. Both groups trained two days per week and completed eight exercises following American College of Sports Medicine recommendations. The LV group completed the concentric contraction over 2-3 seconds; whereas the HV group completed the concentric contraction as quickly as possible. Cognitive function was assessed by the Trail Making Test (TMT) and the
executive function (EF) subscale of the Cognitive Linguistic Quick Test. ANOVA with repeated measures was used for analyses and effect sizes were calculated. Results indicated no significant group-by-time interactions for the TMT Part A, TMT Part B, and EF. The strongest effect size for improvement was seen in the HV group for EF (d = -0.997). The HV group also displayed a small effect for the improvement on the TMT differences (d = 0.149). High velocity training is capable of improving cognitive function in older adults. Higher levels of cognitive function can result in optimal aging. Future studies should further examine the relationship between cognitive function and resistance training among older adults.

**LEG MUSCLE POWER - AN IMPORTANT MEASURE TO DETECT MUSCLE WEAKNESS IN OSTEOARTHRITIS OF THE HIP**

T. Bieler1,2; P.S. Magnusson1,2; M. Kjaer2; N. Beyer1,2. 1. Musculoskeletal Research Unit, Dept. Physical Therapy, Copenhagen University Hospital, Bispebjerg, Copenhagen, Denmark. 2. Institute of Sports Medicine Copenhagen, Copenhagen University Hospital, Bispebjerg, Copenhagen, Denmark.

Background: In patients with unilateral end-stage osteoarthritis of the hip (HOA) the affected leg is weaker than the non-affected leg. Whether asymmetry is present in the early HOA is unknown, and knowledge regarding this could be important in understanding functional decline and disability in this patient group. Objectives: To compare leg muscle function in the affected leg and the non-affected leg in patients with unilateral earlier-stage HOA, and to explore relationships between leg muscle function and functional performance. Method: 118 elderly (60-87 years) with unilateral HOA not on waiting list for hip replacement and 35 healthy elderly (63-82 years) were included. Muscle function (maximal isometric hip and thigh strength; peak leg power) and functional performance (stair climbing (Stair), 30s sit-to-stand (STS) and 6-minute walk (6MW)) were measured. Results: In patients with HOA the affected leg was significantly (p<0.05) weaker compared with the non-affected leg (ratios for muscle strength of the hip:88.9%-94.7%, quadriceps=90.4%, hamstrings=98.8%, and leg power=85.0%). In healthy elderly non-preferred vs. preferred leg showed quadriceps strength ratio=94.0% (p=0.014) and leg muscle power ratio=97.2% (p=0.194). In elderly with HOA a relationship was found between functional performance and affected leg muscle power (Stair: r=-0.523; STS: r=0.567; 6MW: r=0.655, p<0.01) and affected leg muscle strength (Stair: r=-0.245–0.467; STS: r=0.241-560; 6MW: r=0.402-6.03, p<0.01). Conclusion: In elderly with non-end stage HOA the affected leg c. The relationship found between leg muscle power in the affected leg and functional performance may have implications for rehabilitation of patients with early HOA.

**PARTICIPATION IN EVERYDAY ACTIVITIES AND SELF-REPORTED HEALTH AMONG OLDER ADULTS**

B.A. Steinman1, J.E. Mutchler1, S.M. Allen2. 1. Center for Social and Demographic Research on Aging, University of Massachusetts, Boston, Massachusetts. 2. Brown University, Providence, Rhode Island

The International Classification of Functioning (ICF) conceptualizes relationships between participation and other health dimensions as bidirectional. For instance, a common sense approach suggests individuals in poor health would experience difficulty participating in community activities; however, participation may also be antecedent to good health, via incidental physical activity and social connectivity afforded by participation in everyday activities. This study tested the association between participation in everyday activities and self-rated health (SRH) of older adults. We computed five ordinal logistic regression models using baseline data (2011) from the National Health and Aging Trends Study (NHATS). “Participation” was operationalized using 6 items that assessed participation in social and community-based activities, including 1) visiting friends/family; 2) attending religious services; 3) participating in clubs/classes; 4) going out for enjoyment; 5) working for pay; and 6) doing volunteer work. We assessed participation while holding ICF’s other health dimensions constant. Model 1 regressed self-rated health on participation, with controls for personal factors (e.g., demographics); Model 2 included chronic diseases (e.g., heart disease); Model 3 added measures of functioning (e.g., walking up 20 stairs); Model 4 included measures of activity disability (e.g., difficulty eating), and Model 5 included environmental factors (e.g., use of mobility devices). Participation was statistically associated with SRH in five of six items. With the exception of attending religious services, individuals who participated were more likely to report better SRH, independent of other ICF dimensions. These results point to the importance of developing community support and reducing barriers to participation by older adults.

**DUAL-TASK AND GAIT VARIABILITY: EFFECTS OF AGING AND SUB-OPTIMAL SENSORY INFORMATION**

N. Deshpande, P. Hewston, Queen’s University. Kingston, Ontario, Canada

Introduction: Increased gait variability has been shown to be a sensitive measure to predict falls in high-functioning older adults without overt pathology. The purpose of this study was to investigate effects of aging on gait variability under conditions of dual-task and sub-optimal sensory information. Methods: Ten young (YA, age:26.0±2.9 years) and ten older (OA, age:73.0±6.3 years) healthy adults walked along a 6-meter path while subtracting by 3’s (walking-while-talking, WT) or no additional cognitive challenge (no-WT). Somatosensory information was altered using a normal surface (Hard) or compliant surface (Foam). Visual information was intact (vision, V) or impaired using customized blurring goggles (blurred vision, BV). Main outcome measures included step length (StLen), step length variability (StLenVar), step width (StWid) and step width variability (StWidVar). Results: YA increased StLen on Foam (p<0.001) whereas OA StLen was not influenced on Foam (p>0.05). StLenVar increased 33% on Foam (p<0.001). StLen decreased with WT, Foam and BV, concurrently (p<0.05). StWid increased on Foam (p<0.001). StWidVar increased 23% with BV (p<0.05). Discussion: Regardless of age, StLenVar increased on Foam which may be attributed to unstable gait pattern. However, YA were able to increase their StLen on Foam to possibly overcome step-by-step destabilization; a strategy that may not have been safe for OA. This suggests healthy aging may result in OA to be more unstable when walking on unpredictable surfaces. Both YA and OA increased StWid on Foam to compensate for medio-lateral instability. However, increased StWidVar with BV suggests accurate visual inputs were critical for efficient medio-lateral foot-placement.

**PARATHYROID HORMONE BUT NOT VITAMIN D IS ASSOCIATED WITH GAIT IMPAIRMENT IN OLDER ADULTS**

M. Montero-Odasso1,2, S.W. Mair1,2, K. Gopaul1, R. Crilly1. 1. University of Western Ontario, London, Ontario, Canada. 2. Gait & Brain Lab, Parkwood Hospital, London, Ontario, Canada

Background: Vitamin D deficiency is associated with disability, including poor physical performance, weakness, falls and fractures. Elevated parathyroid hormone (PTH) is also associated with increased falls risk. While vitamin D supplementation can improve balance function, its effect on gait is contradictory. The effect of PTH on gait has not been published. The aim was to evaluate the association of vitamin D and PTH levels on spatiotemporal measures of gait. Methods: Cross-sectional study of 66 community-dwelling older adults (mean age = 80.4±7.3, 57.6% female). Gait (usual pace) was evaluated with the GaitRite® mat. A force platform (Bertec®) was used for the Modified Clinical Test for Sensory Integration in Balance (MCTSIB) to measure centre of pressure motion. Multivariable linear regression evaluated
the relationship between serum vitamin D levels and PTH on gait and balance. Results: The distribution of vitamin D levels were: 0% deficient (<30nmol/L); 15.2% insufficient (30-50nmol/L); 16.7% normal (51-75nmol/L); and 68.2% supernormal (>75nmol/L). Elevated levels of PTH (>5.00pmol/L) were found in 25.8%. Vitamin D was not associated with gait performance (p=0.05). Increasing PTH levels were independently associated with poor gait performance. Neither vitamin D nor PTH levels were associated with centre of pressure displacement (total sway area, mediolateral or posterolateral maximal excursion) in any of the MTSSB test conditions. Conclusions: Increasing PTH was independently associated with poor gait performance. Lack of an effect with vitamin D could be that few people were below therapeutic levels. Our findings suggest that PTH may have a neuromuscular action independent of Vitamin D.

BARRIERS FOR OUTDOOR MOBILITY AND UNMET PHYSICAL ACTIVITY NEED IN OLD AGE
J. Eronen, M. von Bonsdorff, M. Rantakokko, E. Portegijs, T. Törmäkangas, T. Rantanen. Gerontology Research Center, University of Jyväskylä, Jyväskylä, Finland

Background: Outdoor walking is important for the health and well-being of older adults. However, many older adults face barriers for outdoor mobility in their everyday lives. Mobility barriers together with mobility limitations may lead to unmet physical activity need, conceptualized as perceived inadequacy of level of physical activity. Methods: Baseline data of the “Life-Space Mobility in Old Age” (LISPE) project were used for cross-sectional analyses. In total, 848 people were interviewed in their homes (mean age 80.1 years, 62% were women). Barriers for outdoor mobility (17 items) and unmet physical activity need were assessed with structured questionnaires. We profiled the participants into latent groups using mixture modeling technique, based on the barriers they report. The prevalences of unmet physical activity need were compared between different barrier profiles. Results: The following five latent groups were identified: 1. Minor barriers (46% of the participants), 2. Barriers related to weather conditions (26.5%), 3. Barriers related to poor health and weather (15.9%), 4. Barriers related to poor health, weather and fears (4.6%) and 5. Barriers related to poor health and poor mobility (6.5%). The prevalences of unmet physical activity need in the groups were 5.0%, 10.2%, 28.1%, 28.2% and 41.8%, respectively. The group with the highest prevalence of unmet physical activity need was also the most physically inactive. Conclusions: Older adults may have a variety of different barriers to overcome in order to walk outdoors. This diversity needs to be carefully considered in promoting physical activity of this population.

EFFECTS OF TASK-SPECIFIC AND TRADITIONAL-BASED EXERCISE IN THE PRE-CLINICALLY DISABLED: A PILOT STUDY

Introduction: This study compared a task-specific exercise (TSE) intervention with a multi-component exercise program recommended by the National Institute of Aging (NIA). Methods: Seventy-one older adults (70.11 ± 8.37 years) who reported no difficulty, but modified the frequency or method of performing daily tasks were randomized to 12 weeks (2 days per week) of TSE or NIA training. The TSE intervention focused on practicing chair rising, rising from the floor, stair climbing and walking with challenges (i.e., navigating obstacles). NIA training included moderate intensity walking, resistance, and balance exercises. Outcomes included number of compensatory strategies used to perform functional tasks, 400-meter walk speed, knee extension strength, and short-physical performance battery (SPPB) score. Outcomes were assessed after 12 weeks of training and following 12 weeks of detraining. Results: TSE reduced compensations during daily tasks by 33.1%, which was slightly greater than NIA (14.4% reduction, p=0.20). TSE increased knee extension strength compared to NIA (11.3% vs. 0.5% respectively, p=0.04). Both groups increased daily task performance speed (24.2% and 21% respectively, p=0.41), SPPB score (TSE: 0.78±0.20, NIA: 0.45±0.21), and 400-meter walking speed (TSE: 0.02±0.02, NIA: 0.04±0.02 m/sec). The effects remained after 12 weeks of detraining. Summary: This pilot study demonstrated that chronic exercise reduced compensatory strategy use and time needed to perform daily tasks in pre-clinically disabled older adults. TSE training resulted in muscle strength gains and a trend for greater reduction in compensatory strategies, compared to an NIA-recommended exercise program. TSE also increased physical performance similarly to a traditional multiple-component exercise program.

ENVIRONMENTAL BARRIERS ARE ASSOCIATED WITH LONELINESS IN COMMUNITY-DWELLING OLDER PEOPLE
M. Rantakokko, S. Vahaluoto, E. Portegijs, A. Viljanen, S. Iwarsson, T. Rantanen. 1. Gerontology Research Center, Department of Health Sciences, University of Jyväskylä, Jyväskylä, Finland, 2. Department of Health Sciences and Centre for Ageing and Supportive Environments, Lund University, Lund, Sweden

Aim: The aim was to examine the association between environmental barriers and loneliness among community-dwelling, 75- to 90-year-old, people. Methods: Baseline data of the “Life-Space Mobility in Old Age” (LISPE) project were used for the cross-sectional analyses. In total, 848 people were interviewed in their homes (mean age 80.1 years, 62% were women). Environmental barriers for outdoor mobility and loneliness were assessed with structured questionnaires. Difficulties in 2 km walking and participation in out-of-home activities were self-reported. Results: In total, 28% of the participants experienced loneliness. Participation in out-of-home activities was not associated with loneliness. Those who experienced loneliness reported more difficulties in 2 km walking and more environmental barriers than people not experiencing loneliness. Especially snow and ice during winter time (OR 1.77, 95% CI [1.29-2.44]), long distances to services (OR 1.79, [1.16-2.79]), lack of resting places (OR 1.61, [1.08-2.39]), dangerous crossings (OR 1.73, [1.06-2.82]), hills in the nearby environment (OR 1.66, [1.17-2.34]), noisy traffic (OR 2.18, [1.05-4.05]) and high curbs (OR 1.86, [1.09-3.16]) roughly doubled the probability of loneliness. Snow and ice, long distances to services and hills in the nearby environment increased loneliness even after adjusting the models for difficulties in 2 km walking, participation, socioeconomic indicators and health. Conclusion: Barriers in the physical environment may increase feelings of loneliness, and participation in out-of-home activities did not explain this association. Confirming the causality of the association warrants further studies.

SELF-MANAGEMENT OF MOBILITY AND FALL RISK BY ELDERLY – THE SENIOR STEP STUDY
K. Bongers, M.J. Graauwman, Y. Schoon, M. Olde Rikkert, Geriatric Medicine, Radboud University Nijmegen Medical Center, Nijmegen, Netherlands

Background In an increasing ageing population, the number of elderly having mobility and fall problems is vastly increasing. The Senior Step Study investigates whether it is possible for elderly to be in control of their own mobility and fall risk by promoting self-management. This requires a simple and feasible self-test for fall risk. As part of the Senior Step Study, the current study investigated whether elderly are capable of performing three possible tests for self-management of mobility at home. Methods Maximum Step Length (MSL), Gait Speed (GS)
and Chair Test (CT), were performed weekly for six months by 56 elderly (age ≥70) living at home, and their informal caregivers. Instruction on performance of the self-tests was given at baseline. After one month, a researcher observed test performance and, if necessary, additional instructions were given. The amount and variety of errors made were compared between the first and last week of performing the self-tests. Results 49 elderly (mean age (sd) 75.7 (4.0) yrs, 22 female) completed the study. The percentage of correct measurements increased after the additional instruction from 75.5%, 44.9%, and 38.8% in week 1 to 91.8%, 84.7%, and 51.0% in week 26, for MSL, GS, and CT, respectively, showing the greatest learning curve for MSL and GS. Conclusions Elderly are capable of performing the self-tests MSL and GS at home, indicating that self-management of mobility and fall risk by elderly at home may be possible.

THE EFFECTS OF AGE-RELATED HIP PROPRIOCEPTION DECLINES ON BALANCE

Falls are the leading cause of hip fractures and injury-related hospitalized admission among older adults. Proprioception, the body’s sense of how it is positioned or moving, is an integral part of overall postural stability. This study evaluated the effects of age on hip proprioception, and determined whether age-related declines in hip proprioception, if present, disrupt balance. We tested ambulatory community-dwelling adults (N = 102) without neurological impairments in three age groups, younger (N = 34, mean age (range): 24.6 years (19-37)), mid-aged (N = 34, 53.3 years (40-64)), and older adults (N = 34, 76.3 years (65-94)). Hip joint-position sense (JPS) and kinesthesia were measured in the transverse plane using a custom built device. JPS error was determined by the magnitude of matching errors during vision and no vision conditions. Kinesthesia was evaluated by the ability to detect passive limb rotation without vision. Root mean square of center of pressure (COP) displacement and velocity of COP displacement measured postural sway during static stance. Clinical balance and fear of falling were assessed with the mini-BESTest and ABC Scale, respectively. Older adults had increased JPS and kinesthesia error compared to younger adults, bilaterally (P < 0.001), and both measures of proprioception error significantly correlated with age (P ≤0.001). There was no relationship between hip proprioception error and postural sway. However, older adults with lower proprioceptive error had significantly higher mini-BESTest scores of dynamic balance abilities (P = 0.007). Therefore, hip proprioception declines with age, and although these declines are not related to increases in postural sway in static stance, they do disrupt dynamic balance. Fall prevention programs should include activities that target improvement of hip proprioception.

FUNCTIONAL RESERVE ASSESSED BY MAXIMAL AND USUAL GAIT SPEED IS ASSOCIATED WITH PHYSICAL HEALTH IN OLDER JAPANESE ADULTS
S. Seino1,2, A. Sezaki1, M. Nibutani1,2, K. Shigemoto1, Y. Otsuka2,2, Y. Okubo1,2, R. Figueroa1, K. Tanaka1, 1. Graduate School of Comprehensive Human Sciences, University of Tsukuba, Tsukuba, Japan, 2. The Japan Society for the Promotion of Science, Chiyoda, Japan

Background: The useful indicators of overall well-being, maximal gait speed (MGS) and usual gait speed (UGS), are more sensitive for young-old people and old people, respectively. Functional reserve (FR), defined as the difference between MGS and UGS, may help identify older adults at the cusp of functional decline. The purpose of this study was to identify whether FR is a useful indicator of physical health. Methods: Trained testers measured participants’ MGS and UGS for a cross-sectional analysis on 449 older Japanese adults (127 men and 322 women) aged 65-96 years (73.8 ± 6.1 yr). We classified participants as high-FR (>0.5 m/s), middle-FR (0.5-0.3 m/s) or low-FR (<0.3 m/s) (FR=MGS-UGS). We considered a SF-36 physical function score of <70 points as the determiner for low physical health. Using a multiple logistic regression analysis adjusted for potential confounders, we analyzed the association between FR and physical health. Results: The means ± SDs of MGS, UGS and FR were 1.85 ± 0.38 m/s, 1.38 ± 0.28 m/s, and 0.47 ± 0.21 m/s, respectively. There were 66 (14.7%) participants with low physical health, and the crude prevalences were 5.9%, 15.9% and 28.6% for high-FR, middle-FR and low-FR categories, respectively. Compared with the high-FR category, adjusted odds ratios (95% confidence intervals) for low physical health were 2.5 (1.1-5.5) for middle-FR category and 5.3 (2.2-12.9) for low-FR category (P for trend < 0.001). Conclusion: A low-FR was tightly associated with low physical health. Calculating FR may be useful for routine assessment of health status in older adults.

DUAL TASK COST AMONG COMMUNITY-DWELLING OLDER ADULTS
D. Klima1, S. Politi1, B. Mills1, H. Taylor1, E. Siegel1, A. Urban1, L. Custis1, K.K. Chu2, 1. UMES, Princess Anne, Maryland, 2. Sacred Heart University, Fairfield, Connecticut

Introduction: The necessity to perform two concurrent tasks occurs frequently in daily life for older adults. Individuals can display a decline in one or both skills during simultaneous task performance, known as dual task cost. Metric comparisons between tools to measure dual task cost in older adults are limited. Objective: To assess and compare select measures of dual task performance among community-dwelling older adults. Methods: Thirty independent community-dwelling older adults (mean age 74.9±10.2) completed a: demographic profile, fear of falling questionnaire, and task circuit of physical performance tests. Dual task cost was assessed using the: Walking and Remembering Test (WART), original and modified (shopping list memory component) Four Square Step Test (FSST), and both the Timed Up and Go (TUG) and TUG-Cog (concurrent subtraction task) instruments. Results: There was a significant difference between initial TUG and TUG-Cog performance (10.7± 2.8 vs. 13.1±4.3 sec; p<0.001), with the added subtraction task resulting in slower mobility performance. Conversely, subjects performed faster on the FSST when a shopping list memory task was added (14.6÷5.7 vs. 16.3±6.9 sec.; p<0.001). There was a significant inverse association between the number of items remembered and performance time (r = -0.48; p=0.01). Performance values approached or surpassed reported cut-off scores for fall risk with added cognitive demand. Conclusion: Older adults demonstrate different adaptation strategies when confronted with competing tasks and the specific cognitive demand imposed upon an activity. A concurrent subtraction drill resulted in greater dual task cost, while a memory task yielded faster motor performance.

SESSION 520 (POSTER)

HEALTH CARE

WHO DID WE REACH WITH CTI®? THE CENTRAL TEXAS EXPERIENCE
J.L. Thorud1, A. Hochhalter1, A.B. Stevens1, R. McGhee2, 1. Program on Aging and Care, Scott & White Healthcare, Temple, Texas, 2. Central Texas ADRC, Belton, Texas

The Texas ADRC Evidence-Based Care Transition Program implemented the Care Transitions Intervention® (CTI) with funding from the Administration on Aging (AoA) and Centers for Medicare & Medicaid Services (CMS). CTI is an evidence-based, patient-centered, 30-day intervention to engage patients to manage their healthcare needs and reduce preventable readmissions. The intervention model consists of a home visit and two follow-up phone calls which focus on setting a personal health goal and four pillars: creating an accurate medication list, preparing for and attending a follow-up medical appointment, identi-

flying signs of exacerbation (red flags), and using a personal health record. The presentation will describe the program’s reach into the target population. After 19 months of operation, we have screened 5516 patients as eligible, 556 patients were enrolled and 292 have completed the intervention. The mean age of patients was 73 years (SD 8.3), 59% were female, 83% were white and 15% were Hispanic. Ninety-three percent lived in a small metro area and 41% had at least some college education. We found that 58% of patients rated their health as good or better and 63% were found to have adequate health literacy. Our data show that the program has reached a large number of patients in Central Texas. Although the diversity of our population is similar to the Texas rates, further work needs to be done to ensure we are reaching patients at highest risk for readmissions.

HOME CARE NEEDS AND THEIR INFLUENCE ON LIFE SATISFACTION, PERCEIVED LIFE STRESS, AND LONELINESS

L. Kadawaki1, A.V. Wister1, N.L. Chappell2, 1. Simon Fraser University, Vancouver, British Columbia, Canada, 2. University of Victoria, Victoria, British Columbia, Canada

Strong evidence has accumulated that has established the benefits of home care services for older adults in terms of medical outcomes and health services utilization. However, little research has been conducted on the potential psycho-social benefits. Resilience Models suggest that unmet service needs cut across all spheres of influence, including the psycho-social domain. In order to examine this gap, older adults receiving home care with their needs met were compared with persons who had unmet needs (whether they received home care or not) on three indicators of quality of life. The specific research question addressed by this study was: Do older adults whose home care needs are being met have higher levels of life satisfaction, and lower levels of perceived life stress and loneliness, than older adults with unmet home care needs? The potential buffering role of social support in these relationships is also investigated. Data were drawn from the 2008-2009 Canadian Community Health Survey, with 3,244 older adults (65+) meeting the study criteria. Regression analyses showed that older adults who had home care needs met reported higher levels of life satisfaction and lower levels of loneliness and perceived life stress than those with unmet needs. These relationships remained robust even after controlling for demographic factors, socioeconomic status, health factors, and social support. Social support appeared to play a mediating role in these relationships. The results suggest that home care plays an important role in the maintenance of quality of life and resilience for older adults.

DIFFERENT LEVELS OF HEALTHCARE USE FOR SELECT CHRONIC DISEASES AMONG RACIAL/ETHNIC IMMIGRANT GROUPS

Y. Yeo, College of Social Work, University of South Carolina, Columbia, South Carolina

Lack of information on racial/ethnic groups’ chronic disease prevalence and unmet healthcare needs among immigrants (65+) limits our efforts in reducing health disparities. K-medoids algorithm and multinomial analyses in the pooled 2002-2008 National Health Interview Survey data (N=9,262) were used, which allows for cross-cultural comparisons of each cluster characterized by different levels of healthcare use and examination of unmet care needs among non-Hispanic-white [White], non-Hispanic-black [Black], Hispanic, and Asian and Pacific Islander [API]. Results: K-medoids algorithm identified the optimum number of clusters was four: ‘Non-Users’ (33%), ‘Low-Ambulatory- and-Inpatient-Service-Users’ (30%), ‘Heavy-Ambulatory- and-Inpatient-Service-Users’ (18%), and ‘Heavy-Ambulatory-Service-Only-Users’ (20%). Non-User rates were highest among Blacks (46%), followed by APIs (42%), Hispanics (34%), and White (24%). Hypertension, musculoskeletal, cardiovascular, diabetes, and cancer were the most prevalent chronic diseases. However, the chronic diseases with high Non-Users rates varied: COPD and dementia among Whites; musculoskeletal, diabetes, asthma, and cancer among Blacks; kidney problems among Hispanics; Cardiovascular, diabetes and kidney problems among APIs. The chronic diseases’ prevalence rates and service use behaviors for the diseases varied among racial/ethnic groups. For example: Blacks: Hypertension (48%), musculoskeletal (36%), diabetes (18%), asthma (10%), and cancer (9%) were prevalent. Heavy-Ambulatory-Service-Only-Users tended to have hypertension or COPD; Heavy-Users, stroke; Low-Users, hypertension. Hispanics: Hypertension (45%), musculoskeletal (32%), diabetes (19%), cardiovascular (18%), cancer (7%), and asthma (7%) were prevalent. Those with musculoskeletal or asthma tended to use both healthcare services. Unlike other groups, Hispanics with stroke tended to be Heavy-Users. Findings will help to guide future interventions and research, improve immigrants’ health, and reduce health disparities.

RELIABILITY OF A GERIATRIC CONSULTATION TO IDENTIFY GERIATRIC SYNDROMES

S. Monod1, C. Bula1, I. Locatelli2, A. Jabri1, L. Herzig2, T. Bischoff2, J. Cornu2, N. Senn2, 1. Department of Geriatric Medicine, Lausanne University Medical Center, Lausanne, Switzerland, 2. Department of Ambulatory Care and Community Medicine, University of Lausanne, Lausanne, Switzerland

Introduction Geriatric consultations are standardized with the use of validated instruments and assessment protocols. However, the overall assessment of patients that integrates also clinical signs and symptoms may differ from a geriatrician to another. The objective of this study was to evaluate the reliability of an academic geriatric consultation for the identification of geriatric conditions. Method Participants (N=20, mean age 79.8 years, 35% female) were community-dwelling elderly persons aged 70 years and over referred by their primary care physician to the geriatric outpatient clinic. Over 2 successive consultations (mean time: 25 days apart), two geriatricians blinded to each other results assessed the presence of the following conditions: cognitive impairment; mood disorder; functional impairment; urinary incontinence; malnutrition; gait and balance impairment; osteoporosis; hearing impairment; visual impairment. Concordance between geriatricians was assessed for each geriatric condition and measured with percentage agreement and Kappa test. Results Prevalence rates for main syndromes were 75% for cognitive impairment, 65% for gait and balance impairment, 60% for mood disorder, and 47% for functional impairment. For all geriatric conditions, agreement between geriatricians was high, ranging from 55% to 90% (Kappa ranging from 0.56 to 0.80). Agreement was highest for mood disorder (90%), cognitive impairment (85%), and gait and balance impairment (83%) and lowest for malnutrition (55%). Conclusion Geriatricians assessing geriatric conditions reached a high level of agreement. These results support the use of such consultation as a criterion standard for research aiming at the investigation of geriatric conditions.

GERIATRIC NURSE PRACTITIONERS’ KNOWLEDGE, USE AND REFERRAL OF COMPLEMENTARY/ALTERNATIVE THERAPIES IN THE U.S.

C. Cheung2, C. Geisler1, 1. University of Minnesota, Minneapolis, Minnesota, 2. St. Catherine University, St. Paul, Minnesota

Many older adults include complementary/alternative therapies (C/AT) for health management and yet most health care providers underestimate the rate of C/AT use by their patients. A national study was conducted to: 1) assess geriatric nurse practitioners’ (GNP) knowledge, use, and referral of C/AT, 2) identify correlations between demographic variables and C/AT referral, and 3) describe factors affecting communication about C/AT use between GNP and their patients. A mixed method cross-sectional on-line survey was sent to member of the Gerontological Advanced Practice Nurses Association (GAPNA) (N = 3,812),
Data from n=170 GNP were used for analysis. The mean age of participants were 34 years (SD 5.8) with an average of 12 years of clinical practice. Over 87% GNP reported being knowledgeable about pet therapy, massage, and mind/body therapies and believed these C/AT to be effective: massage (92%), pet therapy (92%) and mind/body therapies (87%). Over 70% GNP reported using these C/AT and dietary supplements (70%) for personal use. The most commonly recommended C/AT were also massage (78%), dietary supplements (68%), and mind/body therapies (68%). Significant correlations were found among C/AT knowledge, use, and referral (p ≤ .05). Demographic variables were not significantly correlated to C/AT referral. Twenty-four percent of GNP reported discussing C/AT use with all of their patients while 13% never initiated any C/AT dialogue. Lack of time and evidence-based information, unsupportive institutional climate and patient inaccessibility to C/AT were the main barriers to C/AT communication. Most GNPs believed that integration of C/AT into clinical practice will improve patient outcomes.

CHOOSING WISELY: BENZODIAZEPINE AND SEDATIVE-HYPNOTIC USE AMONG OLDER SERIOUSLY ILL VETERANS

M.M. Garrido1,2, K. Boockvar1,2,3, H.G. Priegerson1,5, J.D. Penrod1, 1. James J Peters VAMC, Bronx, New York, 2. Icahn School of Medicine at Mount Sinai, New York, New York, 3. Jewish Home Lifecare Research Institute on Aging, Bronx, New York, 4. Dana-Farber Cancer Institute, Boston, Massachusetts, 5. Harvard Medical School, Boston, Massachusetts

In its recent “Choosing Wisely” list, the American Geriatrics Society recommends against benzodiazepines or sedative-hypnotics (BSH) as first-line treatments for anything besides alcohol withdrawal in older adults. Hospitalized older adults may be at high risk of receiving these potentially inappropriate medications. Agitation and insomnia occur frequently in older hospitalized patients, and BSH are among the treatments available for these symptoms. Using 2008-2010 Veterans Affairs NY/NJ Computerized Patient Record System data, we examined rates of and factors associated with BSH prescriptions among 291 veterans with serious physical illnesses who received palliative care during an index hospitalization (mean age=75, standard deviation=11). Twenty-one percent of patients received BSH for anxiety, agitation, insomnia, or unspecified reasons. BSH for sedation before medical procedures, alcohol withdrawal, and generalized anxiety disorder were excluded. With multivariate logistic regression, older age (Adjusted Odds Ratio[AOR]=0.96/year, 95% Confidence Interval[CI]=0.93-0.99) was associated with lower BSH likelihood, and past-year BSH use (AOR=2.32, 95%CI=1.14-4.70) was associated with greater BSH prescription likelihood during the index hospitalization. Whereas BSH likelihood declined with age, one-fifth of veterans 65+ in our sample were prescribed potentially inappropriate BSH for anxiety, insomnia, and agitation. Some BSH may have been prescribed for appropriate palliative indications, including symptom relief for patients who were imminently dying, but BSH rates did not differ significantly between those who did and did not survive until discharge. Future studies should clarify appropriate BSH indications in older palliative care patients while identifying targets for reducing inappropriate BSH use in older adults.

A COMPREHENSIVE HOME CARE PROGRAM AS AN EDUCATION MODEL INCORPORATES SIX ACGME CORE COMPETENCIES

E.A. Steinberg, 1. Geriatrics, University of Oklahoma, Oklahoma City, Oklahoma, 2. Veterans Affairs, Oklahoma City, Oklahoma

The American College of Graduate Medical Education (ACGME) created a new paradigm in medical education when it introduced the Six Core Competencies (noted below) over a decade ago. Success in care of medically complex homebound patients, who are often the disabled young and frail elderly, involves vigorously applying these six core competencies. We created a comprehensive home care program over 25 years, initially at the VA then in a private home-care practice, that incorporated these competencies in the interprofessional education of learners from the spectrum of health professional disciplines. Example components included: (a) detailed insights into the patient’s nursing, functional, social, psychological, nutritional and community support issues (patient care), (b) clarifying the long list of multiple complex medical problems and attendant polypharmacy (medical knowledge), (c) integrating the interdisciplinary team’s knowledge into patient care (Practice Based Learning and Improvement), (d) integral coordination with ancillary community services including durable medical equipment, home health nursing and rehab, infusion therapy, home counseling, home respiratory services, blood draw and imaging studies to treat this 5% of the Medicare population that consumes 50% of the Medicare budget (Systems Based Practice), (e) developing rapport with the patient and caregiver/family, who are often frightened, adversarial, and needy of attention (professionalism), and (f) frequent communication with the patient, caregiver, and community physicians (Interpersonal Skills and Communication). Experience illustrated that success required seeking a balance between cure and palliation. We believe that comprehensive home care programs are an excellent setting in which to teach challenging medical (and indeed geriatrics) competencies.

MEDICAL STUDENTS’ ATTITUDES TOWARDS CAREERS IN GERIATRIC MEDICINE: A QUALITATIVE PERSPECTIVE

M.L. Black1, M. Curran1, C. Depp1, A. Igleswicz1, L. Palinkas2, J. Reichstadt1, C. Moutier1, D. Jeste1, 1. Psychiatry, University of California, San Diego, La Jolla, California, 2. University of Southern California, Los Angeles, California

Although the number of older adults is expected to double by 2030, the number of medical students choosing to specialize in geriatric medicine is decreasing. The objective of this study was to determine what factors influence medical students’ decisions to pursue careers in academic geriatric medicine including barriers and facilitators. Data were collected from 27 medical students who participated in summer research training programs. All trainees were asked to complete an online survey at the conclusion of the programs. The survey included both open- and close-ended questions about barriers and facilitators to the perceived likelihood of pursuing an academic career and, separately, pursuing a career in geriatrics or an aging-related field. Analysis of the open-ended items followed a general inductive approach where investigators focused on generating themes and identifying relationships between themes. Qualitative analysis revealed 4 major barriers and 3 major facilitators. The barriers included lack of knowledge about academic careers and exposure to geriatrics, lack of adequate compensation, characteristics of the geriatric population, and negative impressions of research relative to clinical work. Facilitators included positive experiences with or impressions of the geriatric population, positive experiences with or impressions of research, and the increased demand for geriatric care due to the rising number of older adults in the population. There is a clear need to attract medical students to the field of geriatric medicine. Based on the results, it appears that medical students’ attitudes about working in this field may be malleable and early exposure to the field is critical.

STUDENT INTEREST IN WORKING WITH AGING POPULATIONS

W.J. Borges, D. Wagner, H.W. Smith, New Mexico State University, Las Cruces, New Mexico

Rowe et al. (2008) discussed the challenges to health care for older Americans and emphasized the lack of training in geriatrics for health care providers. Infusion of geriatric education for graduate health professions students is critical to address this challenge and meet the needs of the rapidly aging population. To assess current student interest in working with the geriatric population, the “Student Interest in Working
BALANCING RISK, SAFETY AND AUTONOMY: HOW DO HEALTH PROFESSIONALS WORK WITH COMMUNITY DWELLING FRAIL OLDER ADULTS WHO CHOOSE TO AGE-IN-PLACE AT ANY COST
H. MacLeod, Geriatric Assessment Outreach Team, Bruyere Continuing Care, Ottawa, Ontario, Canada

An estimated 89% of adults over the age of 50 said that they planned to remain in their present home for as long as possible, even if there were changes in their health (AARP, 2006). However, as one ages, health, home and support changes may occur that can impact on the older adult’s ability to live safely at home, causing family members and health care professionals to be concerned about the older adult’s risk of adverse health outcomes. This is a time where community care health professionals work within a client-centered model of care and want to support successful aging by optimizing the older adult’s health, independence and safety. However, balancing safety and autonomy when working with community-dwelling older adults living in potentially risky situations as they choose to age in place, can be challenging. This qualitative research project documented an understanding of health care professionals’ current practice when working with community-dwelling older adults who are labeled as “living at risk”. The data were collected through 11 individual in-depth interviews with health professionals (Nurses, Occupational Therapists, Physiotherapists and Social workers) who work as either a case manager or geriatric assessor with older adults living in their homes within an urban setting. The presentation will review the results of this research by discussing how health professionals make clinical decisions in this context and what facilitates and hinders this balancing act of safety and autonomy when working with community-dwelling frail older adults.

SESSION 525 (POSTER)

NURSING SCIENCE

FALL OCCURRENCE AMONG OLDER ADULTS: ASSOCIATION WITH NURSE STAFFING ON ACUTE CARE HOSPITAL UNITS
J. Choi, University of Kansas School of Nursing, Kansas City, Kansas

Purpose: Little is known about the effect of nursing staffing levels on fall occurrence among hospitalized older adult patients. The study purpose was to examine the relationship between nurse staffing and the rate of falls among older adults on five types of acute care hospital units. Methods: Longitudinal data on nurse staffing and falls in adult patients (age 65 and over) during 2006-2011 from the National Database of Nursing Quality Indicators® (NDNQI®) were used. Hierarchical Poisson regression analyses were performed. The analytical sample consisted of 18,505 observations from 4,211 units in 904 US hospitals. The included unit types were step-down, medical, surgical, combined medical-surgical, and rehabilitation units. Results: Overall, fall rates among older adults decreased over the 6-year period. Controlling for hospital characteristics (bed size, teaching status, and Magnet status), the fall rate was inversely associated with RN hours per patient day (HPPD), but not with non-RN HPPD. The relationship varied by unit type. Higher RN HPPD was significantly associated with lower fall rates on step-down and medical units but, unexpectedly, with higher fall rates on medical-surgical units. No relationship was found in surgical and rehabilitation units. Conclusions: Although further investigation on the positive relationship found in medical-surgical units is needed, the finding that higher RN HPPD was related to lower fall rates among older adults on step-down and medical units provides evidence to support the importance of adequate RN staffing to improve patient outcomes on acute care units. Strategies to ensure adequate RN staffing must be considered on a unit-by-unit basis.

EDUCATING NURSE PRACTITIONERS TO PRACTICE INTERPROFESSIONALLY
C. Fowler, C. Rutledge, K. Johnson, K. Kott, M. Lemaster, Nursing, Old Dominion University, Norfolk, Virginia

Introduction: Healthcare in the United States is in crisis. One reason is the inability of healthcare professionals to work well with each other. This may occur due to the failure to recognize the importance of interprofessional healthcare. Today’s healthcare issues such as care for older adults with complex health needs have been found to respond best to an interprofessional approach. However, too often, these issues are managed by sole providers. Methods: Through a HRSA grant, an interprofessional group of faculty has developed several courses to be taught by nursing, physical therapy, counseling, and dental hygiene. The courses include, health promotion, gerontology and leadership. Local and distance students from each profession are enrolled together in these web based classes. Students from each profession are placed in interprofessional groups of no more than 5 students. They then use distance technology to complete projects such as: 1) A Multimedia presentation for providers on the role of the various professions in addressing the health promotion needs of specific populations or 2) interprofessional technology driven health promotion educational materials for patient populations (webcasts, websites, Facebook pages, blogs, etc). Results: Currently the health promotion course is underway. There are 107 students from multiple disciplines enrolled. Several projects have been successfully completed. Planning for the gerontology course is also underway; it will be delivered over the summer. The leadership course will follow. A questionnaire about student’s readiness to participate in interprofessional learning was completed before the first course began and will be done again at course completion.

CATEGORIZATION OF PARTICIPANTS’ ACTIVITIES IN A NURSING RANDOMIZED CONTROLLED TRIAL
R. Maher-Imhof, L.B. Imhof, R. Naef, Institute of Nursing, Zurich University of Applied Sciences, Winterthur, Switzerland

Several RCTs investigated the effectiveness of nursing in-home consultation programs for elderly people on health outcomes. Patient-centered and tailored interventions have been shown to be crucial for behavioural changes. However, the aimed behavioural changes, the planned problem-solving activities and the feasibility of those activities from the participants’ perspectives in RCTs has not been reported. A recent RCT (n=461) that evaluated an Advanced Practice Nurse (APN) in-home consultation program for people ≥80 years in Switzerland, was guided by the principles of health promotion, empowerment, as well as patient- and family-centeredness. In the study that showed significant differences in self-reported acute events (RR=0.70, p=.001), falls (RR=0.71, p=.003), consequences of falls (p=.007), and hospitalizations (RR=0.70, p=.03), the participants’ perspectives on activities and factors that contributed to behavioural changes were investigated. Within the intervention sessions, the APN collected data on participants’ goal setting, planned activities and reassessed feasibility of the activities and achieved goals in the next session. The participants’ activities and their assessment of feasibility and achievement were documented. A total of 1395 participants’ activities could be categorized by scope and type of activities with a newly developed measure (Client Goal Categorization, 66th Annual Scientific Meeting 177

Downloaded from https://academic.oup.com/gerontologist/article-abstract/53/S1/NP/563183 on 30 April 2018 by guest
Subgroup-analysis revealed that gender, social support and health conditions correlated positively with participants’ assessment of feasibility and effectiveness of activities. The categorization allows insight in participants’ activities. It has to be further investigated whether significant results in RCT’s depend on a good fit between participants’ goals and their activities.

THE EFFECT OF THE MODERATE-INTENSITY PHYSICAL ACTIVITY ENHANCING PROGRAM FOR ELDERLY WITH HIP FRACTURE POST SURGERY
S. Suwanpasu1, Y. Aungsuroch1, C. Jitapanya2, 1. Nursing, Chulalongkorn University, Bangkok, Thailand, 2. King Chulalongkorn Memorial Hospital, Bangkok, Thailand

THE EFFECT OF THE MODERATE-INTENSITY PHYSICAL ACTIVITY ENHANCING PROGRAM FOR ELDERLY WITH HIP FRACTURE POST SURGERY SUNEESUWANPASU, ASSOC. PROF. YUPIN AUUNGSOUCH, ASSST. PROF. CHANOKPORN JITAPANYA Abstract It is a challenge to promote physical activity among elderly with hip fracture post surgery. A moderate-intensity physical activity enhancing program (MPEP) for hip fracture was designed and evaluated. An interventional study randomly assigned 46 elderly hip fractures to usual care plus a moderate-intensity physical activity enhancing program or usual care alone. The experimental group received physical training and efficacy-based intervention, as well as five telephone calls over six week periods. All the subjects received usual care for hip fracture post surgery. The MPEP was evaluated using pre- and post-tests of physical activity satisfaction in nursing intervention at posttest in experimental group was significantly higher than the control group after controlling delirium (p<.05). The MPEP can provide a reference for nurses who wish to improve the physical activity of elderly with hip fracture.

DESCRIPTION OF OLDER VETERANS’ DAILY TELEHEALTH CALL COMPLIANCE WHILE MONITORING FOR CHANGE IN HEART FAILURE STATUS
M. Murphy, University of Utah, Salt Lake City, Utah

Background: Home-based older adults with heart failure (HF) experience frequent hospital readmissions (Salters, Bailey, & Whyane, 2010). Remote telehealth monitoring programs are designed to provide home-based support services that reduce the need for hospital readmissions. The largest telehealth study of non-veteran older adults with HF (n = 1653) described that 14% of the telehealth group did not initiate the intervention, and, by the final week of the study, only 55% of the telehealth group used the daily service ≥ three times per week (Chaudhry, 2010). Purpose: The purpose of this study is to describe older veterans’ daily telehealth call compliance. Methods: A description of secondary data of daily component submissions for vital signs, medication and diet adherence, symptom recognition of increasing dyspnea and fatigue, and possible alerts generated from out-of-range measurements from predefined limit settings, is being collected from initial 90 days of program participation. Results: Description of the call compliance frequency for daily telehealth submission results will be reported as means and standard deviation. Description of alerts generated from telehealth component measurements (heart rate, systolic blood pressure, weight, behavior response, symptom response) will be reported for each participant’s total, moderate, high, and no alert frequencies. Aggregate data will be described by mean, standard deviation, and range. Limitations: Secondary data does not allow for follow-up interviews related to program participation. Conclusions: Description of older veteran call compliance for daily telehealth submissions revisits the foundational participant measurements (heart rate, systolic blood pressure, weight, behavior response, symptom response) in relation to standardized home health admission process.

WHO SHALL WE VISIT FIRST? GREAT VARIATION IN HOW HOME HEALTH PRIORIZES PATIENTS’ FIRST HOME VISIT
M. Topaz1, D.V. Molkina1, O. Jarrin1, K. Radhakrishnan2, M. O’Connor3, K.H. Bowles1, 1. Nursing, UPenn, Philadelphia, Pennsylvania, 2. University of Texas, Austin, Texas

Introduction: Recent evidence shows that, for certain patients, the timing of the first home nursing visit is an effective strategy to reduce readmissions. Home health managers and intake nurses make important decisions about initial visit timing for over 11 million patients per year. The purpose of this study was to explore how home health agency personnel make decisions about initial visit timing. Methods: Semi-structured interviews were conducted with a purposive sample of 12 home health managers and experienced intake nurses from agencies of different sizes and in different geographic areas of the United States. Interviews focused on sets of factors (i.e. patient characteristics, policies and procedures) that influence decisions to prioritize initial nursing visits. Interview transcripts were exhaustively coded using software for qualitative analysis to reveal themes. Findings: Several strategies we identified: Sickest Quickest - some agencies prioritized patients based on chronic conditions (e.g. heart failure or chronic pulmonary disease); Breaking the Cycle - other agencies prioritized prior hospitalizations or social factors (e.g. availability of informal caregiver); No Norm – overall, there was a great variation in reported factors, procedures, and policies affecting decisions about prioritization of initial home health nursing visits. Formal protocols to guide prioritization of patient visits were uncommon. Discussion: Providing timely home visits for patients at risk of readmission is vital. This study revealed no evidence-based approaches to making these important decisions. Research is needed to identify factors that inform visit prioritization and to standardize the home health admission process.
Effect of Roselle Tea on Improving Urinary Tract Infection Among Taiwanese Nursing Home Residents

W.N. Liu1, C. Liu2, R. Han1, 1. Central Taiwan University of Health Science and Technology, Taichung, Taiwan, 2. National Taichung University of Science and Technology, Taichung, Taiwan

Background: Urinary Tract Infection (UTI) is one of the most common infections in long-term care facilities. Taiwanese Roselle tea containing the same ingredients as Cranberry has not been well studied. Method: 65 participants with a high-risk UTI from a nursing home located in central Taiwan were randomly assigned into the control and experimental groups. Older adults in the control group took 300cc water per day, whereas the other group had the same amount of Roselle tea. Both groups had their urine checked at the baseline, the 6th and the 12th week. Results: In the experimental group, E. coli was significantly decreased between the baseline and the 12th week (t=1.720, p=0.048). E. coli account also differed significantly between the two groups (t=2.323, p=0.012). At the 12th week, E. coli infection in the control group was almost 4 times higher than the other group (OR=0.231, RR=3.333). Moreover, age was a significant factor between Roselle tea and urinary tract infection. In the beginning, age was positively correlated with the infection (rs=0.416, p=0.022); however, this relationship was ended after 6 weeks of drinking Roselle tea (rs=-0.195, p=0.301) and continued to the 12th week (rs=-0.321, p=0.084). Conclusions: Roselle tea was found to be effective in decreasing E. coli colonies at the 12th week.

Evaluating a Pressure Ulcer Prevention Intervention in LTC: Applying Diffusion of Innovation

Pressure ulcer (PU) prevention is a challenge in nursing homes. Numerous factors increase risk for PUs, and evidence is unclear about which, if any, approach to prevention is more effective, but everyone can reduce risk by increasing mobility. Therefore, we conducted a 12-month paired-facility randomized nurse-led intervention in eight Midwestern facilities; musical cues were used to prompt multidisciplinary teams to move/reposition all residents (not just those at risk for PUs) every two hours during the daytime. Mean odds ratios suggested intervention facility residents were 45% less likely than comparison facility residents to develop a new PU. Upon study completion, qualitative focus groups were conducted in all eight intervention facilities (n=45) to explore perceptions of adoptability and effectiveness. Focus group sessions were transcribed verbatim for analysis. Using a priori codes (Compatibility, Complexity, Observability, Relative Advantage, Sustainability, and Trialability) based on Diffusion of Innovation, five analysts (three not original to the study) coded the data. We developed and refined code definitions until we exceeded 85% agreement for inter-rater reliability. Findings indicated that staff perceived the music cueing as helpful and improved quality of life for both residents and staff; they also perceived that PU rates were decreasing. Staff perceived the added documentation required to track movement and sometimes timing of music-cues as barriers. Cueing multidisciplinary teams to encourage movement or repositioning of all residents holds promise for reducing facility-acquired PUs. These findings extend beyond PU interventions and suggest that cueing approaches may be useful for creating other behavior changes in nursing homes.
PATIENT ENGAGEMENT WITHIN AN AGING POPULATION
N. Falk, M. Schumann, School of Nursing, The George Washington University, Washington, DC, District of Columbia

Patient engagement, “the actions individuals must take to obtain the greatest benefit from the health care services available to them” (Center for Advancing Health, 2010) is the responsibility of both patients and providers. In 2012, the Nursing Alliance for Quality Care (NAQC) in Washington, DC, a national alliance of 20 nursing and patient care advocacy organizations developed a multi-pronged initiative to gain greater understanding and build consensus on the topic of Nurses’ Contributions to Fostering Patient Engagement. Guiding principles for patient engagement were developed and disseminated. An interdisciplinary panel of about 18 experts was convened to inform development of a white paper for dissemination. The paper served as the basis for discussion at a national symposium funded by the Agency for Healthcare Research and Quality (AHRQ). The paper, scheduled to be disseminated in the first quarter of 2013, was further developed based on feedback from symposium participants. The final white paper includes a logic model and engagement strategies and behaviors that nurses and other providers can use to positively impact patient outcomes.

SESSION 530 (POSTER)

TECHNOLOGY

PASSIVE AND UNOBSERVABLE SENSOR NETWORK ON AN ALZHEIMER'S SPECIAL CARE UNIT: A SINGLE-SUBJECT FEASIBILITY STUDY
J. Giger, W. Schweinle, S. Smallfield, University of South Dakota, Vermillion, South Dakota

Aim of the Study: Sleep problems are common in nursing home and special care unit (SCU) residents and poor sleep can lead to cognitive decline, falls, and increased mortality. Sleep assessment in an SCU was previously unrealistic due to compliance issues related to the impracticality of using wearable sensors with older adults with dementia. Due to recent advances in sensor technology and data processing, passive and unobtrusive ballistocardiography-based systems can detect sleep quality and trends in older adults. To address the aging U.S. population and accompanying public health costs associated with institutional care, we investigated the feasibility of installing the Wellaware sleep quality system in a SCU. Method: We conducted a single-subject case design study with a 95 year old woman with dementia residing in a SCU in South Dakota. Sensor data from the participant and her clinical record were retrospectively analyzed from December 10th, 2012, to January, 09th, 2013, to determine the sensor network’s functionality. Results: The sensor network is feasible on a SCU and provides detailed resident information on sleep disruptions, rest efficiency, and rest continuity. Sensors detected the participant’s sleep quality was impacted, possibly as a result of non-routine holiday SCU events, but conventional SCU sleep monitoring and reporting did not detect this disruption. Conclusion: Passive sensors show considerable potential by identifying sleep quality and detecting overall sleep trends. More precise SCU sleep ‘ground truth’ could lead to improved biosocial and pharmacological interventions and resident outcomes and decreased staff and unit disruptions. Recommendations for future research are presented.

ATTENTION WORKOUTTM: IMPROVING COGNITION IN OLDER ADULTS ONLINE

Evidence suggests that cognitive training interventions can improve cognitive performance in older adults. Computerized training programs are useful because they are often accessible from older adults’ homes, and are cost effective. In this pilot study, we examined the effect of an online attention-training program, Attention WorkoutTM, on coordination, allocation, and selective focus—three aspects of attention focused on executive control. Participants were cognitively normal, community-dwelling adults age 55 and older (mean=70.8) who completed baseline measures of attention, working memory, and verbal memory, and were assigned to extended or abbreviated attention training. Participants repeated cognitive tests six weeks later. The extended-practice group significantly improved on word-list learning accuracy (Z=-2.69; p<0.01) and number of words recalled (Z=-2.69; p<0.01), while the abbreviated practice group significantly improved on word-list learning accuracy (Z=-3.27; p<0.001), number of words recalled (Z=-3.27; p<0.001), a field of vision distraction task (Z=-2.48; p<0.01), and two measures of a coordinating attention task (Z=-3.51, p<0.001; Z=-2.24; p=0.03). Participants completed a survey post-intervention and both groups found the program enjoyable and easy to use, with a mean score of 4.14 out of 5 on a satisfaction scale. These early results suggest that online training programs like Attention WorkoutTM may lead to gains in verbal memory, coordinating attention, and allocating attention, and that older adults would be likely to enjoy using such programs. Online cognitive-training programs circumvent the need to travel for training, and hold promise for improving cognitive abilities in cognitively normal, community-dwelling older adults.

EVALUATING THE IMPACT OF A DOSE RANGE CHECKING ALERT FOR OPIOIDS IN ELDERLY PATIENTS

To improve safety, computerized physician order entry systems commonly employ clinical decision support systems that target appropriate dosing of medications. We evaluated the impact of a dose range checking alert on opioid prescribing practices in elderly patients. A retrospective, non-matched cohort was identified to include patients aged 70 years and older hospitalized between January 2009 and August 2009 with an order for injectable fentanyl, hydromorphone, and/or morphine. Opioid orders 16-weeks before implementation of the alert (Group 1) were compared with orders 16-weeks after implementation (Group 2). Data included order information (drug, dose, frequency, date, and time) and new medication orders within two hours after the alert to assess prescriber compliance to alert recommendations. Compliance was defined as changing or discontinuing the initial order. 788 patients in Group 1 (53.2% female, 79.7% Caucasian, mean age 79.3 years) were similar to the 419 patients in Group 2 (53.5% female, 80.4% Caucasian, mean age 79.7). There were 1057 opioid orders in Group 1 and 1945 opioid orders 16-weeks after implementation. 788 patients in Group 1 and 788 patients in Group 2 were used in this study. Overall alert compliance was 55.4% in Group 1 vs. 44.5% in Group 2; and fentanyl = 27.9% in Group 1 versus 15.0% in Group 2. Alert compliance by opioid group: morphine = 54% in Group 1 vs. 44.5% in Group 2; hydromorphone = 73.3% in Group 1 vs. 23.1% in Group 2; and fentanyl = 27.9% in Group 1 versus 15.0% in Group 2. Overall alert compliance was 55.4% in Group 1 compared to 31.1% in Group 2 (p<0.001). Implementation of a dose range checking alert did not improve the appropriateness of opioid prescribing in the elderly at the point of order entry by the prescriber.

EFFICACY OF TELEREHABILITATION FOR OLDER ADULTS PRESENTING A CHRONIC OBSTRUCTIVE PULMONARY DISEASE (COPD)
M. Tousignant, N. Marquis, P. Larivée, Y. Poulin, M. Mathieu, 1. Research Centre on Aging, Sherbrooke, Quebec, Canada, 2. Université de Sherbrooke, Sherbrooke, Quebec, Canada, 3. Centre hospitalier universitaire de Sherbrooke, Sherbrooke, Quebec, Canada

Objective. To compare the efficacy of a 15 sessions in-home telerehabilitation program before and after pulmonary rehabilitation for COPD...
THE ROLE OF ONLINE TECHNOLOGY USE ON OLDER BREAST AND PROSTATE CANCER SURVIVORS’ SELF-RATED HEALTH

This study investigated how online technology variable including use of email or texting contributes to older breast and prostate cancer survivors’ self-rated health. 581 older breast and prostate cancer survivors were drawn from the 2011 U.S. National Health and Aging Trends Study (NHATS), a nationally representative study of Medicare beneficiaries. The study’s sample included community-dwelling older cancer survivors aged 65 or above who had access to the Internet or use mobile phone. The outcome variable was measured as older cancer survivors’ self-reported health and online technology variable was measured as usages of email or text messages. Hierarchical regression analysis showed that older cancer survivors’ online technology use was positively associated with their self-rated health while controlling other relevant variables. This study revealed that use of online technology could improve older breast and prostate cancer survivors’ health status, indicating that online technology can be a prominent medium to promote health among older cancer survivors.

SISMOM: HUMAN FALL RISK DETECTOR CAN PROVIDE INDEPENDENCE AT A LOW COST
P.C. Castro1, M.P. Ponti1, J. Oishi1, G. Poli1, G. Santus1. 1. Gerontology, Federal University of São Carlos - UFSCar, São Carlos, São Paulo, Brazil, 2. Universidade de São Paulo - USP, São Carlos, São Paulo, Brazil, 3. INOVA, São Carlos, São Paulo, Brazil

Background: A high-risk fall accident can result in fatalities or cause an impact on the elderly functional capabilities, accounting for frailty and incidence of morbidity. Despite that, there is a lack of commercial real-time fall risk prediction devices that are able to provide monitoring and independence life. Objectives: to use an automatic human fall risk predictor device at a low cost and to perform a pilot test. Method: A tri-axial acceleration sensor was attached to a small development board; also, computer software was developed to process the data and output fall risk on a patient. Pilot: 4 elderly volunteers (2 non-fallers) performed 5 times the Timed Up and Go Test, wearing the device attached to waist (center of mass). Each volunteer was asked, in a single question, about the comfort of the device. Data Analysis: The device data was processed by a feature extractor (time-window acceleration differences), and used by an anomaly detection algorithm (multivariate Gaussian detector) to predict fall risk. At each of the two experiments, one of the two non-faller volunteer data was used to train the algorithm, while the remaining was used as test data. Results: Final cost was around US$ 60. All volunteers considered the device comfortable and wearable for a long period of time. The device was able to correctly predict risk of fall in all experiments. Conclusion: SisMoM is a comfortable and affordable, human fall risk predictor device to monitor patients, with good accuracy potential, and consequently can provide independence for old community-residents.

ELECTROMAGNETIC SIMULATION OF AN ULTRAWIDEBAND WEARABLE WIRELESS RADIOMETER ANTENNA TO MONITOR INTERNAL BODY TEMPERATURE FOR AGING POPULATION
H. Li. School of Information and Electronics, Beijing Institute of Technology, Beijing, China

Internal body temperature (IBT) is one of the most important vital signs for the elderly. The variation of IBT of different organs may represent potential disease risks and long term aging effects, hence is a crucial but missing piece of data for most gerontology researchers. This research addresses a new method of integrated design and implementation of an external passive radiometer for monitoring IBT for the elderly. The goal for the research is to develop a miniature wearable temperature-monitoring device for continuous automatic data collection in a home setting. The proposed system will be a valuable tool for researchers/clinicians and has the potential to provide early diagnosis of changes in the aging process of varies organs for clinicians from the IBT perspective. The technological aspect of the project relies on the basic principles of near-field microwave radiometry, an engineering approach for monitoring IBT in an environment with radio interference, and the electromagnetic simulation of the ultra-wideband (UWB) antenna with near field body effect. The overall goal of the research is the development of a wearable external radiometric thermometer for the elderly, with a spatial resolution on the order of 1cm and temperature resolution of 0.1K. The radiometer data can easily be transmitted using a low-power wireless transceiver for further off-body processing. The results presented herein is the UWB antenna near field simulation, which is a crucial component of the entire system.

PERSONAL ALARMS: DO THE RIGHT OLDER AUSTRALIANS PURCHASE THEM?
G. Lewin1,2, K. De San Miguel1. 1. Curtin University, Perth, Western Australia, Australia, 2. Silver Chain, Perth, Western Australia, Australia

Background: Personal alarms are designed to enable people gain assistance in an emergency. They have been available in Australia for nearly 20 years and elsewhere even longer. There has been surprisingly little research into their use and effectiveness. In Australia, some States provide alarms to “at risk” individuals but the majority of use in Australia is by self-funded users. The study objectives include: - Understanding older people’s alarm purchase decisions - Describing the ‘risk profile’ of purchasers and non-purchasers - Exploring how often emergency assistance is needed and why - Examining the relationship between individuals’ risk profile and having an emergency Study Design A prospective cohort study in which older purchasers and non-purchasers (all having been referred/made enquiries) are being followed up monthly for a year. Results 200 purchasers and 95 non-purchasers were recruited. The groups had similar risk profiles and demographics. Having fallen (47%) and family wishes (35%), were the most common reasons for purchase. Cost was the most common reason for non-purchase (51%). In 2 out of 6 months the non-purchasers were significantly more likely to have had an emergency. Of all 192 emergencies in 6 months, 117 were due to a fall. Across both groups “at risk” individuals were more likely to have had an emergency (43% vs 35%). Conclusions Cost is a significant factor influencing older people’s decision to purchase a personal alarm.
NEW VIDEO-TELEHEALTH GERIATRIC CONSULTATION FOR RURAL PROVIDERS AND VETERANS IN THE VA PALO ALTO HEALTHCARE SYSTEM

N. Oliva1,2, K. McConnell1, B. Wexler1,2, S.R. Brunskill1, D. Chambers1, J. Tenover1,2, 1. VA Palo Alto Healthcare System, Palo Alto, California, 2. University of California, SF, San Francisco, California, 3. Stanford University School of Medicine, Stanford, California.

Background: In 2012, the Geriatric Research, Education and Clinical Center (GRECC) in the VA Palo Alto Healthcare System (VAPAHCs) developed a geriatric consult video-telehealth service (GCVT) for rural community-based outpatient centers (CBOCs) and Veterans. A majority of the 13,782 square miles in the VAPAHCs is rural and home to an estimated 69,000 Vets aged 55+. Driving times of up to six hours preclude most rural Veterans from a face-to-face VAPAHCs geriatric consultation. Method: With survey input from rural CBOCs in the VAPAHCs, the GCVT focused on high priority consult evaluations from primary care providers (PCPs) for dementia and polypharmacy. The GRECC clinical team includes a geriatrician, geriatric Clinical Nurse Specialist, and geriatric social worker and offers interdisciplinary assessment, patient and family education and treatment consultation to Veterans and caregivers. The GCVT team provides written care recommendations to both PCPs and Veterans/caregivers. Results: Over the first five months of the program, GCVT received 16 referrals and directly served 13 community-dwelling Veterans and 18 family caregivers. Veterans ranged in age from 69 to 90, with a median age of 80; 12 of 13 were male. All were referred by PCPs for evaluation of ongoing or new-onset dementia and/or polypharmacy in the presence of numerous comorbidities and functional limitations. A majority of referrals and GCVT evaluations also involved significant caregiver stress. Conclusions: Technology and unexpected staffing issues were challenges in the GCVT implementation; however, there is early evidence that PCPs, Veterans and caregivers benefit from and are satisfied with GCVT services offered.

SESSION 535 (POSTER)

ASSESSMENT AND MEASUREMENT STUDIES

DEVELOPMENT OF THE COMPREHENSIVE FRAILTY ASSESSMENT INSTRUMENT

Purpose The Comprehensive Frailty Assessment Instrument (CFAI) is a new self-report instrument including physical, psychological, social and environmental indicators used for detection of frail community dwelling older people. Methods Scale validation study on data provided by the Belgian Ageing Studies, a cross-sectional survey conducted in 142 municipalities in the Dutch speaking part of Belgium. 33 629 community dwelling respondents aged 60 and over were included. Second-order confirmatory factor analysis with step by step deletion was used and internal consistency was assessed. Results The CFAI showed a Cronbach’s α of .812, explaining 63.6% of the variance in frailty and fit indices of: RMSEA=.032, CFI=.974 en TLI=.970. Emotional aspects contributed more to frailty than social, physical and environmental aspects. Conclusion The CFAI is found to be valid and reliable, providing evidence for the multidimensionality of frailty and can be easily used to detect community dwelling frail older people.

STAYING BLIND IN A COLORFUL WORLD: MINIMIZING COLLECTION BIAS IN TRIALS WITH INTENSIVE INTERVENTIONS

P.B. Arthur2,1, W. Mann1,2, L.N. Gittin1, 1. Rehabilitation Science, University of Florida, Gainesville, Florida, 2. North Florida South Georgia Department of Veteran’s Affairs, Gainesville, Florida, 3. Johns Hopkins University, Baltimore, Maryland.

Purpose: Blinding in clinical trials is critical, though challenging due to complexities of behavioral interventions with older adults and the contexts in which they are implemented. This poster reports on blinding methods used in a home-based intervention and their effectiveness. Methods: In this single-blind parallel randomized controlled trial, participants are randomized into attention control or home-based intervention groups. Attention control participants receive caregiver education telephone calls for 4 months while intervention participants receive in-home interventions for 4 months. A blinded data collector takes assessments at baseline, 4 month, and 8 month (long term) periods. The data collector is blinded to address treatment bias and 6 study controls are implemented to ensure continued blinding. Results: To date, 38 standardized and manualized baseline interviews (T1) and 6 follow-up interviews (T2) have been completed in a trial using a behavioral intervention to address challenging behaviors in Veterans with dementia. The data collector has reported continued blinding to treatment assignment for all 38 participants. Discussion: To ensure blinding, caregivers are notified of data collector blinding and asked not to reveal their assignment. The data collector does not have access to study data that could compromise blinding. Study phone calls are performed in locked offices. The data collector is not present at interventionist meetings. An unblinded monitor distributes study-related messages to the correct party. The data collector records their “guess” of group allocation after each contact with scripted evidence. To date, none of the 6 procedures have been violated and study blinding has been successful.

A MULTILEVEL ANALYSIS OF NET INCOME OF THE URBAN DISABLED ELDERLY IN CHINA

W.J. Jing, Institute of Population Research, Peking University, Beijing, China.

Objective. This study aims to investigate whether the regional factors plays a role in the relationship between individual independent variables and the urban elderly’s net income. Methods. Data from the 2011 National Survey of disabled people in China is used. This research only focuses on participants who are urban residents and at the age of sixty and above. Hierarchical linear models ascertain how micro-level factors is influenced by macro-level attributes and explore how the where element plays a role in the mechanics. Results. Among the micro-level variables, we find that significant risk factors for lower net income are being older, unemployed, higher disability grade, lower levels of education, having no pension, medical insurance and minimum living allowance. This statically significant relationship holds constant even after level-2 control factors are introduced. In the macro-level, we find that lower average minimum living allowance and higher consumer price index have an negative effect on the level of net income. Discussions. This research introduces the where element to advance our understanding of how resource distribution affects the net income of the urban elderly. Hierarchical linear models indicate that as the provinces where the urban elderly live have a lower average minimum living allowance and higher consumer price index and, the odds of being in lower net income increase for the urban elderly.

DEVELOPING A SCALE OF ATTITUDES TOWARD EDUCATION FOR OLDER ADULTS

H. Kim, N. Abell, L.P. Cheatham, College of Social Work, Florida State University, Tallahassee, Florida.

The purpose of this study is to validate a new scale assessing attitudes toward elderly education. For optimal aging, educational programs...
for health management skills and basic computer techniques have been expanded. Senior centers are significant providers of such educational programs, and social workers are highly involved with the programs. Assessing social workers’ attitudes toward elderly education is critical to increase the effectiveness of the educational programs. The 42 items in the initial pool for the Attitudes toward Education for Older Adults (AEOA) scale were developed by focusing on the three subconstructs of attitudes (cognition, emotion, and behavior) across three age groups (young-old, mid-old, and old-old). The survey was administered to 252 college students in 2012. Several reliability and validity analyses were conducted. 38 items were retained in the final AEOA scale. All α coefficients were over .80; stratified α was .96; and the results of SEMs were acceptable. In terms of the validity, CFA indicated a good model fit: the chi-square ratio lower than 2.5, the CFI greater than 0.95, and the RMSEA and the SRMR lower than 0.08. Respondents who were older, who had work experiences with older adults, and who had positive attitudes toward older adults and aging (r = .37, p < .01) were positively associated with the AEOA scale. The AEOA scale was successfully developed and validated. The scale expands this area of gerontological research and provides a new tool for better assessing attitudes regarding educational opportunities for older adults.

MEASURING UNMET CARE NEEDS OF OLDER CANADIANS LIVING IN PRIVATE HOUSEHOLDS

J. Keeffe1, S. Vezina2,3, P. Spin3, 1. Family Studies and Gerontology, Mount Saint Vincent University, Halifax, Nova Scotia, Canada, 2. Institut National de la Recherche Scientifique, Montreal, Quebec, Canada, 3. Dalhousie University, Halifax, Nova Scotia, Canada

Introduction: Past research shows that insufficient help may place vulnerable individuals at risk of functional decline and, if not addressed, institutionalization may occur. This research examine prevalence of unmet and undermet needs for personal assistance with activities of daily living (ADLs) and instrumental ADLs among older Canadians with disabilities. Method: Using the 2006 Participation and Activity Limitation Survey (PALS) data, eight ADLs and IADLs are examined. The overall prevalence of the population with unmet or undermet needs is calculated as well as the prevalence of met, undermet and unmet need for each activity. Binary and multinomial logistic regressions are performed, respectively, for the two models. The independent variables in the model include: age, sex, country of birth, living arrangements, number of surviving children, schooling level, region of residence, number of activities for which help is needed, and disability level. Results: 503,000 older Canadians with a disability, with needs, and living in private households had at least one unmet or undermet need in 2006. Among them, 47.3% don’t receive all the help for 2 or more needs (activity). Highest prevalences of unmet/undermet needs are observed for heavy household chores and moving about. The number of needs, the disability severity, and to a lesser extent education, significantly increases the probability of having unmet/undermet need; age significantly decreases this probability. Conclusion: With the large baby boom generation beginning to enter the 65+ age group, our aging societies need to develop long-term strategies for the delivery of formal and informal care.

WHAT ARE THE DOMINANT PATTERNS OF EXPENDITURE AMONG OLDER PEOPLE AND WHAT EXPLAIN THESE?

D.A. Hayes1, A. Finney2,1. Personal Finance Research Centre, University of Bristol, Bristol, United Kingdom

Policy-makers and practitioners need a good understanding of older people’s expenditure and consumption to inform the design of policies and services that affect their lives. This understanding also informs the wider academic debate surrounding aspects of wellbeing among older people. Although poverty and material deprivation among this population has been the subject of considerable research, the implications of an aging population for levels and patterns of expenditure and consumption more generally have not been explored adequately. Analysing both equivalised and absolute expenditure, this research uses household-level data from the United Kingdom’s Living Costs and Food Survey to: 1. describe expenditure by age and other key variables using descriptive statistics (among households where the Household Representative Person (HRP) is aged 50 or over); 2. segment and construct a typology of older households based on their expenditure patterns (using cluster analysis); 3. determine the drivers of these expenditure patterns (using logistic regression analysis). Early empirical results from the phase one of our analysis include: 1. The proportion spent on food increases with age – the 50-54s spend 11% of their weekly outgoings on food, compared to 16% among the 80+; 2. The proportion of expenditure used for housing, water and electricity doubles from 10% among the 50-54s to 20% among the 80+. Interestingly, expenditure on communication remains the same across all older age groups (3%). This work has implications beyond the United Kingdom. Using an innovative methodology, it generates detailed knowledge of differences in expenditure and consumption among the older population.

OLDER PERSONS TRANSITIONS IN CARE (OPTIC): CHALLENGES IN MEASURING SUCCESS IN TRANSITIONAL CARE ACROSS MULTIPLE SETTINGS

Purpose: The OPTIC study aims to identify: successful nursing home-to-emergency department (NH-ED) transitions from multiple perspectives, organizational and individual factors related to transition success; and improvements in care for frail elderly residents during transitions. Review of Literature: NH residents frequently transition between NHs and EDs. Care during transitions is often suboptimal, and is complex due to involvement of different professionals, and this frail population’s degree of dementia and other chronic conditions. Methods: OPTIC is a mixed method researcher/decision-maker partnership study. Phase 1 used qualitative methods to investigate residents’, family caregivers’, and healthcare providers’ perspectives of NH-ED transitions. Phase 2 consisted of pilot testing all data collection tools and then tracking transitions over a one-year period in two Western Canadian provinces. Phase 3 consists of data cleaning and analyses to identify successful transitions, avoidable transitions and factors influencing both, and recommendations for implementation, policy and future research. Results: In Phase 1, 71 participants were interviewed, and 54 transitions were tracked over a 3-month pilot period. NH-ED transitions were not universally successful. In Phase 2, full data collection was completed on 600 transitions from 41 nursing homes. Results reflected differences by city demographics, organizational and provider characteristics, resident characteristics and other factors. Phase 3 analyses and integrated knowledge translation between decision-makers and researchers are currently underway. Discussion: Patient care records and provider interviews are valuable sources to evaluate transitions. This presentation focuses on challenges to capturing data from multiple sources, settings and providers across transitions, and results in identifying successful/unsuccessful transitions.

THE IMPACT OF AGING & DISABILITY RESOURCE CENTERS (ADRC) ON CONSUMER SATISFACTION AND OTHER OUTCOMES

D.L. White, S. Elliott, Institute on Aging, Portland State University, Portland, Oregon

Two rounds of data were collected through a telephone survey of a random sample of Oregon ADRC consumers. Round 1 (n=247) was
conducted soon after full implementation of ADRC and options counseling (OC) services. Round 2 followed one year later (n=303). Both closed and open-ended questions were used to assess program standards related to access and hospitality, information and assistance, and options counseling. Participants also described their needs, services used, outcomes experienced, and made recommendations. Improvements were noted between Rounds 1 and 2 (e.g., participants reported that the ADRC phone was answered by a person more frequently, more received a home visit, greater satisfaction with decision support, greater follow up). Positive outcomes (e.g., living in a desired place, adequate support to meet needs and preferences, safety and independence) were related to higher ratings of staff, number of services received, and greater understanding of options. Some significant differences were noted between consumers and family members (e.g., rating of staff attributes, some outcomes) and between those receiving OC services and/or home care services, and those receiving I&A service users only. Level of income, number of needs identified, and amount of contact with the ADRC were not related to outcomes or satisfaction ratings. Implications for continued program development and public policy are discussed.

PRELIMINARY RESULTS FROM THE NATIONAL PROCESS EVALUATION OF THE AGING AND DISABILITY RESOURCE CENTER PROGRAM

R.M. Bertrand1, L. Buatti2, S. Jenkins2, T. Barretto3, S. Pedersen1

The Aging and Disability Resource Center (ADRC) Program, a collaborative effort of the Administration for Community Living (ACL) and Federal partners, supports highly visible and trusted sites that provide older adults and individuals with disabilities information on the full range of long-term services and supports (LTSS). By simplifying LTSS access, ADRCs promote optimal aging and serve as the cornerstone for LTC reform. Supported by the ACL, this study is the first national evaluation of the program since its 2003 inception. The primary goal is to assess the ADRCs’ overall effect on LTSS accessibility and evaluate whether or not they are fulfilling their mission. The study includes all ADRC directors at the state- and local-level in a process evaluation; and 23 ADRCs in an outcome evaluation - 20 randomly selected and three selected with intention because they offer state-wide coverage. Twenty Area Agencies on Aging in service areas not covered by an ADRC were matched on region and rural/urban status and serve as the comparison group in both evaluations. This presentation reports the results of the process evaluation conducted via web-based survey, administered through April 2013. Findings address the extent to which ADRCs provide the full range of services, implement the ADRC mission of streamlined access (e.g., no wrong door/single entry point), and utilize strategies that facilitate effective and efficient coordinated provision of LTSS. The results will be used to target technical assistance to sites not fully implementing the ADRC model, and will lead to program refinement and continuous quality management.

SESSION 540 (POSTER)

CIVIC ENGAGEMENT AND POLITICS OF AGING

PREPARING RURAL OLDER ADULTS TO LEAD COMMUNITY CHANGE THROUGH CONTEMPORARY MULTIMEDIA OUTLETS

D.C. Wihry, J. Crittenden, L.W. Kaye, M.R. Noyes, University of Maine, Orono, Maine

This poster will examine the personal impacts and community projects resulting from utilizing a model of intensive training and technical assistance to impart rural older adults with the skills necessary to report, analyze, and disseminate news as citizen reporters of community issues. Thirty-one individuals (average age 66.5, range 52-81) participated in six technical workshops through the Boomer Reporting Corps initiative to develop skills in production of professional multimedia narratives and journalistic products targeting the important issues of their local communities. Increments in participant skill levels were measured to examine knowledge acquisition in new media and citizen journalism techniques. Greatest average knowledge increases as measured pre and post-training on a 10 point Likert scale were: 1) understanding how to identify subjects that lend themselves to multimedia narrative (5.07 increase); 2) understanding how photographs can be grouped and sequenced to create a visual narrative in galleries and slide shows (5.44 increase); and 3) understanding substantive issues in communities that may be explored using multimedia narrative techniques (6.0 increase). Additional personal benefits of participation include: access to affordable skill training, enhanced understanding of news outlets and technologies, and increased confidence to act as citizen journalists. Early findings confirm significant knowledge acquisition registered across all participants regardless of gender and age. Preferred topical areas for reporting community information have included: historical accounts of community life; social and political issues; environmental conservation; spiritual, and emotional wellbeing topics; and accounts of important community figures. Funded with support from the Knight and Maine Community Foundations.

AN ANALYSIS OF PATHWAYS TO RURAL CITIZEN LEADERSHIP AMONG A SAMPLE OF OLDER ADULT VOLUNTEERS

D.C. Wihry, J. Crittenden, L.W. Kaye, University of Maine, Orono, Maine

This poster will examine pathways to rural citizen community leadership among a group of older adult members of a volunteer leadership training program called Encore Leadership Corps. This study utilized the results of interviews (N=40), self-reported volunteer histories (N=240), and electronic surveys (N=78) collected from program participants between 2010 and 2013. Sample participants are 66% female and 34% male and range in age from 50-88 years with a mean age of 65. The majority of the sample is Caucasian (82.5%) and have attained at least a college degree (82.9%). Data analysis was supported by the use of QDA Miner software and grounded theory was utilized as the analytic framework to identify pathways traveled by program participants to becoming volunteer leaders in small towns and rural communities. Analytic focal areas include volunteer history throughout the lifespan, motivations for engaging in volunteer work, and the perceived leadership roles that have shaped their work and civic engagement pursuits. Preliminary analysis of data indicates that while there is diversity in pathways to volunteering among the sample, for many individuals volunteering in later life is a continuation of such pursuits as well as social and political activism that extends back to midlife, and in many cases, childhood. Additional pathways to community engagement cited by participants stemmed from personal responses to significant life changes such as children leaving a household or relocation to new communities. Additionally, the desire to transfer skills gained during former careers to community leadership initiatives was a common factor shaping volunteer choices.

DOES SENSE OF BENEVOLENCE INFLUENCE VOLUNTEERING AND CAREGIVING AMONG OLDER PEOPLE?

H. Shen, University of Missouri-St. Louis, School of Social Work, St. Louis, Missouri

Older people who are active are healthier and happier. To enhance older people’s physical and mental health, discovering the factors that influence their volunteering and caregiving is key. Existing research on productive aging confirms the significant influence of personal...
resources and networks on whether older people volunteer and care for other family members. However, studies emphasizing the psychological effects are rare. Among various types of productive activities, volunteering and caregiving are both helping behaviors occurring within different social contexts. With the theoretical guidance of the Resource and Strategic Mobilization model, the present study aims to elucidate the effects of the sense of benevolence (SBEN) on whether an older adult volunteers or provides care when personal resources (financial and physical) and personal networks (family and social) are controlled. Using 2000 Health and Retirement Study module data, sixteen questions were utilized to construct the SBEN scale (alpha=.70). Among 916 community-dwelling older adults who were 55 and older, t-test results showed that SBEN was significantly higher among older adults who volunteered (p=.01) and among those who provided care (p=.001). When other variables were held constant, findings from two logistic regression models revealed that higher SBEN increased the likelihood for older people to give care (p=.03), but SBEN was not related to whether older people volunteered. The diverse context of older people, as indicated by personal resources, personal networks, and psychological factors (e.g. SBEN), matters in understanding their helping behaviors. Further implementation of factors interacting with older people’s helping behaviors will be discussed.

ACTIVE STREETS, ACTIVE PEOPLE: FINDINGS FROM SENIOR’S WALKING ENVIRONMENTAL AUDIT TOOL (SWEAT-R) BASELINE DATA

The “walkability” of a neighborhood helps maintaining the independence and health of older adults. Current research and policy challenges in this area include: a) better understanding of the pathways in which built environmental aspects influence older adult individual’s physical activity, b) valid and reliable measures of the built environment effecting activity and mobility, and c) sustainable interdisciplinary mechanisms linking planners, researchers and public health officials to make meaningful policy decisions. This poster presents findings of built environment audits from Phase 1 (pre-construction phase) of a multi-year research project titled ‘Active Street, Active People (ASAP)’. The City of Vancouver is redesigning the environment along the Comox-Helmcken Greenway (CHG) located in the downtown core to improve walking and biking opportunities. This research involves collection of data on pre-post construction phases to evaluate the influence of street-level changes on older adult’s mobility and social interactions along the CHG corridor. This will provide an evidence-base for future policies for neighbourhood development that improves quality of life of older adults. The findings presented here is based on street level audit of 177 street segments within 250 meters of the CHG using the Senior’s Walking Environmental Audit Tool (SWEAT-R) to provide a street-level snapshot of the area and determine inter-rater reliability of SWEAT-R. Data is collected for 152 items categorized across four domains of functioning, safety, aesthetics and destinations. Findings indicate that SWEAT-R has a 95% or higher inter-rater reliability for nearly 70% of the items, with the lowest percentage agreement found in the Aesthetics domain

PSU’S AGENDA: CREATING AN AGE-FRIENDLY PORTLAND AND BEYOND
M.B. Neal1, A. DeLaTore3, P. Carver1, K. Wilson4, M. DeShane5, M. Cannon1, 1. Institute on Aging, Portland State University, Portland, Oregon, 2. Jessie F. Richardson Foundation, Clackamas, Oregon, 3. Concepts in Community Living, Clackamas, Oregon

The world is experiencing an unprecedented and significant change: population aging. In the U.S., the first Baby Boomers turned 65 in 2011. For another 19 years, this trend will continue at the rate of more than 7,000 people per day, followed by additional waves of older adults. The opportunities presented by this demographic shift are seldom noted and rarely leveraged. Little planning for population aging has occurred, yet the implications for public policy, finance, business, health care, technology, urban planning and economic development are enormous. This presentation describes one urban university’s role as a “backbone organization” for bringing together community partners interested in creating a region that is a great place for people of all ages and abilities. In 2006-2007, Portland was one of 33 cities in 22 countries to participate in the World Health Organization’s (WHO) Global Age-Friendly Cities project. Building on the study’s findings and relationships developed, as well as a privately-funded initiative, a partnership among the university, the city, the county, and non-profit organizations has been created. Efforts are focusing on three general themes encompassing the WHO’s eight domains of age friendliness: health care technology, service delivery and policy; the physical, social and educational environment; and economic development, employment, and civic participation. These themes suggest a paradigm shift in the making, adopting an asset-based model of aging that emphasizes wellness, interdependence, prevention, and social connectivity. The origins of this initiative, the partnerships developed, successes and challenges to date, as well as activities planned for the future, are detailed.

SOCIAL AND PSYCHOLOGICAL FACTORS OF PARTICIPATION IN NEIGHBORHOOD SOCIAL ACTIVITY GROUPS FOR SENIOR CITIZENS IN JAPAN
Y. Shirase1, R. Ohmukas2, Y. Ohtus1, N. Izumida1, 1. National Institute of Population & Social Security Research, Tokyo, Japan, 2. National Center for Geriatrics & Gerontology, Obu, Aichi, Japan, 3. Keio University, Tokyo, Japan

This qualitative study explores the social and psychological factors that encourage older people to participate in neighborhood social activity groups, Fureai-no-ie. These groups are established to prevent isolation and promote health and well-being. In city A, the groups are organized by neighborhood volunteers and subsidized by the local government as part of a long-term preventive care program. Once a week, each group holds a session to encourage recreation and physical exercise, and participants and volunteers have lunch together. Seasonal events are also held as part of this program. In 2012–13, semi-structured, one-to-one interviews were conducted, recorded, and transcribed for 12 participants (72–93 years old). A coding-based qualitative analysis revealed that all the interviewees were critical about spending their days at home, doing nothing specific. They also shared the willingness to maintain their health and sought opportunities to communicate with others. Most participants in their sixties had taken up sports or hobby lessons, wherein they interacted with neighbors and made friends with like-minded residents. Later, they participated in an activity group together. During this study, most participants were living independently. Even though they were not entirely physically fit, they could participate in these sessions, provided they had means of transportation. The findings suggest that these groups do not necessarily create opportunities to make new friends in old age. However, they help participants maintain existing social networks to promote health and well-being.

PAID WORK, VOLUNTEERING AND MENTAL HEALTH: COMPLEX REALITY OF PRODUCTIVE ACTIVITIES AMONG OLDER ADULTS WITH DIFFERENT ECONOMIC SITUATIONS
S. Han, H. Jun, Department of Child and Family Studies, Yonsei University, Seoul, Republic of Korea

Studies have generally indicated that productive activities, such as paid work and volunteering, have positive influences on the mental health among older adults. However, relatively few researches have examined the extent to which participation in a particular productive activity can be differentiated by contrasting situations that older adults
are faced with, and how this difference may in turn yield different outcomes in their mental health. This study aimed to understand this complex reality of productive activities among older adults from different economic situations by examining specific influences of paid work and volunteering on older adults’ mental health, assessed with depression and life-satisfaction. For the analyses, longitudinal data from five waves of nationally representative Korean Welfare Study was used to analyze a distinctive group of young old (age=65-74) from normal (n=736) and low-income (n=1,759) households, and a stringent methodology of multiple-indicator multilevel growth model was utilized to test the effects of paid work and volunteering on older adults’ mental health after controlling for time-varying and time invariant variables. Results indicated that older adults who volunteered more showed higher mental health levels in normal income group. For the low-income group, while paid work and volunteering were both positively related to mental health, influence of paid work was more important of the two; however, continued and involuntary nature of paid work over time were negatively associated with older adults’ mental health. The findings of this study calls for further studies to enhance our understanding on the complex reality of late-life productive activities.

SOCIAL ENGAGEMENT THROUGH TIMESLIPS: TESTING AN INTERVENTION FOR ENHANCING OPTIMAL AGING OF PERSONS WITH DEMENTIA

M. Bern-Klug, T. Manthai, The University of Iowa, Iowa City, Iowa

This pilot study tested ways to measure the effects of TimeSlips, a group story-creating activity developed by Anne Basting to tap the imagination of people with dementia. 13 sessions were conducted over 2 months in the Memory Care Unit of an assisted living center to test and refine two types of instruments: a survey administered to respondents (25 items reduced to 4) and researcher collected observation data measuring social engagement. Data were collected one hour before TimeSlips, during TimeSlips, and one hour after. Challenges included a high volume of other activities during the week which complicated pre and post intervention measures. TimeSlips was moved to after supper and on the week-end, with mixed results in terms of data collection. Nine tenants were enrolled with four completing data collection for at least 5 of the 13 sessions. Reasons for missing data from the others included: lack of interest in becoming more socially engaged (2 people); high interest in TimeSlips but no interest in answering survey questions (1); death (1); and family member consent form confusion (1 person who was eventually enrolled and 3 whose family repeatedly said they intended to sign the consent form, but did not.) Survey data indicate that the mood level of 2 of the 4 improved, one stayed the same, and one had data that were inconclusive. No survey evidence of effects of TimeSlips were detected one hour after the intervention, although social engagement data do suggest a lingering positive effect for three of the four enrollees.

LATER LIFE LEISURE PARTICIPATION AS A SOURCE OF RURAL SOCIAL CAPITAL

C. Hennessy, University of Plymouth, Plymouth, United Kingdom

The potential of leisure participation in later life as a means of creating community social capital is a nascent area of gerontological research. This perspective is consistent with asset-based approaches in rural community development that view older rural residents as generators of social capital. Using data from a major survey (N=920) of participation among persons aged 60 and over in rural community life in southwest England and Wales and qualitative interviews with 58 respondents, the types, patterns, and influences on leisure involvement within the rural community context are explored. The purpose of this study was to examine older people’s connections and contributions to rural community life through their engagement in leisure activities, including participation in individual pastimes as well as collective pursuits through groups and associations. Survey findings showed that the highest levels of involvement in group/associational activities were for those organised through churches (39%), voluntary or charity groups (28%), and other community groups (26%). Findings from the qualitative interviews indicated that the leisure occupations of these older rural residents—ranging from formal volunteering to keenly pursued avocational interests and activities—all had some contribution to make to the sustainability of rural community life through providing individuals with a sense of identity and belonging to place. These findings are interpreted from the perspective of existing conceptual frameworks, especially innovation theory and social capital theory, to consider the forms and uses of later life leisure within the rural community context.

NATIONAL RESOURCES ASSESSMENT OF SUPPORT SERVICES FOR VETERANS AND MILITARY FAMILIES WITHIN THE RETIRED AND SENIOR VOLUNTEER PROGRAM

P. Burnett, S. Martin, S. Raymond, Center on Aging, University of Maine, Bangor, Maine

With the Corporation for National and Community Service (CNCS) introducing veterans and military families as one of six strategic priorities in 2011, identification of existing programmatic initiatives of this type is essential in assessing promising strategies to be implemented within RSVP programs establishing a state and community military network point of focus. To assess existing program services utilized by other RSVP agencies, the Center on Aging identified 443 RSVP agencies in 49 states for possible engagement and assessment involvement in specialized veterans and military families-related programming. Online survey tools were utilized to assist with collecting and analyzing data reflecting four core program implementation themes (assistance, funding, obstacles, and outcomes) from RSVP partners. The response rate was 25% with 111 agencies from 39 states participating. Data analysis confirmed consistent themes of decentralized program design philosophies irrespective of geographic location or type of service(s) provided. Of the 111 respondents, 83% reported providing veterans and military families-related services with transportation, home support, and food/clothing support registered as the top three services. The highest ranking program implementation obstacles were developing partnerships (19%), funding (14%), and volunteer availability (11%). Two core programmatic outcomes measured by the majority of respondents (62%) were: 1) veterans and military families served; and 2) number and range of services utilized. To facilitate future targeted programs for veterans and military families, RSVP activities will need to emphasize developing meaningful partnerships in the community and identifying reliable funding streams to sustain such services.

GIVING AND RECEIVING: UNDERSTANDING VOLUNTEERING AND WELLBEING FOR OLDER PEOPLE IN TERMS OF RECIPROCITY

C. Stephens1, M. Breheny1, P. Dulin2, F. Alpass1, 1. School of Psychology, Massey University, Palmerston North, New Zealand, 2. University of Alaska, Anchorage, Alaska

Current dominant representations of older people revolve around dependence and overuse of health and social services. These images contradict the moral imperative to contribute to society and create identity problems for older people who need to be seen as participating citizens. Volunteering is an important avenue of contribution. A survey of 1,028 New Zealanders, representing the population aged 57 to 72, found that volunteering was a unique predictor of overall happiness. This was moderated by economic living standards (ELS): those with low ELS reported a stronger relationship between volunteering and happiness than those with high ELS. Subsequently, an interview study of 143 people aged 65 to 93 years, showed that the capability to contribute to the community by volunteering was highly valued, however, ability to contribute was complicated by shifting positions in communities at the intersection of reducing economic resources, diminishing
social networks, and health limitations. Being able to volunteer unpaid work to the community is discussed in terms of norms of reciprocity. Limitations in the capacity to contribute make it difficult for older people to engage in reciprocal social interactions and this has important implications for their identity and wellbeing (including happiness). Relations between older people and their communities provide a context for recognising the contributions which meet the needs of older people to give as well as receive, whatever their ELS. Social policy which supports appropriate community contribution for elders may be understood as an important contribution to successful ageing.

CIVIC ENGAGEMENT IN LATER LIFE: EXAMINING A GENERAL ACTIVITY PATTERN

S. Dury, L. De Donder, T. Buffel, N. De Witte, A. Smetoren, D. Brosens, D. Verté, Vrije Universiteit Brussel, Brussels, Belgium

Civic engagement among older adults has received growing attention among researchers, policymakers, and associations. However, there still remains a lack of knowledge in the multiplicity of civic activities that older adults undertake within research. In order to understand involvement in later life insights into the extent to which activities compete or complement with each other is necessary as well as clustering the activities rather than examining them separately. Data for the present research were derived from the Belgian Aging Studies (N=67144). The main objective is to disentangle six aspects of civic participation, including participation in associations, formal volunteering, informal volunteering, cultural, leisure, and political participation and analyzing whether they contest or match each other. Factor Analyses indicate a strong positive correlation between the types of participation establishing that being active in one domain increased the propensity to be engaged in another domain. The paper concludes by discussing new methodological approaches and how people balance volunteering, caregiving, social roles, and so forth, and with what outcomes.

THE AGING CITY: NEIGHBORHOOD MOVEMENT AS AN ANSWER TO THE CHANGING NEEDS OF OLDER INHABITANTS

A. Domaradzka-Widla, Institute for Social Studies, University of Warsaw, Warszawa, Poland

The paper is based on assumption that place of residence is a space, within which the inhabitants satisfy their various individual and social needs, including the need to establish bonds with other people and to act together. The neighborhood, understood as the social surroundings in the place of residence, remains one of the significant factors that influence the quality of life of individuals, especially nowadays, when due to the weakening welfare state, neither local nor central government is able to satisfy the changing needs of different social groups. This issue increase in importance, particularly in the aging districts of Warsaw, which are threatened by worsening in the quality of life of the most sensitive cohorts, like the elderly. Main idea of the paper is to show how grassroots neighborhood movement can be a remedy to these problems. The paper examines the issue from two perspectives: taking quantitative analyses based on World Values Survey 2005 and 2012 data to provide background description of the changing quality of life at different life stages and social position of elderly in Poland. Qualitative data illustrates these issues further, using data obtained from several case studies of local initiatives aimed at elderly inhabitants of various Warsaw neighborhoods. Most of the respondents were 50+ and described their civic engagement as a coping mechanism, enabling them to deal with everyday problems connected with aging. Results indicate that young elders have a potential to be a driving force behind neighborhood change, as long as they build inter-generational coalitions.

OLDER VOTERS AND THE 2012 ELECTION

L. Rill, L. Polivka, Florida State University, Tallahassee, Florida

In the 2008 presidential election, the majority of older persons failed to vote for the winner, which was only the second time in the past 10 presidential elections. This trend continued in the 2012 election. In Robert Binstock’s studies of the 2008 presidential election and the 2010 midterm election, he examined age-group voting behaviors and attempted to explain the electoral factors that persuade an individual’s vote. His articles focused on older persons’ voting behavior and considered voters partisan leanings, candidates’ contrasting ages and racial identities, and how the voters viewed the candidates’ characteristics as explanations for their Republican support. Specifically, he examined age-groups and opinions about health care reform, party preference, sex, and race/ethnicity. He concluded that although age may have an effect on voting behavior, race seemed to be a greater predictor of voting choices and regional figures suggest a racial period effect among older White voters in the South. This paper is an extension of Binstock’s past studies, and has three sections. First, is a brief overview of the findings from Binstock’s election reports. Second, we present the data from the 2012 election in a similar framework to Binstock’s past studies. Finally, we discuss the findings of voting behaviors by region. We argue that regional political exceptionalism is still strong in the South and has influenced their votes.

THE MORAL CAPITAL OF GENERATIONS: IMPLICATIONS FOR ENTITLEMENT REFORM

K. McGrew, Miami University, Oxford, Ohio

The politics of entitlement reform is intensifying. Evidence that assaults on age-based entitlements will continue to escalate are related to: changing demographics; fiscal pressures and competing priorities; changing conceptions of age and need; the “Great Risk Shift” (Hacker, 2006); the political use of personal freedom rhetoric; and an increasingly overt intergenerational equity debate. How has the moral capital of the Greatest Generation contributed to entitlement growth and public support? Do Baby Boomers have the generational moral capital to withstand threats to entitlements? In this paper, I introduce the concept of generational moral capital and propose its implications for entitlement reform. Social welfare policies are moral decisions in response to moral questions: “Who should receive…on what terms…for what needs and problems…[using] what kinds of remedies…and with what [federal] policy powers?” (Jansson, 1993) Policies are made according to, or at least in the context of, our moral economy, those shared ideas we have about reciprocity and resource distribution, for example, what is due the old and what is owed by the young. Minkler and Estes argued in 1991 that moral economy values of reciprocity and generational interdependence showed “continued strength.” In 2013, a relative deficit in the generational moral capital of Baby Boomers informs at least some part of our ideas about generational worthiness and what is “due” the old. Sources of generational moral capital and opportunities to “grow” moral capital are examined in the context of updated entitlement reform activity.

SESSION 545 (POSTER)

ENVIRONMENT, TRANSPORTATION AND TECHNOLOGY STUDIES

A LONGITUDINAL VIEW OF DRIVING CESSION AMONG OLDER ADULTS FROM THE HEALTH AND RETIREMENT STUDY (2006-2010)

C. Lee, E. Dugan, Gerontology, Univ Mass Boston, Boston, Massachusetts

Background. Personal mobility is important to independence and quality of life. Driving is a preferred means of mobility for most older adults. A number of risk factors (e.g., chronic medical conditions, declines in cognitive functioning, and vision) have been identified using cross-sectional analytic approaches. This study employs a longitudinal approach to identify risk factors for driving cessation among older people. We examine driving cessation over the 4 year period (2006...
DRIVING CAPACITY

THREE-SCREEN DRIVING SIMULATORS TO ASSESS OLDER ADULTS’ ACCEPTANCE OF ONE-SCREEN AND TWO-SCREEN DRIVING SIMULATORS

C. Gibbons1, N.W. Mullen2, P.M. Reguly2, B. Weaver2,3, M. Bedard1,2,3

The purpose of this research is to identify patterns associated with service use of clients of a Texas-based non-profit organization that provides free transportation services to anyone over 60. This research is important because it fills gaps in current literature regarding technological capabilities and transportation services provided for older adults. This is a quantitative analysis of the 2012 FIAC Client Survey. The survey consists of 519 current active clients. Several tests were used to determine statistically significant relationships present including t-tests, ANOVA and chi-square tests of independence. The sample consists of 19% male clients and 81% female clients. The ethnicity of the sample is a majority Caucasian (86%) with 7% African American, 4% Latino and 2% Middle Eastern and 1% Asian/Pacific Islands. The marital status of the respondents is 25% married, 44% widowed, and 31% divorced/single. 62% of the respondents do not use a cell phone compared to 38% that do use a cell phone. Similarly, 67% of the respondents do not access the internet, where as 33% do connect to the internet. Statistically significant relationships exist among the variables age and cell phone use (t=5.8, p<0.001), age and internet use (t=2.6, p<0.01), age and region (F=8.8, p<0.01), Medicaid membership and ethnicity (chi-square=33.2, p<0.01), Medicaid membership and affordability of services (chi-square=12.5, p<0.006), and affordability of services and region (chi-square=41.7, p<0.001).

OLDER ADULTS’ ACCEPTANCE OF ONE-SCREEN AND THREE-SCREEN DRIVING SIMULATORS TO ASSESS DRIVING CAPACITY

C. Gibbons1, N.W. Mullen2, P.M. Reguly2, B. Weaver2,3, M. Bedard1,2,3

Current procedures to assess driving capacity typically comprise clinical and on-road testing. However, on-road assessments create risk management issues and are costly. Driving simulators could potentially help identify at-risk drivers in a highly-standardized and cost-effective manner. However, it is not clear how older adults view driving simulators. Our objective was to examine the acceptability of driving simulators to assess driving capacity. We recruited drivers from two groups: 40 to 55 years (n=16), and 65 years and over (n=16). Participants completed two drives on a STISIM Drive® M400 simulator; the first with a single 17” monitor followed by the same drive with three 17” monitors. They also completed an interview about their experience on the simulator. The number of errors on starting/stopping/backing, moving in a roadway, and passing/speed on the two drives were not statistically significantly different (p=0.56, p=0.07, p=0.31 respectively) and the ICCs (0.62, 0.64 and 0.71 respectively) showed agreement. However, participants committed more errors on the one-screen drive for signal violation/right of way/inattention and turning. Total scores from the two drives were correlated (r=0.73) but participants made more errors during the one-screen drive (p<.001). Participants stated that driving simulator assessments could enhance current procedures to examine fitness to drive (n=12 middle-age, n=9 older) and found simulators to be an acceptable and useful training/teaching tool (n=12 middle-aged, n=10 older). Simulators may offer a safe, face-valid approach for driver assessments. Our findings suggest that drivers may be quite accommodating of simulator use for driving assessment.

TRANSPORTATION SERVICES FOR OLDER ADULTS

C. Gibbons1, N.W. Mullen2, P.M. Reguly2, B. Weaver2,3, M. Bedard1,2,3

The purpose of this research is to identify patterns associated with service use of clients of a Texas-based non-profit organization that provides free transportation services to anyone over 60. This research is important because it fills gaps in current literature regarding technological capabilities and transportation services provided for older adults. This is a quantitative analysis of the 2012 FIAC Client Survey. The survey consists of 519 current active clients. Several tests were used to determine statistically significant relationships present including t-tests, ANOVA and chi-square tests of independence. The sample consists of 19% male clients and 81% female clients. The ethnicity of the sample is a majority Caucasian (86%) with 7% African American, 4% Latino and 2% Middle Eastern and 1% Asian/Pacific Islands. The marital status of the respondents is 25% married, 44% widowed, and 31% divorced/single. 62% of the respondents do not use a cell phone compared to 38% that do use a cell phone. Similarly, 67% of the respondents do not access the internet, where as 33% do connect to the internet. Statistically significant relationships exist among the variables age and cell phone use (t=5.8, p<0.001), age and internet use (t=2.6, p<0.01), age and region (F=8.8, p<0.01), Medicaid membership and ethnicity (chi-square=33.2, p<0.01), Medicaid membership and affordability of services (chi-square=12.5, p<0.006), and affordability of services and region (chi-square=41.7, p<0.001).

The Gerontological Society of America
son centered model this movement is referred to as the culture change movement. This study set out to evaluate a culture change initiative within a rural Midwest state by comparing the facilities which have and have not participated in the culture change initiative. A survey entitled The Artifacts of Culture Change was mailed to the administrators of the rural based long term care facilities (N=79). Over sixty facilities responded to the survey, six of which were involved in a specific enriched training initiative toward the “culture change” program. Findings: There was no significance between the six facilities in the program and the others not enlisted in the intervention program. Facilities involved in the program tested higher in certain sub areas of the survey when compared to other facilities. The major areas of change included areas associated with activities and the environment. While the results showed that the facilities involved in the program had limited significant differences on the Artifacts of Culture Change Tool when compared with other facilities, it was clear that facilities involved with people who have disabilities were further ahead than most facilities. Conclusion: Principles used within the disability movement should be integrated into the aging care arena and adapted for public health facilities, rules and regulations to improve the environments of long term care facilities for older adults.

NO PLACE LIKE HOME? SURVEILLANCE TECHNOLOGIES AND THE MEANING OF HOME IN OLD AGE
A. Sixsmith, W. Mortenson, R. Beringer, Simon Fraser University, Vancouver, British Columbia, Canada

Ambient Assistive Living (AAL) technology is being advanced as a potential solution to the needs of an increasing number of older people. AAL uses data from passive environmental and body worn sensors to create a profile of the patterns of movement, daily activities and health status of “at risk” individuals. Although AAL ostensibly aims to improve security and safety, ethical questions have been raised about the extent to which it compromises the rights and privacy of the person being monitored. Therefore, the purpose of this paper is to understand the ways surveillance technologies impact everyday experiences of the intimate space of the home. In-depth interviews were conducted with 27 older adults (>60 years of age) who had at least one chronic condition or a mobility restriction. Participants were shown a brief video about a potential AAL system in development and asked about how they thought such a system would affect them and their perceptions of home. Drawing on theories about home and Michel Foucault’s ideas of surveillance and governmentality, our analysis identified three main themes. “Safe and sound” described how participants felt ICT surveillance would contribute to their sense of security. “Reliance” explored how it would affect residents’ autonomy, self-confidence and relationship with caregivers. “Under the microscope” revealed how ICT mediated surveillance might alter perceptions of home and activity participation. The findings emphasize the need to better understand how AAL will affect the lives of residents being monitored, before this technology becomes a pervasive aspect of the home environment.

WHAT DO HEALTHCARE PROVIDERS WANT A PERSONAL ROBOT TO DO IN THEIR WORK SETTING?
L. Tiberio, W.A. Rogers, National Research Council of Italy (CNR), Institute for Cognitive Science and Technologies (ISTC), Rome, Italy

One of the promising applications to which personal service robots can be applied is human caregiving. To ensure a robot’s effective interaction in a healthcare setting, it is essential to understand end users’ attitudes and opinions. The purpose of this project was to identify: a) caregiving tasks for which healthcare providers are open to accepting assistance from a personal service robot; and b) barriers and facilitators of such robotic assistance in healthcare providers’ daily work setting. Participants were 14 healthcare providers (aged 19-59) recruited from skilled nursing and assisted living facilities. They participated in individual structured interviews that provided in-depth information about their preferences and attitudes regarding the potential for robots to support caregiving tasks. Prior to the interviews participants completed several questionnaires (e.g., demographics, work experience, robot experience and attitudes) and watched a video about a particular personal robot, the Personal Robot 2, which is a mobile manipulator robot developed by Willow Garage. Overall, healthcare providers were open to the idea of having robot support in their daily work. The providers suggested specific tasks for alleviating physical caregiving burdens and challenges (e.g. transferring, feeding, dressing patients) and the workload of medical staff (e.g. monitoring vital signs, preparing meals). They also identified some barriers and facilitators to using a robot for caregiving tasks in a healthcare setting. These results provide an initial framework for design and deployment of personal robots to supplement human caregiving.

THE DIGITAL DIVIDE AND WELFARE IN OLD AGE: A CONCEPTUAL MODEL OF INFORMATION WELFARE INEQUALITY
M. Kim1, H. Jun2, 1. Duke University, Chapel Hill, North Carolina, 2. Yonsei University, Seoul, Republic of Korea

The digital divide has become an important issue of social inequalities in two waves of informatization and aging society. In the diffusion process of information technologies (IT) older adults, in particular, are likely to experience more disadvantages than the other age groups. This study is to theoretically examine the association between the digital divide and welfare in old age by proposing a conceptual model, and suggest further empirical studies. The digital divide in old age may multi-dimensionally exist and result in inequalities in welfare among older people, as well as between generations. According to IT use/non-use and the extent/quality of IT use/non-use, the digital divide in old age may be triple: between generations; between IT users and non-users; and between different age groups or cohorts. The causal mechanism of digital divide in old age can be simplified: social, economic, demographic, technological, and environmental factors → 3As (availability, abilities, and attitudes) → extent and quality of IT use/non-use → multiple digital divide. Consequently, this study suggests a hypothetical model of the ‘information welfare inequality’ in old age: digital inequalities → dis-/satisfaction with information life → information welfare gap → general welfare inequality. The practical implications of this study are to emphasize the importance of quality of information life in later life and the need for a practical approach to the digital divide in old age from an aspect of the welfare of older adults. Also, this study suggests further empirical studies on social inequalities in the welfare of older adults.

EXPLORING THE ROLE OF BUILT ENVIRONMENT ON WALKABILITY AND SOCIAL INTERACTION OF ETHNICALLY DIVERSE OLDER ADULTS IN ASSISTED LIVING FACILITIES
A. Mahmood, S.D. Koehn, S. Stott, Gerontology, Simon Fraser University, Vancouver, British Columbia, Canada

This pilot study presents findings based on structured observations and assessments of the social and physical environment of Assisted Living (AL) residences in Vancouver, BC - two ethnoculturally targeted (Chinese and South Asian) and one non-targeted. We examine the role these factors play on social interaction and walkability among ethnically diverse older adult residents. The Senior Walkability Environmental Audit Tool (SWEAT-R) was used to evaluate 82 segments of the surrounding urban design as they relate to the functionality, aesthetics, safety, and desirable destinations of the neighbourhoods of each AL site. Findings suggest decreased proximity to services and amenities and low functionality of sidewalks restrict walkability among all three sites. We used a behavior mapping tool to make structured observations of social spaces within the facilities. Our findings reveal that shared spaces designed to serve multiple purposes were conducive to...
increased frequency of higher-level social interactions compared to single use spaces. Levels of nonverbal forms of communication/activities and physical activity varied across the three sites. Cultural differences and environmental design of the shared spaces appear to play an interactive role in determining these observed differences. Both outdoor audit and indoor observations demonstrate that built environment and cultural norms influence (1) walkability, and (2) frequency and type of social interaction of older adults in AL residences. This warrants further exploration of the salience and interactive effects of both cultural norms/expectations and the built environment on the quality of life of older adults in AL residences.

RANDOMIZED CLINICAL TRIAL OF SMARTPHONE-BASED INTERVENTION FOR RECOVERY FOLLOWING TRANSIENT ISCHEMIC ATTACK

Medication adherence is challenging for older adults with chronic health conditions. Recovery from a transient ischemic attack (TIA) typically includes patient education to improve medication adherence, but has not proven effective. The goal was to demonstrate that the intervention—a smartphone-based, comprehensive self-management system—is more effective and improves patient knowledge of stroke, compliance with medications, and provides additional monitoring of other important health behaviors and attitudes such as exercise, activities of daily living, and mood. The intervention application tested, iRxReminder, supports medication adherence, patient education, and data gathering. The design was an open-label randomized controlled trial comparing the smartphone intervention with a stroke education control condition for a 2-month intervention period. Patients undergoing acute treatment for TIA passed a use-test of the smartphone to become eligible, and 20 consented to randomization after discharge. They were assigned to the smartphone intervention or the stroke education control. Patients were 60% women, 25% minorities, and aged 65.2 years (mean, SD = 7.3). The control condition used an education and data collection booklet developed for a previous study. The primary outcome measure was medication adherence, and secondary outcomes included stroke knowledge and patient acceptance of the intervention. Exceptional medication adherence was found in the smartphone intervention group (83% overall), and adherence could not be verified in the control group due to missing data (i.e., misplaced booklets). Stroke knowledge tended to increase in the smartphone intervention group and decrease in the control group. The smartphone intervention group indicated a high level of satisfaction with the smartphone. The feasibility and effectiveness of real-time monitoring and reporting of patient self-management activities using a smartphone application was confirmed.

SPATIAL REQUIREMENTS FOR DESIGNING AN INTERGENERATIONAL FACILITY
N. Norouzi, Virginia Tech, Blacksburg, Virginia

Intergenerational programs can increase interaction and engagement among generations and reduce negative age stereotypes, but architects contracted to design intergenerational facilities have not necessarily received any training in lifespan development. Important questions are how to provide architects with needed background on child and adult development and what are the best design features for intergenerational program spaces to meet the needs of multiple age groups. This project employed three strategies to address these questions. First, based on interviews about best practices with staff at a child care center and a co-located adult day services program, I ascertained workers’ perceptions of optimal spatial designs for intergenerational programming. Second, I integrated elements of developmental theory (Kitswood’s theory of personhood, Bronfenbrenner’s ecological model, and the Reggio Emilia educational philosophy) and architectural design principles from the work of Heidegger, Pallasmaa, and Norberg-Schulz with the interview data. Third, an architecture professor and I incorporated these materials into a project assignment for a fourth-year architecture studio: Design a dynamic, highly functional environment for adult and child day care along with intergenerational space for productive interaction between groups. This assignment sensitizes architecture students to spatial needs for multigenerational programming, prepares them for career opportunities in intergenerational design, and contributes to reducing negative age stereotypes. The outcome of this project is not only a design framework for creating better intergenerational facilities but also a course to be taught to architecture and gerontology students.

A QUALITATIVE INVESTIGATION OF TRAUMA AND STRESS, COPING RESOURCES, AND WELL-BEING AMONG OLDER ADULTS IN PRISON
T.M. Maschi, D. Viola, Fordham University, New York, New York

Background: Research on stress and coping in prison has generally focused on youth and adult populations in prison. However, little is known about the experiences of stress and coping among older adults in prison. The objective of this study was to explore the processes of stress and coping among a sample of older adults in prison. Methods: This study used a cross-sectional, correlation design and a sample of 677 older adults in a northeastern state correctional system. Participants completed a mailed survey that included open-ended questions about their experiences of stress and coping in prison. A grounded theory constant comparative approach was used to identify the processes of stress and coping of older adults in prison. Findings: The results of constant comparative analysis revealed two major prison themes: trauma and oppression and resistant resilience. Participants described trauma and oppression as interpersonal and structural and cultural violence in the form of inmate-on-inmate and staff-inmates attitudes, and violence, institutional and policy abuse, and an internalization of trauma oppression in the form of depression, anxiety, and apathy. Resistant resilience consisted of participants’ use of “well-being practices” or activities to ward off the traumatic and oppressive conditions of confinement. Participants reported engaging in activities that fostered their root (basic survival), physical, cognitive, emotional, social, spiritual, and participatory well-being and empowerment. Implications: These findings suggest areas of gero-informed health promotion, stress management, and trauma-informed care that are useful for older adults under the stressful conditions of prison confinement.

LIVED EXPERIENCES OF OLDER ADULTS, FAMILY AND STAFF WITH SENSOR-BASED REMOTE MONITORING IN LOW-INCOME INDEPENDENT LIVING RESIDENCES
C. Berridge, UC Berkeley, Berkeley, California

A significant innovation in independent living technologies is the shift from actively triggered social alarms (PERS) to passive remote monitoring. Remote monitoring (RM) for position tracking describes sensor-based systems installed in the home that collect and communicate data about an individual’s status or behaviors, such as how many times the restroom is used at night, movement from the bedroom in the a.m., use of refrigerator, and medication access. This shift to sensor-based systems has significant implications for multidimensional concepts of independence, privacy, safety, obtrusiveness, and care in old age. In this paper, I describe real-life decision making about adoption and the lived experiences of ethnically diverse older adults, family caregivers and social workers who use remote monitoring technology in seven low-income independent living residence buildings. Data are collected in three stages of in-depth interviews and participant observation with resident-family member dyads who have used RM for five years, new residents and family members who are deciding about RM adoption, and follow up interviews with adopters and social work staff four
months into use. This presentation will provide an in-depth look at users’ experiences and perspectives on the impact of RM as well as processes that contribute to meaningful use of RM systems.

GLOBAL VIRTUAL FORUM ON HEALTHY ACTIVE AGING AND HEALTHY ACTIVE AGING IN DEMENTIA CARE

L. Skemp,1,3 M. Usher-Patel,2 A. Bossen3,1. Our Lady of the Lake College, Baton Rouge, Louisiana, 2. World Health Organization, Geneva, Switzerland, 3. University of Iowa, Iowa City, Iowa

The global Alliance for Healthy Active Ageing™ was created to identify issues, facilitate interprofessional discussion, and create possibilities for responses to common global concerns in our aging societies. With a growing shortage in the global health care workforce, strained economic resources, and knowledge and access gaps, the purpose of this forum discussion focused on: 1) What are the challenges and opportunities to support healthy active aging? 2) If healthy active aging is our goal, how can we achieve this? 3) What are the challenges and opportunities we are facing to support healthy active aging in the area of dementia care? Supported by the World Health Organization Department of Human Resources for Health (WHO/HROH) in collaboration with the WHO Department of Reproductive Health and Research (WHO/RHR), the University of Iowa Hartford Center of Geriatric Nursing Excellence and global partners, a virtual global discussion forum was convened through the WHO/RHR Knowledge Gateway on healthy active aging during October 2010. Over 600 members from 77 countries participated. Descriptive content analysis of written comments from each daily digest resulted in macro and micro key issues and challenges within the area of healthy aging and then a focus on healthy active aging in the area of dementia care identified. Opportunities, programs, and policy recommendations from developed and developing countries are explained. Description of the on-line format as well as benefits and challenges of the on-line format are outlined. Recommendations for research, policy and future discussions are provided.

SESSON 550 (POSTER)

MINORITY AND DIVERSE POPULATIONS

LINKING THEORY, RESEARCH, EDUCATION, AND PRACTICE IN TEACHING ABOUT DIVERSITY AND AGING

P. Kolb, Department of Social Work, Lehman College, City University of New York, Bronx, New York

Consistent with the focus of the GSA Research, Education, and Practice Committee (REP) on providing examples of connections between research, education, and practice, this paper presents approaches to making these linkages in the classroom. The author’s Sociological Theories of Aging course teaches about theories and research and facilitates understanding of implications for practical and diversity of aging experiences. Most undergraduates enrolled in this elective are sociology, social work, or psychology majors. For students entering applied fields, linking research findings to skill development is important for evidence based practice, and this illustrates the importance of education that links theory and research to gerontological practice. Consistent with the need in many fields for education about diversity, research about individual and collective experiences related to aging in various societies is examined in this course. Diversity is considered through research informed by five theoretical perspectives: phenomenology, gerotranscendence, critical, feminist, and life course. In this presentation, the author’s approaches to teaching about connections between theory, research, practice, and diversity are illustrated by the following: phenomenological gerontology: Black’s research about narratives of forgiveness and Rosenfeld’s research about identity development of older gay men and lesbians; gerotranscendence: Ahmadi Lewin and Thomas’s research about life satisfaction among religious and secular Iranians living in Sweden and older adults in Turkey; critical political economy of aging: Alan Walker’s comparison of aging policy development in several nations; feminist: Meadows and Davidson’s findings about “hegemonic masculinities and emphasized feminities” from their study of older men in the UK.

THE INTERSECTION OF ACCULTURATION AND HEALTH FOR OLDER ASIAN AMERICANS

K.T. Chan, T. Tran, Boston College, Chestnut Hill, Massachusetts

According to census estimates, Asians are one of the fastest growing immigrant groups in the US, and the fastest growing group among all elderly. This study examines the impact of acculturation, measured as English ability, along with other predictors on health for older Asian Americans. Data from the American Community Survey and the National Latino and Asian American Study were used for this study. A broad view of health was examined using items capturing functional disability. Psychological health was examined using the Kessler Psychological Distress Scale (K10). Confirmatory factor analysis was conducted on the two measures. Logistic regression was conducted to estimate the association of language acculturation to functional disability. Path analysis was conducted to investigate the causal pathways to psychological distress. Results from the analysis suggest that the well-being of Asian elders is intricately tied to the experience of acculturation. English ability predicted lower disability, but had no relationship to psychological distress. Higher levels of intergenerational family conflict increased distress for Asian elders. Perceived discrimination, which represents a form of social marginalization, was consistently associated with poorer mental health. This study provided key insights into the applicability and measurement invariance of two measures of health for older Asian Americans. Results suggest that acculturation is a process which involves the individual as well as the family. Policies should emphasize the development of culturally-specific approaches to services for Asian American elders. The study highlights that social workers must engage families across generations and the lifespan when working with Asian elders.

LOS CUIDADORES LATINOS UNIDOS: A FLEXIBLE, FAMILY SYSTEMS BASED INTERVENTION FOR CAREGIVERS IN THE LATINO COMMUNITY

M. DeNomie1, A. Castro2, A. Wells3, S. Mudroch1, M. Villa2, R. Fuentes2, C. Mejia2, Z. Franco1, 1. Family & Community Medicine, Medical College of Wisconsin, Milwaukee, Wisconsin, 2. Centro de la Comunidad Unida (United Community Center), Milwaukee, Wisconsin, 3. Florida International University, Miami, Florida

The Alzheimer’s Association reports that 12% of the 15 million caregivers of dementia patients in the United States self-identify as Latino. Latino caregivers report higher levels of burden than their non-Latino counterparts and face socioeconomic disparities that impact ability to provide in-home care. Little research focuses on culturally competent intervention for caregivers in Latino communities. The Centro de la Comunidad Unida’s (United Community Center; UCC) Latino Geriatric Clinic and the Medical College of Wisconsin designed Los Cuidadores Latinos Unidos, a multi-component pilot intervention to address these gaps. The intervention flexibly applies individual psychoeducation, family educational meetings, workshops, support groups, access to educational materials, and technology. The approach is guided by Family Systems Theory and includes Behavioral Activation techniques nuanced for Latinos. Services are delivered by bilingual, community-embedded family workers, primarily in the caregivers’ homes. The program has served 22 families, with 19 female Latinas, 3 male Latinos in the primary caregiver role. Three caregiver seminars were offered during the project’s first year, with a total of 53 caregivers in attendance. Data from pre-, mid-point, and post-intervention is collected.
The relationship between social support and health-related quality of life among Korean American nursing home residents

S. Park, Social Services, Union Plaza Care Center, Flushing, New York

This descriptive and exploratory mixed-method study examined the relationship between social support and health-related quality of life among Korean American nursing home residents. It examined the social support networks of the Korean American nursing home residents, the nature of their interpersonal transactions, and the association between social support and quality of life indicators. A cross-sectional survey involving face-to-face interviews (using the social support questionnaire) and data extraction from an existing dataset (Minimum Data Set-MDS) on a sample of 73 cognitively intact Korean American nursing home residents were utilized to examine and understand the relationship between social support and health-related quality of life indicators. Bivariate and multiple regression analyses revealed that social support had main and interactive effects on health-related quality of life indicators. In the bivariate analysis, the appraisal support variable was significantly associated with ADL impairments, depressive symptoms, and self-rated health. In addition, satisfaction with support person was significantly associated with depressive symptoms and self-rated health. Other social support variables, including negative behaviors (being hurt or being upset), perceptions of giving, and perceptions of support were significantly associated with self-rated health among Korean American nursing home residents. After controlling for the covariates, four social support variables were found to be predictive of depressive symptoms: negative behaviors; perceptions of control; frequency interacting with negative behaviors; and negative behaviors interacting with perceptions of control. In addition, perceptions of control and negative behaviors were found to be predictive of negative self-rated health among Korean American nursing home residents. These findings demonstrate the most important sources and types of social support for Korean American nursing home residents and suggest interventions that may help facilitate their quality of life in a nursing home setting. Implications for social work practice and future directions for research are also discussed.

Racial/Ethnic Differences in Medication Adherence and Medicare Part D: A Longitudinal Comparison

L. Bak, University at Buffalo, Buffalo, New York

Prior to Medicare Part D, older Blacks and Hispanics reported greater cost-related medication nonadherence (CRN) compared to older non-Hispanic Whites. The viability of Part D as a means of reducing or eliminating racial and ethnic disparities in CRN remains uncertain. Using cumulative advantage/disadvantage theory as a framework, this longitudinal study examined 1) whether racial and ethnic disparities in CRN have changed since Part D, and 2) whether socioeconomic and health status mediate the relationship between race, ethnicity, and CRN over time. Data from the 2005, 2007, and 2009 waves of the Prescription Drug Study (PDS), a subsample of the Health and Retirement Study (HRS), were used to evaluate CRN before and after Medicare Part D’s enactment. The analytic sample consisted of 1,672 respondents age 65 and older that were Medicare-eligible and taking at least one prescribed medication. The outcome variable of interest was CRN, which included not filling, stopping, or skipping doses of a prescription because of cost. The analysis was conducted using mixed-effects logistic regression models. Results indicated that older Blacks and Hispanics were significantly more likely to report CRN both before and after Medicare Part D compared to older non-Hispanic Whites. While socioeconomic and health status did not affect racial differentials, annual household income mediated ethnic differences in CRN. Further, the rate of CRN for Hispanics significantly decreased over time in comparison to non-Hispanic Whites. Results suggest that while older Hispanics had improvement in CRN over time, racial and ethnic disparities continue to persist despite Medicare Part D.

Perceived Neighborhood Cohesion in a Community Dwelling US Chinese Population: Findings from a Cross-Sectional Study of Chinese Older Adults in Chicago

R. Chen1, E. Chang1, J. Ruan1, Y. Zhen1, C. Li1, M.A. Simon1, X. Dong1, J. Rush Institute for Healthy Aging, Chicago, Illinois, 2. Northwestern University, Chicago, Illinois

Background: Higher level of neighborhood cohesion lowers the risks of comorbidities and mental disorders in late life. Neighborhood cohesion also plays an important role in reducing immigrant older adults’ acculturation stress in the process of adaptation. Great knowledge gaps still persist in understanding the perceived neighborhood cohesion among Chinese older adults. Methods: This is a cross-sectional study with community-dwelling Chinese older adults over the age of 60 in Chicago. In an interview format, we measured cohesion by 6 items assessing frequency of contact and social interactions with neighbors. Community-based participatory research approach was utilized to partner with Chicago Chinese community. Results: Among surveyed participants (N=3,018), the mean age was 73 (SD 8.3) and 59.3% were women. 64% of participants often or sometimes often or sometimes saw neighbors and friends talking outside in the yard or on the street, and 44% often or sometimes saw neighbors taking care of each other such as doing yard work or watching out for each other. However, 52% reported that they personally did not have any neighbors whom they could call for help or assistance, and 25% of the participants did not know any neighbor’s name, Conclusion: Although neighbors’ interactions were commonly observed by Chinese older adults, the contacts amongst participants themselves and neighbors remain limited. Future studies are needed to further examine the role of neighborhood context in the lives of older Chinese residents, including health status measures and social support variables.

Informal Care for Older Adults in Mexico: Estimation of its Supply and Challenges for Future Aging Policies

M. Lopez Ortega, Instituto Nacional de Geriatría, Mexico, Mexico

Mexico is still a young country with a significant burden on secondary and higher education and high numbers of potential workers entering the labor market every year. Given the declining fertility rates and a significant increase in life expectancy, the country will complete its demographic transition in the next 20 to 25 years. While the supply and demand of formal health services have been widely studied, supply of informal care remains much less examined. In Mexico, as in many other countries, studies of health system fail to Health Sector Satellite Accounts (2008-2010), generated for the first time in aspart of the National Health Accounts show that 19% of the Health Sector Product was provided through non-remunerated health care provision, compared to 36% and 44.4% by the public and private sector respectively. This study explores characteristics and determinants of household informal care for older adults in Mexico. In addition, it discusses strategies that cut be put forward in the future, in order to support informal care givers and reduce their burden of care and the opportunity costs of caring. Using the National Time Use Survey 2009 a Heckman selection model is used to model both determinants of time spent in care giving activities and the decision to care. Marked gender differences are found both in the decision to care and time care giving, with women taking up most
of the care, even when faced with competing responsibilities such as caring for other household members.

EMPLOYMENT ISSUES AMONG JAPANESE SENIORS: A LONGITUDINAL STUDY ON A PUBLIC EMPLOYMENT SUPPORT CENTER

M. Kuraoka, H. Suzuki, Y. Fujiwara, Research Team for Social Participation and Community Health, Tokyo Metropolitan Institute of Gerontology; Ibabashi, Tokyo, Japan

In 2012, Japanese baby-boomers reached 65, and the government revised the Elderly Employment Stabilization Law obligating the mandatory retirement age be raised to 65 or the introduction of a continued employment system to 65. In this political transition, it is a national priority to respond to the vast number of seniors who continue actively seeking jobs as well as securing their long-term healthy living. However, previous studies were conducted mainly on seniors who retired from large corporations or the elderly in the general population. The employment of the growing number of seniors who are socially disadvantaged in the society has not been studied. This study will collect the basic information to create training programs for seniors who continue to work as they age as well as to promote awareness of health to prevent any physical and mental risks and social isolation in the future. The study targets people age 55 and above who use an Active Senior Employment Support Center in Tokyo to find a job. This study will examine how the seniors who search for jobs behave before and after they find a job, and what kind of socio-economic background they have as well as mental and physical characteristics. The longitudinal questionnaire survey targeting 250 seniors will be conducted six times on the same subjects who responded to the first survey. Preliminary findings indicate low educational and financial background as well as low social activities or interactions with others.

THE ROLE OF RURAL COMMUNITY-BASED ORGANIZATIONS IN THE IMPLEMENTATION OF CHINA’S NEW RURAL SOCIAL OLD INSURANCE POLICY: A PATH ANALYSIS-BASED MULTI-REGIONAL RESEARCH

H. Mi, C. Niu, G. Wang, Public Affair, Zhejiang University, Hangzhou, Zhejiang, China

This research describes the implementation of the new rural social old-aged insurance policy in the remote and backward rural areas in China, and especially highlights the role of rural community-based organizations. It also measures the effect of relative factors on the policy performance. We applied the framework of implementation process presented by D. S. Van Meter and C. E. Vanhorn to analyze the role of rural community-based organizations during the policy implementation. Path analysis model was used to test the effect. Data came from the field survey of 113 villages and 2104 old-aged residents from 6 provinces all over China. 1) Villager’s autonomy organization in China played important roles in such aspects as interpreting policy to villagers, giving public feedback to government, helping disabled and empty-nested elders withdraw their pension and check their account. 2) The result of the path analysis model (GFI=0.9, AGFI=0.8) showed organization participation, measured by organization input to this policy implementation and villagers’ dependent degree of the organization, was a significant and positive predictor of policy performance(p<0.05). 3) Relative public service condition (information service condition and financial service condition) of the village, not only directly affected policy performance, but also negatively affected organization participation. Besides, villages with more empty-nested families and lower average income tend to have higher organization participation. 4) Villager’s autonomy organizations’ participation did help to achieve better policy performance. However, government should take supervision measures to avoid power abuse in these organizations.

THE ROLE OF MEANING IN LIFE: MEDIATING THE EFFECT OF SUBJECTIVE UNDERSTANDING OF STROKE IN DEPRESSION AND LIFE SATISFACTION AMONG CHINESE STROKE SURVIVORS

E.O. Chow, C. Tang, City University of Hong Kong, Hong Kong, XXX, Hong Kong

Introduction: Cardiovascular disease (CVDs), such as stroke, is one of the most significant global health threats among elders. The experience of stroke not only has a significant impact on the physical functioning of stroke survivors (SSs), but also on their psychological well-being. While psychoeducational approach is incorporated as a common practice following stroke, evidences on its effectiveness are inconsistent and its mechanism remains unclear. According to the stress and coping theory (Lazarus & Folkman, 1984; Park and Folkman, 1997), the provision of stroke information to SSs may help to decrease the distress brought by the illness via regaining their meaning in life. Methodology: 192 SSs were recruited through the local stroke registries in Hong Kong and completed a questionnaire through home interview. The questionnaire assessed their cognitive functioning, physical impairment, subjective understanding to stroke, meaning in life, depressive symptoms and life satisfaction. Results: After controlling demographic characteristics, cognitive functioning, physical impairment, both subjective understanding of stroke and meaning in life predicted depressive symptoms and life satisfaction. Moreover, meaning in life mediates the effect of subjective understanding of stroke on depressive symptoms and life satisfaction. Conclusion: The findings supported the proposed framework of stress and coping theory. Compare with subjective understanding of stroke, meaning in life is a stronger predictor of depressive symptoms and life satisfaction among stroke survivors. Meaning-based intervention approach should be further explored for stroke survivors.

CONNECTING RURAL VETERANS TO AGING AND DISABILITY RESOURCE CENTERS FOR OPTIONS COUNSELING

B.L. Hicken1,2, J.N. Morgan2, R. Rupper1,2, M. Henry1, 1. VA Rural Health Resource Center- Western Region, VA Salt Lake City Health Care System, Salt Lake City, Utah, 2. University of Utah, Salt Lake City, Utah

Nearly 9,000,000 veterans in the US are 65 years of age or older. Though many are eligible for benefits from the Department of Veterans Affairs (VA), a majority of veterans do not know about their VA benefits. For veterans in scattered rural communities, learning about their VA benefits can be especially challenging. Aging and Disability Resource Centers (ADRC) provide information and referral and specialize in options counseling to assist older adults and persons with disabilities to obtain long term services and supports. Within local communities, veterans could connect to local ADRCs to receive information, assistance, and options counseling for their VA benefits. In 2012, the Utah ADRC conducted a needs assessment of ADRC sites throughout the US to assess the typical needs of their veteran clientele and their experiences helping veterans access the VA system to obtain services and benefits. Thirty sites completed parts of the survey with 20 surveys fully completed. Approximately 95% of respondents usually or always asked about veteran status. However, their knowledge of VA benefits was generally poor—on average, 81% of respondents reported needing more information about 38 different benefit categories. Overall, respondents rated the ease of finding information about the VA at 2.0 (5=Very Easy 1=Very Difficult). Overwhelmingly, these agencies indicated that they would like training about VA benefits and services. These data formed the basis for an ongoing pilot project between the VA Office of Rural Health and the Utah ADRC to provide extensive training to ADRC options counselors in VA benefits.
A GLOBAL EXAMINATION OF POLICIES AND PRACTICES FOR LIFELONG LEARNING

P. Cummins†, S. Kunkel†, J. Sociology & Gerontology, Miami University, Oxford, Ohio, 2. Scripps Gerontology Center, Oxford, Ohio

Historically, the life course has been partitioned into three sequential phases: education and training for work, continuous work activity, and retirement. Over the past several decades, age structuring between education and work has become less pronounced; more people are alternating between education and work, or pursuing both simultaneously. Investments in human capital throughout the life course are important to remain competitive in a knowledge economy. Globalization and automation have increased the need for investments in human capital among those currently in the workforce. Skills are becoming obsolete more rapidly, increasing the need for occupational training in new skills. In addition to the benefits of a more competitive workforce, lifelong learning has been associated with improved mental health and well-being and cognitive function. Lifelong learning has been an educational strategy in OECD countries for the past several decades. This study examined policies and practices that encourage lifelong learning in the U.S., Australia, Canada, and Europe. Lifelong learning is increasingly encouraged throughout the world, but the implementation of policies, such as Lifelong Learning Accounts, has been slow to develop. One of the challenges in implementing lifelong learning programs is creating a structure so they will be available to all, including disadvantaged groups and those working in the informal economy. Involvement of individuals, the community, and the government are all important in implementing policies and practices that encourage lifelong learning. Alternatives for effective lifelong learning practices and financing structures will be provided.

AGING AND LONGEVITY: MEDIEVAL UNDERSTANDINGS

During the twelfth and thirteenth centuries, in the Latin West, there was considerable debate about the truth of human nature and the determinants of human growth decline and death, exemplified in such writings as Arnold de Villanova’s Treatise on the Radical Moisture. Central to these debates was (a) the nature of the radical moisture (b) its links to nutrition and the environment (c) the causes and nature of its diminution and (d) the consequent opportunities and limitations for affecting the rate and degree of aging. Although couched in the pre-scientific ideas of Aristotle, Galen and Ibn Sina, these ideas have their modern counterpart in contemporary biogerontological theories that emphasise either an intrinsic rate of living limitation or the assumption of cumulative errors – expressed in Latin as the contrast between ‘consumptio’ and ‘corruptio’.

MIGRATION OF WORKING AGE POPULATION AND ITS IMPACT ON CAREGIVER AVAILABILITY?

S. Mehlduzadeh, Scripps Gerontology Center, Miami University, Oxford, Ohio

States’ anticipated aging and migration patterns were interrupted in the last decade particularly, during 2007–2009. In the automobile industry dependent states, population growth was sharply down (Ohio: 0.66% in 2003–2007 and 0.19% in 2007–2009; Michigan: 0.15% and .81%) while the overall U.S. population grew at 4.5% and 1.8% respectively. Although the economies in States of Ohio and Michigan are improving the slow population growth and in state migration has made some regions gray much faster than anticipated with implications for availability of formal and informal caregivers. Our county by county study of population aging and outmigration demonstrated that in certain counties with lack of employment opportunity family caregiver shortages were observed. Our projections of prevalence of disability among older people in Ohio repeatedly has shown that about 10.2% of all people over age 65 will experience a severe disability needing assistance of another person for daily care. Slightly more than 14% of total Ohio population were age 65+ in 2010, while in the 11 of the smaller, rural counties the proportion of 65+ were 17% or higher with one county at 21%. This study shows how Ohio & Michigan’s efforts in diversifying and rebuilding their economies to retrain their work force will ultimately benefit older population in need of assistance from family or paid caregivers.

CHALLENGES AND OPPORTUNITIES FOR SENIOR CENTERS: SERVING A GROWING AND INCREASINGLY DIVERSE POPULATION IN THE PORTLAND METROPOLITAN AREA

M. Cannon, Institute on Aging, Portland State University, Portland, Oregon

Since the establishment of the Older Americans Act (OAA) in 1965, senior centers have developed and grown in number to a current total of over 11,000 in the United States. They have generally represented two dominant conceptual models: the social agency model, designed primarily to meet the needs of low-income and socially isolated older adults, and the voluntary organization model, designed for older people who are active in voluntary organizations and strongly attached to their communities. Senior centers today are facing changing circumstances, such as funding cuts and a growing and increasingly diverse older population, which will create unique challenges and opportunities for different models of senior centers. This poster details the findings from a multiple-case study of five urban senior centers in the Portland metropolitan region. Two cases represented the social agency model, two represented the voluntary organization model, and one was a nationally accredited senior center that had succeeded in meeting nine national standards set by the National Institute of Senior Centers (NISC). Data were gathered through interviews with senior center directors, staff members, and attendees, and also with experts in aging services. Focus groups were also conducted with senior center attendees. The findings from the study contribute to a better understanding of the challenges, constraints and opportunities that urban senior centers face. Potential strategies are offered for senior centers to best serve their members and attract new members as the Baby Boomers reach traditional retirement age and as the older population grows in size and diversity.

SESSION 555 (SYMPOSIUM)

EXERCISE AS MEDICINE IN THE ELDERLY

Chair: C.A. Peterson, University of Kentucky, Lexington, Kentucky

This symposium will address mechanisms underlying the beneficial effects of aerobic exercise on physical function in the elderly. The first presentation by Dr. Elena Volpi will ask the question “Can aerobic exercise promote muscle anabolism and function in older adults?” Aerobic exercise clearly improves metabolism, but its effects on protein synthesis and muscle mass are less clear. Mechanisms underlying the effects of regular aerobic exercise on risk factors for cardiovascular vascular disease in the elderly will be discussed by Dr. Doug Seals in the second presentation. Effects on large elastic artery stiffness and vascular endothelial dysfunction will be presented. Finally, the third presentation, by Dr. Scott Trappe, will highlight new information on cardiovascular and skeletal muscle health in octogenarian lifelong endurance athletes. The knowledge presented will be crosscutting for numerous scientific disciplines and health care providers involved with health and preventative medicine.

THE AGING ATHLETE

S. Trappe, Ball State University, Muncie, Indiana

The aging athlete is an emerging exercise model that is starting to yield more quantifiable information on the long-term aspects of exercise and it’s impact on health. This lecture will highlight new information on cardiovascular and skeletal muscle health in octogenarian life.
long endurance athletes. The octogenarian athletes show a distinct endurance phenotype that is comparable to healthy nonendurance trained men 40 years younger. The quantitative and qualitative myocellular performance at the single muscle fiber level provides unique insight into the impact of lifelong exercise on slow-twitch and fast-twitch muscle fiber health. The knowledge presented will be crosscutting for numerous scientific disciplines and health care providers involved with health and preventative medicine.

CAN AEROBIC EXERCISE PROMOTE MUSCLE ANABOLISM AND FUNCTION IN OLDER ADULTS?
E. Volpi, University of Texas Medical Branch, Galveston, Texas

Aerobic exercise is well known to improve glucose and lipid metabolism and reduce cardiovascular risk. Less information is available with regards to the effects of aerobic training on muscle size strength and function, particularly in sedentary older adults with or at risk for sarcopenia. Sarcopenia, the loss of muscle mass and function with aging, is characterized by a relative resistance of muscle protein metabolism to the anabolic action of insulin and nutrients. Recent studies suggest that the improvements in muscle perfusion and insulin sensitivity induced by aerobic exercise can also ameliorate the muscle protein anabolic response to nutrients and insulin. As a consequence, aerobic exercise may be able to reduce muscle loss and sarcopenia, particularly in physically inactive older adult. Preliminary data from an ongoing clinical trial on the effects of aerobic training on muscle metabolism, size and function will also be presented.

AEROBIC EXERCISE AND ARTERIAL AGING
D.R. Seals, Integrative Physiology, University of Colorado Boulder, Boulder, Colorado

Aging is associated with stiffening of the large elastic arteries and vascular endothelial dysfunction (e.g., impaired endothelium-dependent dilatation, EDD). Endurance exercise-trained middle-aged/older adults demonstrate lower large elastic artery stiffness and greater EDD than their sedentary peers. With daily brisk walking, previously sedentary middle-aged/older adults show reduced stiffness and improved EDD. The mechanisms underlying the effects of regular aerobic exercise on arterial stiffness likely include changes in arterial wall composition. Enhanced EDD in older exercising adults is mediated by increased nitric oxide (NO) bioavailability associated with reduced oxidative stress. Arteries from old rodents that perform regular aerobic exercise demonstrate increased endothelial NO synthase, reduced oxidative damage associated with lower levels of the oxidant enzyme NADPH oxidase, and increased activity of the antioxidant enzyme superoxide dismutase. Aerobic exercise also may protect arteries with aging by increasing resistance to risk factors. Habitual aerobic exercise is an effective strategy to combat arterial aging.

SESSION 560 (SYMPOSIUM)

METABOLISM AND NUTRITION, IGF PATHWAYS
Chair: B. Kennedy, Buck Institute, Novato, California

Investigators presenting during this symposium will discuss the role of the IGF system in longevity in humans and mammals and the link between diet and IGF-reduction in prolonging lifespan. Paradoxically, low GH/IGF-1 signaling is linked to many age-related diseases in humans. Dr. Barzilai will discuss if many ‘good’ effects of IGF-1 can be accentuated in mammals by increasing central and/or decreasing peripheral IGF-1 signaling. Dr. Cohen will provide an overview of the current state of pharmacological development of antagonists to the IGF system.

SPEAKER PENDING
B. Kennedy, Buck Institute, Novato, California

Speaker Pending

ORGAN DISTRIBUTION OF IGF-1 SIGNALING AND LONGEVITY
N. Einstein, D.M. Huffman, Einstein, Bronx, New York

The link between altered insulin-IGF pathway and longevity was shown in lower organisms, deletion of GH-IGF axis molecules result in extended life span in dwarf mice, dwarf animal models live longer, and we have demonstrated functional IGF-1 receptor abnormality in female centenarians. While low GH/IGF-1 signaling is beneficial for lifespan, it is paradoxically linked to many age-related diseases in humans including diabetes and cognitive decline. Furthermore we have previously shown that administration of IGF-1 near the hypothalamus improves insulin action. Therefore, we hypothesize that many ‘good’ effects of IGF-1 can be accentuated in mammalians by increasing central, and/or decreasing peripheral IGF-1 signaling. By altering IGF-I levels in the brain by several approaches and inhibiting IGF-1 receptors in the periphery we will test a new models with different distribution of IGF-1 for the possible prevention, slowing and reversal of aging.

IS THERE A FUTURE FOR STRATEGIES TARGETING THE IGF PATHWAY FOR CANCER AND LONGEVITY?
P. Cohen, USC Davis School of Gerontology, Los Angeles, California

There is extensive evidence for the role of multiple components of the IGF-system in the progression of cancer as well as the regulation of lifespan. Initial prospective epidemiological data suggested that higher IGF-I levels, in healthy subjects, were associated with a substantial increased risk of cancer development. Longevity in human and animal models has been linked to mutations in the IGF-receptor pathway and the lifespan-prolonging effects of diet have been attributed to IGF-reduction. This body of data has led to a frenzy of pharmacological development of antagonists of the IGF system by over a dozen pharmaceutical companies. At this time, however, due to disappointing clinical outcomes in human studies, it is unclear if any of the IGF-antagonists will achieve FDA approval, and if so, for what indications. Potential combination approaches including adding additional drugs such as metformin, rapamycin, or dietary measures, may improve the safety and efficacy of IGF blockade.

SESSION 565 (SYMPOSIUM)

AFFIRMING AND EVALUATING CREATIVE EXPRESSION IN PERSONS WITH DEMENTIA
Chair: L. Snyder, University of California, San Diego, San Diego, California
Discussant: M.S. Mittelman, New York University, New York, New York

Persons with dementia are largely evaluated and assessed based on cognitive deficits and decline. There is, however, both a neuropsychological and humanistic foundation for the role that creative expression can play in affirming the enduring capacities and retained selfhood of persons with advancing dementia. This symposium addresses both the methodological challenges and rich outcomes of engaging persons with dementia in varied forms of creative expression. Johnson provides a conceptual overview of the methodological challenges in researching outcomes and efficacy of creative arts interventions with persons with dementia. Three examples of program interventions with varied research methods follow. Mechino discusses a multimedia creative arts program aimed at building capacity and awakening abilities in participants. Camp provides an overview of the procedural learning systems that are retained in persons with mild-to-moderate dementia and reviews promising methods and outcomes of teaching individuals to play musical instruments and perform in a musical ensemble. Phinney reports on a phenomenological analysis of interview and observational data gathered from seven artists to better understand the subjective meaning of creative expression in light of their advancing dementia. Together these presentations provide rich content to broaden our understanding of the

66th Annual Scientific Meeting

195
ways in which creative arts interventions can build on the enduring resiliency and personhood of individuals with dementia, and how researchers can work to better capture observed beneficial outcomes.

AN OVERVIEW OF THE CHALLENGES IN EVALUATING CREATIVE EXPRESSION IN PERSONS WITH DEMENTIA

J.K. Johnson¹, T.A. Allison², 1. Institute for Health and Aging, University of California, San Francisco, San Francisco, California, 2. UCSF School of Medicine, San Francisco, California

There are numerous anecdotal reports from both families and researchers suggesting that creative expression can remain preserved in persons with dementia. However, evaluating these accounts remains challenging. It is important to find improved methods for documenting creative expression to 1) improve our understanding of the capacity for creative expression and its impact on well-being and 2) expand opportunities for creative expression in persons with dementia. The purpose of this talk is to provide an overview of both qualitative and quantitative methods currently used to evaluate creative expression in persons with dementia. The strengths and weaknesses of these methods will be discussed, and recommendations for future approaches will be provided. After attending this presentation, participants will be able to identify two new ways to evaluate creative expression in dementia.

BUILDING CAPACITY AND AWAKENING ABILITIES FOR PERSONS WITH DEMENTIA THROUGH A VISUAL ARTS PROGRAM

L. Meschino, S. Dupuis, Murray Alzheimer Research and Education Centre LHI, University of Waterloo, Waterloo, Ontario, Canada

Gather at the Gallery is a community-based visual art program and research initiative that provided people with dementia and their care partners the opportunity to visit local galleries and make art with local artists in a series of five 10-week modules. This paper examines how the program challenged misperceptions of the abilities of persons with dementia through detailed descriptions of participants’ and educators’ evolving expectations and experiences of creativity. Interpretations of the long-term impact on participants’ sense of self and relationships with others are explored in terms of the phenomena of awakened creative consciousness and process of co-creation (i.e., shared learning and mutual discovery). Finally, key aspects of the program are proposed as a step toward identifying what is unique about arts-based as opposed to other kinds of social activities for challenging assumptions around dementia.

HEAR MY SONG: TEACHING PERSONS WITH DEMENTIA TO PLAY MUSICAL INSTRUMENTS IN CONCERT

C.J. Camp¹, M. Bourgeois², J. Brello², K. Bescan³, E. Bescan³, 1. Center for Applied Research in Dementia, Solon, Ohio, 2. Ohio State University, Columbus, Ohio, 3. Constellations Schools, Cleveland, Ohio

While persons with dementia benefit from listening to music, there has been little research on teaching persons with dementia to play musical instruments, nor on the resulting effects of such teaching on these persons and their caregivers. Given that procedural learning systems are available to persons with mild to moderate dementia, we developed and initially assessed a music program involving Orff instruments (e.g., metallophones), making music through striking instruments with mallets. Using external cues, errorless learning, motor learning, priming, and other techniques from music education and neuropsychological rehabilitation, we taught persons with dementia to play components of songs such that, as an ensemble, they presented songs in a “concert” format. The activity was highly and positively engaging for persons with dementia as well as for their caregivers. Increased self-esteem and self-confidence in persons with dementia also were obtained.

THE EXPERIENCE AND MEANING OF CREATIVE EXPRESSION FOR ARTISTS WITH DEMENTIA

A. Phinney, 1. University of British Columbia, Vancouver, British Columbia, Canada, 2. Centre for Research on Personhood in Dementia, Vancouver, British Columbia, Canada

This study is based on empirical notions of meaningful activity in dementia, tied together with theoretical ideas of embodiment. Using an existing data set, I conducted a phenomenological analysis of many hours of interview and observational data gathered from seven people with dementia who self-identified as artists. The purpose of the interpretation was to understand what their involvement in creative expression meant to them. Findings showed that the meaning of creative expression is a “multi-faceted thing”, with the artists experiencing powerful feelings of continuity, connection, and delight. At the same time however, the urge to make art is fading as people feel their bodies weakening and becoming less active. Results will be discussed in light of how the capacity for creative expression is sustained through the lived body in dementia, even as the desire to create diminishes. Learning Objectives: (1) Describe the benefits of creative expression as perceived by artists with dementia. (2) Explain how artists with dementia experience shifting patterns of involvement in creative activity.

DISSEMINATION OF ONLINE BONE HEALTH INTERVENTIONS: IMPLICATIONS FOR RESEARCH AND CLINICAL PRACTICE

Chair: E. Nahm, University of Maryland School of Nursing, Baltimore, Maryland

Currently, more than 44 million American people are either living with osteoporosis or at high risk due to low bone mass. Although significant advancements in bone health research have yielded multiple effective behavioral measures to improve and maintain bone density, these measures have not been effectively incorporated into the individuals’ lives. With the rapid growth in information technology and the global emphasis on ehealth, the Internet can be an effective vehicle to disseminate those interventions to the public. Research on dissemination emphasizes strategic mechanisms that package and deliver health interventions, resulting in positive health behavior changes. This symposium includes four papers that address methodological approaches to disseminate online bone health programs and their practice implications. The first paper reports on the comparative effects of two theory-based online bone health interventions (2-week vs. 8-week) on health outcomes of community-dwelling older adults. The second paper focuses on bone health related health conditions of MyHealthEvet participants as compared to their counterparts and their clinical implications in bone health practice. The third paper discusses participants’ current interest in bone health information based on the qualitative findings from the inquiries submitted via an “Ask-the-Experts” section and emails in a large scale online bone health study. The final paper reports on the reliability and validity of a revised Osteoporosis Calcium Knowledge scale that can be used online to evaluate knowledge of bone health behavior among community-dwelling older adults.

HEALTH PROMOTION: HOW EHEALTH TOOLS MAY BE USED TO EFFECTIVELY PROMOTE BONE HEALTH

K.G. Charters¹, E. Nahm², K. Nazi³, K. Painter¹, 1. Office of the Chief Medical Officer, TRICARE Management Activity, Falls Church, Virginia, 2. University of Maryland School of Nursing, Baltimore, Maryland, 3. Department of Veterans Affairs, Silver Spring, Maryland

Bone health findings have not been fully incorporated into the daily lives of adults, and many are unaware of the magnitude of bone-health problems. A large-scale online study (N = 866) compared the long-term effects of online bone health interventions in adults age 50 and
older targeting two large online communities (SeniorNet, My HealtheVet). In this study, My HealtheVet participants were younger with a greater representation of males and a higher rate of self-identified health conditions. In comparison to the SeniorNet population, the My HealtheVet population reported a higher incidence of bone health issues. However, knowledge about calcium and exercise osteoporosis was significantly lower and their perceived risk of osteoporosis was significantly higher. Yet, in the past 12 months, more than half had not discussed bone health with their primary care provider. Findings from this study contribute to current eHealth practice and research for other online health promotion projects.

RELIABILITY AND VALIDITY OF THE REVISED OSTEOPOROSIS KNOWLEDGE TEST
B. Resnick1, B. Qi2, E. Nahm1, 1. University of Maryland School of Nursing, Baltimore, Maryland, 2. Villanova University, Villanova, Pennsylvania

The purpose of this study was to test the reliability and validity of the revised Osteoporosis Knowledge Test (OKT), which was revised to incorporate current knowledge about bone health. The sample included 866 participants from the Bone Health Study. More than half (63%) of the participants were male with a mean age of 62.8 (SD= 8.5). The majority was white (89%), married (53%) and had some college (87%). Rasch analysis was used to test the reliability and validity of the measure and a DIF analysis was done to compare responses based on gender and race. The items all fit the model, there was evidence of internal consistency and, as anticipated, women and those with a diagnosis of osteoporosis had more knowledge about the disease. The findings from this study add to prior information about the OKT and will facilitate the use of this measure in research and clinical work.

COMPARATIVE EFFECTS OF TWO ONLINE HEALTH BEHAVIOR INTERVENTIONS: 2-WEEK VS. 8-WEEK
E. Nahm, S. Zhu, B. Resnick, M. An, University of Maryland School of Nursing, Baltimore, Maryland

Despite a great deal of research on eHealth interventions, little information is available regarding the methodologies to develop and implement effective online health behavior interventions. In this study, we compared the effects of two theory-based online health behavior interventions used in two trials with participants recruited from SeniorNet. The first trial (N=245; mean age, 69.3) used a 2-week intervention and the second trial (N=183; 69.5) used an 8-week intervention. Both included similar content (diet, exercise, fall prevention, etc.); however, the 8-week intervention had more extensive content. When the pre-post outcomes were compared, participants in both trials showed improvement in osteoporosis knowledge and all calcium-related outcomes. Only the 8-week intervention, however, showed improvement in exercise-related outcomes. Its effect sizes were higher for all study outcomes except knowledge when compared to the 2-week intervention. Further studies are needed to determine optimal “doses” of online interventions to change health behaviors in older adults.

ASSESSMENT OF CURRENT BONE HEALTH-RELATED INFORMATION NEEDS AMONG COMMUNITY-DWELLING OLDER ADULTS
B. Park, J. Brown, E. Nahm, University of Maryland School of Nursing, Baltimore, Maryland

Currently, an estimated 10 million Americans age 50 and older are living with osteoporosis. Of these, one in two women and one in four men will experience osteoporosis-related fractures during their lifetime. The purpose of this study was to identify older adults’ current bone health-related information needs based on the findings from an “Ask-the-Experts” section and email inquiries in an online trial. Content analysis of 88 independent inquiries revealed 9 topical categories, including Calcium and Vitamin D (22 inquiries), Bone Density/Bone Mineral Density Tests (17), Osteoporosis (14), etc. Interestingly, many inquiries about calcium were related to concerns about consuming more calcium than needed. Most vitamin D inquiries were related to taking the optimal dose. Inquiries regarding bone density were related to the impact of the participants’ other health conditions or medications. The study’s findings can provide helpful information for the development of bone health promotion interventions targeting community-dwelling older adults.

SESSION 575 (SYMPOSIUM)

EFFECTIVE WORK-LIFE FIT FOR OLDER WORKERS: FINDINGS FROM THE TIME & PLACE MANAGEMENT STUDY
Chair: J. James, Sloan Center on Aging & Work, Boston College, Chestnut Hill, Massachusetts
Co-Chair: M. Pitt-Catsouphes, Sloan Center on Aging & Work, Boston College, Chestnut Hill, Massachusetts
Discussant: P. Taylor, Monash University, Melbourne, Victoria, Australia

Today’s older workers, many of whom indicate a need and/or desire to work past conventional retirement ages (Moen & Huang, 2010), indicate that having a flexible schedule is an essential element of their ideal job (Goreneman, 2008). Yet, studies reveal that older workers are not likely to perceive that they have the flexibility they need to fulfill their work and personal responsibilities (e.g., Pitt-Catsouphes, Matz-Costa, & Besen, 2009). There are many barriers, both real and perceived, to providing flexible work options (Van Deusen et al., 2007). One such barrier is the lack of training or development of successful implementation strategies for flexible work option policies; the other may follow from the first—supervisors are skeptical of their relevance to business success and therefore unsupportive of employee requests. In this symposium, we will use data from the Boston College Study of Time & Place Management to examine innovations in the development of effective implementation strategies. We will use data from one large organization in a finance and insurance super sector (N=968) and from one large healthcare system (N=3,950) to answer the questions: in a world of a few, which supervisors do successfully provide flexible work options? And what do they do? What are the elements of successful strategies in both settings? And to what extent is age a factor for each? Findings suggest the importance of training, awareness-building and “going against the grain,” and suggest ways that a small few positive deviants might influence the many.

WHAT’S UP? WHAT’S HAPPENING WITH THE BOSTON COLLEGE TIME & PLACE MANAGEMENT STUDY?
J. James, M. Pitt-Catsouphes, K.E. Cahill, Sloan Center on Aging & Work, Boston College, Chestnut Hill, Massachusetts

The Boston College Time & Place Management Study is set of field experiments designed to assess the effectiveness of policies relevant to time and place management (TPM) in the work place. While previous research suggests that TPM policies can be beneficial to business, few studies have used experimental design to examine business-relevant benefits over time. In the context of the aging of the workforce, the availability of TPM policies is particularly important because they can affect the ability of older workers to extend their labor force participation. This first paper will provide an overview of the study along with methods and measures. “Company A is a large organization in the finance and insurance super sector (n=968). “ModernMedical” is a large healthcare system located in the northwestern region of the United States (n=3,950). Subsequent papers, all of which are based on these data, will then focus on findings and discussion.
The importance of flexible work options has gained salience in light of the aging workforce and knowledge of many older workers’ criteria for continued work. Scholars have long recognized the important role of supervisors as gatekeepers in the implementation of flexible work policies (e.g., Hammer, Kossek, Anger, Bodner, & Hanson, 2009). We present data collected from a large health care organization (‘ModMed’) involved in the Time & Place Management Study conducted by the Sloan Center on Aging & Work. We focus on a sub-group of innovative supervisors who report that they ‘make flexibility work’ without formal organizational policies. We explore two sets of questions: Which managers are most likely to be these Innovators/Early Adopters? Do they report higher team performance compared to other managers? What difference does the age composition of the team make? Findings suggest innovative pathways that might become a tipping point for making flexible work normative.

**SESSION 580 (SYMPOSIUM)**

**FACULTY DEVELOPMENT: HOW A NATIONAL COMMITTEE’S INITIATIVES FILL IN THE GAPS IN A TIME OF SCARCE RESOURCES**

Chair: K. Kopera-Frye, University of Louisiana at Monroe, Monroe, Louisiana
Co-Chair: L.K. Donorfio, University of Connecticut/Dept. of Human Dev & Fam Studies, Waterbury, Connecticut
Discussant: J. Frank, UCLA, Los Angeles, California

The educational unit of the OSA, the Association for Gerontology in Higher Education (AGHE), provides an important role in professional development for educators in gerontology and geriatrics. Through its committees, AGHE gives guidance in areas including program development, competency-based curriculum development, training approaches, and publishing. The Faculty Development Committee is an example of ways in which a national organization’s committee can provide faculty with the resources and tools for professional development. In these tough economic times, association-based committees such as this committee can supplement institutional faculty development programs which vary from school to school and are often the first to lose resources. This symposium highlights ways in which this committee supports current and future faculty in scholarly productivity. Donorfio and Kopera-Frye will present on the annual AGHE Teaching Institute with faculty comprised of recipients of the AGHE Distinguished Teaching Honor, sharing their innovative pedagogical approaches. Waters and Howe will report on distance learning approaches for faculty development, including webinar series on topics related to professional development. Howe, Silverstein, Niles-Yokum and Covian will discuss AGHE’s initiatives in publications and providing mentorship to emerging scholars on publishing, including programs sponsored by its official journal, Gerontology & Geriatrics Education. Karasik and Bradley will discuss innovative trends in pedagogical approaches and creative ways to support faculty. Finally, AGHE President Frank will discuss common themes and the applicability of AGHE’s initiatives in other settings.

**HOW A TEACHING INSTITUTE CAN SUPPORT FACULTY DEVELOPMENT AND ENGAGED STUDENT LEARNING**

Prior research on pedagogy suggests that faculty are not really “taught” how to teach in higher education venues. In these times of scrutinized institutional effectiveness and accountability, engaged student learning is a necessity. Engaged student learning is both beneficial to the instructor and the student and often results in positive outcomes such as increased critical thinking and student retention. For the last 3 years, 5 Distinguished Teacher awardees have led a preconference Teaching Institute at AGHE’s annual conference. Themes have varied across the 3 years, including such topics as innovative teaching approaches in gerontology, teaching via different modalities, and getting students interested in learning about aging. Attendees help shape the topics to be included in future institutes by identifying their biggest teaching challenges and topics they would like more information. The Institutes have been well-received serve a much needed function in supporting faculty development at low cost to the faculty’s home institution.

**STRATEGIES FOR SUCCESS IN ACADEMIA: FACULTY DEVELOPMENT THROUGH DISTANCE LEARNING**

L. Waters, J.L. Howe, 1. Virginia Center on Aging, Virginia Commonwealth University, Richmond, Virginia, 2. Brookdale Department of Geriatrics & Palliative Medicine, Mount Sinai School of Medicine, Bronx, New York

Faculty are expected to be proficient in a broad repertoire of skills, including classroom teaching and academic advising, field supervision...
and evaluation, mentoring and role modeling. Both new and experienced faculty members often struggle with heavy workloads and a lack of collegial feedback. Facing increased enrollments and shrinking financial support, higher educational institutions have limited resources for professional development. In response to the needs of faculty to balance and integrate these responsibilities, the AGHE Faculty Development Committee developed a four-part webinar series on strategies for success. The series is intended for advanced graduate students, junior and mid-level faculty members, and others interested in learning more about academic mentoring, advancement, and academic pathways. Session topics include mentoring, navigating appointments for tenure and promotion, and developing strategic academic relationships. This presentation will provide an overview of the project design, implementation, program structure, content, and ongoing replication through federally funded Geriatric Education Centers.

AGHE’s ROLE IN PROMOTING FACULTY DEVELOPMENT THROUGH THE PUBLICATION OF SCHOLARLY ARTICLES

Gerontology and Geriatrics Education is the official journal of AGHE and is geared toward the exchange of information related to research, curriculum development, program evaluation, and education innovations. The Editor-in-Chief, formerly the Chair of the Faculty Development Committee, and the editorial staff, in partnership with the Editorial Board, have initiated several programs geared to mentoring emerging scholars in publishing. These include a reviewer-in-training program, an international authors’ mentoring program, and the development of presentations and workshops at the annual meetings of AGHE and GSA about publishing in peer-reviewed journals. Additionally, we will address manuscript themes that have emerged over the last few years including new roles for gerontology and geriatrics educators in the face of an aging population, strategies for enhancing our relevancy in the years ahead, methods for measuring the impact of programs to ensure continued resources and relevance, and strategies for attracting students and professionals into the field.

INNOVATIVE TRENDS IN GERONTOLOGICAL EDUCATION: SUPPORTING OUR TEACHING FACULTY

R.J. Karasik1, D.B. Bradley7, 1. Gerontology, St. Cloud State University, St. Cloud, Minnesota, 2. Western Kentucky University, Bowling Green, Kentucky

Pedagogical approaches for teaching Gerontology are keeping pace with the rapidly evolving trends of higher education. As early and ardent adopters of intergenerational service-learning and other experiential approaches, it is not surprising that Gerontology educators are branching out to such varied applications as asynchronous learning, blended learning, multiple teaching platforms, on-line learning systems, “flipped” classrooms, social media, and perhaps the newest approach — MOOCS (Massive Open Online Courses). Implications of these emerging trends for Gerontological education and their impact on educator training will be examined. Further, creative ways the AGHE Faculty Development Committee and similar entities can support Gerontology faculty in these endeavors will be explored.

SESSION 585 (SYMPOSIUM)

FEAR OF FALLING: NEW ISSUES ON MEASUREMENT, DETERMINANTS AND INTERVENTIONS

Chair: G. Zijlstra, CAPHRI - Dept. of Health Services Research, Maastricht University, Maastricht, Netherlands
Co-Chair: G.I. Kempen, CAPHRI - Dept. of Health Services Research, Maastricht University, Maastricht, Netherlands
Discussant: S. Iwarsson, Lund University - Department of Health Sciences, Lund, Sweden

Fear of falling and related activity restriction are highly prevalent among older people. Their impact on quality of life and social and physical functioning is substantial and negatively influencing optimal aging. In view of the increase in life expectancy and the commonness of (co)morbidities and frailty in older people, it is likely that fear of falling and activity restriction will be even more prevalent in the near future. This warrants research which is relevant for the development and evaluation of programs that focus on (cost) effective treatment. During this symposium five researchers from the US and the Netherlands will present new research findings either on tools that may contribute to the development and evaluation of new fear of falling programs in the future or on the effects of fear of falling programs that have recently been developed. The presentations will focus on: 1) a new tool of measuring avoidance behavior due to fear of falling, 2) nursing home resident’s and staff member’s perceptions on fear of falling, 3) fear of falling as a variable to improve the ability to get rise from the floor, 4) the impact of social support on fear of falling, and 5) the effects of a recently developed cognitive behavioral in-home program on fear of falling. Our discussant from Sweden will shortly reflect on the presented findings in view of GSA’s theme ‘Optimal Aging Through Research’ and will facilitate a discussion on-site.

MEASURING AVOIDANCE BEHAVIOR DUE TO FEAR OF FALLING IN COMMUNITY-LIVING OLDER ADULTS

G. Zijlstra1, T. Dorresteijn1, J. Vlaeyen1,2, G.I. Kempen1, 1. Maastricht University, CAPHRI - Dept. of Health Services Research, Maastricht, Netherlands, 2. University of Leuven, Research Group Health Psychology, Leuven, Belgium, 3. Maastricht University, Dept. of Clinical Psychology Science, Maastricht, Netherlands

Fear of falling is a common disabling concern in community-living older adults. Reliable and valid measures for activity avoidance due to fear of falling are scarce. In the process of developing a questionnaire we explored the prevalence of such avoidance behavior for 7 activities varying in difficulty, e.g. getting dressed or undressed and going up or down the stairs. In this cross-sectional study 2,684 community-living older adults (mean age: 77.4 years (range 70-94); male: 43%) completed a postal questionnaire. Preliminary analyses showed that for each of the 7 activities the majority of the population never avoided activities as they were not concerned about falling (range 58-84%). Of those concerned about falling (N varied per activity; range 451-1,135) the majority never avoided activities (range 43-79%) and about 15% often avoided activities like going up or down stairs and going out to a social event.

FEAR OF FALLING AMONG NURSING HOME RESIDENTS: PERCEPTIONS AND PERFORMANCE

H. Lach, J. Parsons, Saint Louis University, St. Louis, Missouri

Fear of falling is associated with functional decline among nursing home residents. This mixed methods study explored the concordance among nursing home residents’ self-efficacy (the Nursing Home Falls Self-efficacy Scale), ADLs (Katz), physical function (Nursing Home Physical Performance Test), fall risk (Morse Fall Scale), and perceptions (qualitative interviews). Participants were 30 residents from 3 nursing homes (50% female, mean age 82+6.8, 100% White, mean length of stay 1.6 years); all had self-reported fear of falling (mean score 6 + 2.1 on 1-10 scale). Participants with higher fear of falling had lower
self-efficacy scores and poorer function, but not ADLs. Qualitative comments indicated participants did much to adjust to fear of falling as a way of life through cautious behavior, although there was a desire among some to remain independent. Nursing home staff members need to identify fear of falling and intervene to help residents maintain functional abilities.

FALL RECOVERY AND FEAR OF FALLING: PREDICTIVE DETERMINANTS OF THE SUPINE TO STAND TRANSITION
D. Klima, D. Patel, C. Gilbert, D. Hamad, UMES, Princess Anne, Maryland

Purpose: The purpose of this study was to identify correlates and predictive determinants of the supine to stand transition. Methods: Subjects included 61 community-dwelling elders (x=79.6±8.6) independent in ambulation. During a task circuit, subjects performed the Activities-specific Balance Confidence (ABC) Scale, a timed supine to stand test, the 10 meter walk test, grip strength, and the Modified Clinical Test for Sensory Interaction in Balance Test (MCTSIB). Results: The mean time for supine to stand performance was 7.9+/-5.4 seconds; moreover, this performance time was significantly correlated with self-selected gait speed (r=-.61;p<.01), fast gait speed (r=-.66;p<.01), ABC scores (r=-.51;p<.01) and grip strength (r=-.30;p<.05). Fast gait speed, the composite MCTSIB score, and use of a device to rise predicted 54% of the variance in supine to stand performance time (p<.001). Conclusions: The supine to stand task is related to balance, gait, and balance confidence measures. Multidimensional fall prevention programs should incorporate floor transfer interventions.

UNDERSTANDING THE IMPORTANCE OF SOCIAL SUPPORT ON FEAR OF FALLING FOR COMMUNITY-DWELLING OLDER ADULTS
C.M. Headley, Exercise & Sport Science, Judson University, Elgin, Illinois

This replication study examined the effects of a community-based program reducing the risk of falls, exploring fear of falling and social support in older adults. The program (N’Balance©) focused on challenging the sensory systems through multi-factorial, multi-dimensional classes using two sites. An 8-week program met twice weekly for 50 minutes and included pre- and post-test physical and psychosocial assessments. Measures in the study include the 30-second chair stand, 8-foot Up-and-Go, 50- foot Gait Analysis, M-CTSIB, Fullerton Advanced Balance Scale, postural analysis, and a questionnaire. Results of the initial study indicated that N’Balance© participation was associated with improved balance (.00), the fear of falling (.04), and approached significance with leisure self-efficacy (.06) with the replication study currently being evaluated. The replication study augments the previous study that N’Balance may improve social support, perceptions of leisure, reduces the risk of falls, and reduces fear of falling, in older adults.

EFFECTS OF A COGNITIVE BEHAVIORAL IN-HOME INTERVENTION TO REDUCE FEAR OF FALLING AND ASSOCIATED ACTIVITY RESTRICTION IN FRAIL OLDER PERSONS
G.I. Kempen1, T. Dorrestein1, J. Vlaeyen2,3, G. Zijlstra1, 1. CAPHRI - Dept. of Health Services Research, Maastricht University, Maastricht, Netherlands, 2. Research Group Health Psychology - University of Leuven, Leuven, Belgium, 3. Department of Clinical Psychological Science - Maastricht University, Maastricht, Netherlands

A cognitive behavioral in-home intervention to reduce fear of falling and associated activity restriction was evaluated in a randomized controlled trial in the Netherlands. Community-living people aged 70+ who reported at least some fear of falling, associated activity restriction, and fair/poor perceived health were eligible. Participants (N=389) were randomly allocated to either intervention or control group. The intervention comprised 3 home visits and 4 telephone consultations during a 5 months period. The control group received no intervention. Data was collected at baseline and at 5 and 12 months. Primary outcomes were concerns about falls, avoidance of activity, (catastrophic) beliefs about falls, perceived consequences of falling, and anxious and depressed mood. In contrast to symptoms of anxiety and depression, concerns about falls, avoidance of activity and catastrophic beliefs were significantly reduced until 12 months follow-up and perceived consequences until 5 months follow-up (p<.01) when comparing the intervention and control group.

SESSION 590 (SYMPOSIUM)

INTERNATIONAL PERSPECTIVES ON AGING IN URBAN CONTEXT: COMMONALITIES AND CONTRASTS
Chair: J. Kelley-Moore, Sociology, Case Western Reserve University, Cleveland, Ohio
Discussant: C. Phillipson, University of Manchester, Manchester, United Kingdom

The World Health Organization (WHO) model of “age-friendly cities” emphasizes the theme of supportive urban environments for older citizens. These are defined as encouraging “active aging” by “optimizing opportunities for health, participation and security in order to enhance quality of life as people age.” The dual global trends of population aging and urbanization compel questions about the extent to which cities are, or could become, age-friendly communities. Will so-called global cities integrate or segregate their aging populations? In what ways may the needs and strategies differ by country? Much of the study of urban aging has been country-centric, with little cross-national synthesis. This symposium brings together scholars from five countries to address aspects of neighborhoods and broader urban context that influence the physical location of older adults, as well as access to resources and well-being. Drawing from research in the Netherlands, Belgium, United States, and Australia, this collection of papers focuses on social structural, economic, and policy forces that shape the age-friendliness of cities. Christopher Phillipson of Manchester University will then synthesize this work, highlighting the commonalities and contrasts across national contexts and outline an agenda for studying age-friendly global cities.

COHORT DIFFERENCES IN NEIGHBOURHOOD INTEGRATION AND INSTITUTIONALIZATION IN THE NETHERLANDS: THINGS WILL NEVER BE THE SAME AGAIN?
F. Thomese, Sociology, VU University, Amsterdam, Netherlands

Aging societies are becoming more mobile and global. At the local level, this leads to changes in neighborhood composition and greater diversity among older adults in local involvement. At the same time, Dutch policy counts on local relationships to help older adults postpone institutionalization. We explore whether this policy standpoint still holds when comparing cohorts of community dwelling people before and after the turn of the century. Both age and cohort changes may impact on the effects of neighborhoods on the ability to live independently. The Longitudinal Aging Study Amsterdam provides data on two successive cohorts, aged 55-65 in 1992 and 2002, respectively (n= 1,270 and 1,007). Looking at personal (education, health, wealth), social (partner, children, network), and neighborhood (services, like-minded people) resources, we see that neighborhood diversification economically and ethnically. Between cohorts, (small) effects of personal and social resources become smaller, and environmental factors increase.
EXPERIENCES OF URBAN LIFE AMONG AGEING MIGRANTS: CHALLENGES AND PERSPECTIVES FOR DEVELOPING AGE-FRIENDLY COMMUNITIES
T. Buffel1, S. Güven2, C. Phillipson1, D. Verté1, I. The University of Manchester, Manchester, United Kingdom, 2. Hacettepe University, Ankara, Ankara, Turkey, 3. Vrije Universiteit Brussel, Brussel, Belgium

This contribution aims to explore experiences of urban life among first-generation Turkish migrants who are ageing in place. The data for the present research are derived from a qualitative study in inner-city neighbourhoods in Brussels. Drawing on semi-structured interviews with Turkish people aged 60 and over, the paper reviews the variety of ways in which the idea of ‘home’ is created, and the constraints and environmental pressures which may prevent people from developing a sense of ‘home’. Thematic analysis of interview data identifies four issues in relation to the meaning of home: home as a site of care provision; home as experienced and imagined in ‘community’; home as a site of (multiple) attachments; and the politics of home. The final part discusses the implications of the study in respect of re-thinking the debate about developing age-friendly communities in a global world — where people ‘revisit’ home physically, virtually and psychologically.

PUBLIC HOUSING POLICY PRIORITIES AND STRUCTURAL AGEISM: HOW HOPE VI CONTRIBUTED TO THE HYPER-SEGREGATION OF THE VERY OLD AND VERY POOR
J. Kelley-Moore, M.L. Boehm, Sociology, Case Western Reserve University, Cleveland, Ohio

It is widely recognized that the most extreme concentrations of urban poverty in the United States are found in public housing developments. The HOPE VI program launched in 1992 (Housing Opportunities for People Everywhere), funding mixed-income development to replace high-density concentrations of public housing. Since employment and self-sustainability are anticipated outcomes of a mixed-use housing strategy, young families and employment-age adults are prioritized for relocation. The net effect, however, has been the increasing concentration of older adults in residential units that have the lowest priority for demolition. These are predominantly large high-rise buildings, located furthest from shopping and other resources. We undertake a critical policy analysis to examine the structural ageism inherent in public housing policy priorities. Using Cleveland as a case study, we trace the 20-year history of HOPE IV construction and deconstruction of public housing properties and document the increasing segregation of the oldest residents in the system.

AGEING IN PLACE IN AUSTRALIA: LONGITUDINAL PREDICTORS AND POLICY INFLUENCES
H. Kendig1, N. Lucas2, C. Browning2, 1. Centre for Ageing, Health and Wellbeing, Canberra, Australian Capital Territory, Australia, 2. ARC Centre of Excellence in Population Ageing Research, Canberra, Australian Capital Territory, Australia, 3. Faculty of Medicine, Monash University, Melbourne, Victoria, Australia

Older Australians overwhelmingly wish to ‘age in place’. This paper reviews Australian policies related to primary and community care services, accommodation programs and age-friendly city initiatives. It reports findings from the 1994–2012 Melbourne Longitudinal Surveys of Healthy Ageing (MELSHA) on 1000 people aged 65 years or older, showing that fully 80% remained in their homes to within two years before death. A logistic regression analysis found that people most likely to remain in their baseline residence were those dependent in daily living and those relying on government pensions. Earlier analyses showed that entry to residential care was also predicted by dependency in daily living, as well as medical conditions and low social activity, but that socio-economic resources were not independently significant. After attending this session participants will better understand ‘pull’ and ‘push’ factors enabling ageing in place, consequences for wellbeing, and the influence of care, housing, and land use policies.

MENTAL HEALTH DISPARITIES IN RACIALLY AND ETHNICALLY DIVERSE POPULATIONS
Chair: G. Kim, Center for Mental Health and Aging / Department of Psychology, University of Alabama, Tuscaloosa, Alabama
Discussant: P.A. Lichtenberg, Wayne State University, Detroit, Michigan

As our nation becomes more racially and ethnically diverse, understanding mental health needs of diverse elderly groups becomes more important. National Institute on Aging (NIA) has also been putting strong efforts to reduce or eliminate health disparities between racial/ethnic minorities and nonminorities among older adults. The purpose of this symposium is to (1) address current issues of racial/ethnic disparities in mental health and mental health care among older adults and (2) discuss ways to reduce or eliminate existing mental health disparities among racial/ethnic minority older adults. Racial/ethnic minority elderly groups that will be discussed in this symposium are African Americans/Blacks, Latinos/Hispanics (especially Mexican Americans), and Asians (especially Vietnamese). To reflect NIA’s strong support for using publicly available secondary data, presentations also include findings from several major secondary data sets. Experts in the field will discuss the following topics related to aging and mental health disparities: First, the role of race/ethnicity in self-rated mental health will be discussed in a sample of older men from the Medical Expenditure Panel Survey (MEPS); Second, racial/ethnic differences in the association between interpersonal context and depressive symptomatology will be discussed in a racially/ethnically sample of patients receiving treatment for type 2 diabetes; Third, the important role of geography in mental health service use and satisfaction with services people receive will be discussed among racial/ethnic minority elders drawn from a nationally representative survey; Lastly, focusing on older Mexican Americans drawn from a large epidemiological survey, multiple risk factors for the experience of loneliness will be discussed.

INTERPERSONAL CONTEXT AND DEPRESSIVE SYMPTOMATOLOGY: ETHNIC/RACIAL DIFFERENCES
D. Sorkin, University of California, Irvine, Irvine, California

Historically clinical approaches to the study of depression have minimized the complex interpersonal context of the disorder. Depression is expressed in the ways that individuals interact, and, in turn, the interpersonal context can shape a person’s risk for, and experience of, the disorder. This study seeks to evaluate racial/ethnic differences in the association between characteristics of the interpersonal context and depressive symptomatology in a sample of patients with type 2 diabetes. Data were analyzed from an ethnically/racially diverse sample of 1,026 Hispanic, Vietnamese, and non-Hispanic white patients. Vietnamese and Mexican American patients reported significantly higher rates of depressive symptomatology compared to non Hispanic whites (p<.001). Results suggested that after adjusting for socio-demographic, health, access, cost, and neighborhood, among white patients perceived social support was inversely associated with depressive symptoms (Beta=-0.22, p<.007), whereas Vietnamese respondents reported a positive association (Beta=0.02, p=.05). Cultural differences in the experience of depression will be discussed.

LONELINESS AMONG VERY OLD MEXICAN AMERICANS
K.G. Emerson1, T.E. Shovali1, K. Markides2, 1. Institute of Gerontology, University of Georgia, Athens, Georgia, 2. University of Texas Medical Branch, Galveston, Texas

Increasingly research shows that loneliness is a significant risk factor for morbidity and mortality. However, much of the research has

66th Annual Scientific Meeting

201

Downloaded from https://academic.oup.com/gerontologist/article-abstract/53/S1/NP/563183
by guest
on 30 April 2018
focused on the general older population, with little research focusing on minority populations. Our study examines the prevalence and correlates of loneliness among a community-dwelling older Mexican American population. We used the most recent wave (2011) of the Hispanic Established Populations for the Epidemiologic Studies of the Elderly (H-EPSE). The mean score on the scale for this sample suggest relatively low levels of loneliness. Results indicate that depressive symptoms, cognitive status, physical limitations, being married, having a confidante, and living alone are significantly associated with higher loneliness scores. Age, number of close relatives and frequency of contact are not associated with loneliness. Loneliness is a significant public health topic and public health workers should be aware of the various factors that can affect loneliness among older Mexican Americans.

THE ROLE OF GEOGRAPHY IN RACIAL/ETHNIC DISPARITIES IN MENTAL HEALTH CARE: RESULTS FROM THE COLLABORATIVE PSYCHIATRIC EPIDEMIOLOGY SURVEYS (CPES)  
G. Kim, J. Parton, A.N. Bryant, K. Ford, P.A. Parmelee, Center for Mental Health and Aging / Department of Psychology, University of Alabama, Tuscaloosa, Alabama

Given the lack of research on the role of geography in mental health care, this symposium presentation discusses whether racial/ethnic differences in mental health care vary across geographic regions among racially/ethnically diverse older adults in the U.S. Results from two studies using the Collaborative Psychiatric Epidemiology Surveys (CPES) are presented. Study 1 discusses findings on significant geographic variation of Black-White disparities in mental health service use, showing Blacks’ lower mental health service utilization rates in the South. Study 2 discusses findings on significant geographic variation of racial/ethnic differences in satisfaction with and perceived benefits from mental health services, showing Hispanics’ lower levels of satisfaction with and perceived benefits from mental health services compared with Blacks and Whites only in the West. The findings from the two studies suggest that to reduce racial/ethnic disparities at the national level, improving the access to mental health care in certain areas may be essential.

RACIAL/ETHNIC DIFFERENCES IN SELF-RATED MENTAL HEALTH IN OLDER MEN IN THE UNITED STATES: FINDINGS FROM THE MEDICAL EXPENDITURE PANEL SURVEY  
R. Thorpe¹, G. Kim², R. McCleary³, D. Miller³, 1. Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland, 2. University of Alabama, Tuscaloosa, Alabama, 3. Rowan University, Glassboro, New Jersey

Little is known about racial/ethnic differences in self-rated mental health (SRMH) among older men. We examined the association between race/ethnicity and SRMH in 12,456 whites (59%), blacks (16%), Hispanics (17%), and Asians (7%) who participated in the 2008-2010 Medical Expenditure Panel Surveys. Men rated their mental health as excellent, very good, good, fair or poor. Psychological distress was measured with the K6 scale. After accounting for demographic variables, nativity, health factors, and psychological distress, Blacks (OR=0.74; 95% CI=0.63-0.87) and Asians (OR=0.60; 95% CI=0.45-0.79) had a lower odds of reporting excellent/very good mental health compared to Whites. Perceptions of SRMH vary by race/ethnicity among older men. Understanding SRMH in older male populations is essential for the development of future policies that focus attention on addressing key quality of life and productivity concerns for individuals, families, communities while ultimately decreasing mental health inequalities.
SESSION 605 (PAPER)

ECONOMICS OF AGING

DIFFERENTIALS IN PENSION PROTECTION AMONGST ETHNIC MINORITIES IN BRITAIN

A. Vlachantoni1, M. Evandroo1, J.C. Falkingham1, Z. Feng2, 1. ESRC Centre for Population Change, University of Southampton, Southampton, United Kingdom, 2. Centre for Research on Ageing, University of Southampton, Southampton, United Kingdom

According to the 2011 Census, individuals from Black and Minority Ethnic (BME) groups comprised about 14% of the total population in England and Wales, while the younger age structure of the BME population means that BME groups comprise less than 4% of the population aged 50 and over. Academic literature over the last two decades has emphasised the health and socio-economic disadvantage experienced by BME groups, as well as the key policy challenge associated with the ageing of the BME population, and with their pension protection in particular. For example, more than half of Pakistani and Bangladeshi older people (60 and over), half of Indian older people and about one-third of Black Caribbean older people, are in the bottom-fifth of the income distribution, while pensioners from these groups are more likely to rely on means-tested benefits. This paper analyses data from the first wave of Understanding Society, a nationally-representative dataset with information from individuals in over 40,000 households in the UK, in order to explore patterns of state pension receipt and the determinants of membership in an occupational pension scheme among older people aged 65 and over in five ethnic minority groups: Bangladesh, Indian, Pakistani, Caribbean and African. In addition, the paper revisits existing research exploring the interaction of ethnicity and gender to the detriment of pension protection for both women and men of working age from the Bangladeshi and Pakistani communities.

LONG-TERM CARE SERVICES EXPENDITURE PROJECTION IN SOUTH KOREA FROM 2015 TO 2050

N. Kim, Yonsei Univ, Seoul, Republic of Korea

South Korea has been undergoing significant change in its population structure over the past three decades. Within 10 years, South Korean baby-boomers will reach the age of 65 and accelerate this change. This trend in population structure is crucial, because an aging population may increase medical demand, especially that for long-term care (LTC) services, which would create a financial burden on society. This study estimates total LTC expenditure in South Korea from 2015 to 2050 by modifying the method proposed by the UK Personal Social Science Research Unit (PSSRU), the seminal study on projecting costs of LTC services. Using population data from the projections of the Korean Statistical Information Service (KOSIS), I stratify the projected population by gender and age, using the groups 65-69, 70-74, 75-79, and 80 or over, and divide LTC services into two categories, namely facility and home care. South Korea’s total LTC expenditure is predicted to continuously increase and then reach 4.2 percent of GDP in 2050. Expenditure on LTC services for females is higher than that for males. Moreover, the increase in total expenditure is dramatic after 2040 for home-based services, but is constant for facility services. This study shows that the presence of baby-boomers heavily influences LTC expenditure in South Korea.

THE IMPACT OF THE FINANCIAL CRISIS ON PHYSICAL HEALTH IN MIDDLE-AGED AND OLDER ADULTS

B. Whitehead, C.S. Bergeman, University of Notre Dame, South Bend, Indiana

The recent financial crisis has had a substantial impact on stress experiences and overall quality of life for individuals nationwide. The Notre Dame Study of Health & Well-Being (NDHWB), a longitudinal study exploring health and well-being in mid- and later life, began collecting information on financial strain—along with a myriad of other psychosocial and physical health outcomes—in 2006, and has captured well the experience of participants during the economic downturn of 2008-2009 and the ensuing recession and recovery. In order to ascertain the impact of the financial crisis on current health in our overall sample of 774 adults (aged 41-91), we calculated the intrapersonal intercept, slope, and quadratic curve parameters capturing the trends in financial situation and perceived stress (PSS) across the 5-year period. Results revealed that PSS trends were not associated with Year 5 (Y5) health, whereas Financial trends were. The sample was split into two groups—positive financial slope and negative financial slope—in order to elucidate these effects. Findings indicate that experiencing a negative change in financial situation is associated with poorer health at Y5, which fully explains the effect of PSS on health. For those who experience a positive change in financial situation, however, financial changes do not influence health; rather, overall levels of PSS are most salient. These results demonstrate that financial strain over this period was the primary contributor to overall stress levels and concomitant health outcomes; those who did not experience financial strain, however, still experienced stress, albeit from different sources.

AN EXPLORATION OF THE HEALTH AND PERSONAL FINANCE INFORMATION NEEDS OF OLDER ADULTS THROUGH FOCUS GROUPS

M. Gillen, L. Bobroff, Department of Family, Youth and Community Sciences, University of Florida, Gainesville, Florida

Longer life expectancy, rapid population growth, and concern for the well-being of older adults justify the need for better understanding older adults’ health and personal finance needs. The purpose of this focus group study was to gain an understanding of the health and finance information needs of older adults. Fifteen consumer focus groups were conducted with older Floridians. A semi-structured approach was used during the focus groups. The questions asked included: 1) What health topics would you like more information about?; 2) What personal finance topics would you like more information about?; and 3) Do you see your health and finances as being related and if yes, how? The majority of the 93 individuals who participated were women (n = 71), and were age 60 and older. Results from the focus group data identified 26 information themes. The most significant topics mentioned were Medicare, long-term care planning, informed decision making, independent living, aging process, and fixed income. The majority of the participants voiced a connection between their health and finances. Knowledge gained from these focus groups was used to inform community education programming aimed at improving the quality of life of older adults by meeting their information needs.

EARLY LIFE CHARACTERISTICS AND ADULT COGNITIVE FUNCTIONING: EVIDENCE FORM THE HEALTH AND RETIREMENT STUDY

R. Basu, Quality Improvement, Scott & White Health Plan, Temple, Texas

Objective: Early life characteristics contribute to cognitive function in adulthood. However, the impact of early life conditions on the change in cognitive function in later life is not conclusive. The objective of this study was to examine the cumulative as well as individual impacts of early life conditions on the rate of cognitive decline among individuals aged 50 or above from the population based Health and Retirement survey (HRS), 1998-2008. Methods: Cognitive functioning was measured by immediate and delayed word recalls, subtraction for working memory, backward counting, and date and naming orientation (0-35). For participants under 65 years naming and orientation were not used (0-27). Early life conditions include childhood socioeconomic status (SES), parental education, and father’s occupation. Childhood disadvantage was measured by an index created including four individual components. Mixed effect linear regression technique was used to assess
the decline in cognitive function over time. Results: After adjusting for demographic characteristics, cumulative effect of childhood disadvantage and other individual components of early life conditions were associated with absolute level of cognitive score ($p<0.0001$). However, father’s occupation and cumulative effect of childhood disadvantage significantly predicted the rate of cognitive decline among individuals below 65 years old ($p=0.088$, $p<0.001$). Among individuals older than 65 years of age, childhood disadvantage and individual components were strongly and negatively correlated with cognitive status, but not with the rate of cognitive decline. Conclusion: Early life conditions are responsible for level of cognitive functions as well as decline in cognitive function among middle-aged and older adults.

SESSION 610 (SYMPOSIUM)

CHRONIC DISEASES AND QUALITY OF CARE IN OLDER PEOPLE: RESULTS FROM ENGLISH AND US COHORT STUDIES
Chair: N. Steel, Norwich Medical School, Norwich, United Kingdom
Discussant: N. Steel, Norwich Medical School, Norwich, United Kingdom

This symposium explores the quality of healthcare in England and the US, using the English Longitudinal Study of Ageing (ELSA) and the US Health and Retirement Study (HRS). The objectives are to describe variations in quality of care between conditions and healthcare systems, and to understand the characteristics of older patients who received good quality of care. ELSA is a national cohort study of up to 12,000 participants aged 50+ years, with two-yearly interviews from 2002. ELSA captured self-reported chronic conditions and RAND-derived quality of care indicators for public and private care. ELSA is supported by the National Institute on Aging and is harmonised with HRS, a longitudinal survey that interviews more than 10,000 Americans aged 60+ years every 2 years. The five abstracts in this symposium will: 1. show that deficits in care for geriatric conditions compared to general medical conditions worsened over time 2. show counter-intuitively that quality of care improved with increasing numbers of co-morbidities 3. describe the characteristics of ELSA participants who received either good or poor quality of care for osteoarthritis, cardiovascular disease and diabetes, and show the importance of physical activity 4. compare hypertension care for US and English older people, and for US private and public health insurance, showing that the US system is better at identifying hypertension, but quality of treatment is similar to England. 5. show that increasing comorbidity only partly explains loss of physical function and health, and argue that a practical definition of multi-morbidity should include physical function.

QUALITY OF CARE INCREASES WITH NUMBER OF COMORBIDITIES
J. Ford, A. Hardcastle, N. Steel, University of East Anglia, Norwich, United Kingdom

The number of people with multiple medical problems is increasing, and delivering high-quality care is complex. We assessed how quality of care changed with increasing numbers of co-morbidities. Quality of care was measured by achievement of eligible indicators, and compared with the number of diagnosed conditions in wave 5 of ELSA. Linear regression was used to test the percentage increase in quality for each additional co-morbidity (adjusted for age, sex, physical activity, alcohol, smoking, marital status, wealth and education). Quality of care increased with the number of diagnosed diseases ($p<0.001$). The overall percentage of quality indicators increased by approximately 2% per additional disease. These findings from England are counter-intuitive, but a similar relationship between increasing quality and comorbidities has been previously reported from a large study in the USA. One possible explanation is that patients with multiple medical problems have more opportunities to receive care.

FUNCTIONAL MEASURES AND SYMPTOMS POORLY PREDICT NUMBER OF CO-MORBIDITIES
J. Ford, A. Hardcastle, N. Steel, University of East Anglia, Norwich, United Kingdom

Functioning and symptoms are more important to patients with multimorbidity than counts of diseases. Our aim was to explore the relationship between functional/symptom measures and number of co-morbidities. Using ELSA questionnaire responses and nurse-led assessments, number of co-morbidities was compared with eight measures: ADLs, IADLs, mobility, ability to walk a block, triple test (balance, chair rises and 4m walk), self-rated health, self-reported limiting illness and symptoms. Age and sex adjusted linear regression was used to calculate $R^2$ for each measure. Number of comorbidities was associated with self-rated health ($R^2=0.2977$), basic mobility ($R^2=0.2921$), ability to walk a block ($R^2=0.2468$), IADLs ($R^2=0.1852$), ADLs ($R^2=0.1795$), symptoms ($R^2=0.1783$), self-reported limiting illness ($R^2=0.1322$) and triple test ($R^2=0.1143$). All were statistically significant ($P<0.001$). Whilst functionality and symptoms are undoubtedly related to number of co-morbidities, they only explain at best 30%. A patient-centred definition of multi-morbidity should include physical function.

HAS THE QUALITY OF CARE WORSENED FOR GERIATRIC CONDITIONS?
A. Hardcastle1, L.T. Mounce2, N. Steel1, J. University of East Anglia, Norwich, United Kingdom, 2. University of Exeter, Exeter, United Kingdom

We examined differences in the quality of care for geriatric compared to general medical conditions, for elderly people with at least one medical condition, over 4 waves of ELSA. Quality of care was measured by achievement of eligible quality indicators (QIs). We classified osteoarthritis, falls, incontinence, vision and poor hearing as geriatric conditions. General medical conditions included diabetes, stroke and hypertension. Quality for geriatric conditions was considerably worse than for general medical ones. Over eight years, achievement of geriatric medical QIs improved by 10% (wave 2, 76.7%, wave 5, 86.3%, $p<0.001$) and decreased by 9% for geriatric QIs (wave 2, 54.0%, wave 5, 45.1%, $p<0.001$). Deficits in care for geriatric conditions worsened over time, compared to general medical conditions. General medical conditions such as hypertension and diabetes have been the target of major quality improvement and pay-for-performance initiatives, whereas geriatric conditions have not.
WHAT PREDICTS QUALITY OF CARE: RESULTS FROM THE ENGLISH LONGITUDINAL STUDY OF AGEING
A. Hardcastle', L.T. Mounce', N. Steel', 1. University of East Anglia, Norwich, United Kingdom, 2. University of Exeter, Exeter, United Kingdom

We assessed which characteristics of older adults predicted receipt of good quality of care for osteoarthritis, cardiovascular disease (CVD) and diabetes, over two years. Quality of care was measured by achievement of quality indicators, and potential predictors were identified by an expert panel. Increased physical activity was associated with better quality for osteoarthritis (odds ratio (OR) 0.74, 95% CI 0.55-0.98), CVD 2.07 (1.41-3.02) and diabetes 2.09 (1.04-4.22) (logistic regression). For CVD, being female, increasing age and poor self-rated health predicted better quality, as did knowledge about disease management for diabetes (OR 1.97, 1.26-3.16). Marriage was associated with good care for CVD and diabetes. Good eyesight and limiting long-standing illnesses predicted better care for osteoarthritis. Physical activity is an established risk factor for osteoarthritis, diabetes and CVD. These results suggest that it may also lead to poorer care. If verified on other data sources, these findings could inform quality improvement initiatives.

SESSION 615 (SYMPOSIUM)

CONTEMPORARY ART INTERVENTIONS TO SUPPORT CREATIVE AGEING
Chair: D. Edvardsson, La Trobe University, Melbourne, Victoria, Australia, Umeå University, Umeå, Sweden
Discussant: K. Love, Center for Excellence in Assisted Living, Falls Church, Virginia

This symposium will highlight contemporary cutting edge initiatives and research evidence on artistic interventions to support creative ageing and person-centred dying. The first presentation will explore ways the arts can create a safe and nurturing space for people to explore their fears and achieve a “good death” as defined by each individual patient while facing death in sterile hospital environments of isolation and alienation. The second presentation will use narrative data from an exploratory study into a hospital-based Guerrilla knitting initiative for cancer patients to explore existential outcomes of arts-based interventions. Data gathered from patients, families and visitors will be incorporated to illustrate both individual and community impacts of the “Yarning Around” project. The third presentation will describe the award-winning GroundSwell Project which uses the arts to promote resilience and community wellbeing through all stages of life. The project spans across a range of health settings and traditional arts (theatre, film, visual arts), social media, digital storytelling to foster intergenerational relationships, developing ‘death literacy’ and the transmission of held knowledge about death and dying. The fourth presentation will describe the Garments for the Grave initiative and draw upon fashion design theory and practice to highlight creative and environmentally sustainable interventions for personal clothing in the context of death and dying. The Garments for the Grave initiative engages individuals in the design and production of their own burial garment and can create a safe conversational environment for people to explore their thoughts and feelings about death.

THE ART OF DYING WELL
M. Cartile, 1. La Trobe University, Melbourne, Victoria, Australia, 2. Austin Health, Melbourne, Victoria, Australia

This presentation will use the contemporary literature on hospital environments and dying in institutional settings to explore ways the arts can create a safe and nurturing space for people to explore their fears and achieve a “good death” as defined by each individual patient. The presentation will suggest ways to bridge feelings of being isolated and frightened when facing imminent death and loss in a sterile hospital environment, and will discuss strategies to facilitate feelings of familiality, trust and connectedness at a time when people are at their most vulnerable.

SESSION 620 (SYMPOSIUM)

DIVERSITY, HEALTH AND HEALTH-RELATED BEHAVIORS: THE HEALTHY AGING RESEARCH INITIATIVE
Chair: R.M. Tappen, College of Nursing, Florida Atlantic University, Boca Raton, Florida
Co-Chair: J.G. Ouslander, College of Nursing, Florida Atlantic University, Boca Raton, Florida

The Healthy Aging Research Initiative is an ongoing study of community dwelling African American, Afro-Caribbean, Hispanic and European American older adults in South Florida. The core sample represents both immigrant and non-immigrant, English and non-English speaking populations. Participants are asked a series of questions regarding their physical and mental health, social support, social networks and cognitive function. They are also asked to perform several physical function tests and to provide blood samples for immediate and future analysis. In addition to the core sample, several spin-off studies related to spirituality, pain management, indicators of stress related to discrimination and the effect of culture and lifestyle factors on glycemic control are being conducted. The papers to be presented report results from the core sample and spin-off studies including the relationship of acculturation and depression in Hispanic Americans, lower level of physical performance in Afro-Caribbeans and the role of culture in pharmacological and nonpharmacological pain management across these four groups.

RELATIONSHIP OF DEPRESSION TO ACCULTURATION IN MINORITY AND MAINSTREAM OLDER ADULTS
C.L. Williams, Christine E. Lynn College of Nursing, Florida Atlantic University, Boca Raton, Florida

Few studies have compared acculturation to depressive symptomatology in older adults. In a sample of 456 ethnically diverse community dwelling adults aged > 60 (M = 74, SD = .68) Hispanic Americans were found to have significantly (p < .0001) higher levels of depressive symptomatology measured by 20-item CES-D with a mean of 14.14 (SD = 13.31) compared to 6.75 (SD = 7.75) for African Americans, 7.9 (SD = 7.70) for Afro-Caribbeans and 8.4 (SD = 8.9) for European Americans. Predictors of depression differed by ethnic group. Orientation to mainstream American culture was significantly related to depression in Hispanic Americans (r = -.27, p = .02, B = -.54) but not in the Afro-Caribbeans, another immigrant group, or the other groups. Age was a significant predictor in the African Americans. Gender and degree of orientation to heritage culture were predictors in the European Americans.

PHYSICAL PERFORMANCE DIFFERENCES IN AN ETHNICALLY DIVERSE COMMUNITY DWELLING POPULATION
D.J. Hain, G. Engstrom, Florida Atlantic University, Boca Raton, Florida

Physical ability plays an important role in the life of older adults. We examined ethnic differences among 456 community dwelling adults age > 60, mean age 74 (SD = .68). Afro-Caribbeans were found to have significantly (p < .0001) lower mean scores as measured by Short Physical Performance Battery with a mean score of 6.57 (SD = 1.75) out of 12, compared to African Americans (M = 6.9, SD = 1.64), Hispanic Americans (M = 7.10, SD = 1.89) and European Americans (M = 7.16, SD = 1.88). Age, BMI and ethnic group membership were significant predictors of performance in the Afro-Caribbeans. Afro-Caribbeans were also found to have significantly lower scores for the Physical Health
PAIN MANAGEMENT ASSOCIATED WITH POLYPHARMACY AMONG ETHNICALLY DIVERSE OLDER ADULTS
L. Chiang-Hanisko, Nursing, Florida Atlantic University, Boca Raton, Florida
This study investigates pharmacological pain management associated with polypharmacy among ethnically diverse older adult populations (African American, Afro-Caribbean, European American and Hispanic American). Qualitative data were collected through semi-structured face-to-face, recorded interviews with 12 participants age 60 and over. The medication usage was from 7 to 12 with the average of 9.5 drugs. Data revealed concerns, apprehensions and misconceptions about pain medication practice including fear of addiction, use of additional medications to overcome side effects, use of self-prescribed herbs undisclosed to healthcare professionals, coping styles to ignore or bear pain, use of pain medication based upon availability and finances, and altering daily activities to adjust to levels of pain. Findings from this study elucidate the importance of understanding the experience of pain within the context of the patients’ beliefs, values and coping strategies as well as cultural, familial and socioeconomic.

NONPHARMACOLOGICAL PAIN MANAGEMENT AMONG ETHNICALLY DIVERSE OLDER ADULTS: CONSTANT COMPARISONS
J. Park, School of Social Work, Florida Atlantic University, Boca Raton, Florida
This study explored nonpharmacological pain therapies for older adults (≥60 years, M = 70.3, SD = 6.8). Qualitative data from face-to-face interviews with 44 ethnically diverse community-dwelling older adults (10 African Americans, 10 Hispanics, 12 Afro-Caribbeans, & 12 European Americans) were collected and a grounded theory methodology was utilized to analyze data. Analysis revealed functional and psychosocial (depression, social isolation) changes due to pain. The three minority groups (African Americans, Hispanics, Afro-Caribbeans) reported using culturally based treatments (e.g., herbal tea, Mauve/Malva leaves, avocado leaves), home remedies (cream), and psychological therapies such as distraction, relaxation, and support groups to manage chronic pain. In particular, African Americans heavily relied on religious coping methods (prayer; God as “healer”). In contrast, European Americans used physical interventions such as exercise, massage, and chiropractic. Study findings suggest differences in preferred nonpharmacological pain interventions for an ethnically diverse older adult population.

SESSION 625 (SYMPOSIUM)

USING ACCELEROMETRY TO ASSESS PHYSICAL ACTIVITY IN OLD AGE: HOW TO CHOOSE THE TYPE OF ACCELEROMETER
Chair: A. Koster, Maastricht University, Maastricht, Netherlands
Co-Chair: P. Caserotti, University of Southern Denmark, Odense, Denmark
Discussant: T. Harris, National Institute on Aging, Bethesda, Maryland
Objective measurement of physical activity across the full range of activity intensities is increasingly important in studies of aging. Accelerometers capture objective physical activity but the choice of the accelerometer is a challenge. For example, accelerometers can be worn at many body locations; however, it is not known which location best captures total activity in older adults, how “counts” from different body locations are comparable in terms of metabolic equivalent and whether the association with health/functional outcomes is similar across body locations. The choice of accelerometer depends on the type of study, the research questions, and the study population. This symposium will give an overview of different widely-used accelerometers, discuss the pros and cons of each monitor and experience with the monitor in actual studies. Dr. Martin will discuss the use of Actigraph hip-worn accelerometers in NHANES and the AGES-Reykjavik Study. Dr. Koster, will discuss her choice of the thigh-worn ActivPal in the Maastricht Study. Dr. Caserotti focuses on his decision to use a wrist-worn accelerometer in a community active-life style intervention in older people with reduced function, and Dr. Ferrucci will talk about a chest-worn accelerometer with a built-in heart rate recorder used in the BLSA. These presentations will provide an overview of the monitor including advantages and disadvantages and present data from the study to support these points. Finally, Dr. Harris will summarize the previous presentations and will present a large validation project in older adults with the aim to compare accelerometer worn at different body locations.

CONSIDERATIONS FOR USING A HIP OR WAIST WORN ACCELEROMETER TO CAPTURE PHYSICAL ACTIVITY
K.R. Martin, National Institute on Aging - Laboratory of Epidemiology and Population Sciences, Bethesda, Maryland
Hip/waist-worn accelerometers are popular because they measure motion close to the center of mass in the body. One such device, from Actigraph, has been applied in two large population-based studies (i.e., NHANES; AGES-Reykjavik). Acceleration of motion is typically measured in either one axis (uniaxial) or three (triaxial). Benefits include an internal sampling frequency programmable for customized data output and a long battery-life (i.e., up to 20 days). Users can process raw data to determine levels of activity (e.g., light, lifestyle, moderate and vigorous) according to meaningful cutpoints. Known limitations of hip/waist accelerometers are that they are bulky in size, do not capture cycling well, and are usually removed during nighttime sleep and water-based activities (e.g., showering, swimming), which may increase the likelihood of participants forgetting to re-attach the device. Accuracy of overall activity measurement may be reduced due to these limitations; however, methods can be taken to increase precision.

THE USE OF THIGH-WORN TO ASSESS PHYSICAL ACTIVITY
A. Koster, Maastricht University, Maastricht, Netherlands
This presentation will give an overview of the use a thigh-worn accelerometer to measure physical activity, discuss its pros and cons and its application in a large epidemiological study. Thigh-worn accelerometry data (ActivPal) are currently being collected in the Maastricht Study, a large ongoing cohort study in the Netherlands among men and women aged 40-75 of which by design 50% has type 2 diabetes. An advantage of this type of accelerometer is the use of the inclinometer to distinguish changes in posture and to accurately measure sedentary time. Further, a waterproofed attachment on the thigh can provide 7 days continuous wear which increases compliance and ensures high-quality data and moves away from the difficulty to distinguish wear time from nonwear time. A person’s activity can be classified into periods spent sitting/lying, standing and stepping (i.e. walking). Additionally, raw accelerometer data are collected that provides the most precise estimate of meaningful movement.
WRIST-WORN ACCELEROMETERS FOR PRESCRIBING PHYSICAL ACTIVITY IN OLDER PEOPLE WITH REDUCED MOBILITY

P. Caserotti1, A. Koster1, T. Harris3, L. Hvid1, 1. University of Southern Denmark, Odense, Denmark, 2. Maastricht University, Maastricht, Netherlands, 3. Intramural Research Program, National Institute on Aging, Bethesda, Maryland

Older people with reduced mobility spend considerable amount of waking hours in sitting/laying conditions. Capturing upper body activities and identifying their association with health/functional outcomes is therefore highly relevant in this group, particularly when designing a physical activity intervention study. This presentation will provide an overview of the use of wrist-worn accelerometers and discuss their application, including pros and cons as 1) a screening tool for people with reduced physical function and 2) continuous monitoring to prescribe and monitor activity levels in a comminute-based physical activity intervention. Wrist-worn Actigraph wGT3x+ accelerometers are currently used in a European “active-life style” intervention study (HANC) for older men and women aged 76+ with reduced function (walking speed <0.9 m/s). Wrist-worn devices allow continuous monitoring including sleeping time (2-4 weeks) and show high compliance. Results should be interpreted according to several methodological issues including dominant vs non-dominant location and metabolic interpretation of “counts”.

USE OF THE ACITHEART ACCELEROMETER IN THE BALTIMORE LONGITUDINAL STUDY ON AGING (BLSA)

L. Ferrucci, NIA/NIH, Baltimore, Maryland

The BLSA is a unique resource for the study of aging and one aspect of its uniqueness has been the measurement of underlying physiology in multiple organ systems combined with measurements of energy expenditure and endurance. Objective measurement of physical activity in the free-living situation was added to the study with Actiheart accelerometers that were worn in the period following the BLSA examination to allow for better classification of physical activity based on heart rate, which had been calibrated to performance during the BLSA exam. Dr. Ferrucci will review the performance of this accelerometer with regard to calculation of energy expenditure and ease of use by participants as well as discuss the decision to switch to a different accelerometer format.

AGING RESEARCH EVALUATING ACCELEROMETRY (AREA): COMPARISON OF ACCELEROMETER PERFORMANCE IN OLDER PEOPLE

M. Hung1, T. Harris3, P. Caserotti2, K.Y. Chen1, B. Lange-Maia4, N.W. Glynn1, D.R. Van Domen1, A. Koster2, 1. NIA/IRP, Bethesda, Maryland, 2. University of Southern Denmark, Odense, Denmark, 3. NIDDK, Bethesda, Maryland, 4. University of Pittsburgh, Pittsburgh, Pennsylvania, 5. Emory University, Atlanta, Georgia, 6. Maastricht University, Maastricht, Netherlands

PURPOSE: 1. Can wrist, hip, arm, or thigh accelerometers equally reflect tasks of daily living? 2. Which accelerometer position best measures physical function? And, 3. Is accelerometry an independent contributor to physical function in older persons? METHODS: Subjects wore multiple accelerometers: Actigraph GT3X+ on right, left wrist and right hip (80 Hz), Sensewear on left arm, and 50 subjects wore ActivPal on right thigh. With Cosmed monitoring, subjects performed five sets of activities: (1) laying, standing still; (2) upper body movement while standing; simulated dishwashing, dough kneading, dressing, folding towels; (3) upper body movement while walking; vacuuming, shopping; (4) upper body movement while sitting; writing, dealing cards, chair stands; (5) lower body movement: usual and fast paced walks for 20 meters performed with and without using arms. Subjects were asked to provide 7 days of free-living data while wearing all monitors. Other functional measures were collected at the same session.

SESSION 630 (PAPER)

COGNITION

DIABETES AND COGNITIVE FUNCTIONING IN OLDER ADULTS: THE GINKGO EVALUATION OF MEMORY STUDY

P. Palla1, M. Carlson1, S. Yasar2, R. Nahin1, S.T. DeKosky1, B.E. Snitz2, J.D. Williamson3, S.H. Golden2, 1. Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland, 2. Johns Hopkins University School of Medicine, Baltimore, Maryland, 3. National Center for Complementary and Alternative Medicine, National Institutes of Health, Bethesda, Maryland, 4. University of Virginia, Charlottesville, Virginia, 5. University of Pittsburgh, Pittsburgh, Pennsylvania, 6. Wake Forest University School of Medicine, Winston-Salem, North Carolina

Populations of individuals with diabetes exhibit accelerated cognitive decline. The strongest evidence exists for the domains of executive function, memory and psychomotor speed. Heterogeneity in study design, cognitive test administration and analysis of cognitive data has made it difficult to synthesize prior literature. Additionally, few prospective studies have evaluated longitudinal changes in these and other domains. We analyzed longitudinal data from the Ginkgo Evaluation of Memory Study to determine if older adults with diabetes have greater test-specific and domain-specific cognitive declines compared to those without diabetes. Memory, visuo-spatial construction, language, psychomotor-speed and executive function domains were measured. Test scores were standardized to z-scores and averaged, yielding domain scores. Linear random-effects models were used to compare repeated measures of raw test and domain scores within participants. Among the 3,069 adults, aged 72-96 years, 9.3% reported diabetes. Over a median follow-up of 6.1 years, participants with diabetes exhibited greater declines in phonemic verbal fluency (language), WAIS-R Digit Span-Forward (psychomotor speed) and the Stroop Color/Word Interference Test (executive function). Individuals with diabetes also had significantly greater declines in psychomotor-speed and executive function domain scores as compared to individuals without diabetes. No differences were seen in rates of decline on tests of memory or visuo-spatial construction. Identifying these specific diabetes-associated preclinical cognitive changes can lead to targeted risk modification early in the course of cognitive decline when cognitive rehabilitation therapies and lifestyle interventions, including aggressive control of diabetes and vascular risk factors, may be most effective in alleviating symptoms and slowing progression to dementia.

ANTECEDENTS OF COGNITIVE COMPETENCE AND DEMENTIA AT AGE 90: A 70 YEAR PROSPECTIVE STUDY

G.E. Vaillant, Mass. General Hospital; 1. Boston, Massachusetts

Objective: To examine the antecedents of both dementia and sustained cognitive competence at age 90 among men who, with little attrition, underwent a prospective, intensive, multidisciplinary assessment from age 19 to 90, Method: A 70-year study of 268 male Caucasian college sophomores, begun in 1938 with data points every 2-5 years and multiple blinded raters assessed the 196 men who survived until age 69. Prospectively gathered measurements included assessment of childhood environment, dominant personality traits, and objective mental and physical health over time, smoking, alcohol abuse and depression. Cognitive status was assessed at age 80, 85 and 90. Questionnaires were obtained every two years; physical exams obtained every five years. Results: The most important finding was how few commonly cited variables were prospectively associated at 90 with either clear cognitive competence (n = 40) or dementia (n = 44). We found only six suggestive predictors that distinguished cognitive competence at age 90 from dementia: excellent childhood relationship with mother, maternal education, good vision, age of mother at subject’s birth, exercise at age 60
VITAMIN D INSUFFICIENCY IS ASSOCIATED WITH COGNITIVE IMPAIRMENT IN INDIVIDUALS WITH LONGEVITY

S. Milman1, M. Schulder-Katz1, J.A. Deluty2, M.E. Zimmerman2, M. Melamed1, J. Crandall1, N. Barzilai1, G. Atzmon1, L. Lipsitz1,2, C. Rosano4, S. Black3, L.K. Harootyan5

The elderly are at increased risk for vitamin D deficiency and low vitamin D levels have been related to increased risk of cognitive dysfunction. However, this association has never been investigated in centenarians, who exhibit delayed onset of aging. We aimed to define vitamin D levels and their association with cognition in subjects with exceptional longevity. We conducted a cross-sectional study in Ashkenazi Jewish (AJ) subjects (n=253) with exceptional longevity, with comparison made to NHANES III participants age 70-90+. Vitamin D levels were measured using LC/MS/MS. Cognitive function was assessed using the Mini Mental State Exam (MMSE) and clock drawing test (CDT; command and copy). Median age of the AJ subjects was 97 years. Age-associated rise in the prevalence of vitamin D insufficiency, defined as serum vitamin D level <30ng/mL, was noted in NHANES III (p=0.001). In AJ with longevity, the rate of vitamin D sufficiency was comparable to the NHANES III group age <90 years. In the AJ group, vitamin D insufficiency was more prevalent in individuals with impaired cognition, defined by the MMSE, compared to those with normal cognition (71.8% vs. 57.7%, p=0.02). In an adjusted logistic regression model, vitamin D insufficiency was associated with cognitive impairment on MMSE and CDT: copy in centenarians (OR 3.2, 95% CI 1.1-9.29, p=0.03 and OR 8.96, 95% CI 1.08-74.69, p=0.04, respectively). We conclude that low vitamin D levels are associated with cognitive impairment in individuals achieving exceptional longevity and that higher vitamin D levels may be a marker of delayed aging.

HEART RATE VARIABILITY AND 9-YEAR COGNITIVE DECLINE IN THE CARDIOVASCULAR HEALTH STUDY

J.A. Deal1, P.K. Stein2, A. Sharrett3, M. Carlson4, X. Que5, A. Arnold6, M. Carnethon4, P.H. Chaves1, L. Lipsitz1,2, C. Rosano4, S. Black3, L.K. Harootyan5

Objective: To test if abnormal heart rate variability (HRV) at baseline is associated with faster rates of cognitive decline in community-dwelling older adults. Background: HRV is a common measure of autonomic nervous system (ANS) function. The ANS regulates physiologic processes important for cognition. Abnormal HRV is associated with dysregulation of these processes, and with diseases linked to poor cognition. Cross-sectional studies suggest differences in cognitive function by HRV status. Methods: Prospective study in a subset of the Cardiovascular Health Study (mean age 72.2 ± 4.7 years, 56% female, 96% white race). Time-domain, frequency-domain, and nonlinear HRV measures were derived from 24-hour Holter recordings. Reduced HRV was defined as < the median value. Trajectories of 9-year cognitive change on the Modified Mini-Mental State Exam (3MSE) and Digit Symbol Substitution Test (DSST) were modeled using linear mixed models (N=10,156 observations, N=1,145 individuals); the time axis was age (years). Results: Longitudinally, we found no association between baseline HRV and cognitive decline. Cross-sectionally, the difference in DSST comparing persons with and without reduced VLF was -2.47 points (95% Confidence Interval: -3.73, -1.22). Conclusions: HRV was not associated with longitudinal change in global function or attention. HRV is a valid measure of ANS regulation of heart rate dynamics, but may not be a sensitive measure of ANS regulation of processes important for cognition (i.e., the role of autonomic dysfunction in the promotion of concomitant dysregulation in multiple, cognitive-relevant physiologic processes). HRV may not be a useful predictor of accelerated cognitive decline in older adults.

ALZHEIMER’S RISK FACTOR GENETIC VARIANTS ARE ASSOCIATED WITH MILD COGNITIVE IMPAIRMENT

B. Whitehead1, C. DeCarlo2, S.W. Mac Donald3, R.A. Dixon1, J. Deluty2, M. Melamed1, J. Crandall1, N. Barzilai1, G. Atzmon1, L. Lipsitz1,2, C. Rosano4, S. Black3, L.K. Harootyan5

The clinical utility of the Mild Cognitive Impairment (MCI) classification is diminished by uncertainty regarding future transition to Alzheimer’s disease (AD). Although many MCI patients transition to AD, others may remain MCI indefinitely or revert to normal status. Integration of AD genetic markers with objective MCI classification procedures may clarify the presence of underlying AD etiology, thereby improving classification accuracy. We use a subset of data from genotyped participants of the Victoria Longitudinal Study (baseline n = 237; ages 64-91; 62% women). We determine if three focal AD-related genotypes [Clusterin (CLU; rs11136000), Complement Receptor 1 (CR1; rs6656401), Phosphatidylinositol Binding Clathrin Assembly Protein (PICALM; rs541458)] independently or interactively (in two-way combinations or with APOE) distinguish among (a) MCI patients (n=101) and normal aging (NA) adults (n=136) at baseline, and (b) longitudinal groups representing two-wave (M=4.5 years) profiles of MCI chronicity (MCI-to-MCI) and emerging impairment (NA-to-MCI). Hierarchical logistic regression models are used for all analyses. The focal genes did not distinguish MCI from NA adults at baseline. However, longitudinal analyses revealed a (a) dominant CLU main effect, with odds of chronic MCI status in CLU risk allele carriers increasing 9.72-fold; (b) recessive PICALM main effect, whereby for each additional risk allele, odds of chronic MCI decreased by a factor of .52; and (c) dominant CR1(2) x APOE(2) interaction, with odds of emerging or chronic MCI increasing 5.36-fold in carriers of APOE and CR1 risk alleles. Results indicate AD-related genetic markers can be used to improve early detection of cognitive impairment in older adults.

SESSION 635 (PAPER)

FALLS

NEUROLOGICAL MECHANISMS OF MOBILITY IMPAIRMENTS: A SUMMARY OF THE PRE-CONFERENCE WORKSHOP ON AGING, CENTRAL NERVOUS SYSTEM, AND MOBILITY IN OLDER ADULTS

L. Lipstz1,2, C. Rosano1, S. Black1, L.K. Harootyan3, J. Deluty2, M. Melamed1, J. Crandall1, N. Barzilai1, L. Lipsitz1,2, C. Rosano4, S. Black3, L.K. Harootyan5, B. Whitehead1, C. DeCarlo2, S.W. Mac Donald3, R.A. Dixon1

A variety of pathological processes in the central nervous system may lead to mobility disability, including vascular, inflammatory, degenerative, or age-related abnormalities. The focus of this workshop is on the neural mechanisms underlying mobility impairments in older age. The CNS alterations associated with mobility impairment appear to be related to ischemia, inflammation, and abnormal protein deposition; metabolic, hormonal, and neurotrophic processes; and genetic factors
FEASIBILITY OF A WELLNESS MOTIVATION INTERVENTION TO REDUCE FALL RISK AMONG COMMUNITY DWELLING OLDER ADULTS: MAIN EFFECTS

S. McMahon1,2, J.F. Wyman1, E. Hekler3, N. Shearer2, M. Belyea2, J. Fleury2, 1. University of Minnesota, Minneapolis, Minnesota, 2. Arizona State University, Phoenix, Arizona

Purpose: Falls prevention interventions are needed that address complex motivational processes central to physical activity behaviors. The study’s purpose was to evaluate the feasibility (acceptability, demand, implementation, efficacy) of a wellness motivation intervention (WMI). Methods: A community-based randomized controlled trial was conducted targeting rural dwelling older adults with fall risk. WMI content included empowering education, motivational support, and social network support, augmented by a mobile computer app (Ready~Steady), and light-intensity balance, leg strengthening, and walking activities (Otago). Atention Control content included health topics. Theoretical mechanisms of change, behavioral outcomes, and health outcomes were measured pre and post intervention. Results: Thirty adults, mostly female, mean age of 84, evaluated the WMI as satisfying and helpful. Attrition was 7% and mean attendance was 7.2 out of 8 sessions. Evaluation of implementation using fidelity measures was very good. Theoretical mechanisms of change and outcomes that significantly improved with WMI participation were social support from friends, F (1, 27) = 11.4, p = .002, readiness, F (1, 27) = 9.34, p = .005, self-regulation, F (1, 26) = 38.8, p = .000, physical activity behavior via accelerometer, F (1, 23) = 11.4, p = .003 and CHAMPS, F (1, 26), 11.92, p = .002, fall risk using the Berg Balance Scale, F (1, 26) = 8.7, p = .007 and the Short Physical Performance Battery, F (1, 23) = 11.4, p = .003. Conclusion: The WMI has promise as a means to increase physical activity and reduce fall risk among rural, community-dwelling older adults.

FEAR OF FALLING AND SELF-REPORTED MOBILITY DISABILITY IN COMMUNITY-LIVING OLDER PERSONS AT FIVE DIVERSE SITES OF THE IMIAS STUDY

N. Deshpande1, C. Curcio2, A. Ylli3, A. Garcia1, 1. Queen’s University, Kingston, Ontario, Canada, 2. Research Group on Gerontology and Geriatrics, University of Caldas, Manizales, Colombia, 3. Institute of Public Health, Tirana, Albania, 4. Albanian Association of Geriatrics & Gerontology, Tirana, Albania

Background: Fear of falling (FoF) has been recognized as a major health problem among elderly people living in the community. We compared FoF across five global sites and examined its association with mobility disability. Methods: 1939 elderly (65-74 years) performed 2 trials of rapid stepping in response to an auditory cue. SET, consisting of reaction time (RT) plus movement time (MT), is significantly slower in older adults with fear of falling (FoF+). The purpose of this study was to identify systemic contributors to falls in stroke survivors in acute and rehabilitation hospitals. Falls of 16 stroke survivors during their acute care and rehabilitation were investigated using Systemic Falls Investigative Method (SFIM). In addition to interviews with the faller, family members, staff, management and leadership, SFIM included observations, policy reviews, environmental assessments and discussions. Comprehensive case study reports were produced using the SFIM Database. Summary tables of contributing factors were coded to identify similarities and differences between acute care and rehabilitation hospitals. The stroke survivors’ physical and cognitive consequences of stroke combined with their desire to remain independent which lead to unsafe acts and resulted in falls. On the system’s level, opportunities for learning from mishaps were often missed, falls prevention strategies were unadjusted and staff was poorly trained for safety. Formal supervision was inadequate at shift changes and staff breaks, while poor communication between patient-staff, staff-staff and hospital-hospital contributed to delayed or erroneous responses. To prevent falls and injuries in post-stroke acute care and rehabilitation, innovative falls prevention procedures are needed to include policies and procedures that recognize and address stroke-specific health causes and system-wide factors affecting patient safety.

CONTRIBUTIONS OF REACTION AND MOVEMENT TIMES TO STEP EXECUTION IN OLDER ADULTS WITH FEAR OF FALLING

S.A. Talley1, A. Goldberg1, 1. Physical Therapy Program, Wayne State University, Detroit, Michigan, 2. Wayne State University Institute of Gerontology, Detroit, Michigan

Introduction Step execution time (SET) must be sufficiently rapid to enable older adults to successfully execute a compensatory step to prevent a fall. SET, consisting of reaction time (RT) plus movement time (MT), is significantly slower in older adults with fear of falling (FOF+). The purpose of this study was to determine the relative contributions of RT and MT to SET in individuals FOF+ and without fear of falling (FOF−). Methods Seventy-four older adults (mean age 69.1 years) performed 2 trials of rapid stepping in response to an auditory stimulus in a mobility research laboratory. SET, RT, and MT were
recorded in milliseconds (ms). Differences in SET, RT and MT between FOF+ (n=23) and FOF- (n=51) were analyzed using the Mann-Whitney U test for independent samples. Alpha was set at 0.05. Results SET was significantly slower in the FOF+ group (mean 952.8ms) compared to the FOF- group (mean 850.9ms) (p<.001). There was no difference in RT comparing the FOF+ group (mean 368.3ms) to the FOF- group (mean 364.6ms) (p=.83). MT was significantly slower in the FOF+ group (mean 584.4ms) compared to the FOF- group (mean 486.3ms) (p=.01). Conclusion While there were significant differences in SET comparing the FOF+ and FOF- groups, there were no differences in RT. Slower SET in the FOF+ group compared to the FOF- group is explained by significantly slower MT in the FOF+ group. Studies are needed to determine contributors to slow MT in order to develop effective rehabilitation programs for older adults with FOF.

SESSION 640 (PAPER)

ORAL HEALTH PAPERS

USING A CBPR APPROACH TO ADDRESS ORAL HEALTH AND HEALTHCARE IN MEALS-ON-WHEELS RECIPIENTS IN NYC

Background: Home Delivered Meals (HDM) is one of a number of community-based services intended to help older adults maintain independence; HDMs are designed to provide food and nutrition for older adults, but they do not address oral disease/dysfunction which are central to ability to eat. A CBPR approach was used to assess the oral health needs of HDM recipients, and how and where oral health related interventions can be integrated into the HDM system. Since HDMs are provided across the nation, these data and methods can inform interventions in other settings. Methods: A community advisory board which included case management/HDM providers and policy makers was convened to provide leadership and advice. A cross-sectional telephone survey using a 54-item instrument was used to assess oral health needs in a random sample of 300 NYC HDM recipients. Focus groups with stakeholders who were conducted to assess feasibility of integrating interventions in the HDM system. Results: Over 20% of HDM recipients were edentulous, of those only 49% had replacement dentures; 35% had uncomfortable dentures. Thirty-eight percent of the sample reported difficulty chewing and/or avoiding foods and mean time since last dental visit was three years. Case workers reported poor knowledge of oral health and healthcare. Outcomes/implications: NYC’s Department For The Aging will further incorporate oral health in its intake and annual assessment, pilot delivery and assessment of toothbrushes/toothpaste/denturebrushes and oral health promotion messages for HDM recipients is planned, and interventions to improve access to dental services and/or changes in food texture are being considered.

TRAJECTORIES OF COGNITIVE FUNCTIONING AND EDENTUALISM AMONG OLDER AMERICANS

J. Liang1, B. Wu1, B.L. Plassman1, J.M. Bennett1. 1. Health Management & Policy, University of Michigan, Ann Arbor, Michigan; 2. Duke University, Durham, North Carolina

There is growing evidence that cognitive impairment is associated with poor oral health in later life. However, the vast majority of research is based on cross-sectional data which does not take into account the fact that cognitive functioning changes over time. This research analyzes the linkages between trajectories of cognitive functioning (i.e., Telephone Interview for Cognitive Status [TICS], immediate recall [IMR], and delayed recall [DR]) and edentulism among older Americans. Data came from the Health and Retirement Study (HRS) which consisted of a national sample of 924 individuals aged 65 and over who were selected for the 2008 Dental Survey Supplement and their preceding HRS interviews from 1998-2008. Trajectories of cognitive functioning were derived from group-based mixture models, while multivariate logistic regression analysis was employed to assess the associations between trajectories of cognitive functioning and edentulism. TICS, IMR, and DR were positively correlated and could each be characterized by three trajectories: (a) high functioning with little decline, (b) medium functioning with moderate decline, and (c) lower functioning with significant decline. Cross-sectional measures of TICS, IMR, and DR were not correlated with edentulism. In contrast, trajectories of higher cognitive functioning measured by TICS and IMR were associated with two to fourfold less risk of edentulism even with demographic and socioeconomic status adjusted, although edentulism was uncorrelated with trajectories of DR. Furthermore, the effects of the trajectories of TICS and IMR were confounded by physical health conditions, particularly chronic diseases. Supported by NIH/NIDCR (R21 DE019518-01 and R01 DE08060).

THE EFFECT OF ORAL HEALTH PROBLEMS AND REHABILITATION ON DEPRESSION IN THE HEALTH AND RETIREMENT STUDY

F.M. Yang1, S.T. Kao2. 1. Institute for Aging Research, Hebrew SeniorLife, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, Massachusetts; 2. College of Dental Medicine, Georgia Regents University, Augusta, Georgia

Oral health is an important public health issue as the gateway towards eating, nutrition, overall well-being, and for achieving optimal healthy aging. The relationship between oral health care problems and rehabilitation on depression is understudied among middle age and older Americans. One of the symptoms of depression is appetite change, either loss or increase that is more than usual everyday for two weeks. There are a number of reasons that an older adult may experience an appetite change, which include problems with oral health and barriers to oral rehabilitation services. This study investigates the effects of oral health problems and rehabilitation provided by oral surgeons, prosthodontists, periodontists, dentists, and/or dental hygienists, between 2006-2008, on depression experienced between 2007-2008 by adults, aged 54 and older, in the Health and Retirement Study. The respondents were asked if they felt sad, blue, or depressed for two weeks or more during the past year, followed by the specific depressive symptoms that they endorsed. The oral health problems include losing natural teeth and avoiding foods due to problems related to teeth, mouth, dentures, or gums. The types of oral health rehabilitation services include receiving a filling, crown, root canal, dentures, an inlay, orthodontics, gum treatment, implants, bonding, prosthetics, extractions, and surgery. While controlling for sociodemographic characteristics and frequency of oral health visits, we found that for oral health problems, those who avoided particular foods because of gum bleeding when they brushed their teeth had a higher risk for depression (adjusted OR=1.43, 95% CI 1.05-1.95). For oral rehabilitation treatment, adults who received gum treatment (adjusted OR=0.19, 95% CI 0.05-0.77) were at a lower risk of experi-
Oral health continues to be one of the most important issues in aging societies. Along with the promotion of the 8020 campaign undertaken by the central government in Japan, it is expected that a certain number of the general public has increased their knowledge about the importance of oral health in connection with general health status. To examine public awareness of the importance of oral health in connection with general health and risk factors, we conducted a mail survey among the residents of Hyogo prefecture in June 2012. The number of adult responders between ages 20 and 99 was 11,228 (2,433 men and 8,795 women). Among these, the awareness of the connection between oral health and general health increases with age. Women know more about the relationship between oral health and general health than men. The ratio of people visiting a personal doctor becomes higher with age with its peak in the 70s. The importance of food for oral health is less related to age especially for men. Although both men and women fully realize that dental caries and gum disease contribute to oral odor, they have less knowledge about smoking as another risk factor. Respondents became less concerned about a dirty tongue as a risk of oral odor with age. It is concluded that the importance of oral health should be emphasized throughout an individual’s life course to achieve general health in aging societies. To do so, oral health promotion to increase public awareness should continuously be highlighted.

SESSION 645 (SYMPOSIUM)

COMBATTING ELDER ABUSE THROUGH MULTIDISCIPLINARY COLLABORATION: LOS ANGELES COUNTY FORENSIC CENTER

Chair: S.C. Dato, Community & Senior Services, County of Los Angeles, Los Angeles, California
Co-Chair: K. Wilber, Davis School of Gerontology, Los Angeles, California
Discussant: X. Dong, Rush Institute for Healthy Aging, Chicago, Illinois

Elder abuse is a growing phenomenon in the United States (U.S.), due in part to population aging, reports of elder abuse have increased steadily over the past decade. And while considerable effort has been put toward the creation of intervention programs, almost no systematic evaluations have taken place to determine their efficacy. Indeed, no prior studies have found significant benefits as a result of an elder abuse intervention program. This symposium presents information about the demonstrably effective and increasingly popular Elder Abuse Forensic Center model, its effect on cases, and the impact it has had on Adult Protective Services (APS). The first presentation provides an overview of the model as implemented at the Los Angeles County Elder Abuse Forensic Center. Subsequent presenters discuss the improved outcomes that have been observed in three key areas: cases referred to the public guardian for guardianship/conservatorship, cases sent to the District Attorney for prosecution, and clients that exhibit recidivism within the APS system. The final presentation provides reflections from the evaluation project’s research partners, highlighting the APS response to the Forensic Center model and experiences working on a collaborative research project. The symposium provides context and motivation for implementation of the Elder Abuse Forensic Center model, as well as provides insights about its placement within a County’s existing senior services infrastructure. With increasing interest in replicating the model across the U.S., we provide evidence and guidance to support these efforts.

BUILDING AN EFFECTIVE MULTIDISCIPLINARY TEAM: MISSION, COMPOSITION, AND PROCEDURES

D.C. Homeier, Davis School of Gerontology, University of Southern California, Los Angeles, California

The Los Angeles Elder Abuse Forensic Center provides comprehensive case examination, documentation, consultation, and prosecution for cases of elder and dependent adult abuse. Launched in 2006, the Forensic Center has heard nearly 1,000 cases. Each week, members review 3–4 new cases; most are presented by APS and/or law enforcement. Presentations include a brief background and history of the problem with descriptions of interventions attempted or completed. Following case discussion, attendees identify goals and make recommendations. Outside the weekly meetings, team members assist those working the case (usually APS and law enforcement) through activities such as: assessing health status, capacity, and need for health/mental health care or social services; reviewing medical records; conducting home assessment; doing neuropsychological testing; and providing ongoing case consultation. This paper describes the unique structure, the diverse participating agencies, the process used to conduct reviews, and the team’s activities during the “other 38 hours” of the week.

PROMOTING APPROPRIATE CONSERVATORSHIP INTERVENTION IN LOS ANGELES: THE ELDER ABUSE FORENSIC CENTER

J.M. Yonashiro-Cho1, A.E. Navarro2, Z.D. Gassoumis1, K. Wilber1, J. Leonard Davis School of Gerontology, University of Southern California, Los Angeles, California, 2. School of Behavioral and Applied Sciences, Azusa Pacific University, Azusa, California

Cognitive incapacity is a common factor in cases of elder mistreatment and self-neglect. Conservatorship (or guardianship), a sometimes necessary and appropriate intervention to halt or reverse abuse, is one tool used by the Los Angeles County Elder Abuse Forensic Center (FC) to promote safety and well-being for cases presented. This session examines the FC’s effectiveness in supporting conservatorship by comparing cases seen at the FC with a propensity score-matched sample of usual care Adult Protective Services (APS) cases. Data were obtained from APS, the Office of Public Guardian, and public records. Preliminary analysis (N=573) shows FC cases to have over seven times greater odds of being referred for conservatorship (OR 8.5, CI:4.6-15.9, p<.001), which leads to higher rates of conservatorship among FC cases (19.6% vs. 1.7%; χ2=47.9). Results point to the FC as a catalyst for increasing access to conservatorship, which can enhance safety for cognitively impaired victims of abuse.

PROTECTING VICTIMS OF FINANCIAL EXPLOITATION: THE FORENSIC CENTER EFFECT ON PROSECUTIONS

A.E. Navarro1, Z.D. Gassoumis, K. Wilber2, J. Azusa Pacific University, Azusa, California, 2. Univ. of Southern California, Los Angeles, California

Elder financial exploitation is defined as the taking or misappropriation of an older person’s property, possessions, or financial assets. For cases reported to Adult Protective Services (APS), arriving at a remedy can be time-consuming and complex, requiring cooperation from various professionals. This presentation highlights the Los Angeles Elder Abuse Forensic Center’s effect in facilitating one aspect of case remediation: prosecution. Using a propensity score-matched sample, we assessed the “value added” of Forensic Center presentation for APS cases. Each victim reviewed at the Center from April 2007-December 2009 (n=241) was matched with an unduplicated APS client served during the same period (n=33,650). Logistic regression has revealed that Forensic Center cases have 10 times greater odds of being presented to the District Attorney (OR 11.0, CI:4.7-26.0, p<.001). A new extraction
of clients’ APS case files has augmented the results to underscore the great value of Forensic Center involvement for achieving prosecutorial outcomes.

CLIENTS’ APS RECIDIVISM IS REDUCED AFTER INVOLVEMENT OF AN ELDER ABUSE FORENSIC CENTER

Z.D. Gassounis, J. Wyssong, K. Wilber, Davis School of Gerontology, University of Southern California, Los Angeles, California

A primary goal in elder abuse interventions is the cessation of current abuse and prevention of future abuse. As such, client recidivism in the Adult Protective Services (APS) system—having a new case of abuse after the baseline case is closed—is a key metric of success for the Los Angeles County Elder Abuse Forensic Center, an intervention targeting complex cases of abuse, neglect, and self-neglect. We report recidivism patterns for a propensity score-matched sample (n=568) of cases seen at the Forensic Center or provided usual care from APS. Preliminary results have shown presentation at the Forensic Center to significantly reduce recidivism (from 41% to 20%), but that recidivism remains higher for the Forensic Center cases than the usual care group (11%). This paper builds on these results with data extracted directly from the APS case files to provide support for the effectiveness of the Forensic Center model.

ADULT PROTECTIVE SERVICES: PERSPECTIVE ON THE FORENSIC CENTER AND PARTICIPATION IN EFFICACY STUDIES

S.C. Dato, L. Sanchez, Community & Senior Services, County of Los Angeles, Los Angeles, California

Health and Human Services organizations are punctuated by a disinclination to share information with different systems of care. This results in service fragmentation and poses a significant barrier to obtaining evidenced-based outcomes needed for service planning. This section identifies barriers to APS’ participation in the implementation of the Forensic Center and subsequent efficacy studies, which include: resistance to change from “traditional” ways of doing business; and, confidentiality of records. The section also includes the following solutions and best practices for overcoming these barriers: obtaining executive support for change; correcting perceptions through cross training and team building; and, separating legal constraints on privacy from those that stem from “traditional” practices and developing procedures to safe-guard privacy. APS will close with a commentary on the success and effectiveness of the Forensic Center in facilitating a multifaceted approach to the development of a comprehensive case plan and the prosecution of elder abuse perpetrators.

SESSION 650 (SYMPOSIUM)

DIVERSITY AND CHALLENGES IN LATE LIFE CAREGIVING EXPERIENCES

Chair: N.P. Kropf, Georgia State University, Atlanta, Georgia
Co-Chair: S.M. Cummings, University of Tennesse, Nashville, Tennessee

With increases in the older population, caring for older adults has become a more typical experience within the family life course. In a national survey, an estimated 28 million households (24% of all households in the country) are involved in providing care to an older family member (National Alliance for Caregiving, 2009). Furthermore, only 35% of the caregivers receive help from paid sources which means that the majority of elder care is completed by informal types of support. The complexities of elder care can tax the coping and resources of families, resulting in challenges with functioning and performing social roles. As the baby boom population enters their later years, these issues are expected to intensify over the coming decades. The population of older adults is increasing in diversity as well as in size, and this symposium will provide research on four diverse caregiving arrangements of later life. One presentation will present on a qualitative study that identified unique stresses of caring for depressed older adults. A second presentation reports on research on anxiety and depression of caregivers of older adults who have severe mental illness. A third study used medical examiner data to analyze caregiving experiences prior to the death of older adults. The final study compares care provision by gender of the primary caregiver to determine uniqueness and difference by male and female care providers. The four papers highlight diverse caregiving arrangements that create challenges for those who provide care, and provide implications for interventions, policy, and future study.

CARING FOR OLDER ADULTS WITH DEPRESSION: THE LIVED EXPERIENCE OF FAMILY MEMBERS

M. Luptak, M. Henry, C.E. Dufty, S.M. Metzner, College of Social Work, University of Utah, Salt Lake City, Utah

Although depression is the most widespread mental health issue in late life, the study of social factors such as family involvement and life events has been overshadowed by a focus on biological factors. This study explored the lived experience of 38 family members as they provided support for 20 community-dwelling relatives age 60 and above with a diagnosis of major depression. Qualitative data collection strategies included in-depth individual face-to-face audio-recorded interviews with family members and the use of field notes. Four general themes (with multiple subthemes) emerged: a) effects of the older adult’s depression on family functioning; b) challenges of caregiving; c) caregiver’s understanding of the older adult’s depression; and d) efficacy of depression treatments, including needed services for the caregiver. Findings illuminate complex factors that should be considered when shaping public policy and when developing evidence-informed interventions for older adults with depression and family members who care for them.

CHARACTERISTICS OF DEPRESSION AND ANXIETY SYMPTOM SEVERITY AMONG FAMILY MEMBERS OF OLDER ADULTS WITH SEVERE PSYCHIATRIC DISORDERS

S.M. Cummings, N.P. Kropf, Social Work, University of Tennessee
College of Social Work, Nashville, Tennessee

A rapidly expanding population of older adults with severe psychiatric disorders (SPD) is aging in the community and receiving care from their family members. Yet little is known little is known about caregivers of older with SPD. This study examined depression and anxiety among 96 caregivers of older adults (55 year+) with major recurrent depression, bipolar disorder, and schizophrenia-spectrum disorders. One-quarter and over 1/3rd of the caregivers met the clinical cut-offs for depression and anxiety, respectively, as measured by the Brief Symptom Inventory. A strong correlation (r=.72, p >.001) was found between depression and anxiety symptoms. However, linear regression analyses revealed differing profiles of predictors for the two constructs. Low income and being a female caring for a male were significant correlates of depression (R² =.26) while greater subjective burden, poorer health and being a spouse of the care recipient significantly predicted anxiety (R² = .40).

MODERATORS OF THE IMPACT OF SOCIODEMOGRAPHIC AND ECONOMIC FACTORS ON THE WELL-BEING OF CAREGIVING MEN

A. Schwartz, Boston College, Chestnut Hill, Massachusetts

This study was a secondary data analysis that focused on the relationship between sociodemographic and economic factors on the well-being of male caregivers of older adults, including moderators of these relationships. The sample included 908 caregivers (297 men, 611 women) for individuals age 60 and over. Two significant results were found. Chow’s test indicated a significant difference between men’s and women’s level of emotional stress among sandwich generation caregivers (OR=4.46), with higher emotional stress among men than women.
There was also a significant difference between unemployed males and females who used technology to gather caregiving information (OR=4.71). In this situation, the male sample also reported higher emotional stress than their female counterparts. This study contributes to understanding the risk factors for well-being within various subgroups of caregivers and how these relationships differ by gender. Implications for practice and policy will be discussed.

SUDDEN DEATH IN ELDERS: HOW INVOLVED WERE THE CAREGIVERS?
S. Sanders, University of Iowa, Iowa City, IA, Iowa

Not all caregivers are involved at the same level in the care of older adults. The involvement of the caregivers can impact the end-of-life process of the older adult, with some older adults not receiving the care from professional or family caregivers dying in sudden, unexpected ways. This study, utilizing cases from a Midwestern medical examiner’s department, examined the role of caregivers prior to the death of older adults. A review of cases over a 9 month period revealed that less than 30% of the older adults were receiving assistance from a professional or family caregiver at the time of their death. Through further analysis of these cases, it was determined that greater caregiver involvement could have assisted in preventing some of the factors that led to the death of the older adults, particularly greater monitoring of the older adult for safety concerns and assistance with activities of daily living.

SESSION 655 (SYMPOSIUM)

GEDI WISE: A CMS HEALTH CARE INNOVATION AWARD PROGRAM TO IMPROVE GERIATRIC ED CARE
Chair: U. Hwang, Icahn School of Medicine at Mount Sinai, Rye, New York, James J. Peters VAMC, Bronx, New York
Discussant: J. Schumacher, University of Maryland, Baltimore County, Baltimore, Maryland

Geriatric Emergency Department Innovations in care through Workforce, Informatics and Structural Enhancements (GEDI WISE) is a collaboration of 3 emergency departments (ED) at The Mount Sinai Medical Center in New York City; St. Joseph’s Regional Medical Center in Paterson, New Jersey; and Northwestern Memorial Hospital in Chicago. These hospitals have embraced a new care paradigm, the geriatric emergency department, and have transformed both the physical environment and processes of care in their EDs. From 1/1/12 to 1/31/12, there were a total of 161,390 ED visits at these 3 EDs; 16% by patients ≥65 years old. By site, admission rates ranged from 50-62%, 30-day readmission rates 13-19%, and 72-hour ED revisit rates 2.7-2.73%. Median ED length of stay ranged from 4.0-5.2 hours for discharged patients and 5.8-10.1 hours for admitted patients. GEDI WISE uses evidence-based geriatric clinical protocols, informatics support for patient monitoring, notification and clinical decision support, and structural enhancements in the ED to improve the health and healthcare of older adults while decreasing hospitalizations, rehospitalizations and repeat ED visits. Five symposiums will discuss unique features and programs across the 3 Geriatric EDs. These include: 1. a GEDI nurse “liaison” curriculum, 2. a holistic program using a medical harpist and concierge bedside patient care services, 3. use of a regional health information exchange system to coordinate patient care across multiple hospital systems and electronic templated geriatric ED care documentation, 4. structural modifications to the ED environment, and 5. a transitional care team to facilitate patient discharge from ED to home.

GEDI-WISE: INCIDENCE OF ED FALLS BY OLDER ADULTS BEFORE AND AFTER THE IMPLEMENTATION OF STRUCTURAL GERIATRIC SAFETY ENHANCEMENTS

In-hospital falls are a marker of quality care though little is known about in-ED falls. To characterize the in-ED fall rate among patients ≥65 years old and assess if fall rates decreased following the institution of geriatric structural enhancements to prevent falls (improved lighting, non-slip floors, handrails, geriatric chairs), we conducted a retrospective review of falls reported in the hospital’s medical event reporting system (MERS) among patients ≥65 years old before (May 2011-Jan 2012) and after the institution of structural geriatric safety enhancements (Feb-Dec 2012). The overall fall rate among patients ≥65 years old during the entire study period was 0.561 per 1000 visits. The fall rate before and after the structural enhancements were put in place was 0.594 and 0.502 falls per 1000 visits, respectively. ED fall rate among older patients has decreased following the implementation of structural geriatric safety enhancements.

HOLOSIC Adjuncts TO GERIATRIC EMERGENCY CARE IN AN INNER CITY ACADEMIC MEDICAL CENTER
M. Rosenberg, M. Christensen, D. Adinario, S. Pineda, Emergency Medicine, St Josephs Healthcare System, Paterson, New Jersey

As an adjunct to traditional emergency care in the ED, holistic and non-traditional modalities can be a perceived benefit to staff and patients as well as family and caregivers. Specifically music has been shown to significantly decrease anxiety among patients as well as staff. In addition, music creates a quieter, more relaxed environment. The Geriatric ED at St. Joseph’s Regional Medical Center has supplemented their emergency services with holistic modalities to include a Medical Harp, Aromatherapy, Pranic Healing and Therapeutic Touch. The Bedside Harp program, initiated in September of 2012, has demonstrated positive outcomes in terms of patient and staff comments. Representative comments include, “…it is so calming and relaxing” and “…it makes such a difference” and “…the music is so soothing.” Each month, the Bedside Harp program encounters more than 250 Geriatric ED patients, staff, and visitors and provides approximately 100 one-on-one harp therapy sessions.

GEDI-WISE: HEALTH IT - ENHANCED GERIATRIC EMERGENCY DEPARTMENT SCREENING AND CARE COORDINATION
N. Genes1, J.S. Shapiro1, G. Abraham1, C. Grudzen1, U. Hwang1, D. Nassisi1, K. Baumlín.1, Emergency Medicine, Icahn School of Medicine at Mount Sinai, New York, New York, 2. James J. Peters VAMC, Bronx, New York

GEDI WISE interventions include emergency department (ED) screening of patients aged ≥65 for risks of high utilization, falls and delirium. Validated tools like ISAR (Identification of Seniors at Risk), Get-Up-and-Go (GUG) testing, and CAM (Confusion Assessment Method) were embedded into the electronic health record templates to facilitate screening by ED clinical staff and allow automated data capture of screening findings. In 3,320 ED visits by ≥65 patients from 12/2012-2/2013, increasing use of ISAR, CAM, and GUG occurred each month (ISAR: Dec 77%, Jan 79%, Feb 85% completed; p<0.0001). GEDI WISE event notification services, created with the Healthix health information exchange (HIE), notify the GEDI WISE team, in real time, whenever any patients (currently n=665) being followed by its Transitional Care Management Team have an ED visit, admission or discharge from any of >40 other Healthix hospitals. HIE-enhanced care coordination across institutions may prevent hospitalizations, readmissions and shorten length of stay.
A CURRICULUM FOR GEDI NURSE LIAISONS
A. Aldeen, S. Malik, J.G. Adams, L. Lindquist, D.M. Courtney, Emergency Medicine, Northwestern University Feinberg School of Medicine, Chicago, Illinois

ED nurses trained in validated geriatric assessment tools may help reduce unnecessary hospital admissions and revisits for geriatric patients. At Northwestern Memorial Hospital, 4 ED nurses were selected to serve as GEDI nurse liaisons. Collectively these 4 nurses possess 98 years of clinical experience. The liaisons were trained using a comprehensive curriculum created by an interdisciplinary team of EM, geriatrics, and palliative medicine educators. The curriculum included inpatient geriatrics, outpatient geriatrics, inpatient palliative consults, palliative simulator sessions, asynchronous education, lectures, education in palliative and end-of-life care in emergency medicine (EPEC-EM), and independent study. Each nurse underwent 18 inpatient hours, 32 outpatient, 4 simulation, 22 independent, 4 asynchronous, 20 inpatient palliative, 16 EPEC-EM, and 12 lecture hours for a total of 128 hours of structured instruction over a 4-month period. After curriculum completion, the liaisons have been working alongside regular ED clinical staff, providing geriatric assessments and consultations to older adults.

GEDI WISE: AN INFORMATICS ENHANCED TRANSITIONAL CARE INTERVENTION FROM ED TO HOME
M. Sanon1, B. Morano2. 1. Brookdale Department of Geriatrics and Palliative Medicine, Icahn School of Medicine at Mount Sinai, New York, New York, 2. Emergency Medicine, Icahn School of Medicine at Mount Sinai, New York, New York

A visit to the ED offers a unique opportunity to identify the complex care needs of older adults and facilitate care coordination among other health care reform programs. An interdisciplinary transitional care team made up of an ED physician, Geriatrician, NP, pharmacist, PT and SW work together to develop a comprehensive plan of care for vulnerable older adults at high risk for adverse outcomes. A landing page in the EHR prevents duplication of services among other recently launched care coordination programs and ensures appropriate hand-off back to them. For those unassigned patients discharged to home, the ED Transitional Care NP will follow up telephonically at 48 hours and 10-14 days post index ED visit to insure medication compliance, referrals for newly identified homecare needs, and appropriate handoff to PCP. Access to a regional electronic health information network further improves care coordination by providing notifications of subsequent ED use.

SESSION 660 (SYMPOSIUM)

NATIONAL SEXUALITY, AGING, AND HEALTH RESEARCH: OPTIMAL AGING AMONG LGBT OLDER ADULTS
Chair: K.I. Fredriksen-Goldsen, University of Washington, Seattle, Washington

Given population aging and the increasing diversity of the older adult population, the number of lesbian, gay, bisexual, and transgender (LGBT) older adults is steadily increasing. The Institute of Medicine and the CDC both identify the lack of attention to sexual orientation and age critical gaps in our understanding to reduce health disparities. While recent research has documented health disparities among LGBT older adults, little is known about optimal aging among LGBT older adults and the risks and resources that influence aging in these historically disadvantaged populations. This symposium highlights important findings from the ground-breaking study of LGBT health and aging, with 2,560 demographically diverse LGBT adults 50 and older, conducted through community based collaborations. Fredriksen-Goldsen and colleagues present an innovative model for investigating quality of life and the range of health outcomes among LGBT older adults. The relationship between race and ethnicity and personal and social resources and risks are explored by Kim and colleagues, as they relate to psychological well-being among LGBT older adults.

RACIAL AND ETHNIC DIFFERENCES ON PSYCHOLOGICAL WELL-BEING AMONG LESBIAN, GAY, BISEXUAL AND TRANSGENDER OLDER ADULTS AND THE IMPACTS OF LIFE STRESSORS AND SOCIAL RELATIONS
H. Kim, K.I. Fredriksen-Goldsen, School of Social Work, University of Washington, Seattle, Washington

Psychological well-being is an important part of optimal aging. Little is known about racial and ethnic disparities in psychological well-being among LGBT older adults. This study examines associations between race/ethnicity and psychological well-being (mental health related quality of life). By adding life stressors (the number of life-time discrimination events and internalized stigma) and social support (social network size, availability of social support, and perceived isolation) to the regression model, we will examine whether life stressors and social relations account for racial and ethnic differences of psychological well-being among LGBT older adults. To counter multiple types of discrimination, macro level interventions may improve outcomes. Micro level interventions to alleviate internalized stigma, fostering higher quality of social support and reducing feeling of isolation may also improve the psychological well-being among racial/ethnic minorities within lesbian, gay, bisexual and transgender older adult communities.

THE IMPACT OF HIV ON THE LIVES OF LGBT OLDER ADULTS

HIV disproportionately impacts the LGBT community, particularly gay and bisexual men. The CDC indicate that a quarter million adults age 50+ are living with HIV disease in the U.S. This paper explores the impact of HIV disease on older LGBT participants of Caring and Aging with Pride. Utilizing data from LGBT older adults with and without HIV disease, demographic and health outcomes are examined. Results: Those living with HIV were significantly more likely to be men, people of color, and live below 200% of the poverty level. They experienced poorer physical and mental health, were more likely to live alone and had greater emergency room use. Those living with HIV were more likely to engage in sexual risk behavior. Education and interventions are needed to reduce sexual risk as well as address the physical health and psychosocial well-being of LGBT older adults living with HIV to support optimal health.
THE ROLE OF PROXIMAL MINORITY STRESSORS IN LGB OLDER ADULTS’ PSYCHOLOGICAL WELL-BEING
C.P. Hoy-Ellis, School of Social Work, University of Washington, Seattle, Washington

In the general population, psychological distress begins to decrease at around age 50, even more so after age 65. The rates among lesbian, gay, and bisexual (LGB) older adults may be three to four times higher than their heterosexual peers. Psychological well-being among LGB populations is negatively impacted by concealment of sexual orientation and internalized heterosexism. This study uses structural equation modeling to examine the relationship between these stressors and psychological distress among LGB adults aged 50 older. Findings indicate that internalized heterosexism fully mediates the relationship between concealment and psychological distress/well-being. Furthermore, despite a statistically significant increase in psychological well-being among those aged 65 and older, the rates of psychological distress remain unacceptably high for these populations. Implications for optimal aging among LGB older adults are discussed.

UNDERSTANDING SOCIAL NETWORKS AND SOCIAL SUPPORT IN THE LIVES OF LESBIAN, GAY, BISEXUAL, AND TRANSGENDER OLDER ADULTS

Little is known about the structure of social networks and its relationship with social support among lesbian, gay, bisexual, and transgender older adults. This paper contributes to the social network theory and literature on measurement of social networks by examining the properties of social networks among lesbian, gay, bisexual, and transgender older adults. We use egocentric social network data collected as part of the CAP project to examine the size of social networks (also known as degree) and intersections of social networks by age (older or younger than 50), gender (men or women) and sexual orientation and gender identity (lesbian, gay, bisexual, and transgender). In addition, we examine network diversity as defined by existence of links to individuals in other sexual orientation subgroups. Finally, we look into the relationship between social network structures and the amount and quality of social support and their joint influence on health outcomes.

REFLECTIONS OF AGING AND OTHER LIFE EXPERIENCES FOR LESBIAN, GAY, AND BISEXUAL ADULTS AGE 50 AND OLDER
A. Muraco, K.I. Fredriksen-Goldsen, 1. Loyola Marymount University, Los Angeles, CA, 2. University of Washington, Seattle, Washington

This paper examines experiences of aging in the lives of lesbian, gay, and bisexual (LGB) adults, age 50 and over from a symbolic interaction perspective. The paper examines LGB adults’ responses to questions about their specific aging processes and how they perceive aging in LGB and heterosexual communities. Using data collected from in-depth interviews with LGB adults age 50 and older (N =34) as part of Caring and Aging with Pride, we examine how partnership status, health status, and other factors affect self-perceptions of aging and their views of the future. The findings show that participants who co-reside with a partner have more positive views of aging than individuals who are single or partnered, but not co-residing. Having multiple health conditions, including disabilities, tends to be associated with a more negative perception of aging and of the future, more broadly. While many participants see little difference in aging by sexual orientation, others point to specific differences between heterosexual and LGB communities including pressures to maintain health and fitness and concerns about future housing and financial support.

SESSION 665 (SYMPOSIUM)

NATIONAL STUDY OF LONG-TERM CARE PROVIDERS: A NEW RESOURCE TO SUPPORT RESEARCH, POLICY AND PRACTICE
Chair: L. Harris-Kojetin, National Center for Health Statistics, Hyattsville, Maryland
Discussant: N. Castle, University of Pittsburgh, Pittsburgh, Pennsylvania

The National Study of Long-Term Care Providers (NSLTC) is a groundbreaking new initiative by the National Center for Health Statistics (NCHS) to help monitor the United States’ diverse and evolving long-term care (LTC) services industry and inform healthcare practice and policy. NSLTC uses two key data sources to provide information on the supply, use, and characteristics of the five major LTC sectors: (1) survey data on adult day services centers, and assisted living and similar residential care communities (RCCs); and (2) administrative data on home health agencies, nursing homes and hospices. NCHS plans to conduct NSLTC every two years and release report findings from the first wave of data collection in December 2013. This symposium describes NSLTC, presents selected findings from upcoming NSLTC reports, and provides reflections on NSLTC from a distinguished discussant with broad LTC research experience. The first presentation introduces the NSLTC goals, design, and lessons learned from the 2012 wave of NSLTC. The second through fourth presentations present national estimates and, where feasible, state estimates. The second presentation gives a profile of adult day services centers, RCCs, nursing homes, home health agencies, and hospices, and describes services offered, payment sources, staffing, and the demographic characteristics and functional status of the people served. The third and fourth presentations, respectively, provide a profile of RCCs and their residents, and a profile of adult day services centers and their participants.

INTRODUCTION TO THE NATIONAL STUDY OF LONG-TERM CARE PROVIDERS (NSLTC)
L. Harris-Kojetin, National Center for Health Statistics, Hyattsville, Maryland

In 2012, the National Center for Health Statistics (NCHS) launched the integrated National Study of Long-Term Care Providers (NSLTC), which replaced the National Nursing Home Survey, National Home and Hospice Care Survey, and National Survey of Residential Care Facilities. The NSLTC aims to provide reliable, accurate, and timely statistical information on the U.S. national supply of five major sectors of paid, regulated LTC services providers: adult day, residential care, home health, nursing home, and hospice. Information collected includes key characteristics of these providers and services offered, allowing for comparisons among the sectors and monitoring trends over time. NCHS fielded surveys of 5,000 adult day providers and 11,700 residential care communities, completed data collection in February 2013, and is working with administrative data sources on home health agencies, nursing homes and hospices. This presentation highlights the NSLTC design and methods, upcoming products, and lessons learned from the first wave of NSLTC.

THE SUPPLY AND USE OF PAID, REGULATED LONG-TERM CARE SERVICES: UNITED STATES, 2012
M. Sengupta, E. Park-Lee, L. Harris-Kojetin, CDC/NCHS, Hyattsville, Maryland

The National Study of Long-Term Care Providers (NSLTC) collects information on providers and users of long-term care services using nationally representative surveys and administrative data. Using data from the NSLTC, this presentation provides an overview of the supply and use of major types of paid, regulated long-term care services in the United States. A national profile of the five major sectors of long-term care services include adult day services centers, residential care...
A PROFILE OF ASSISTED LIVING AND SIMILAR RESIDENTIAL CARE COMMUNITIES: UNITED STATES, 2012
C. Caffrey, L. Harris-Kojetin, M. Sengupta, National Center for Health Statistics, Hyattsville, Maryland

The National Study of Long-Term Care Providers (NSLTCP) includes a nationally representative survey of assisted living and similar residential care communities. Using 2012 NSLTCP data, this study provides a national profile of residential care communities and their residents. Results will be presented on the overall characteristics, staffing, and service provision of residential care communities. Demographic and health characteristics of residents in residential care communities will be included in the presentation. We will highlight findings on special topics, like Medicaid participation, person-centered care, emergency department use and hospitalizations, and use of electronic health information systems. We will present trends and state-level estimates for select characteristics. This study provides information useful to researchers, policymakers, service providers, and consumer advocates in their plans to meet future long-term care needs.

A PROFILE OF ADULT DAY SERVICES CENTERS: UNITED STATES, 2012
L.L. Dwyer, L. Harris-Kojetin, Division of Health Care Statistics, National Center for Health Statistics, Hyattsville, Maryland

The 2012 National Study of Long-Term Care Providers (NSLTCP) collected information on over 3,000 adult day services centers (ADSCs) in the United States. ADSCs, a growing sector in the long-term care continuum, offer a variety of critical services aimed at meeting the needs of non-institutionalized elderly and chronically-ill individuals in their communities. Using 2012 NSLTCP data, this session will present estimates on ADSCs’ licensure, enrollment, and capacity; funding and revenue sources; and transportation services. Estimates also will be provided on admission screenings for cognitive impairment and depression, and for disease-specific programs for better management of selected chronic conditions. Furthermore, the prevalence of two significant health policy-relevant practices—person-centered care and electronic health records—will be presented. This presentation will highlight the value of these important national and state-level data, which are infrequently available to policymakers, providers, and researchers involved in planning for the long-term care needs of the U.S. population.

SESSION 670 (SYMPOSIUM)

OPTIMIZING CARE TRANSITIONS: IMPROVING SERVICES, PROGRAMS AND POLICIES FOR VULNERABLE OLDER ADULTS
Chair: S.E. Lowey, University of Rochester, Rochester, New York, The College at Brockport State University of New York, Brockport, New York
Co-Chair: T.J. Roberts, William S. Middleton Veteran Affairs Hospital, Madison, Wisconsin
Discussant: M.D. Naylor, University of Pennsylvania, Philadelphia, Pennsylvania

Older adults with multiple chronic conditions are at high risk for many adverse outcomes, particularly when transitioning from one care setting to another. With the number of older adults expected to double by the year 2025, greater assurance of optimal quality care transitions for this population is of vital importance. Poor quality transitions are associated with various adverse outcomes for older adults and likely contribute to costly and avoidable high rates of re-hospitalization. Advances in transitional care research have led to improved satisfaction, care coordination and reduced re-hospitalization rates. The aim of this symposium will be to highlight current research focused on advancing the evidence-base of transitional care services for older adults across the continuum of aging. The first presentation will emphasize the transition from independence to dependence by exploring the impact of driving cessation on changes in older adult living environments. The second presentation will highlight the implementation of a transitional care program designed to improve coordination of care for older adults discharged from hospital to community settings. The third and fourth presentation will underscore the challenges of transitions for special populations; persons with dementia and persons at the end of life. The former will describe factors that complicate transitions for persons with dementia transitioning from the hospital to nursing home. The final presentation will explore transitions surrounding health care utilization and resource use during the last year of life. The influence of policy on care transitions will be discussed.

DRIVING CESSATION AND RISK OF INSTITUTIONALIZATION
M. Choi. 1. University of Kentucky College of Social Work, Lexington, Kentucky, 2. University of Kentucky Sanders-Brown Center on Aging, Lexington, Kentucky

Driving is necessary for mobility and independence to many older Americans. This study examined the relationship between driving cessation and transition from home to long-term care of adults aged 65 and older, using logistic regression and discrete-time multivariate hazard models. Data came from the 1998–2008 waves of Health and Retirement Study (N=9,347; 58.6% female; Mean age=74.3); 7.2% of respondents were institutionalized during follow-up. Logistic regression results showed that non-drivers (former and never drivers) at baseline were more likely to enter into long-term care as compared to active drivers (OR=1.42, 95% CI=1.01–1.99) after accounting for baseline sociodemographic and health characteristics. Discrete-time hazard model results indicated that driving cessation was significantly associated with the likelihood of institutionalization (HR=7.7, 95% CI=5.9–10.04) after accounting for sociodemographic characteristics and time-varying health status. The findings imply that the loss of independent means of transportation is associated with care transitions in later life.

IMPLEMENTATION OF THE C-TRAC PROGRAM: A TRANSITIONAL CARE OPTION DESIGNED FOR LOW-RESOURCE AND RURAL AREAS
A. Kind1,2, L.L. Jensen1, A.L. Gilmore-Bykovskiy1,4, B. Kordahl1, J. GRECC William S. Middleton Memorial Veteran Affairs Hospital, Madison, Wisconsin, 2. UW School of Medicine and Public Health Department of Medicine, Division of Geriatrics, Madison, Wisconsin, 3. University of Wisconsin Madison School of Nursing, Madison, Wisconsin, 4. Health Innovation Program, Madison, Wisconsin

Background: Transitions can be treacherous for all high-risk populations, yet virtually no transitional care programs are designed to operate within low-resource or rural settings. Methods: To combat this care gap we developed and implemented the Coordinated-Transitional Care (C-TraC) program—a phone-based, nurse case manager-led program, which uses defined protocols to improve transitional care quality even for patients who reside at great distances. Implementation of C-TraC required multiple, iterative phases. Widespread stakeholder engagement, adaptations to accommodate a phone-based approach, and integration with existing discharge processes were critical to success. Results: C-TraC costs $250/patient enrolled, but decreases 30-day rehospitaliza-
FACTORS THAT IMPACT THE QUALITY OF HOSPITAL-TO-SKILLED NURSING FACILITY TRANSITIONS FOR PERSONS WITH DEMENTIA: A QUALITATIVE STUDY

A.L. Gilmore-Bykovskyi1, B.J. King1, R. Roiland2, B. Bowers1, T.J. Robers1, A. Kud2, I. University of Wisconsin-Madison, Madison, Wisconsin, 2. William S. Middleton VA Geriatric Education and Research Clinical Center, Madison, Wisconsin

Background: Very little research has examined transitional care quality for persons with dementia (PWD) discharged to skilled nursing facilities (SNFs) despite their high risk for rehospitalization. Methods: This qualitative study utilized individual/group interviews with nurses (N=33) employed at 8 SNFs in Wisconsin to identify factors that impact transitional care quality for PWD. Data were analyzed using Grounded Dimensional Analysis. Results: Nurses described hospital-SNF transitions for PWD as difficult and resource-intensive, especially for individuals with challenging behaviors who often experience rehospitalization. Engaged caregivers during transition, high quality discharge communication and access to knowledgeable informants to establish social history prior to admission were critical to facilitating high quality transitions for PWD. Conclusions: Engagement of caregivers in the transition process and detailed social history can improve the quality of transitions for PWD. Future work should explore strategies to reduce rehospitalizations for persons with challenging behaviors.

HEALTH CARE & RESOURCE UTILIZATION AMONG MEDICARE BENEFICIARIES WITH ADVANCED ILLNESSES

S.E. Lowey1,2, B. Powers1, Y. Xue1, I. University of Rochester, Rochester, New York, 2. The College at Brockport State University of New York, Brockport, New York

Older adults with advanced illnesses often live in a cycle of intermittent hospitalizations and home care services which disrupts care continuity at end of life and results in higher costs and resource utilization. The purpose of this study was to explore care transitions among Medicare beneficiaries with heart failure, COPD, and lung cancer at end of life. We used Chronic Condition Warehouse data to examine relationships between diagnosis and healthcare utilization among 213,042 Medicare beneficiaries who died in 2009. Beneficiaries diagnosed with heart failure (32%) or heart failure and COPD (24%) experienced the greatest number of transitions during the last year of life. Beneficiaries with lung cancer were more likely to use hospice at the end of life, therefore had fewer transitions between healthcare settings. These findings illustrate how health conditions influence numbers and types of transitions and have implications for target and design of transitional care programs.

SESSION 675 (PAPER)

DEPRESSION RELATED RESEARCH AMONG COMMUNITY DWELLING ELDERS

OUTCOMES OF A TELEHEALTH INTERVENTION FOR DEPRESSED OLDER ADULTS WITH HEART OR CHRONIC RESPIRATORY FAILURE

B.L. Kenaley1, Z.D. Gellis1, I. School of Social Work, Boise State University, Boise, Idaho, 2. The University of Pennsylvania, Philadelphia, Pennsylvania

Telehealth is emerging as a viable intervention to treat complex chronic conditions including heart failure (HF) and comorbid depression which is prevalent among older adults. This randomized field trial in the homecare sector examines the impact of an integrated telehealth depression care intervention on health, depression, and service utilization outcomes among homebound older adults with HF. Patients were randomly assigned to the standard homecare (SHC) group or a telehealth intervention group. Over a three month period, SHC patients (n = 51) received weekly face-to-face homecare visits augmented with psychoeducation. Patients assigned to the telehealth group (n = 51) received evidenced-based problem-solving therapy and were also monitored for blood pressure, heart rate, weight, temperature, and oxygen saturation daily, using an in-home telehealth device. Telemetric data were electronically sent to the homecare-based telehealth nurse for review. An intent to treat analysis (ITT) was conducted with all randomized patients kept in the analysis. Random effects modeling was the main analytic method used for assessing outcome measures and intervention robustness. Telehealth participants reported significant reductions in depression scores and improvements in perceived general health and social functioning as compared to SHC participants. ER visits and episodes of care were significantly reduced with an observed trend toward fewer hospital days for telehealth participants compared to controls. Telehealth was found to be a feasible, economical, and generalizable health care delivery model. After attending this activity, attendees will be able to discuss the health and mental health and service utilization benefits associated with using a telehealth intervention.

DEPRESSIVE SYMPTOMS AMONG OLDER ADULTS LIVING ALONE: FINDINGS FROM MULTILEVEL MODELING ANALYSIS

K. Kim1, M. Lee2, I. University of Maryland, Baltimore, Maryland, 2. Dong-eui University, Busan, Republic of Korea

Limited empirical evidence is known regarding neighborhood effects on depressive symptoms among Korean older adults living alone. Understanding of the neighborhood effects on depressive symptoms could help to reach the larger number of older adults by using environmental intervention strategies. To fill the existing gap, this study, guided by Andersen’s behavioral model of health service utilization, examines whether individual characteristics are associated with depressive symptoms, and identifies whether neighborhood characteristics are predictors of depressive symptoms among Korean older adults living alone, controlling for individual characteristics. Data using a cross-sectional design and stratified probability samplings were collected from 1,023 Korean older adults living alone in the Busan Metropolitan area in South Korea. A multilevel modeling analysis was conducted to test the hypothesis that neighborhood characteristics are predictive of depressive symptoms. The results revealed that male gender, lower income, lower level of functional abilities, higher number of chronic diseases, and lack of social networks were related to higher risk of depressive symptoms. There was no relationship between age and depressive symptoms. Neighborhood poverty, elderly concentration, and the ratio of senior centers to older adults were not associated with depressive symptoms. On the basis of this study’s findings, these results can be used for practice and policy to target and provide educational outreach programs and supportive services to people in high risk populations. This study suggests that future research may examine more applicable neighborhood characteristics by means of a longitudinal design.

AGING WITH A MAJOR MENTAL ILLNESS IN THE COMMUNITY: FINANCIAL BURDENS OF HEALTH CARE

J. Greenberg, University of Wisconsin, Madison, Wisconsin

Growing numbers of older people with a mental illness live independently in the community. It is well established that they are at increased risk for health problems. Yet little is known about the barriers they face in accessing appropriate health care and the associated health care costs. Data were drawn from the Wisconsin Longitudinal Survey, a long-term study of a random sample of 1957 high school graduates (n=10,317) and their randomly selected sibling. Comparisons were
made with respect to the quality and cost of health care between 342 WLS respondents (average age of 62), who had a mental illness (MI) and their WLS age peers who did not have a MI. No group differences were found in their satisfaction with the quality of health care or their access to routine health care. However, older adults with MI reported substantially higher health care costs. They experienced higher out-of-pocket costs for total medical care (a difference of ~$300, t=5.96, p<.001) and higher medication costs (cost difference of ~$100, t=5.64 p<.001). They were three times as likely to delay seeking medical care because of concerns about the cost of care, but more likely to be hospitalized (28% vs. 16%, t=4.601, p<.001). The financial burden of health care faced by older adults with a MI may lead to delays in seeking treatment, leading to higher rates of hospitalization. Implications for improving services to better meet the health care needs of older adults with MI will be discussed.

FACTORS AFFECTING DEPRESSION AMONG COMMUNITY-DWELLING ELDERLY IN TAICHUNG, TAIWAN

T. Kuo1, F.M. Yang2, S. Tsay3, I. Chung Shan Medical University, Taichung, Taiwan, 2. Institute for Aging Research, Hebrew SeniorLife, Harvard Medical School, Boston, Massachusetts, 3. Health Bureau of Taichung City Government, Taichung, Taiwan

Taiwan has become one of the fastest aging places in the world and the current elderly population consists of 11% of the total population in Taiwan. Depression and suicides are also fast growing in communities but screening for depression often poses difficulties due to social stigma, sampling, and screening tools. The purpose of this study was to use the Depression Quasi-Adaptive Form, a method of Pyramidal Adaptive Test using depression questions from the Patient Reported Outcomes Measurement Information System hosted by the National Institute on Health. All residents of Taichung City age 65 and older were randomly selected to participate in depression screening. A total of 1292 community-dwelling older adults participated in the screening. The results showed that 14.5% of the elderly living in Taichung was depressed. The demographic characteristics of the participants were almost 75 years old, with half being women (50.2%). The age distribution of the participants showed that the largest proportion were 70-74 years old, consisted of almost 30% of the elderly population. The results showed that age, marital status, living arrangement, having chronic diseases and availabilities of local community activities were the significant factors for depression. Disparities between depression and community resources in 29 districts within the City were also discussed. This study showed a first-time effort for Taichung City to perform a city-wide depression screening for the city’s elderly residents. The conclusion proposes interventions for mental health promotion including education for depression awareness, community referrals and risks management.

SUICIDE IDEATION AMONG OLDER CHINESE ADULTS LIVING IN RURAL COMMUNITIES

H. Li1, I. Cha1, L. Xu1, 1. University of Illinois at Urbana-Champaign, Urbana, Illinois, 2. University of Southern California, Los Angeles, California

The suicide rate in mainland China is among the highest in the world. In the literature, very few studies have discussed the suicide issues related to older Chinese adults living in rural communities. Using the data extracted from the Sample Survey on Aged Population in Urban/Rural China in 2006, this study describes the prevalence of suicidal thoughts reported by older Chinese adults. Guided by the bio-psychosocial model of mental health, this study also examined factors that are related to older adults’ suicidal thoughts. The study included 7,939 older Chinese adults living in rural communities. Of them 0.9 percent reported thoughts of suicide in the last year. A logistic regression analysis showed that the likelihood of reporting suicidal thoughts was lower among older adults who were older (OR=.95, p=.03), lived with their children (OR=.53, p=.02), and had a confidant (OR=.53, p=.02). On the contrary, the likelihood of reporting suicidal thoughts were higher among older adults who experienced higher levels of financial strain (OR=1.54, p=.03), functional impairments (OR=1.07, p=.01), and depression (OR=1.26, p=.00). Study findings could help health care professionals and community service providers develop programs that address older adults’ suicidal thoughts and prevent their suicidal behaviors.

SESSION 680 (PAPER)

ORGANIZATIONAL STRUCTURES AND PROCESSES AND RESIDENT CARE IN ASSISTED LIVING

THE RELATIONSHIP BETWEEN ORGANIZATIONAL CHARACTERISTICS AND END OF LIFE CARE PRACTICES IN ASSISTED LIVING

D.J. Dobbs1,2, A.A. Holup1,2, K. Hyer3, H. Meng1,2, 1. School of Aging Studies, University of South Florida, Tampa, Florida, 2. Florida Policy Exchange Center on Aging, Tampa, Florida

Close to one million seniors live in assisted living (AL) settings in the U.S. Hospice and palliative care (PC) enable residents to remain in AL until death to avoid transfer to a nursing home. The association between organizational structures and processes and hospice/PC use in AL has not been studied in prior research. This study examined structures and processes associated with hospice/PC/discharge to nursing home. Three logistic regression models were analyzed for the likelihood of hospice/PC use and discharge to nursing home in a stratified random sample of AL facilities in one state (N=76). The models included structural (resident case mix, staffing levels, discharge criteria, license and profit status) and process (training, administrator attitudes, presence of PC services) characteristics. Findings indicated that ALs who reported that end-of-life care was important to their mission were more likely to use hospice (OR=4.20, CI=1.18-14.90); more positive administrator attitudes towards hospice increased the likelihood of hospice use by (OR=1.08, CI=1.10-1.16). Increased NH discharges increased the likelihood of ALs to use PC (OR=3.42; 1.21-9.70). ALs were less likely to discharge residents to nursing homes who were in need of PC and ineligible for hospice (OR=0.40; CI=0.17-0.94). ALs with an Extended Congregate Care license were less likely to discharge to NH (OR=0.09; CI=0.02-0.45); and increased direct care staffing levels increased the likelihood of discharge to NH (OR=1.07; CI=1.01-1.13). These findings suggest that both structural and process characteristics are associated with increased use of hospice, PC and NH.

PREDICTORS OF CARE TRANSITIONS AMONG DUAL-ELIGIBLE ASSISTED LIVING FACILITY RESIDENTS

H. Meng, K. Hyer, D. Dobbs, University of South Florida, Tampa, Florida

Care transitions across multiple health and long-term care settings has remained a major contributor to poor quality of care and high cost of care in the Medicare and Medicaid populations. This study aimed to examine care transition patterns among assisted living facility (ALF) residents in Florida and to identify predictors of burdensome transitions. We identified 311 newly enrolled dual-eligible ALF residents in the state of Florida in 2003 with at least one hospital or nursing home admission between 2003 and 2004. We linked state Medicaid enrollment records, state vital records, Medicare, and Medicaid claims data to construct resident history for these individuals and identify care transitions. Transition was defined as transfer among the following settings: ALF, hospital, and nursing home. We examined the association between baseline individual characteristics and the number of transitions. We used Poisson regression model to examine predictors of the number of transitions and logistic regression model to estimate the effect of these predictors on the likelihood of having burdensome transitions. The study sample
had a mean age of 82 years and 77% were female. We found that 44% of residents had one transition, 28% had two transitions, and 28% had three or more transitions during the study period. Female, widowed, never married, ADL/IADL limitations, and comorbidities were associated with more transitions while older age, Black or Hispanic, and having caregiver were associated with fewer transitions. Future studies should investigate intervention strategies aimed at reducing burdensome transitions and promote aging in place in this vulnerable population.

THE AGE-IN-PLACE DISPARITY OF ASSISTED LIVING: MEDICAL NEEDS IN NON-MEDICAL FACILITIES

C.L. Selder, C.M. Murphy, Consumer Advocates for RCFE Reform, San Diego, California

The assisted living care option continues to evolve from a social model to one that allows residents to age-in-place. To allow aging-in-place is to accept a resident population whose needs are elevated from basic assistance to complex and acute care. Little attention has been given to the inherent risks in caring for medically needy residents in non-medical facilities. This study examined California’s age-in-place policy within San Diego’s assisted living industry and reviewed the results in terms of California’s assisted living regulations. Using public records obtained from California’s Department of Social Services, this study collected data from state-issued licenses and waivers on 632 assisted living facilities in San Diego, CA (i.e. authorizations for hospice, bedridden and dementia residents). The resulting trend was reviewed in conjunction with California regulations (Title 22). 73% of assisted living facilities were authorized to care for at least one medically needy resident. 14% of facilities were authorized to have 50% or more (up to 100%) of their capacity as medically needy residents. Title 22 does not require facilities to staff skilled medical professionals, or maintain staffing ratios for any mix of residents. This study identified that a significant number of facilities are electing to permanently take on the responsibility of frail, medically needy residents, without the additional requirements of medical staff or staffing ratios.

INNOVATION IN RESIDENTIAL CARE FACILITIES: THE ASSOCIATION BETWEEN EHR USE AND RCF CHARACTERISTICS

J. Davis, 1. Management and Marketing, The University of Alabama, Tuscaloosa, Alabama, 2. Center for Mental Health and Aging, Tuscaloosa, Alabama

An organization is innovative only if the processes, programs, or products are implemented in advance of an external market demand. Thus, rarity (as well as timing) is an integral feature of innovation. Research on the use of electronic health records (EHR) reveals that while they are steadily increasing, their use among residential care facilities (RCFs) is rare. This study explored the organizational factors associated with the use of EHR within RCFs. Given that research has found that organizations that are innovative in one service area may also be innovative in others, we hypothesize that using EHR will be associated with other types of innovations in RCFs. The data come from the 2010 National Survey of Residential Care Facilities. There were 2,302 facilities in the sample. The data were analyzed using the logistic regression accounting for the stratified nature of the survey. The results show that 20 percent of RCFs reported using EHRs. These facilities were also more likely to have higher levels of nurses to resident ratios, use a functional assessment tool, have a designated dementia/Alzheimer’s unit, allow residents to have pets, and have a physician or pharmacist review medication orders. Furthermore, the administrators of these facilities were more likely to have a baccalaureate degree than were administrators of facilities that did not use an EHR. These findings suggest that innovation can be present across various structures and processes within RCFs. Further research is required to understand the relationship between innovation and resident quality of care/quality of life.

JOB ABANDONMENT AND STAFF TURNOVER IN ASSISTED LIVING

E. Sikorska-Simmons, UCF, Orlando, Florida

Job abandonment is recognized as a major problem in long-term care facilities. This self-initiated separation (i.e., voluntary turnover) is unexpected by administrators and is frequently referred to as “no call/no show turnover.” Although a considerable body of research exists on staff turnover in long-term care facilities, little is known about job abandonment as a distinct type of turnover. Therefore, the purpose of this study was to examine factors associated with job abandonment among staff in assisted living (AL). The sample included 950 staff in twenty-two AL facilities. All staff members who were hired and paid by the facility during a twelve-month period were assessed. Turnover data were collected in interviews with administrators and through the review of facility records. Descriptive statistics and logistic regression were used to identify factors associated with job abandonment. Of the 950 staff members assessed, 390 (41%) left their jobs during the twelve-month period. One hundred and five (27%) were dismissed, and 282 (72%) left voluntarily. More than one-third of the voluntary leavers (105 or 37%) abandoned their jobs. Compared to other voluntary leavers, they tended to be younger, non-white, U.S. born, full-time workers, and they were more likely occupy paraprofessional positions. This research suggests that job abandonment constitutes a major problem in AL. More research is needed to better understand it as a distinct type of turnover. Efforts to reduce staff turnover might be more effective if they specifically target job abandonment.

SESSION 685 (PAPER)

POLICY, COSTS, AND SERVICE UTILIZATION IN STATE MEDICAID PROGRAMS

IMPLICATIONS OF RHODE ISLAND’S GLOBAL MEDICAID WAIVER FOR REBALANCING LONG-TERM CARE UNDER THE ACA

Federal approval of the Global Waiver (GW) in 2009 provided Rhode Island (RI) with greater flexibility to modify its Medicaid program. Because 89% of long-term care (LTC) expenditures in RI are directed toward institutional settings, a primary goal was to facilitate the state’s efforts to shift the locus of LTC to non-institutional settings. This study draws lessons from RI’s experience with the GW for the LTC rebalancing provisions of the Affordable Care Act (ACA). Data derive from 325 archival sources and 26 semi-structured interviews. Results suggest that prospectively documenting home- and community-based services (HCBS) capacity is necessary to ensure that sufficient resources are available to meet the complex care needs of a larger service clientele. Results also suggest that increased reimbursement is especially important for attracting participating providers; so too is maintaining sufficient numbers of state regulators for purposes of monitoring quality. Ultimately, the distribution of LTC spending is likely to remain stagnant given just how difficult it is for laggard states such as RI to make more than marginal progress even with the provision of additional options and incentives that otherwise should promote rebalancing. Nursing home care continues to be a mandatory benefit while HCBS remains an optional benefit states may offer at their discretion. This leaves investments in HCBS especially vulnerable to the vagaries of state budget and
IMPLICATIONS OF RHODE ISLAND’S GLOBAL WAIVER FOR DESIGNING AND IMPLEMENTING LONG-TERM CARE REFORM

C.A. Graham, D. McDonnell, J. Stiles, K. Foster, S.L. Ivey, UC Berkeley School of Public Health, Berkeley, California

As part of Medicaid expansion related to the implementation of the Affordable Care Act, between May 2011 and June 2012, California’s Department of Health Care Services transitioned approximately 380,000 Medicaid-only seniors and people with disabilities (SPD) from fee for service Medi-Cal to managed care plans. This is a precursor to the planned transition of over 1 million beneficiaries who are dually eligible for Medicaid and Medicare into Medi-Cal managed care plans, scheduled in California for September 2013. This paper presents results from an evaluation of the SPD transition, including a retrospective telephone survey with beneficiaries and their proxies (N=1,521), as well as 6 supplemental focus groups. Results will examine 1) beneficiaries experiences with notification and enrollment in managed care, 2) beneficiaries experiences accessing care through managed care plans, 3) groups of beneficiaries who were particularly vulnerable during the transition, and 4) the results of efforts to link beneficiaries to managed care plans based on FFS utilization data. Lessons learned from the transition of SPDs to managed care will be discussed in light of further Medicaid expansion activities. In particular, implications for the planned Dual Demonstration Project in California, and Medicaid expansion in other states.

HEALTHCARE UTILIZATION OUTCOMES FOR MEDICAID CUSTOMERS: A COMPARISON OF THE PROGRAM OF ALL-INCLUSIVE CARE FOR THE ELDERLY, HOME AND COMMUNITY BASED SERVICES, AND NURSING FACILITIES

C.L. Wendel, S.T. Landry, S.N. Leedahl, R.K. Chapin, School of Social Welfare, University of Kansas, Lawrence, Kansas

The Program of All-Inclusive Care for the Elderly (PACE) is a capitated healthcare and long term care program that holds great promise for delivering affordable, quality care for dual eligibles based on its model of holistic, coordinated care. While some research establishes the benefits of PACE, there is also wide variation in cost and benefit outcomes across PACE sites and states. The Kansas Department for Aging and Disability Services (KDADS) contracted with the Office of Aging and Long Term Care (OALT), of the University of Kansas, to conduct a cost-benefit analysis of PACE compared to Home and Community Based Services/Frail Elderly (HCBS/FE) and nursing facility (NF) services for Medicaid customers in Kansas. In this presentation, we will present findings on healthcare utilization outcomes. We matched 136 PACE customers to HCBS/FE and NF customers by demographic and functional capacity characteristics using propensity score matching. We tracked hospital admissions and days, ER visits, and long term nursing facility admissions between 2006-2011 using data from MMIS and PACE sites. We will discuss challenges related to securing and comparing data across fee-for-service and capitated Medicaid programs. Results showed similar rates of hospitalization and ER visits across all three groups, but PACE customers experienced significantly fewer days in the hospital (p<.01). Among PACE and HCBS/FE customers, both programs demonstrated overall low rates of long term NF usage that were not significantly different. Additional research is needed to understand use of routine and preventative healthcare across these programs.

HOSPICE EFFECT ON NURSING HOME PATIENT OUTCOMES AND MODERATING EFFECT OF MEDICAID POLICIES

P.L. Gozalo, K. Acquah, V. Mor, S.C. Miller, Health Services, Policy, and Practice, Brown University, Providence, Rhode Island

Objective: Hospice has experienced large growth among nursing home (NH) residents, nearly tripling from 15% of all NH decedents in 2000 to close to 40% in 2010. This study estimates the effect of hospice care and the moderating effect of Medicaid NH reimbursement policies on end-of-life NH hospitalizations. Population Studied: All decedents in 15,854 NHs in the U.S.A. spanning 10 years, July 1, 1999 to June 30, 2009 (N=3,199,660). Methods: The primary outcome was hospitalization in the last 30 days of life. Independent variables were hospice election before death (yes/no), and two Medicaid state NH policies: Medicaid NH payment rates, and the presence of Medicaid case-mix reimbursement. Medicare Part A claims and NH resident assessment data (MDS) were longitudinally concatenated for each NH decedent. Facility fixed effects estimation, adjusting for patient case-mix and for time-varying facility characteristics, was used for patient level analyses. Hospice propensity scores were used to control for selection on observable risk factors. Results: Twenty-six percent of hospice and 42 percent of non-hospice residents were hospitalized in the last 30 days of life. Adjusted estimates show hospice reduces the odds of hospitalizations in the last 30 days of life by 50% (AOR 0.504; 95%CI 0.498-0.512). Higher NH Medicaid reimbursements (per $10 increment) were associated with reduced terminal hospitalizations (AOR 0.912; 95%CI 0.894-0.921), while case-mix reimbursement had a small increasing effect (AOR 1.005; 95%CI 1.002-1.009). Conclusions: Hospice is associated with reduced terminal hospitalizations among NH decedents, and Medicaid NH reimbursement policies have an independent effect.
CELLULAR SENESCENCE AND INFLAMMATION
Chair: J. Sedivy, Brown University, Providence, Rhode Island

Replicative cellular senescence is an important tumor suppression mechanism and also contributes to aging. Progression of both cancer and aging include significant epigenetic components, but the chromatin changes that take place during cellular senescence are only beginning to emerge. We used high throughput methods to map genome-wide chromatin chromatin accessibility. In contrast to growing cells, whose genomes are rich with features of both open and closed chromatin, the profiles of senescent cells are significantly smoothed. This is due to signal loss in promoters and enhancers of active genes, and signal gain in heterochromatin gene poor regions. Chromatin of major retrotransposon classes, Alu, SVA and L1, becomes relatively more open in senescent cells, affecting most strongly the evolutionarily recent elements, and leads to an increase in their transcription and ultimately transposition. Constitutive heterochromatin in centromeric and peri-centromeric regions also becomes relatively more open, and the transcription of satellite sequences increases. The peripheral heterochromatic compartment becomes less prominent, and centromere structure becomes notably enlarged. These epigenetic changes progress slowly after the onset of senescence, with some, such as mobilization of retrotransposable elements, becoming prominent only at late times. Retrotransposition is known to destabilize genomes, and hence preventing its activation may have therapeutic benefits.

STEM AND PROGENITOR CELL SENESCENCE IN AGING
J. Van Deursen, D. Baker, R. Weaver, Mayo Clinic, Rochester, Minnesota

Senescent cells accumulate with aging and have been causally implicated in aging, but which cell types are subject to cellular senescence is unclear. Mice with low amounts of BubR1 accumulate large amounts of p16INK4a positive-senescent cells in eye, skeletal muscle, and fat, at a young age and develop age-related pathologies in these tissues. Clearance of senescent cells from these animals, either by genetic inactivation of p16INK4a or drug-induced apoptosis considerably delays premature aging. To understand the mechanism of senescence mediated tissue dysfunction in this progeroid model we FACS sorted various cell types from skeletal muscle and fat of BubR1 progeroid mice and analyzed them for the presence of senescence markers. Our data indicate that progenitors rather than stem cells or terminally differentiated cell types express p16INK4a and other senescence markers. Our findings provide evidence that progenitor cell senescence contributes to age-related decline in tissue function and regeneration.

SENESCENT CELLS: YIN AND YANG
J. Campisi, Buck Institute, Movato, California

Cellular senescence suppresses cancer by arresting the proliferation (growth) of cells at risk for malignant transformation. Senescent cells arrest growth, essentially irreversibly, and adopt complex phenotype that entails the secretion of numerous inflammatory cytokines, growth factors and proteases (the senescent-associated secretory phenotype or SASP). Senescent cells also accumulate with age and at sites of age-related pathology, both degenerative and preneoplastic. Several lines of evidence suggest that the senescent cells that accumulate with age, in large part by virtue of the SASP, cause or contribute to age-related pathology, including, ironically, late-life cancer. We find that certain SASP factors can, indeed, drive phenotypes associated with aging. We also find that other SASP factors can be beneficial, particularly under transient conditions such as wound healing. Thus, the SASP may have evolved to promote wound healing and tissue repair. However, as senescent cells increase and persist in aging tissues, their presence may become maladaptive and thus drive aging phenotypes.

SESSION 695 (SYMPOSIUM)

PHYSIOLOGICAL DYSREGULATION, STATISTICAL DISTANCE, AND AGING
Chair: A.A. Cohen, Université de Sherbrooke, Sherbrooke, Quebec, Canada
Discussant: A.S. Karlamangla, David Geffen School of Medicine at UCLA, Los Angeles, California

Many researchers believe that aging is a result of progressive physiological dysregulation of homeostatic regulatory networks. A new approach to measuring physiological dysregulation is based on the statistical or Mahalanobis distance (MD) of biomarker profiles, a way of identifying how normal or strange a patient’s profile is relative to a reference population. Previous work has shown that MD for certain combinations of markers is highly predictive of age and risk for health outcomes including frailty, mortality, and chronic diseases. Here, we seek to assemble presentations that follow up on these initial observations by either testing the validity of the approach under differing conditions or by applying MD in new ways. Leroux et al. test the sensitivity of the results on the reference population, comparing MD calculated in one population using another reference population. Milot et al. examine the shape of MD trajectories over time using Bayesian models. Arbeev et al. use long-term data from the Framingham study to incorporate MD in mathematical models examining optimal versus realized trajectories with age. Together, these studies help establish the variety of applications possible for this method.

REFERENCE POPULATIONS FOR STATISTICAL DISTANCE OF PHYSIOLOGICAL DYSREGULATION DEMONSTRATE WITHIN-COUNTRY HOMOGENEITY BUT INTER-COUNTRY HETEROGENEITY OF BIOMARKER PATTERNS IN AGING

Using Mahalanobis Distance (MD) to measure physiological deregulation requires choosing the right reference population (RP). Because MD is calculated using the mean and the covariance matrix of an RP, different RPs could potentially lead to inconsistent results. Here we compare results of analyses on three populations to identify the best RP for each. Two of these populations are American (WHAS and NHANES) while the other is Italian (InCHIANTI). WHAS and InCHIANTI contain many older people and few young while NHANES contains an even age distribution. We thus hypothesized that a subsample of younger people from NHANES could be a better RP for all three populations. Instead, we found that InCHIANTI’s best RP is itself, while the best one for WHAS and NHANES is a subsample of young people from NHANES. We also present data on the implications of sex, race, age, and sample size for RP choice, and discuss biological implications. Objective 1: After attending this activity, participants will be able to discuss the sensitivity of Mahalanobis Distance to different references populations and the implications for choosing a reference population. Objective 2: After attending this activity, participants will understand the biological implications of why reference populations are best drawn from young individuals from a similar cultural milieu.
MULTIVARIATE ANALYSIS OF INFLAMMATORY MARKERS AND THEIR RELATIONSHIP WITH AGE
V. Morissette-Thomas1, A.A. Cohen2, F. Dusseault-Belanger3, V. Legault4, L. Ferrucci1, I. Mathematics, Sherbrooke University, Sherbrooke, Quebec, Canada, 2. Centre Hospitalier de l’Université de Sherbrooke, Sherbrooke, Quebec, Canada, 3. National Institute on Aging, Bethesda, Maryland

Many biodemographic studies use biomarkers of inflammation to understand or predict chronic disease and aging. However, most studies use just one marker at a time, sometimes leading to conflicting results. A multidimensional approach allows a more robust interpretation of the various relationships between the markers. We applied and compared two different multivariate approaches – principal components analysis (PCA) and Mahalanobis distance (i.e., statistical distance, MD) – to 20 inflammatory biomarkers from the InCHIANTI study. With PCA, we found that TNF-a, Soluble (S)TNF-a receptor(R)-I, STNF-a RII, IL6, CRP, IL18, were highly correlated and explained 19% of the variation. We also found a strong positive correlation (r=0.5711, p<2.2e-16) with age for the first component of the PCA. With MD we found that greater distance (i.e., “unusual” combinations of markers) was not necessarily associated with age (r=0.2156, p= 9.292e-12). We discuss the biological implications of these contrasting results.

BAYESIAN ANALYSIS OF PHYSIOLOGICAL DYSREGULATION TRAJECTORIES DURING AGING
E. Milot1, A.A. Cohen1, Q. Li2, L.P. Fried3, L. Ferrucci1, I. Groupe de Recherche Primes, Centre hospitalier universitaire de Sherbrooke, Sherbrooke, Quebec, Canada, 2. Mailman School of Public Health, Columbia University, New York, North Carolina, 3. National Institute of Aging, National Institutes of Health, Bethesda, Maryland

While the state of physiological dysregulation of an individual at a given time can be associated with health outcome risk, how this state was reached may also modulate this risk. Here we computed Mahalanobis distance (MD) from biomarker data to assess the level of physiological dysregulation of subjects followed in longitudinal surveys (WHAS, BLSA, InCHIANTI) of two American and one Italian populations. We fitted Bayesian linear mixed-effect models to estimate the MD trajectory of each individual with age. We then used the parameters quantifying these individual trajectories as predictors of outcome risks in Cox regression models. We found that these parameters can be strong predictors of outcomes. For instance, in InCHIANTI relative mortality risk doubled with each unit basal MD (as measured by the random intercept). We discuss how MD trajectories can be useful not only for prediction but also to understand the role of dysregulation in aging. Objective 1: After attending this presentation, participants will know how we can model individual trajectories of statistical distance to measure changing physiological dysregulation with age. Objective 2: After attending this presentation, participants will have an overview of how estimated individual physiological trajectories can be used to predict outcomes such as mortality.

MATHEMATICAL MODELS OF PHYSIOLOGICAL DYSREGULATION TRAJECTORIES DURING AGING
K.G. Arbeev1, A.A. Cohen2, L. Arbeeva2, E. Milot1, I. Akushevich1, A. Kulminski1, A.I. Yashin2, 1. SSRI, Duke University, Durham, North Carolina, 2. University of Sherbrooke, Sherbrooke, Quebec, Canada

We implemented the recently developed measure of physiological dysregulation based on the statistical distance of biomarker profiles (Cohen et al. 2013, Mech. Ageing Dev., forthcoming) in the frameworks of the stochastic process model of aging (Yashin et al. 2007, Math. Biosci. 208: 538-551). We show that this combination provides a useful approach that allows for evaluating how such a measure of physiological dysregulation is related to different aging-related characteristics such as decline in stress resistance and adaptive capacity (which typically are not observed in the data and thus they can be analyzed only indirectly), and, ultimately, estimating how such dynamic relationships increase the risk of death with age. We illustrate the methodology by application to data on longitudinal measurements of physiological variables and mortality in the Framingham Original cohort. We discuss extensions of the approach aimed at investigating genetic effects on the measure of physiological dysregulation and respective aging-related characteristics.

SESSION 700 (SYMPOSIUM)

COGNITIVE TRAINING: RESULTS FROM THE ACTIVE STUDY AT 10 YEARS
Chair: S. Tennstedt, New England Research Institutes, Watertown, Massachusetts
Discussant: J.W. King, National Institute on Aging, National Institutes of Health, Bethesda, Maryland

Methods to maintain daily function and independence of older adults are of great public interest. ACTIVE was designed to study the effects of cognitive interventions on cognitive abilities as a way to maintain daily function. The study (1998-2010) was a multi-site, randomized, controlled clinical trial (n=2,802) of 3 cognitive training programs - reasoning, memory, and processing speed - hypothesized to improve the targeted cognitive ability and transfer to daily function over time. This symposium presents data at 10 years regarding: 1) training effects on cognitive abilities and IADL function; 2) training effects on a range of secondary outcomes, including driving and mobility, health and quality of life; 3) consideration of methodological challenges to designing and conducting this trial and longitudinal follow-up study; and 4) an assessment of sampling attrition bias and the generalizability of results to the US population. At mean age of 82 years, about 60% of trained participants compared to 50% of controls (p<.05) were at or above their baseline level of self-reported IADL function at 10 years. Training effects on targeted cognitive abilities were maintained for the reasoning and speed-of-processing interventions, but not for the memory intervention. Differential training effects on mobility, health and quality of life were observed. With the use of created sampling weights to correct for attrition bias, the observed training effects can be generalized to the US population. Implications of these findings for the value of cognitive training and design of future studies will be discussed.

COGNITIVE TRAINING: RESULTS FROM THE ACTIVE STUDY AT 10 YEARS

We evaluated the effects of cognitive training on cognitive abilities and everyday function over 10 years. Participants were older adults (age 65-94) studied in the Advanced Cognitive Training for Independent and Vital Elderly (ACTIVE 1998-2010) randomized controlled trial (N=2,802). Participants in each intervention group (memory, reasoning, speed-of-processing) reported less difficulty with instrumental activities of daily living (IADL) (memory: effect size, 0.48; reasoning: effect size, 0.38 [99% CI, 0.02-0.74]; speed-of-processing: effect size, 0.36 [99% CI, 0.01-0.72]). At mean age of 82 years, about 60% of trained participants compared to 50% of controls (p<.05) were at or above their baseline level of self-reported IADL function at 10 years. The reasoning and speed-of-processing interventions maintained their effects on their targeted cognitive abilities at 10 years (reasoning: effect size, 0.23 [99% CI, 0.09-0.38]; speed-of-processing: effect size, 0.66 [99% CI,
COGNITIVE TRAINING IMPACT ON SELF-RATED HEALTH AND DEPRESSION: 10 YEARS LATER

BACKGROUND: Previously, Wolinsky and colleagues have shown that the ACTIVE interventions positively impact depression and self-rated health up to 5 years after training. Our goal is to determine if the effects last through 10 years. METHOD: We used latent growth curve (LGC) and LGC mixture models to test the hypotheses that intervention assignment was related to an overall slower pace of accumulation of depressive symptoms. Similar analyses were conducted for self-rated health. RESULTS: We found no evidence for a significant association between assignment to one of the intervention groups and pace of accumulation of depressive symptoms. We also found no evidence of differential change in self-rated health. DISCUSSION: Intention-to-treat analysis of secondary outcomes related to global measures of mood and self-rated health fail to produce evidence that the ACTIVE cognitive interventions had a time-limited or durable effect on symptoms.

SESSION 705 (SYMPOSIUM)

EARLY LIFE/CHILDHOOD EXPERIENCES AND THE IMPLICATIONS FOR LATE LIFE HEALTH AND MORTALITY
Chair: C. Roan, Sociology, University of Wisconsin, Madison, Wisconsin
Discussant: P. Herd, Sociology, University of Wisconsin, Madison, Wisconsin

This set of papers uses a single data source, the Wisconsin Longitudinal Study, to examine how early life experiences, ranging from childhood abuse to broader family life experiences, shape late life health and mortality. These papers draw on the unique elements of the WLS, which covers over 50 years of the participants’ lives, including sibling and spouse data and high quality prospective measures, to examine these relationships. As a whole, these papers demonstrate the critical importance of early life in understanding a range of health outcomes among older adults.

MILITARY SERVICE AND SMOKING ACROSS THE LIFE COURSE: EVIDENCE FROM THE WLS
P. Herd1, A.S. London2, J. Wilmoth2, 1. UW-Madison, Madison, Wisconsin, 2. Syracuse University, Syracuse, New York

It is widely acknowledged that the military’s pro-smoking culture shaped the smoking patterns of successive cohorts of active-duty personnel. However, few studies have examined the long-term consequences of military service for smoking or taken the potential effects of nonrandom selection into military service into account. This study uses data from the Wisconsin Longitudinal Study to estimate sibling fixed-effect models of the association between veteran status and smoking behavior among a cohort that served during the Cold War era. The models also control for observed demographic, socioeconomic, and personality factors. The results indicate that introducing the family fixed effects significantly improves model fit and approximately 40% of model error variance is explained by the family fixed effect. Military service is significantly related to ever smoking, number of years smoked, and intensity of smoking. Overall, the findings underscore the enduring effects of military service on smoking across the life course.
IDENTIFICATION OF THE SES-MORTALITY GRADIENTS USING SIBLING AND SPOUSE MODELS

D. Kuo, A. Palloni, University of Wisconsin, Madison, Wisconsin

We estimate the relationship between socioeconomic status (SES) and mortality using data from a sample of high school graduates, their siblings and spouses in the Wisconsin Longitudinal Study (WLS). Our goal is to assess the SES gradient while controlling for shared unmeasured factors that contaminate parameter estimates in conventional study designs. Sibling models enable us to remove the effects of shared (unmeasured) early conditions while spouse models reduce biases induced by effects of unmeasured conditions shared by spouses during their adult lives. We include indicators of cognitive abilities (IQ) and of non-cognitive skills (high school rank) that are known to influence the SES-mortality relation. We compare estimates from individual, sibling, and spouse models to identify the overall magnitude of the SES-mortality gradient and to assess the magnitude of the contribution of early conditions and adult traits. To handle paired failure times we use both bivariate probit and multistate hazard models.

GENDER AND THE RECIPROCAL EFFECTS OF SOCIOECONOMIC DISADVANTAGE AND BODY MASS OVER THE LIFE COURSE

T. Pudovska, E.N. Reither, E. Logan, Pennsylvania State University, University Park, Pennsylvania, Utah State University, Logan, Utah

We explore the reciprocal relationship between socioeconomic status (SES) and body mass over the life course. We found that, among women, early-life socioeconomic disadvantage launched interrelated life-course trajectories of higher body mass and lower status attainment producing greater disparities in body mass index (BMI) in later life. This reciprocal disadvantage was not observed among men for two reasons. First, low SES in adolescence, adulthood, and later life was a stronger predictor of women’s than men’s BMI. Second, heavier weight in adolescence and young adulthood was more adversely related to status attainment among women than men. Thus, overweight and obesity should be viewed not only as a health risk but also as a social risk for women. The cultural meanings of body size make women more vulnerable to socioeconomic antecedents and consequences of heavier weight. A biosocial approach should be applied to further elucidate the long-term embodiment of women’s social disadvantage.

CARING FOR MY ABUSERS: CHILD MALTREATMENT AND CAREGIVER DEPRESSION

J. Kong, S. Moorman, Boston College Graduate School of Social Work, Chestnut Hill, Massachusetts, Boston College Graduate School of Sociology, Chestnut Hill, Massachusetts

This study examined depressive symptoms among adult survivors of childhood maltreatment who provide care to their former abusive/neglectful parent(s). Among 1,001 parental caregivers who were selected from the 2003-2005 wave of the Wisconsin Longitudinal Study, 226 respondents had experienced parental abuse or neglect during childhood. Ordinary least squares regression models were estimated. Ordinary least squares regression models were estimated. First, low SES in adolescence, adulthood, and later life was a stronger predictor of women’s than men’s BMI. Second, heavier weight in adolescence and young adulthood was more adversely related to status attainment among women than men. Thus, overweight and obesity should be viewed not only as a health risk but also as a social risk for women. The cultural meanings of body size make women more vulnerable to socioeconomic antecedents and consequences of heavier weight. A biosocial approach should be applied to further elucidate the long-term embodiment of women’s social disadvantage.

SESSION 710 (SYMPOSIUM)

EFFECTIVE AND ETHICAL RECRUITMENT AND RETENTION IN GRANDPARENT CAREGIVER RESEARCH AND INTERVENTION

Chair: C.A. Fruehaufl Human Development & Family Studies, Colorado State University, Fort Collins, Colorado
Co-Chair: M.L. Dolbin-MacNab, Virginia Tech, Blacksburg, Virginia
Discussant: G.C. Smith, Kent State University, Kent, Ohio

The effective and ethical recruitment and retention of custodial grandparents and their families into research studies is central to building greater understanding of this family unit and to developing interventions designed to support them. When examining grandfamilies, researchers often express a desire to have larger, more representative, and more diverse samples. However, given that grandfamilies can be hard to locate and often experience a number of life stressors, they may be difficult to recruit for and retain in research studies. Therefore, questions remain to be answered in reference to effective strategies for locating grandfamilies, recruiting and retaining diverse samples, and treating research participants in an ethical manner. In this symposium, investigators with extensive experience in research focusing on grandparents raising grandchildren will present methodological lessons learned in recruiting and retaining grandfamilies for their empirical studies. The first paper, by Musil and Warner, will address strategies employed in their longitudinal survey research. Dolbin-MacNab and colleagues will address recruitment, retention, and ethical issues in research with the entire grandfamily system. Hayslip’s paper will focus on grandparents in intervention studies, whereas Whitley will follow and address recruitment and retention of African American custodial grandparents in a community-based intervention study. The final paper, which will be presented by Fruehaufl and colleagues, will focus on the usefulness of community-based participatory research to engage grandparents in empirical studies. Smith, the discussant, will integrate the findings from these papers and will address considerations for the effective and ethical treatment of grandparent caregivers in future research studies.

GRANDMOTHER CAREGIVERS AND RESEARCH: ENGAGEMENT FOR THE LONG HAUL

C. Musil, C. Warner, Case Western Reserve University, Cleveland, Ohio

We draw on data from our 5 wave longitudinal study of 485 Ohio grandmothers as caregivers to grandchildren to describe the successes and challenges of survey research to recruit and retain this population. Decisions on sampling (random with supplemental convenience sampling; geographic representation; stratification for race and ethnicity) and recruitment using a multi-layered approach had positive implications for study outcomes. Careful implementation of a data collection strategy using mailed questionnaires, following Dillman’s total design method with advance phone calls at each time point, contributed to success. Factors that enhanced study credibility, built rapport with participants, and yielded strong recruitment and retention over nearly 8 years included tangible (planned correspondence, a study website, and incentives) and intangible (friendly phone presence, diversity of research team, and mutual respect) strategies. Ethical considerations, including the importance of developing relationships and “giving back” to the grandparent community, are discussed within the context of survey research.
CUSTODIAL GRANDPARENT FAMILIES: RECRUITMENT AND RETENTION STRATEGIES FOR FAMILY RESEARCHERS

Drawing from our collective experiences gathering survey, interview, and observational data across three studies of custodial grandparents and their adolescent grandchildren, this presentation will highlight lessons learned in recruiting and retaining grandparent-headed families in research studies. Recommendations will focus on the importance of partnering with community organizations to assist with recruitment and logistical arrangements, building trust with referral sources and potential participant families, utilizing strategies to reduce barriers to participation (e.g., providing transportation or meals), establishing clear eligibility criteria, and selecting data collection methods that are sensitive to the development and needs both grandparents and grandchildren. In addition, we will address ethical considerations that can arise in studies that include multiple grandparent-headed family members. Some of these ethical considerations include participant burden, intra-familial coercion, confidentiality between family members, and appropriate compensation. Suggestions for family-based research with grandparent-headed families will also be addressed, with particular attention given to novel methodological approaches.

CHALLENGES IN RECRUITING AND RETAINING GRANDPARENT CAREGIVERS IN INTERVENTION RESEARCH

B. Hayslip, University of North Texas, Denton, Texas

Intervening productively with grandparent caregivers and their grandchildren to enhance their well-being is paramount. Challenges facing researchers bearing on a given intervention’s ecological and personal relevance are: (1) identifying the target populations of interest (e.g., grandmothers vs. grandfathers, skipped generation vs. co-parenting families, minority vs. Caucasian grandparents); (2) accessing service providers and community-based agency staff who interact with grandfamilies and convincing them of a project’s credibility regarding its nature and goals; (3) communicating ethically yet accurately the overall intent of the project to grandfamilies; (4) availability and accessibility issues particular to the project (meeting locales, group leaders’ schedules, grandparent caregivers’ complicated lives); (5) providing grandparent caregivers with a credible treatment rationale; (6) retaining participants over multiple sessions and after the intervention has concluded; and (7) adapting grandparent caregivers’ needs and experiences to a project’s goals. The effectiveness of strategies for overcoming these barriers will be discussed.

RECRUITMENT AND RETENTION OF AFRICAN AMERICAN CUSTODIAL GRANDPARENTS IN UNIVERSITY-SPONSORED RESEARCH

D. Whiteley1, S.J. Kelley2, 1. School of Social Work Georgia State University, Atlanta, Georgia, 2. School of Nursing Georgia State University, Atlanta, Georgia

African Americans’ participation in research studies has had a conflicted history. But there are research studies that have successfully recruited and retained participants over the life of the project. After attending this session, attendees will be able to identify recruitment and retention (R&R) strategies based on accruing grandparent-headed families to a community-based program, Project Healthy Grandparents (PHG). PHG is a university sponsored collaborative designed to enhance the well-being of custodial grandparents. Since its inception in 1996, the project has served 834 families, including 1,842 grandchildren, with an average annual retention rate of 90%, exceeding other behavioral studies. The multiple R&R approaches used by PHG align with client-focused service delivery systems and incentives. Various elements of the R&R strategies illustrate the necessity to balance project goals with client and community needs. Acknowledging ethical risks specific to families experiencing the effects of child abuse and neglect is also discussed.

COLLABORATING WITH GRANDPARENTS RAISING GRANDCHILDREN FOR COMMUNITY-BASED PARTICIPATORY RESEARCH

C. Fruhauf1, K. Bundy-Fazioli2, L. Yancura2, 1. Colorado State University, Fort Collins, Colorado, 2. University of Hawaii at Manoa, Honolulu, Hawaii

Over the past two decades, increased attention has been given to developing and implementing methods in community-based participatory research (CBPR), which is often used to identify and meet the needs of at-risk populations. CBPR methods seek to engage at-risk persons through an equitable sharing of power. Despite the increase in the number of grandparent caregivers, CBPR is minimally used with grandparent caregivers. This may be due to the difficulty some researchers encounter to establish trusting community connections, as they may be considered outsiders by community members. This paper extends the literature on CBPR principles by describing researchers’ successful recruitment strategies and collaborative working relationships with local and state agencies serving grandparent caregivers. It also discusses the theoretical background of CBPR, the challenges and benefits of using CBPR as a recruitment and retention strategy, and suggests guidelines for ethically using this method to support grandparent caregivers in the community.

SESSION 715 (SYMPOSIUM)

FINDINGS FROM THE PRISM FIELD TRIAL: A TECHNOLOGY-BASED INTERVENTION FOR “AT RISK” OLDER ADULTS

Chair: S.J. Czaja, University of Miami Miller School of Medicine, Miami, Florida
Discussant: J.W. King, National Institute on Aging, Washington D.C., District of Columbia

The Center for Research on Aging and Technology Enhancement (CREATE) conducted a randomized clinical trial that evaluated the efficacy of a computer-based personal reminder, information, and social management (PRISM) system designed to support socialization, memory, and improve overall quality of life of people aged 65+ at risk for isolation. The computer-based system was compared to a booklet version of PRISM. This symposium will present data from the baseline and 6 month outcome assessments regarding system usability and use, technology acceptance, memory complaints, social connectivity, and behavioral integration. S. Czaja will present an overview of the trial; describe the characteristics of the sample; and present data regarding how access to PRISM supported social connectivity. J. Sharit will focus on the usability aspects of the PRISM system and will also discuss the relationship between individual characteristics such as technology experience, perceived health, cognitive abilities, and perceptions of usability. N. Charness will present findings regarding the relationship between depression symptoms and memory complaints and how this varied with participant characteristics and over the course of the trial. W. Boot will describe the digital game feature of the system and present data regarding change in game use over time and predictors of game use and game preference. W. Rogers will discuss individual differences in perceptions of usefulness of PRISM and will present data regarding how access to PRISM impacted on everyday activities. J. King will lead a discussion of these topics and highlight some of the challenges and opportunities associated with the PRISM trial.
PREDICTING TECHNOLOGY ACCEPTANCE THROUGH INDIVIDUAL DIFFERENCES AND PERCEPTIONS OF USEFULNESS AND EASE OF USE

W.A. Rogers1, T.L. Mitzen2, W.R. Boot2, N. Charness1, S.J. Czaja1, A.D. Fisk1, J. Sharit2, 1. School of Psychology, Georgia Institute of Technology, Atlanta, Georgia, 2. Florida State University, Tallahassee, Florida, 3. University of Miami, Miami, Florida

Extant theoretical models of technology acceptance are extremely limited—they do not account for specific characteristics of older adults, have not been empirically tested in the context of senior-focused technologies, and frequently only measure intention to use a technology rather than behavioral integration of a technology into everyday life. The PRISM field trial assessed usage patterns of a computer system specifically designed for older adults. Prior to randomization into the field trial, 300 participants completed a technology acceptance scale regarding their perceptions of ease of use and usefulness of the system. We will report the baseline data to assess the individual difference variables that predict these perceptions. We also analyze usage rates after 6 months to identify the predictors of behavior integration of a computer technology into everyday activities. These data provide insights for broader-based models of technology acceptance to guide design, instruction, and deployment of products for older adults.

DEPRESSION AS A PREDICTOR OF MEMORY COMPLAINTS IN THE PRISM SAMPLE

N. Charness1, W.R. Boot2, S. Czaja2, J. Sharit3, W.A. Rogers1, A.D. Fisk1, I. Psychology, Florida State University, Tallahassee, Florida, 2. University of Miami, Miami, Florida, 3. Georgia Institute of Technology, Atlanta, Georgia

Gilewski et al. (1990) suggested that the Memory Functioning Questionnaire (MFQ) might differentiate depression from minor memory impairment such that Seriousness of Forgetting and Retrospective Functioning scores would tap depressive affect whereas mnemonic usage score would not. We tested these hypotheses in a sample of 300 older adults at risk for social isolation who had been randomized to the PRISM study and who had baseline MFQ and CES-D (depression) scores. Depression score was a moderate predictor for the MFQ scale of General Frequency of Forgetting (r=−.339), and a weak predictor of Retrospective Functioning (r=−.177) but not a significant predictor for Seriousness of Forgetting (r=−.120) nor for Mnemonics Usage (r=−.009). Results suggest than in a sample restricted to older adults with variability in depressive state (M=11, SD = 9), higher depression scale scores would not. We tested these hypotheses in a sample of 300 older adults at risk for social isolation who had been randomized to the PRISM study and who had baseline MFQ and CES-D (depression) scores. Depression score was a moderate predictor for the MFQ scale of General Frequency of Forgetting (r=−.339), and a weak predictor of Retrospective Functioning (r=−.177) but not a significant predictor for Seriousness of Forgetting (r=−.120) nor for Mnemonics Usage (r=−.009). Results suggest that in a sample restricted to older adults with variability in depressive state (M=11, SD = 9), higher depression scale scores are most strongly related to self-reported frequency of forgetting. We will report on changes at the 6-month follow-up.

ASSESSING THE USABILITY OF THE COMPUTER-BASED PRISM SYSTEM

J. Sharit, Univ Miami, Coral Gables, Florida

This presentation will focus on the usability aspects of the computer-based PRISM system over the initial six months of the PRISM trial for the 150 participants who were randomized into this intervention condition. Using web log data, general usability will be assessed by examining the average amount of time participants were engaged with the system as well as increasing or decreasing trends in engagement of PRISM’s various functionalities. In addition, participants’ use of PRISM’s internal help functionalities will be analyzed, including both general help and specific help with the PRISM features. Qualitative data related to usability issues in the form of anecdotal reports from three-month check-in calls and the six-month home visit will also be collected and evaluated. Overall, relationships between these data and measures of age, technology experience, perceived health, and cognitive abilities provide a clearer understanding of the nature and potential sources of usability issues with this system.

PREDICTORS OF OLDER ADULTS’ DIGITAL GAME ACCEPTANCE AND PREFERENCE

W.R. Boot1, N. Charness1, S.J. Czaja1, J. Sharit2, W.A. Rogers1, A.D. Fisk3, 1. Psychology, Florida State University, Tallahassee, Florida, 2. University of Miami, Miami, Florida, 3. Georgia Institute of Technology, Atlanta, Georgia

Recent evidence suggests that digital game play can reverse age-related cognitive decline. However, these benefits will not be realized if digital game-based interventions are poorly accepted by seniors. We discuss barriers to adoption and present the first six months of game-related data from an ongoing clinical trial (the PRISM trial) in which 150 seniors at risk for social isolation were provided with an easy-to-use computer system and internet connection. Digital game use was substantial, with games being one of the most frequently used features of the system, although there were individual differences in game use and game preference. Using this dataset, we explored how digital game play changed over time and predictors of digital game use and game preference using demographic, technology experience, and personality variables. Implications for designing games that are both effective at improving cognition and games seniors are willing and able to play will be discussed.

AN OVERVIEW OF THE PRISM TRIAL AND CHALLENGES TO IMPLEMENTATION

S.J. Czaja1, W.R. Boot2, N. Charness1, A.D. Fisk3, W.A. Rogers1, J. Sharit2, S.N. Nair1, 1. University of Miami Miller School of Medicine, Miami, Florida, 2. Florida State University, tallahassee, Florida, 3. Georgia Institute of Technology, Atlanta, Georgia, 4. University of Miami, Miami, Florida

Rigorous, empirical evidence about the value of technology in improving the lives of older adults is limited. The efficacy of the PRISM system, designed to socialization, memory, and improve overall quality of life of older people at risk for isolation, was evaluated in a large scale randomized clinical trial. This presentation will present an overview of the trial and data on the characteristics of the PRISM sample, which included 300 ethnically diverse, mostly female (78%) adults aged from 64-98 years who lived alone, had minimal prior computer experience and were of lower SES status (87%). Data will also presented on how the features of PRISM specifically, access to the Internet, email and the photo features supported social connectivity among the participants. Challenges to implementing the trial which included specification of the trial inclusion criteria; outreach to the study sample; and development of protocols to maximize retention will also be discussed.

SESSION 720 (SYMPOSIUM)

FUNCTIONAL HEALTH: HISTORICAL CONTEXT, PRESENT INEQUALITIES, AND RELATIONSHIPS WITH OTHER HEALTH DIMENSIONS

Chair: S. Cavalli, Center for Interdisciplinary Study of Gerontology and Vulnerability, University of Geneva, Geneva, Switzerland, NCCR LIVES, University of Geneva, Geneva, Switzerland
Co-Chair: C. Ludwig, School of Health, University of Applied Sciences Western Switzerland, Geneva, Switzerland
Discussant: J. Kelley-Moore, Department of Sociology, Case Western Reserve University, Cleveland, Ohio

In the last decade, functional health has been a cardinal focus of gerontology. Given its etiologic importance as a predictor of well-being, disablement, social participation, institutionalization, and mortality, research on functional health cannot be under valued. There are many dimensions to this concept, ranging from actual physical limitations to subjective or perceived disability. This symposium brings together studies from the U.S. and Switzerland to explore the evolution of functional health over the last 30 years, the impact of socioeconomic inequalities, and the relationship with other dimensions of...
health. To provide additional insight, two studies examine subsets of vulnerable individuals: Cancer survivors and low back pain sufferers. Three papers are drawn from a large repeated cross-sectional survey. In 1979 and 1994, data were collected in two areas of French-speaking Switzerland. In the 2011 third wave, the survey was extended to additional geographical areas (German- and Italian-speaking Switzerland), and new fields of investigation were implemented in the questionnaire (e.g., pain). The samples (N=1519, N=1783, and N=4200, respectively) were randomly selected in population records and stratified by age and gender. They comprised individuals aged 65 and over either community-dwelling or living in nursing homes. The fourth paper draws from a rare long-term study of cancer survivors. Taken together, this symposium contextualizes the study of functional health by providing an historical, cross-national, and multidimensional perspective.

TRENDS AND SOCIOECONOMIC INEQUALITIES OF FUNCTIONAL HEALTH OVER 30 YEARS IN SWITZERLAND

S. Cavalli1,2, J. Kelley-Moore3, T. Bhatta3, A. Tholomier1,2, M. Oris1,2,4. 1. Center for Interdisciplinary Study of Gerontology and Vulnerability, University of Geneva, Geneva, Switzerland, 2. NCCR LIVES, University of Geneva, Geneva, Switzerland, 3. Department of Sociology, Case Western Reserve University, Cleveland, Ohio, 4. Institute of Socio-Economics, University of Geneva, Geneva, Switzerland.

In this paper we analyze the trends and the socioeconomic determinants of functional health (ADL) using data from a repeated cross-sectional study conducted in two French-speaking areas of Switzerland in 1979, 1994, and 2011. The samples, randomly selected, comprised individuals aged 65 and over, either community-dwelling or in living a nursing home. Results show a decline in late-life disability during the past three decades. However, if between 1979 and 1994 there is an improvement in functional health at all ages, between 1994 and 2011 we observe a decline in the prevalence of ADL disability only among people aged 80 and over. The positive trends are partly explained by the socio-professional structure transformations (reduction of farmers and blue-collar workers). Functional health is related to socioeconomic factors like education, occupation, and income. These reported changes over time are discussed in terms of “democratization”, or not, of aging.

PERCEIVED DISABILITY IN OLDER ADULT CANCER SURVIVORS

H.T. Renzhofer, J. Kelley-Moore, G. Deimling, S. Brown. Case Western Reserve University, Cleveland, Ohio.

Older adult cancer survivors are becoming more prevalent as the population continues to age, and as cancer treatment extends the life of those diagnosed with this disease. Thus, more older individuals are likely to live decades beyond treatment but with cancer-related disability. This research examines how cancer-related and other illness factors influence survivors’ perception of being “disabled” among 321 long-term survivors. We constructed a scale of perceived disability and identified those who reported perceived disability on any item. Logistic regression models estimated likelihood of being “disabled.” Interestingly, cancer-related factors do not predict whether or not survivors consider themselves disabled. Further, survivors with greater functional difficulties are actually less likely to consider themselves disabled. However, survivors who are black, and those with more co-morbidities are more likely to consider themselves disabled. The data suggest that cancer-related factors are less important than other health factors in determining survivors’ perception of disability.

FUNCTIONAL HEALTH COMPONENTS IN HEALTH-RELATED QUALITY OF LIFE AFTER AGE 65

C. Luthy1, C. Ludvig2, D. Spini3,4, C. Cedraschi1,2, F.R. Hermann5, 1. Division of General Medical Rehabilitation, Geneva University Hospitals and University of Geneva, Geneva, Switzerland, 2. School of Health, Geneva, University of Applied Sciences Western Switzerland, Geneva, Switzerland, 3. Institute for Social Sciences, University of Lausanne, Lausanne, Switzerland, 4. NCCR LIVES, University of Lausanne, Lausanne, Switzerland, 5. Division of Clinical Pharmacology and Toxicology, Geneva University Hospitals and University of Geneva, Geneva, Switzerland, 6. Department of Internal Medicine, Rehabilitation and Geriatrics, Geneva University Hospitals and University of Geneva, Thonex, Switzerland.

This communication reports findings from a large survey conducted on a sample of >3000 Swiss community-dwelling individuals aged 65 and above who completed the EQ5D questionnaire, a measure of Health-Related Quality of Life (HRQoL). The scale comprises measures of functional abilities (Mobility, Self-Care, Usual Activities), Pain/Discomfort, and Anxiety/Depression, along with an estimate of global health rated on a 0 to 100 visual analog scale (VAS). Results demonstrate an average VAS of 75, ranging from 71 to 79 between the oldest and youngest groups. Age accounts for more than 10% of the variance for Mobility, Self-Care, Usual Activities, slightly less for Pain/Discomfort, and is not significant for Anxiety/Depression. Regional, gender and education differences are significant on most measures, although the variance explained is marginal (<5%). The results suggest that functional dimensions remain central indicators of HRQoL in aged populations.

CAN LOW BACK PAIN BE CONSIDERED AS A RISK FACTOR OF FUNCTIONAL LIMITATIONS?

This communication reports findings from a large survey conducted on a sample of >3000 Swiss community-dwelling individuals aged 65 and above who completed the Delphi DOLBaPP, a scale providing a standardized definition of Low Back Pain (LBP) for use in prevalence studies. Results show that 30% of the sample report LBP, among which 52% present “most days” or “every day” pain and limited activities in the same proportion. Increasing age is associated with pain frequency and duration. As compared to a matched pain-free sample, LBP show lower scores on Mobility, Usual Activities and Anxiety/Depression items of the EQ5D scale, a measure of Health-Related Quality of Life (HRQoL). Results suggest that LBP tends to become a permanent condition with increasing age, progressively affecting functional and psycho-emotional dimensions of HRQoL. Age-related chronic LBP appears to be a condition that places individuals at risk of developing functional limitations and psychological difficulties.

SESSION 725 (SYMPOSIUM)

GENDER AND OLDER WORKERS: NEW PERSPECTIVES ON AN OLD CHALLENGE

Chair: A. Ni Leime, Social Gerontology, National University of Ireland, Galway, Galway, Ireland
Co-Chair: C. Krekula, University of Karlstad, Karlstad, Sweden
Discussant: T. Calasanti, Virginia Polytechnic Institute and State University, Blacksburg, Virginia

In response to population aging, many countries have increased the age at which citizens are eligible to receive retirement pensions. Other
countries are considering similar measures, leading researchers to pay greater attention to older workers. Representing different national contexts (the UK, Ireland, USA, Sweden), the four papers in this symposium consider how policies designed to extend working life are experienced differentially by older male and female workers in varying socio-economic contexts. Each paper identifies an aspect of the challenges associated with the study of late working life and retirement. Collectively, the papers engage with recent theoretical debates, and draw on feminist, masculinist and life-course approaches. Vickerstaff and Loretto draw on UK data to highlight how the understanding of the concept of retirement itself is gendered and evolving. Ni Léime illustrates how adopting a life-course analysis enhances understanding of the gendered differences associated with retirement decision-making in Ireland. Street and Bagchi-Sen analyse by gender and discuss policy changes in the rapidly-changing prospects for older U.S. workers in the context of recession. Drawing on masculinist theory, Krekula emphasizes the way in which age is used as an organizing dimension at male-dominated workplaces involving heavy labor in Sweden resulting in older men occupying less-favoured positions. Together, the papers interrogate the idea that policies designed to extend working life are (1) experienced equivalently by women and men; or, (2) can unproblematically address the challenges posed by demographic aging.

GENDERED MEANINGS OF RETIREMENT

W.A. Loretto, S.A. Vickerstaff. Business School, University of Edinburgh, Edinburgh, United Kingdom

We are witnessing profound changes to retirement in Europe. In the late twentieth century, retirement appeared to have evolved into a predictable part of the life course, but is now undergoing a series of changes such that the word itself is often qualified (e.g. ‘gradual’ or ‘partial’ retirement). Whilst there is general agreement that retirement is changing, there is considerable debate about how and why. So far, a neglected aspect of the discussion is the extent to which the very notion of retirement is gendered. In this paper, we consider how women and men talk about retirement and their aspirations for it with reference to a qualitative study which interviewed 96 people over the age of 50 in the UK. Session participants will gain understanding of the gendered meanings of “retirement” and insight into the implications for retirement policy within the UK context.

RETIREMENT DECISIONS IN IRELAND: IMPACTS OF GENDER AND THE LIFE COURSE

A. Ni Leime. Social Gerontology, National University of Ireland, Galway, Galway, Ireland

Demographic aging has led governments in many countries to introduce policies designed to extend working life. In Ireland such policies include the delaying of state pension payments and the removal of mandatory retirement age. This paper draws on data from 105 semi-structured interviews with men and women aged 50 – 64 at various grades in the Irish civil service. A life course analysis explores how the previous work-life biographies of individuals impact on their retirement decisions and finds evidence of cumulative advantage and disadvantage, influenced by gender, by position in the organisational hierarchy and by employment status (whether employees are long-term workers or not). The research also found that legislation, policy, conditions in the economy and gendered norms inside and outside the workplace impact on retirement decision-making. Symposium attendees will gain understanding of how a life-course analysis enhances our comprehension of the gender-differentiated impacts of policy designed to extend working life.

GENDER, OLDER WORKERS AND LABOR MARKET INTERMEDIARIES IN THE UNITED STATES

D. Street, S. Bagchi-Sen. Department of Sociology, University at Buffalo, SUNY, Buffalo, New York

In the early 2000s, looming Baby Boomer retirements (fuelled by large retirement nest eggs) hinted at possible labor market shortages. One policy approach to stem the tide of talent lost to early retirement was using labor market intermediaries (LMIs). Instead of retiring altogether, LMIs could assist Boomers’ transitions into appealing and creative bridge jobs, switching from demanding (but lucrative) careers to less remunerative but intrinsically rewarding pre-retirement work. We report findings from field research conducted in Arizona, proposed under assumptions of early retirement, but executed after the economic downturn. The women (n=115) and men (n=110) we expected to report using LMIs (n=6) to identify novel pathways into rewarding bridge jobs instead recounted foreclosures, emergency food pantries, and desperate attempts to find employment. Attendees will understand (1) gendered differences in older workers’ experiences and (2) how policies shifted focus from acquiring dream jobs to employability in response to new economic conditions.

AGE, AGEING AND MASCULINITIES IN HEAVY LABOR

C. Krekula. Karlstad University, Karlstad, Sweden

In response to ageing populations, many countries have extended working life through delaying the statutory age for retirement. Physically demanding work is a particularly challenging issue in this regard. In this paper I illustrate age as an organizing principle and discuss the meaning of old age within male-dominated professions involving heavy labor. In analyzing data from Swedish firefighters I discuss how notions of ageing and masculine norms shape older workers’ positions. The analyses are based on interviews and on written comments that were provided in conjunction with questions in a survey conducted among 1176 employees at 25 randomly selected fire stations. The results indicate that shifting to physically lighter jobs on the one hand make it possible to continue in the profession, on the other hand may result in older employees being relegated to lower positions in the local informal age hierarchies.

SESSION 730 (SYMPOSIUM)

I’VE GOT YOU UNDER MY SKIN: IMPLICATIONS OF SOCIAL TIES FOR PHYSICAL HEALTH

Chair: K.S. Birditt, Institute for Social Research, University of Michigan, Ann Arbor, Michigan

This symposium examines the pathways by which relationships “get under the skin” to influence physical health. Several dimensions of physical well-being are considered including self-reported physical health, the hypothalamic pituitary adrenal axis, the cardiovascular system, and the brain. Mogle and colleagues examined the effects of planning goals with romantic partners on daily interpersonal stress and self-reported physical symptoms. The more planful individuals reported fewer arguments and were less reactive to arguments reporting fewer physical symptoms. Birditt assessed links between social networks, daily social interactions and diurnal cortisol rhythms (HPA axis marker) among middle-aged and older adults. Individuals with larger close networks and individuals who experienced fewer negative daily interactions had lower bedtime cortisol levels. Zarit and colleagues studied dementia family caregivers to examine associations between the use of adult day care services and biological indicators of stress. ADS use had same-day effects on cortisol levels and lagged effects on dehydroepiandrosterone-sulfate (DHEA-S; HPA axis marker). Sherman and colleagues investigated links between social support, physical activity, and volume of subcortical emotional reward systems among older adults. More social support was correlated with smaller right amygdala volume. Luong and Charles examined age differences in cardiovascular reactivity to negative interactions with a stranger. Older adults exhibited less cardiovascular reactivity (lower blood pressure/pulse rate reactivity) than younger adults. Together, these papers provide compelling new evidence for the
influential role of relationships on physical health via multiple physiological pathways.

**JOINT GOAL SETTING BY SPOUSES: EFFECTS ON DAILY STRESS AND PHYSICAL HEALTH**

J. Mogle, J. Gere, D. Almeida, L.M. Martire, *Center for Healthy Aging, Penn State University, State College, Pennsylvania*

Using data from the MIDUS, we examined the effects of planning goals with a romantic partner on daily interpersonal stress (exposure and severity) and physical symptoms. Participants (N = 2801) completed baseline measures of planning together with their partner and their relationship quality. A subset (N = 717) also participated in an 8-day daily diary assessment, where they answered questions about daily stressors and physical symptoms at the end of each day. Results showed that people who were less likely to plan together with their partner reported more arguments with their partner and appraised these arguments as more stressful. On days when they argued with their partner, those who planned with their partner less were also more likely to report experiencing more physical symptoms. Implications of joint goal setting and the impact on daily life will be discussed with regard to long term relationship satisfaction.

**IMPLICATIONS OF SOCIAL NETWORKS AND DAILY SOCIAL INTERACTIONS FOR DIURNAL CORTISOL RHYTHMS**

K. Birditt, *Institute for Social Research, University of Michigan, Ann Arbor, Michigan*

Although social relationships are associated with health, the pathways that account for this link are still unclear. This study examined associations among social networks, daily social interactions, and cortisol (an indicator of HPA axis activity). Participants included 110 adults ages 40 to 95 who completed daily phone interviews every day for 14 days. Participants completed diagrams for their close and irritating networks and reported their social interactions every day. Participants also provided saliva samples which were analyzed for cortisol. Analyses controlling for age and gender revealed that individuals with larger closer networks had lower bedtime cortisol and individuals with larger ambivalent networks had higher overall cortisol levels (AUCg). Individuals who reported more frequent daily negative interactions had higher bedtime cortisol. Thus, the quality of social networks, daily interactions and the HPA axis may be important pathways by which social ties influence health.

**FAMILY CAREGIVERS’ RESPONSES TO DAILY STRESSORS: EFFECTS OF ADULT DAY SERVICES**

A group exposed to high levels of chronic stressors, family caregivers, has increasingly been the focus of studies of biological markers of stress. In this presentation, we discuss the methods and findings of the DaSH Study, which focuses on family caregivers whose relatives with dementia were using Adult Day Services (ADS). ADS creates a large decrease in stressor exposure for caregivers on days their relative attend the program compared to days when they do not. A sample of 173 caregivers completed 8 days of daily interviews and provided 5 saliva samples on each day, including days their relative attended and did not attend ADS. ADS use had same-day effects on cortisol levels and lagged effects on dehydroepiandrosterone-sulfate (DHEA-S). Increases in DHEA-S following ADS use were associated with positive affect. Findings demonstrate the impact of daily stressors on caregivers’ biological responses and the potential for biological markers in treatment evaluation.

**THE RELATIONSHIP BETWEEN SOCIAL SUPPORT AND EMOTIONAL REWARD BRAIN SYSTEMS IN THE ELDERLY**

S. Sherman, Y. Cheng, D. Schnyer, K. Fingerman, *University of Texas at Austin, Austin, Texas*

Research links older adults’ social and physical activities to cognitive well-being. This study examined daily experiences and the volume of subcortical emotional reward systems to better understand this relationship. Nineteen adults aged 60 to 78 completed daily reports of activities and mood while wearing an actigraph continuously for 10 days. Actigraphs are motion sensitive devices that measure physical activity and sleep. In addition, participants completed a series of cognitive tests and underwent structural magnetic resonance imaging (MRI). The results suggested that social support was associated with cognitive performance and amygdala volume. Specifically, more social support was correlated with better associative memory performance (r = -.49, p < .05) and smaller right amygdala volume (corrected for intracranial volume; r = -.45, p < .05). Discussion focuses on associations between brain structures, cognitive performance, and daily activities in late life.

**AGE DIFFERENCES IN AFFECTIVE AND CARDIOVASCULAR RESPONSES TO A NEGATIVE SOCIAL INTERACTION**

G. Luong1, S.T. Charles2, 1. Affect Across the Life Span Research Group, Max Planck Institute for Human Development, Berlin, Germany, 2. University of California, Irvine, Irvine, California

Older age is associated with less affective reactivity to interpersonal tensions (Birditt & Fingerman, 2003). It is unclear, however, whether older adults’ social partners treat them more kindly (Fingerman & Charles, 2010) or older adults are more adept at emotion regulation in social contexts (Blanchard-Fields, 2007). The current study subjected 80 younger and 79 older adults to a controlled negative social interaction with a confederate. Although younger and older adults interacted with equally negative confederates, older adults exhibited less negative affect/diastolic blood pressure/pulse rate reactivity and more pronounced affective recovery following the task. Age differences in diastolic blood pressure reactivity were larger among the Chinese Americans compared to the European Americans. Coping goals and emotion regulation strategies partially explained age differences. In sum, older adults’ prioritization of different goals and more effective use of emotion regulation may help to dampen reactivity to, and promote greater recovery from, negative social exchanges.

**SESSION 735 (SYMPOSIUM)**

**IDENTIFYING PATHS TO OPTIMAL AGING: CONTRIBUTIONS FROM UNIQUE COHORT STUDIES**

Chair: H.H. Dodge, Oregon Health & Science University, Portland, Oregon, University of Michigan, Ann Arbor, Michigan, University of Pittsburgh, Pittsburgh, Pennsylvania

Discussant: T.M. Gill, Yale University, New Haven, Connecticut

Discussion: J. Kaye, Oregon Health & Science University, Portland, Oregon

It is of significant clinical and public health importance to detect older adults at risk of developing adverse health outcomes so that cost effective prevention strategies can be designed to promote optimal aging. However, each individual differs considerably in their pre-morbid conditions including psychological well-being, cognitive functions, and daily activity levels. As a result, applying aggregated population norms to identify those at risk often fails. An alternative and more informative approach is to identify the at-risk population is to monitor intra-individual changes over time and classify heterogeneous aging paths using longitudinal data. In this symposium, we present 4 papers, each using unique and well-established longitudinal cohort studies to identify paths to optimal aging. The first paper uses the Yale Precipitating Events Project
In longitudinal studies of healthy aging, missing data that depend on unobserved values can bias estimates of effects of predictors of change. In the Einstein Aging Study we partially correct for this bias by jointly modeling change in the Free and Cued Selective Reminding Test (FCRST), an in-person instrument used to assess episodic memory, with the Memory Impairment Screen for Telephone (MIST), which was conducted at Oregon Health & Science University to identify those at risk of developing dementia. Using these 4 unique longitudinal studies, each presenter revolutionizes our understanding towards optimal aging.

CORRECTING BIAS IN EFFECTS OF EFFECTS OF PREDICTORS OF LONGITUDINAL CHANGE DUE TO NON-RANDOM MISSINGNESS USING AUXILIARY DATA
C.B. Hall, C. Wang, M.J. Katz, R.B. Lipton, Epidemiology and Population Health, Albert Einstein College of Medicine, Bronx, New York

In longitudinal studies of healthy aging, missing data that depend on unobserved values can bias estimates of effects of predictors of change. In the Einstein Aging Study we partially correct for this bias by jointly modeling change in the Free and Cued Selective Reminding Test (FCRST), an in-person instrument used to assess episodic memory, with the Memory Impairment Screen for Telephone (MIST), which was conducted at Oregon Health & Science University to identify those at risk of developing dementia. Using these 4 unique longitudinal studies, each presenter revolutionizes our understanding towards optimal aging.

LATE-LIFE PREDICTORS OF OPTIMAL AGING: THE HAWAII LIFESPAN STUDY
B. Willeon1,2, R. Chen1, K. Masaki1,2, Q. He1, P. Yee1, J.S. Grover1,2, T. Donlon1, C.L. Bell1, I. Kuakini Medical Center, Honolulu, Hawaii, 2. University of Hawaii, Honolulu, Hawaii

Objective: Identify potentially modifiable late-life risk factors predicting optimal aging. Methods: The Hawaii Lifespan Study followed 1,292 American men of Japanese ancestry (mean age 75.7 years, range 71-82) free of major chronic diseases, functional and/or cognitive disability at baseline, in a 21-year prospective cohort study. Using logistic regression, we assessed risk factors predicting three outcomes at ages 85, 90, 95, and 100 years: death; suboptimal aging (survival with chronic disease and/or disability); and optimal aging (survival free of chronic disease and disability). Results: Predictors of optimal aging included biological (BMI, ankle:brachial index, cognitive score, hypertension, inflammatory markers); lifestyle (smoking, alcohol, physical activity), and socio-demographic factors (education, marriage). Cumulative multivariable risk factor modeling demonstrated that probability of optimal aging varied substantially, in a graded manner, up to 19-fold, between those with and those without multiple risk factors. Conclusion: Even in old age the probability for optimal aging may be highly modifiable. Supported by NIA grants 2R01AG027060 and 1R01AG038707.
African Americans. Dr. Lisa Barnes will present her research about diverse sociocultural experiences of African Americans throughout the lifespan that impact cognitive decline. Dr. Cleopatra Abdou will discuss community-based participatory research approaches, created by RCMARs, to recruit and retain older African Americans in cognitive aging research. Funding mechanisms that may facilitate interdisciplinary cognitive aging research in African Americans will be discussed.

**GENETIC INFLUENCES ON COGNITIVE AGING IN AFRICAN AMERICANS**

K.E. Whitfield, Duke University, Durham, North Carolina

Genes are an important source of individual variability for understanding the cognitive aging process. Twin studies offer important insights about the proportion of genes and environment to individual differences in aging. Less well understood is the contribution of genes and environment to variability in aging observed in understudied populations like African Americans. This presentation will discuss findings from the Carolina African American Twin Study of Aging (CAATSA). The CAATSA consists of 265 pairs of twins and members of non-intact twin pairs and consists of 39% men with an average age of 50 years. The result from quantitative genetic analyses suggest that there are genetic contributions to cognitive impairment (43%), memory (0%-49%) and speed of information processing (.32%). Additional findings about how health factors like blood pressure impact genetic and environmental estimates of cognitive functioning as well as suggestions for future directions will be discussed.

**LIFECOURSE FACTORS AND COGNITIVE DECLINE IN OLDER AFRICAN AMERICANS AND WHITES**

L.L. Barnes1, R.S. Wilson1, S. Everson-Rose2, D.A. Evans1, C. Mendes de Leon1, 1. Rush University Medical Center, Chicago, Illinois, 2. University of Minnesota, Minneapolis, Minnesota, 3. University of Michigan, Ann Arbor, Michigan

There is a growing interest in identifying lifecourse factors that may account for health disparities in cognitive aging. Previous studies suggest that social/experiential factors experienced prior to old age affect late-life cognitive function, but most research has focused on older Whites. We examined several early-life factors using data from the Chicago Health and Aging Project, a longitudinal, population-based study of community-dwelling adults aged 65 years and older. In a series of multivariate mixed effects models, we found differential effects by race of early life exposures (SES, personality, and childhood adversity) on cognitive health outcomes. Neither education nor county-level SES in early life predicted change in cognitive function, but neuroticism was related to a higher risk of Alzheimer’s Disease among African Americans. This presentation will discuss findings from the study of community-dwelling adults aged 65 years and older. In a series of multivariate mixed effects models, we found differential effects by race of early life exposures (SES, personality, and childhood adversity) on cognitive health outcomes. Neither education nor county-level SES in early life predicted change in cognitive function, but neuroticism was related to a higher risk of Alzheimer’s Disease among African Americans. Previous studies have found that racial group differences in cognitive function are related to social and environmental factors. This presentation will discuss findings from the study of community-dwelling adults aged 65 years and older. In a series of multivariate mixed effects models, we found differential effects by race of early life exposures (SES, personality, and childhood adversity) on cognitive health outcomes. Neither education nor county-level SES in early life predicted change in cognitive function, but neuroticism was related to a higher risk of Alzheimer’s Disease among African Americans. This presentation will discuss findings from the study of community-dwelling adults aged 65 years and older.

**SESSION 745 (SYMPOSIUM)**

**OPTIMAL CANCER SCREENING: EXAMINING PREDICTORS OF AND STRATEGIES TO ADDRESS UNDER SCREENING AND OVER SCREENING**

Chair: C. Leach, Behavioral Research Center, American Cancer Society, Atlanta, Georgia
Discussant: E.S. Breslow, National Cancer Institute, Bethesda, Maryland

As the population ages and average life expectancy increases in the U.S., issues of primary and secondary prevention become increasingly important. To promote optimal patient-centered care for older persons, strategies must consider factors beyond chronologic age, and address the multiple and complex influences on people’s everyday lives and individual behavior. Research suggests that cancer screening may benefit some older persons while causing a burden to others as well as an unnecessary increase in healthcare expenditures. Optimal screening is defined as patient-centered strategies tailored to an individual’s risk of developing the disease to achieve maximum survival benefit. Certain groups, such as rural populations, continue to be under screened while some older adults with limited life expectancy continue to receive screening with little mortality or morbidity benefit. This symposium will start with two presentations on under screening. First, Dr. Schoenberg will present on the patterns and determinants of breast and cervical cancer under screening among Appalachian women. Next, Dr. Leach will address prevalence and predictors of non-adherence to colorectal surveillance and screening guidelines among long-term cancer survivors. The subsequent two presentations will focus on the importance of life expectancy when making screening decisions. Dr. Bellizzi will explore colorectal screening patterns in adults 75 years and older by 5 year life expectancy. Next, Ms. Garcia will describe the prevalence and characteristics of patient-provider discussions among older adults who receive breast and prostate cancer screening beyond the guideline recommended age. Finally, Dr. Breslow, discussant, will propose recommendations for future research that encourage optimal screening.
COLORECTAL CANCER SCREENING IN OLDER ADULTS BY 5 YEAR LIFE EXPECTANCY

K. Bellizzi1, E.S. Breslau1, 1. HDFS, UConn, Storrs, Connecticut, 2. National Cancer Institute, Bethesda, Maryland

Background: This study describes colorectal screening patterns (according to USPSTF recommendations) in older adults by 5 year life expectancy. Methods: Analytic sample comprised 1,027 men and women 75 years and older from the 2010 National Health Interview Survey. A validated 5 year mortality index was used to assess individual life expectancy. Results: Screening rates varied by estimated 5 year life expectancy: rates were 63.9% in individuals with high life expectancy (<15% probability of 5-year mortality), 56.1% in men and women with intermediate life expectancy (16% to 48% probability), and 52.5% in individuals with low life expectancy (>48% probability). In multivariate logistic regression models, differences by age, education, race/ethnicity, and comorbid conditions were found. Discussion: A large proportion of older adults with low life expectancy continue to be screened despite the low likelihood of any survival benefit. Benefits and harms of continued screening need to be discussed with patients.

PATTERNS AND DETERMINANTS OF BREAST AND CERVICAL CANCER NON-SCREENING AMONG APPALACHIAN WOMEN

N.E. Schoenberg, C.R. Studts, J. Hatcher, Behavioral Science, University of KY, Lexington, Kentucky

Background: Breast and cervical cancer account for nearly one-third of new cases and one-sixth of cancer deaths, respectively, particularly unfortunate since effective modes of early detection should practically eliminate breast and cervical cancer. Methods: We examined patterns of non-screening among women, with a special focus on the significant cancer disparities experienced by Appalachian women. In person interviews were conducted with 222 Appalachian women outside of screening recommendations for Pap tests and mammograms. Results: Participants who were rarely or never screened for breast cancer were also likely to be rarely or never screened for cervical cancer. In addition, four key barriers were identified as independently and significantly associated with being rarely or never screened for both cervical and breast cancer. Discussion: An improved understanding of cancer screening patterns plus the barriers underlying lack of screening may move us closer to developing effective interventions that facilitate women’s use of screening.

MEDICAL, DEMOGRAPHIC AND HEALTH BELIEF PREDICTORS OF COLORECTAL SCREENING AND SURVEILLANCE AMONG CANCER SURVIVORS

C. Leach1, T. Smith1, A. Best1, K. Bellizzi2, K. Stein2, 1. Behavioral Research Center, American Cancer Society, Atlanta, Georgia, 2. University of Connecticut, Storrs, Connecticut

Background: Cancer survivors may experience a recurrence or a second primary cancer. Colorectal cancer (CRC) screening helps identify a recurrence or new cancer early when prognosis is better and treatment is less aggressive. Methods: Data from a cancer registry-based national survey examined the prevalence and predictors of CRC surveillance among 9-year CRC survivors (N=441, mean age=68) and CRC screening among 9-year survivors of other cancers (N=2487, mean age=67). Logistic regression modeled demographic, medical, cancer, and health belief predictors. Results Findings indicated that 90.2% of CRC survivors received surveillance consistent with NCCN guidelines. Predictors of surveillance non-adherence include age, comorbid conditions, perceived susceptibility, perceived barriers, and perceived benefits of screening. Fewer non-CRC survivors (82.7%) met ACS guidelines. Predictors of non-adherence included education, comorbid conditions, perceived barriers and perceived benefits. Discussion: Findings that health beliefs about cancer screening influence adherence to guidelines suggest avenues for intervention.

SCREENING BEYOND THE RECOMMENDED AGE: THE IMPORTANCE OF PATIENT-PROVIDER DISCUSSIONS

K. Garcia, E. Crimmins, Davis School of Gerontology, University of Southern California, Los Angeles, California

Background: Due to patient heterogeneity, guidelines recommend discussion of risks/benefits and consideration of the patient’s health and preference before making a shared decision to screen. This presentation will describe the prevalence and characteristics of patient-provider discussions among adults who undergo screening for breast/prostate cancer past the recommended age. Methods: Data from the ninth wave (2008) of the Health and Retirement Study were analyzed using multiple logistic regression. The analytic sample included respondents with no history of breast/prostate cancer who completed a cancer screening module. Results: Adults over the recommended age (80+) were less likely than younger adults to report having a discussion with a provider before undergoing a screening (OR, 0.61; P=0.02). Only 50% of older adults (80+) screened report having a discussion, of which less than half report making a shared decision. Discussion: Individual characteristics (demographics, health status and behavior, screening history) influence patient-provider discussions and decisions to screen.

SESSION 750 (PAPER)

DRIVING AND DRIVING CESSATION

PRODUCTIVE AND SOCIAL ENGAGEMENT FOLLOWING DRIVING CESSATION AMONG OLDER COUPLES

A.L. Curl1, J.D. Stowe2, C.M. Proulx2, T.M. Cooney2, 1. School of Social Work - University of Missouri, Columbia, Missouri, 2. Human Development & Family Studies - University of Missouri, Columbia, Missouri

Many older adults consider driving vital to maintaining their preferred lifestyle and engagement with society, yet it is normative to eventually stop driving. For married/partnered individuals, having a spouse/partner who remains able to drive may allow optimal engagement post-driving cessation. We employed longitudinal data from 7 waves (1998-2010) of the Health and Retirement Study (HRS) to examine whether driving cessation of self or partner impacts the productive and social engagement of partnered adults. Outcomes included involvement in productive roles (paid work, formal volunteering, and informal help to relatives, friends and neighbors), and social engagement. Couples were included if both spouses participated in HRS, were age 65+ at baseline, and neither volunteered that they had never driven; data provided by proxies were not used. Multilevel model results of 1,457 couples provide strong evidence of the negative impact of both one’s own driving cessation and the driving cessation of one’s partner on productive engagement. After controlling for sociodemographic factors, physical health, and cognitive ability, husbands’ driving cessation reduced their likelihood of engagement across all four outcome measures, and wives’ driving cessation reduced the odds of their productive but not social engagement. A wife’s driving cessation also lowers her husband’s odds of working and formal volunteering, while a husband’s driving cessation lowers her wife’s odds of working and informal volunteering. Results suggest the importance of maintaining safe driving for as long as possible, and enhanced services or rehabilitation efforts to maintain driving even among couples with one remaining driver.
EVIDENCE FOR A SUCCESSFUL FOCUSED EDUCATION PROGRAM TO MEET THE NEEDS OF THE OLDER DRIVER IN MEDICAL SETTINGS

A. Dickerson¹, F. Chew², S. Touchinsky³, E. Schold Davis³, 1. Occupational Therapy, East Carolina University, Greenville, North Carolina, 2. Genesis Rehab Services, Kennett Square, Pennsylvania, 3. American Occupational Therapy Association, Bethesda, Maryland

With the increasing numbers of baby boomers living longer and wanting to maintain their independence in the community, driving will be a critical IADL to be addressed. With the limited number of driver rehabilitation specialists available to assist with enhancing driving skills and/or transition to driving cessation, it will likely be essential for general practice occupational therapists to address driving and community mobility. This can be done by general practitioners screening their clients and meeting older adults’ initial needs in the general clinic. In 2011, 32 experienced (mean of 12 years) occupational therapists from Genesis Rehab Services volunteered for an focused 2 day training course to address driving and community mobility for their clients in a wide range of medical settings (e.g., SNF, long term care, assistive living centers, rehabilitation centers). Although all therapists confirmed that driving and community mobility was an important issue for their clients, their overall confidence and competence in the area of driving and community mobility were low. Using a pre-test/post-test design, examples of significant changes in confidence immediately after the focused education included: 1) addressing driving with clients (t=-5.33, p <.001), 2) addressing community mobility (t=-7.89, p<.001), and 3) mentoring other therapists (t=-5.23, p<.001). The same therapists were followed with similar quantitative questions after 3 months, 6 months, 12 months, and 24 months. Analysis of results indicated a high maintenance of confidence and enthusiasm even after 2 years. Although there was high mortality due to promotions and/or individuals leaving the company, over half (n =17) of the participants continued to respond to the surveys over the two year period. Descriptive statistics will be used to highlight the results over the six measurement times. Additionally, open ended statements will be summarized to qualitatively characterize the change in attitude, confidence, and outlook of the therapists. As a joint project between the American Occupational Therapy Association and Genesis Rehab Services, this pilot project can be a model for using general practitioners for promoting and enhancing safe driving as a means of community mobility to maintain older adults’ independence.

PERIPHERAL MOTION SENSITIVITY AS A PREDICTOR OF OLDER DRIVERS’ PERFORMANCE DURING SIMULATED DRIVING SCENARIOS

H. Woods-Fry¹, C. Collin¹, S. Gagnon¹, S. Henderson², M. Bedard³, H. Maxwell³, S. Marshall¹, 1. University of Ottawa, Ottawa, Ontario, Canada, 2. Transportation Safety Board of Canada, Ottawa, Ontario, Canada, 3. Centre for Research on Safe Driving, Lakehead University, Thunder Bay, Ontario, Canada, 4. The Ottawa Hospital Rehabilitation Centre, Ottawa, Ontario, Canada

Older drivers have an increased rate of automobile crashes per kilometer driven, likely due in part to age-related declines in motion perception. Previous research has demonstrated that tests of motion sensitivity are essential in order to accurately predict driving safety of older drivers. Our research group has developed the Rapid Peripheral Motion Contrast Threshold (RPMCT) test as a measure of peripheral motion sensitivity. In the current study, we investigated how effective the RPMCT is at predicting driving safety on a driving simulator. We tested 25 older drivers in the STISIM high fidelity driving simulator. Performance was measured in terms of number of collisions and time to collision. Participants completed the RPMCT, which consists of Gabors (0.4 cpd, 13.75°/s drift) positioned 15° to either side of fixation, and uses a two-alternative forced choice variation on the ascending Bekesy Method. Results show a significant moderate positive correlation (r=.56) between overall collisions and RPMCT. Our research demonstrates the ability of the RPMCT to effectively predict the occurrence of hazardous driving under simulated conditions in older drivers.

EXAMINATION OF DRIVING CESSION AND TIMING OF RELOCATION IN RETIREMENT LIVING SENIORS

C. Janssen-Grieve, A.M. Myers, A. Cidlak, University of Waterloo, Waterloo, Ontario, Ontario, Canada

To examine possible associations between driving cessation and relocation, as well as transportation use, we surveyed 273 former drivers (183 women and 90 men) from four retirement villages in southern Ontario ranging in age from 65 to 100 (mean age 86.5±6.0). Nearly 57% of the sample had stopped driving prior to relocation (average two years), while 25% had quit after relocation (average 18 months). For 18%, these transitions took place in the same month. Overall comparisons did not reveal any differences in age or gender between these three groups. However, those who stopped driving before versus after relocation were significantly more likely to live in units with support services than apartments (70% versus 30%, χ²=8.882, p<.001). The men in this category were also significantly younger than those who quit driving after the move (84.7±7.0 versus 89.2±6.5, t=-2.081, p>.05). Those who stopped driving after moving were more likely than those who stopped driving and relocated simultaneously to live in apartments compared to units providing support services (71% versus 29%, χ²=18.973, p<.001). For over half the sample (55%) driving cessation and relocation occurred within 12 months, suggesting there is a temporal association between these life transitions. As for current transportation use, the majority of the sample (90%) reportedly got rides from others (65% were driven by adult children; 28% by other relatives; 24% by friends; 8% by spouses; 2% by volunteers). Over half (52%) reported using the village shuttle; 18% use public buses, 73% taxis, 41% paratransit, and 22% motorized scooters.

DRIVING AND ALZHEIMER’S DISEASE: LINKING ATTENTIONAL DEFICITS TO SIMULATOR DRIVING PERFORMANCE IN EARLY AD DRIVERS

S. Yamin, S. Gagnon, A. Stinchcombe, H. Bruce, Psychology, University of Ottawa, Ottawa, Ontario, Canada

This study aimed to explore the degree of association between performance on a simulated driving task and performance on a neuropsychological test battery in individuals with early AD. Forty-one drivers were recruited from two groups; 20 individuals diagnosed with early AD and 21 healthy age-matched controls. All participants were administered the following neuropsychological tests: the Mini-Mental Status Exam (MMSE), the Dementia Rating Scale (DRS-2), the Test of Everyday Attention (TEA), the Visual Object and Space Perception Test (VOSP) and the Useful Field of View (UFOV). The simulated driving task consisted of an 11 km assessment course. Driving performance was scored based on simulator derived parameters as well as on a demerit point system scale scored by one of the experimenters. Results suggest that drivers with early AD made significantly more driving errors (p<.05) and that a large proportion of errors committed were caused by handling difficulties. Individuals with early AD performed poorly on most attentional tests (p<.05), though their performance on subtests of sustained attention and attentional switching were most correlated with their driving errors. The relationship between driving errors and attentional deficits will be discussed in length as well as the relevance of using driving simulators to assess driving performance in cognitively impaired drivers.
EXPLORING THE ROLE OF A FIREHOUSE SERVICE COORDINATOR IN SUPPORTING COMMUNITY-DWELLING SENIORS

A.K. Gibson, The Ohio State University, Columbus, Ohio

In an effort to reduce public long-term care expenditures and support individual’s right in self-determination, federal and state policymakers are increasingly turning to service coordination as a way of providing a community-based long-term care alternative to address the needs of frail elderly residents (Kim, Karlawish & Caine, 2004; National Association of Aging, 2011; Pynoos, Liebig, Alley & Nishita, 2004). Traditionally, service coordinators have been placed in housing designated for the elderly to assess, monitor, and coordinate services for their residents (Sheehan & Guzzardo, 2008). In recent years, the use of service coordination to address the needs of seniors who are community-dwelling has grown substantially (Duke & Genge, 2009; Ohio Area Agencies on Aging, 2012). By implementing a geriatric-trained service coordinator (grant funded, contract employee) in the local Fire Division, one community was able to link community-based senior residents to supportive services and healthcare providers that can assist them to safely and successfully age in place. Services To Age In Your Upper Arlington (STAY UAA) is a relatively new way to access this population. Responding to individual needs by connecting them through first responders at the “point of entry” can enhance seniors’ ties to their local aging and healthcare networks. Outcomes were examined from a three year period as part of the service coordinator’s role including types of referrals received, frequency of successful referral and referrals declined, frequency of specific intervention (fire hazard, home safety, home adaptations, medication management, and senior fraud/scam), and characteristics of clients served by the service coordinator.

PREDICTORS OF INDIVIDUAL SOCIAL VULNERABILITY AMONG OLDER ADULTS: A MULTILEVEL ANALYSIS

R. Ferreira, A.C. Faul, I. Tulane University, New Orleans, Louisiana, 2. University of Louisville, Louisville, Kentucky

The increase in disasters and the associated impacts are evident in our society. The impact of disasters on older adults can have more chronic impacts generating social and economic hardship, loss of employment, dissolution of personal relationships, and the long-term decline of physical and mental health. Hurricane Katrina and “Superstorm Sandy” have shown that older adults are at higher risk for illness or even death. This paper presents important findings from a study undertaken to develop an understanding of the predictors of individual social vulnerability among older adults. Methods: The research design was a multilevel repeated cross-sectional design with a three level-structured design. The software package MLwiN was used to conduct multilevel analysis using empirical Bayes Markov chain Monte Carlo (MCMC) estimation. Using a representative sample of 34,685 individuals from 2004-2010, nested in Louisiana parishes the trend study allowed for an understanding of the internal and external resources of old age can be maximize to overcome the challenges presented by this stage of life. Results: The results of this study identified 5 important strengths of older people experiencing with sever natural disasters were conducted. Results: The results of this study identified 5 important strengths of older people, including (1) optimism and self-acceptance, (2) self-management, (3) religious and cultural beliefs (4) social networks, (5) community consciousness; serving as assets rather than problems and pathologies. The results present a practical framework for applying strengths perspective to help the elderly to overcome the challenges of natural disasters. Implications: This study suggests that older adults’ resiliency and spiritual resources can provide positive attributes for community disaster preparedness and reconstruction. It also demonstrates ways in which the internal and external resources of old age can be maximized to overcome the challenges presented by this stage of life.

COMPREHENSION, RETENTION, & ACTION OF DENTON COUNTY ELDERLY TOWARDS DISASTER PREPAREDNESS EDUCATION

B. Knight, Applied Gerontology Program, Dept. of Sociology, University of North Texas, Denton, Texas

The purpose of this exploratory study was to operationalize the responses from a sample of the community dwelling older population from Denton County, Texas on disaster preparedness education given by Denton County Health Department (DCHD) personnel. The goals and objectives were drawn from the Texas Public Health and Medical Emergency Management 5-Year Strategic Plan 2012-2016. It was hypothesized that after the disaster preparedness education was received, then comprehension, retention, and application of the information would increase and the goals set forth by the DCHD would be reached. Thirteen Denton County sites were used to educate the 224 willing participants between August 2011 and April 2012. The data were received using a pre-test survey before the training, a post-test immediately after the training, and a follow-up survey call approximately 30 days later. Using Cronbach’s alpha, logistic regression and regression analysis through SAS software program, the data revealed that all DCHD goals were met by this training method and outcome which include the sample population increasing comprehension, retention, and action on the information learned. This study not only educated a sample population of Denton County’s elderly, but also allowed Denton County Health Department to test new tools created to measure the effectiveness of their educational training being provided to the elderly population. It also gave them a method to measure costs verses effectiveness of the educational training with this cohort because it was shown that their training must be uniquely customized to increase effectiveness.

A STRENGTHS PERSPECTIVE FOR ASSESSING OLDER ADULTS IN DISASTER PREPAREDNESS AND COMMUNITY RECONSTRUCTION

L. Liu, J. Zhang, Social Work, Tunghai University, Taichung City, Taiwan

Purpose: Older people have been considered to be vulnerable to natural disaster. However, they can experience resilience in spite of the deleterious affects of the natural disaster. From strengths perspective, this study aims to explore the lived experiences of the elderly with natural disaster as it relates to strengths and resilience in dealing with devastating catastrophes. Methods: Data for this study are gathered from two sources, including: (1) semi-structured in-depth interviews with staff and managers of 5 organizations heavily involving in disaster relief and post-disaster community reconstruction; (2) 2 focus groups with 14 older people experiencing with sever natural disasters were conducted. Results: The results of this study identified 5 important strengths of older people, including (1) optimism and self-acceptance, (2) self-management, (3) religious and cultural beliefs (4) social networks, (5) community consciousness; serving as assets rather than problems and pathologies. The results present a practical framework for applying strengths perspective to help the elderly to overcome the challenges of natural disasters. Implications: This study suggests that older adults’ resiliency and spiritual resources can provide positive attributes for community disaster preparedness and reconstruction. It also demonstrates ways in which the internal and external resources of old age can be maximized to overcome the challenges presented by this stage of life.

AGING IN FEAR: DISTRACTION BURGLARY AND SECURITY TECHNOLOGY IN LATER LIFE

G.W. Pritchard, K. Britain, Institute of Health and Society, Newcastle University, Newcastle upon Tyne, United Kingdom

This paper offers a sociologically grounded assessment of crime prevention technology designed specifically for elderly people, exploring their effectiveness for reducing both crime and fear of it. Our examination centers on the threat of ‘bogus callers’ and ‘distraction burglars’...
who trick their way into older people’s homes in order to steal. Our paper draws from primary and secondary sources in the form of a content analysis of various publicly available documents and interview and focus group data elicited from older people (n=30) and their carers (n=12). We ground our analysis in moral panic theory (Cohen 1973), exploring the social process that constructs the victimization of older people as a correctable problem in need of intervention. We conclude that currently available technology is ineffectual, counter productive and potentially harmful to users and propose that future devices should be less responsive-driven and instead work to reduce fear of crime, promote an ‘affirmation model’ of aging and build social capital.

SESSION 760 (SYMPOSIUM)

DEVELOPMENT AND EFFECTIVENESS OF A PATIENT-CENTERED CARE PROGRAM ON PHYSICAL FUNCTIONING OF FRAIL OLDER PERSONS

Chair: M. Schuurmans, University Medical Center Utrecht, Department Rehabilitation, Nursing Science and Sport, Utrecht, Utrecht, Netherlands
Co-Chair: N. Bleijenberg, General Practice, Julius Center for Health Sciences and Primary Care, Utrecht, Netherlands

Providing optimal care for frail older people with complex care needs challenges primary care professionals. The present reactive approach is expensive and does not meet the needs of older patients. As a result, many older patients experience unnecessary loss of physical functioning and a suboptimal quality of life. A transition is needed towards proactive care focusing on preservation of physical functioning. We developed a frailty screening and monitoring intervention based on routine primary care registration data (U-PRIM) followed by a patient-centered nurse-led care intervention (U-CARE). We evaluated the effectiveness of U-PRIM, and of U-PRIM followed by U-CARE in a three-armed cluster randomized trial in primary care including 3000 patients. This symposium aims to present the development and the effectiveness of our proactive patient-centered care strategy to preserve physical functioning in frail older people, through 4 presentations: 1. First, we demonstrate the development, predictive performance and construct validity of the U-PRIM intervention and its components. 2. Second, we present the development of the multicomponent U-CARE intervention. 3. Third, we present the effectiveness of U-PRIM and U-CARE on physical functioning and quality of life of frail older persons. 4. Finally, we discuss a mixed-methods evaluation regarding the delivery of the U-CARE intervention by nurses, and the satisfaction of patients and professionals.

FRAILTY SCREENING AND MONITORING IN ROUTINE PRIMARY CARE DATA: DEVELOPMENT AND VALIDATION OF THE U-PRIM INSTRUMENT

I. Drubbel1, M.E. Numans2, N. Bleijenberg3, V.H. ten Dam1, M. Schuurmans2, N. de Wit1, 1. University Medical Center Utrecht, Department Julius Center for Health Sciences and Primary Care, Utrecht, Netherlands, 2. University Medical Center Utrecht, Department Rehabilitation Nursing Science and Sport, Utrecht, Netherlands

The U-PRIM software application aims to stratify older patients by frailty level using readily available primary care EMR data. In the U-PROFIT trial, GPs received a quarterly U-PRIM report to provide proactive care according to current guidelines. U-PRIM selected patients aged ≥ 60 years with multimorbidity, polypharmacy or a ‘consultation gap. Multimorbidity is defined using a Frailty Index (FI) score. The FI consists of a list of ICPC encoded health deficits, and a patients’ FI score is defined as the proportion of deficits present. In a retrospective cohort study (n=1,679) we concluded that U-PRIM adequately predicts adverse health outcomes. We will discuss U-PRIM development and extensive validation studies in which the predictive value of U-PRIM is further explored (n = 18,000) and in which concordance with self-reported measures of physical functioning, quality of life and healthcare consumption is evaluated (n=2870).

THE EFFECTIVENESS OF PROACTIVE PRIMARY CARE ON PHYSICAL FUNCTIONING OF FRAIL OLDER PATIENTS: THE U-PROFIT TRIAL

N. Bleijenberg1, I. Drubbel1, M. Schuurmans2, V.H. ten Dam1, P. Zuithoff1, W. Laan1, M.E. Numans2, N. de Wit1, 1. University Medical Center, Department Julius Center for Health Sciences and Primary Care, Utrecht, Netherlands, 2. University Medical Center, Department Rehabilitation Nursing Science and Sport, Utrecht, Netherlands

We investigate the effect of U-PRIM, a quarterly screening and monitoring intervention, and of U-PRIM followed by U-CARE, a multicomponent nurse-led care program on physical functioning of frail older people in primary care. A single-blind three-armed cluster randomised trial including 39 primary care centers (3092 older patients) was conducted between October 2010 and March 2012, including 1 year follow-up. The primary outcome was physical functioning measured on a modified Katz-15 ADL/IADL scale. Secondary outcomes were quality of life, primary care consultations, hospital admission, ED visits, nursing home admission and mortality. Patients of both intervention groups showed significantly better preservation of physical functioning compared with the control group patients at 12 months. Patients in the U-PRIM+U-CARE intervention group consulted their primary care center significantly more often compared with patients of the other two groups. High and low educated patients receiving U-PRIM + U-CARE visited the ED significantly less.

DEVELOPMENT OF A MULTICOMPONENT NURSE-LED CARE INTERVENTION TO PRESERVE PHYSICAL FUNCTIONING IN OLDER PERSONS

N. Bleijenberg1, V.H. ten Dam1, I. Drubbel1, M.E. Numans2, N. de Wit1, M. Schuurmans2, 1. University Medical Center Utrecht, Julius Center for Health Sciences and Primary Care, Utrecht, Netherlands, 2. University Medical Center Utrecht, Rehabilitation, Nursing Science and Sport, Utrecht, Netherlands

To understand the different components of a complex intervention and to allow thorough review and replication, a detailed description of the intervention and its development process is needed. Therefore, we will present the development and feasibility of the U-CARE intervention. An extended stepwise multi-method procedure was applied and a team of researchers, GPs, nurses, experts and an independent panel of older people were actively involved in the development to increase the feasibility in clinical practice. The U-CARE intervention includes Frailty Assessment, a Comprehensive Geriatric Assessment (CGA), evidence-based and tailored care planning and delivery, care coordination and follow-up visits. For eleven geriatric conditions, evidence-based care plans with a total set of interventions were developed. A total of 21 registered practice nurses were recruited, employed and extensively trained during a six week training program.

A MIXED-METHODS STUDY REGARDING THE ACTUAL INTERVENTION DELIVERED BY NURSES AND SATISFACTION U-CARE

N. Bleijenberg1, V.H. ten Dam1, I. Drubbel1, M.E. Numans2, N. de Wit1, M. Schuurmans2, 1. University Medical Center Utrecht, Department Julius Center for Health Sciences and Primary Care, Utrecht, Netherlands, 2. University Medical Center Utrecht, Department Rehabilitation Nursing Science and Sport, Utrecht, Netherlands

To gain a better understanding of obtained trial results, a mixed-methods study was conducted regarding the actual intervention delivered by nurses and the barriers and facilitators of the U-PRIM-U-CARE intervention. During one-year follow-up, data were collected at the level of the patient and providers of the intervention using questionnaires, focus groups, interviews, log books and web-based registration. Most
provided interventions will be presented. Referrals were most frequent for patients with falls, cognition and loneliness. Both patients and providers were satisfied receiving and delivering the intervention. Patients highlighted the important value of the nurse. In the beginning, the nurses indicated that delivering proactive care was difficult, but, after 6 months, a transition towards proactive care was achieved. Nurses and GPs emphasized that the program enhances the coordination of care.

SESSION 765 (SYMPOSIUM)

DIGNITY, OPTIMAL AGING, AND DIGNIFIED CARE
Chair: C. Jacelon, University of Massachusetts, Amherst, Massachusetts
Discussant: A. Gallagher, University of Surrey, Surrey, United Kingdom

Dignity is an important concept in relation to the health and health care of older adults. It is necessary for optimal aging. There has been a good deal of media and research attention to care practices that diminish dignity in older people, but less attention has been given to understanding activities that promote and sustain dignity in the daily lives of older adults or when they interact with health care systems. Although the research on dignity and older adults has increased internationally, the definitions of dignity remain varied. In this symposium we will present an analysis of current definitions found in the health care literature focused on dignity in older adults and identify which components are integral to the meaning of dignity across definitions and across the globe. In the second paper, using the Attributed Dignity Scale, we will present an analysis of the relationships between dignity, life situations, and both physical and mental status in community dwelling older adults with chronic health problems in the United States from the viewpoint of the older adult. Next we will present research using qualitative methods to explore the experience of frail older adult’s dignity during care transitions in England. Finally, we will present issues of dignity for older adults with dementia from the perspective of nursing students. As discussant, Dr. Gallagher will highlight the similarities and differences among the findings across settings and countries, and suggest a way to continue to advance our understanding of dignity in older adults.

COMPARATIVE ANALYSIS OF THE CONCEPT OF DIGNITY IN HEALTH LITERATURE
Q. Guo, School of Nursing, University of Massachusetts Amherst, Amherst, Massachusetts

There are many conceptualizations of dignity in the health literature. By comparing descriptions of dignity in relation to older adults, dying persons, and care, the components integral to the meaning of dignity across definitions have been identified. A keyword search of health and psychology databases was performed. The comparative approach and matrix method were used to analyze information regarding dignity. Findings indicate that both older adults and dying persons possess basic dignity, personal dignity and relational dignity. Due to different social roles, their dignity has different foci, such as “living vs. dying”, “wisdom of age vs. meaning of death”, and “aging vs. sick role”. With diminishing independence, their dignity is affected by the care they receive. Dignified care, which respects clients’ basic, personal, and relational dignity is important for the dignity of both older adults and dying persons.

ATTRIBUTED DIGNITY, OPTIMAL AGING, AND HEALTH
C. Jacelon, School of Nursing, University of Massachusetts, Amherst, Massachusetts

Maintaining dignity is thought to be related to health status and critical for optimal aging. Yet, until now it has been difficult to test this assumption. For this research dignity is defined as an intrinsic quality of being human that is manifested as an attributed, dynamic quality of the self, connoting self-value, perceived value from others, self in relation to others, and behaving with respect. Attributed dignity has been operationalized as the Attributed Dignity Scale. In order to test the hypothesis that dignity and health are positively related, 287 community-dwelling older adults age 65 - 96 years old in the northeastern United States provided demographic information, and completed the Attributed Dignity Scale, and the SF-12v2 health survey. The relationships among age, SES, education, living status, physical and mental health are presented, and the implications for older adults and will be discussed.

TRANSITIONS FOR FRAIL OLDER PEOPLE FROM ACUTE HOSPITAL WARDS: A DIGNIFIED EXPERIENCE
L. Baillie, Faculty of Health and Social Care, London South Bank University and University College London Hospitals, London, United Kingdom

The project was based in one healthcare system, with integrated acute hospital and community service provision. The study used a qualitative case study approach to investigate barriers and facilitators to timely and appropriate transitions for frail older people from acute hospital wards. Data collection methods were individual interviews with key hospital and community staff and patients, and focus groups with staff on acute and community hospital wards. The presentation will focus on transition from a perspective of dignity in care. Most staff recognised the importance of patient and family involvement but with pressure to move patients from acute beds quickly, and insufficient community-based health and social care services, a dignified transition experience for patients appeared to be a low priority. Patients’ experiences revealed a lack of any control and minimal involvement in the process. These findings will be discussed in relation to improving dignified care during transition from acute wards.

CARING FOR OLDER PEOPLE WITH DEMENTIA IN HOSPITAL: STUDENT NURSES’ VIEWS ABOUT DIGNITY IN CARE
L. Baillie, Faculty of Health and Social Care, London South Bank University and University College London Hospitals, London, United Kingdom

There are growing numbers of older people with dementia globally, many of whom have other concurrent health conditions for which they are admitted to hospital. Nursing students frequently care for older people with dementia during hospital-based practice learning and these experiences will influence their practice as registered nurses. This presentation reports on a cross-sectional survey of student nurses in England, which used questionnaires and focus groups. While most students reported that care relating to respect and dignity was good, much fewer considered person-centred care, and involvement in decision-making, was achieved well. Students described challenges they encountered caring for older people with dementia in practice but they developed care strategies: getting to know the person and building a relationship; involvement of families; flexible and creative care approaches; use of comfort and communication. The implications of the results for nurse education, and for hospital staff, will be explored.

SESSION 770 (SYMPOSIUM)

EXERCISE AND BONE HEALTH: WHAT DOES THE RESEARCH SAY?
Chair: T. Kauffman, Timothy Kauffman, Columbia University, Lancaster, Pennsylvania, Kauffman Physical Therapy, Lancaster, Pennsylvania
Discussant: K. Kline-Mangione, Arcadia University, Philadelphia, Pennsylvania

Osteoporosis, the most common bone disease in humans, is a major concern for persons of all ages with significant implications for morbidity and mortality. It is estimated, worldwide there are nearly 9 million osteoporotic-related fractures a year. One in three females and one in five males over age 50 years will have an osteoporotic fracture and
the incidence of fractures is projected to increase. Based on research, the International Osteoporosis Foundation recognizes the importance of exercise as well as physical activity during leisure time, sport, work and daily living chores on bone health from childhood through old age. In the US, the National Osteoporosis Foundation established an Exercise and Rehabilitation Advisory Council (ERAC), which is developing an exercise position statement. The ERAC includes physical therapists, physicians and exercise physiologists. This symposium is based on this extensive literature review and will present the strength of evidence that physical activity and exercise can enhance bone health in children, adolescents, post-menopausal women, males and frail elderly. Exercise is a generic term for a host of activities and thus the more effective physical exercises will be differentiated from the less beneficial. This symposium is pertinent to persons of all ages, both genders and all ethnic groups. Knowledge gained from it will promote optimal aging based on research.

MULTIMODAL EXERCISE: OF BENEFIT TO BONE?
C. Jankowski, University of Colorado, College of Nursing, Denver, Colorado

A literature review was conducted to evaluate the effects of multimodal exercise training, defined as combinations of high-impact weight-bearing (e.g., running, jumping) and resistance (e.g., calisthenics, free weights) exercises on bone mineral density (BMD). The purpose of progressive multimodal training is to expose the skeleton to a variety of loading forces. Studies of premenopausal women (3 randomized controlled trials, RCTs), postmenopausal women (5 RCTs and 1 systematic review), and older men (1 RCT) were included. Supervised training occurred 2-3 days per week for 12-24 months. The balance of evidence (level 2a-b, Centre for Evidence Based Medicine, 2009) suggested increased hip BMD in response to multimodal exercise emphasizing jumping in pre-, and early postmenopausal women and older men. Some bone responses were site-specific and directly related to acceleration forces. In older postmenopausal women, and women with a fracture history, increased or attenuated loss of hip BMD compared to controls was found.

MULTIMODAL EXERCISE: OF BENEFIT TO BONE?
C. Jankowski, 1. College of Nursing, University of Colorado Denver, Aurora, Colorado, 2. Division of Geriatric Medicine, University of Colorado Denver, Aurora, Colorado

A literature review was conducted to evaluate the effects of multimodal exercise training, defined as combinations of high-impact weight-bearing (e.g., running, jumping) and resistance (e.g., calisthenics, free weights) exercises on bone mineral density (BMD). The purpose of progressive multimodal training is to expose the skeleton to a variety of loading forces. Studies of premenopausal women (3 randomized controlled trials, RCTs), postmenopausal women (5 RCTs and 1 systematic review), and older men (1 RCT) were included. Supervised training occurred 2-3 days per week for 12-24 months. The balance of evidence (level 2a-b, Centre for Evidence Based Medicine, 2009) suggested increased hip BMD in response to multimodal exercise emphasizing jumping in pre-, and early postmenopausal women and older men. Some bone responses were site-specific and directly related to acceleration forces. In older postmenopausal women, and women with a fracture history, increased or attenuated loss of hip BMD compared to controls was found.

EXERCISE FOR REHABILITATION AFTER OSTEOPOROTIC FRACTURE
K. Shipp, Duke University, Durham, North Carolina

Exercise recommendations following fragility fractures are specific to fracture location. This presentation will focus on evidence in the literature for the two most common locations: vertebral and hip. The highest quality evidence exists for hip fracture (13 RCTs, 3 systematic reviews, 2 meta-analyses). Both home- and community-based interventions of 1-12 month duration, primarily progressive resistance training, were shown to improve strength, balance, fast walking speed, and physical performance. One RCT demonstrated that high-intensity strength training reduced risk of death, nursing home admission, and ADL decline post hip fracture. Little evidence exists to guide exercise after vertebral fracture (8 RCTs, 3 systematic reviews). Some studies reported improved pain, walking speed, back extensor strength/endurance, and quality of life. Knowledge regarding exercise after vertebral fracture is extremely limited. Long duration progressive resistance exercise is beneficial after hip fracture, but implementing this type exercise program cost effectively on a large scale remains unexamined.

EXERCISE TO OPTIMIZE SKELETAL HEALTH: A LIFESPAN APPROACH
K. Gunter, Oregon State University, Corvallis, Oregon

Physical inactivity in childhood is rarely discussed as a significant contributor to osteoporosis, a disease typical of old age. In 2013 ample evidence exists to recommend physical activity undertaken in childhood as perhaps the best defense against skeletal frailty in later life. Approximately 50% of bone mass variability in older adults relates to the degree of bone mineralization during childhood and adolescence. This presentation will provide evidence supporting the beneficial effects of physical activity in youth to optimize skeletal development. We will discuss the current scientific understanding of the role of childhood physical activity on bone health and, ultimately, fracture risk. We include an overview of the physical activity dose required for bone mass and structural response and recommendations for promoting bone-enhancing physical activity among children and adolescents. We conclude with new research suggesting a unique relationship between childhood physical activity and adult bone health.

SESSION 775 (SYMPOSIUM)

THE USE OF BIOMARKERS IN GERONTOLOGICAL NURSING RESEARCH
Chair: P.Z. Cacchione, University of Pennsylvania, Philadelphia, Pennsylvania
Co-Chair: K.A. Gretebeck, University of Wisconsin-Madison, Madison, Wisconsin
Discussant: D.L. Schutte, Michigan State University, East Lansing, Michigan

During this Nursing Care of Older Adults Special Interest Group Symposium expert nurse researchers will provide methodological insights of including biomarkers in gerontological nursing research. The advantages and methodological challenges of using biomarkers will be addressed through illustrations from their programs of research. Dr. Nancy McCain will discuss the use of the psychoneuroimmunological framework in immunosenescence in infectious diseases and cancer in older adults. Dr. Kathy Richards will present the use of neuroimaging and adherence biomarkers for sleep interventions in her MEMORIES trial. Dr. Hilare Thompson will share the importance of matching the serum biomarkers with the specific aims of the study by describing the use of predictive immune biomarkers following traumatic brain injury in older adults. Lauren Massimo, PhD-C will follow Dr. Thompson to share her expertise in neuroimaging biomarkers in the investigation of the impaired motivation/apathy associated with behavioral variant frontotemporal degeneration. Our discussant is Dr. Debra Shute. She will draw on her expertise in the use of genetic biomarkers in persons with dementia and hearing loss to discuss the advantages and challenges of the use of biomarkers in gerontological nursing research.

66th Annual Scientific Meeting
PSYCHONEUROIMMUNOLOGY (PNI) AND IMMUNONESSENCE

N.L. McCain, Virginia Commonwealth University, Richmond, Virginia

Although longitudinal research is limited, immunosenescence associated with aging is thought to contribute to the increased incidence and severity of infectious disease and cancer in the elderly. Further, there is evidence suggesting that immunosenescence can be accelerated by factors such as chronic stress via psychoneuroimmunological mechanisms. PNI provides a framework that is not disease-specific; rather, inflammatory mediation and moderation are of key interest as central aspects of a vast array of health–illness states and interventions. PNI explains multidimensional interactions among psychosocial factors and physiological mechanisms of the neuroendocrine and immune systems. It is known that the stress response involves both direct and indirect effects on the immune system, such that numerous cytokines and other bio-chemicals such as endogenous opioids are elaborated by immune cells. Evaluation of immune signatures or patterns will be explored as biomarkers of immune function, along with research suggesting that immunosenescence can be attenuated by PNI-based interventions.

BIOBEHAVIORAL RESEARCH CHALLENGES AND SOLUTIONS IN THE MEMORIES TRIAL

K.C. Richards, George Mason University, Fairfax, Virginia

This methodological paper will present biobehavioral research challenges and the corresponding solutions in MEMORIES, an ongoing National Institute on Aging funded trial. The purpose of the study is to determine the 6-month and 1-year effects of treating obstructive sleep apnea (OSA) with continuous positive airway pressure (CPAP) in older adults with mild cognitive impairment (MCI). Study outcomes include neurocognitive and everyday function, and structural neuroimaging biomarkers. Polysomnography, genetic, and CPAP adherence biomarkers will be used to predict the effect of CPAP on the study outcomes. Challenges associated with the study outcome and predictor biomarkers included recruitment challenges, ethical concerns regarding follow-up of abnormal biomarker results and data security, and data management issues surrounding multi-site data collection, transport and storage. An interactive interprofessional problem-solving process was used to develop solutions for each challenge. The paper will conclude with a description of the problem-solving process and the solutions for each challenge.

METHODOLOGICAL CONSIDERATIONS IN THE USE OF BLOOD SPECIMENS IN AGING-RELATED BIOMARKER RESEARCH

H.J. Thompson, University of Washington, Seattle, Washington

Blood is a frequent source of specimens for aging-related biomarker research as it can yield various elements for analysis such as plasma, white blood cells, and DNA. However the use of such specimens may not be appropriate in all study designs as they need to match specific aims and be reflective of underlying biological processes. This session will focus on how nurse scientists can best integrate blood specimens for biomarker research within clinical research studies. Topics discussed will include prognostic vs. predictive biomarkers specimen collection, handling and storage, available assays and both statistical and cost considerations. Application of methodological issues will be presented in the context of an ongoing program of research focused on immune biomarkers for predicting outcome following traumatic brain injury in older adults.

NEUROIMAGING BIOMARKERS TO EXAMINE APATHY IN FRONTOTEMPORAL DEGENERATION

The study of neuroanatomical biomarkers is of scientific interest in Frontotemporal degeneration (FTD) since this can validate the contribution of cognitive impairments to apathy. By using neurobiological tools such as voxel based morphometry (VBM) to study persons with apathy, the nature and anatomic localization of the contributing processes can be identified. Morphometry analysis is a common tool used for measurement of structural differences within a group or across groups. When pathology in the brain structures occur, there is an impact on the fine morphology of the gray matter and cortical thinning occurs. The measurement of cortical thinning is especially helpful in determining disease in FTD since the prefrontal cortex is especially sensitive to this volumetric change. This session will incorporate experiences with a current study of apathy in FTD and conclude with a description of potential limitations which need to be considered when planning similar investigations and interpreting the results.

SESSION 780 (SYMPOSIUM)

VA GRECC SYMPOSIUM: ISCHEMIA AND EXERCISE IN THE PATHOGENESIS AND TREATMENT OF COGNITIVE DECLINE

Chair: S.H. Graham, VA Geriatric Research Education and Clinical Center, Pittsburgh, Pennsylvania, University of Pittsburgh, Pittsburgh, Pennsylvania
Co-Chair: R. Macko, VA Geriatric Research Education and Clinical Center, Baltimore, Maryland

Alzheimer’s disease (AD) and cerebrovascular disease are the two major causes of dementia, and often coexist and may interact to produce cognitive decline in the elderly. Reduced physical activity is associated with increased risk of both stroke and dementia, and exercise therapy may have a role in both the prevention and treatment of these disorders. This symposium addresses the association between stroke, dementia, and exercise from the bench to the bedside. Individual sessions will address: 1) How the epidemiological association between cerebrovascular disease and physical activity varies with age, and how the dynamic of these factors at different age periods is essential for the implementation of primary prevention treatments for AD. 2) A hypothesized link between cerebral ischemia and the pathogenesis of AD: the effect of reactive lipid species upon protein aggregation and amyloid beta metabolism. 3) The molecular and cellular mechanisms by which exercise improves brain function in aged rats after injury. 4) The interactions between physical activity and the genetic risk for AD on brain function and cognition. 5) An operational approach toward implementing exercise programs at the community level to improve brain health for individuals aging with cerebrovascular disease.

PATTERNS OF COMPENSATION AND VULNERABILITY IN NORMAL SUBJECTS AT RISK OF ALZHEIMER’S DISEASE

O. Lopez, J. Becker, L.H. Kuller, University of Pittsburgh, Pittsburgh, Pennsylvania

Alzheimer’s disease (AD) is the most frequent form of dementia in elderly individuals and its incidence and prevalence increases with age. There are medical risk modifiers including systemic cerebrovascular disease that increase the vulnerability for AD. By contrast, there are lifestyle risk modifiers that reduce the effects of AD risk factors include physical and cognitive activity. Interactions among these risk factors with the pathobiological cascade of AD determine the likelihood of developing cognitive impairment. After attending this session, participants will understand the association between “vulnerability” and “protective” factors and how they vary with age and understand how the dynamic of these factors at different age periods will be essential for the implementation of primary prevention treatments for AD. Specifically, participants will learn about: cardiovascular and non-cardiovascular risk factors for dementia, neuroimaging correlates of cardiovascular disorders, neuroimaging predictors of dementia, factors that attenuate the risk of dementia.
MECHANISMS LINKING ISCHEMIA AND ALZHEIMER’S DISEASE: EFFECT OF REACTIVE LIPIDS ON PROTEIN UBQUITINATION AND AMYLOID METABOLISM
S.H. Graham1,2, H. Liu1,2, M. Rose1,2, W. Li1,2, 1. VA Geriatric Research Education and Clinical Center, Pittsburgh, Pennsylvania, 2. Neurology, University of Pittsburgh, Pittsburgh, Pennsylvania

Cerebrovascular disease and white matter hyperintensities are associated with cognitive decline in the elderly and increase the risk of Alzheimer’s disease. Cerebral ischemia increases the formation of reactive lipid species including cyclopentenone prostaglandins (CyPgs) in animal models of cerebral ischemia. CyPgs bind to ubiquitin-C-terminal hydrolase L1 (UCH-L1) and CyPg-UCH-L1 adducts are detected within neurons in vitro. CyPgs also result in accumulation of insoluble ubiquinated proteins within neurons. Decreased Uch-L1 activity interferes with the degradation of beta-secretase 1 by lysosomes, thus the addition of Uch-L1 by CyPg and other reactive lipid species produced by ischemia may result in increased concentrations of amyloid-beta in brain. Thus, this session addresses a possible mechanistic link between the pathogenesis of Alzheimer’s disease and cerebral ischemia.

MECHANISMS OF EXERCISE INDUCED BRAIN RECOVERY
A.D. Smith1,2, S. Castro1, M.J. Zigmond1, 1. VA Pittsburgh Geriatric Research Educational and Clinical Center, Pittsburgh, Pennsylvania, 2. University of Pittsburgh, Pittsburgh, Pennsylvania

Having greatly diminished the incidence of most infectious diseases, the world population is experiencing a rise in aging-related diseases including stroke and dementia. The cause undoubtedly includes changes in our life style, which typically involves a diet and levels of physical activity very different from those to which we are adapted through evolution. An increasing body of evidence suggests that physical activity is correlated with decreased incidence and severity of a variety of age-related deficits. Using animal models of dopamine deficiency, we find that physical exercise can reduce neurotoxin-induced brain dysfunction. Attendees will learn the mechanisms by which exercise increases the resiliency of the brain to cellular stress, including enhancement of the availability of neurotrophic factors and the subsequent activation of intracellular survival cascades. These mechanisms may underlie the effect of exercise therapy in both the prevention and treatment of stroke and dementia. Learning objectives: 1) Learn how exercise improves brain function in young and aged rodents after neurotoxin injury. 2) Understand mechanisms by which exercise improves brain function after injury: increasing neurotrophic factor levels and activation of intraneuronal survival pathways.

EXERCISE AND BRAIN FUNCTION WITH INCREASED RISK FOR ALZHEIMER’S DISEASE
J. Smith1,2, K.A. Nielsen1, 1. Kinesiology, University of Maryland, College Park, Maryland, 2. Baltimore VA GRECC, Baltimore, Maryland, 3. Marquette University, Milwaukee, Wisconsin

There is a desperate search ongoing for effective treatments and preventive strategies for Alzheimer’s disease (AD) in those who are at increased AD risk. A recent NIH consensus panel concluded there was no solid evidence for any intervention or modifiable factor to improve clinical symptoms or prevent AD – with the exception of notable promise for physical exercise. Exercise performed by healthy older adults may improve cognitive function and reduce the risk for dementia. However, less is known regarding the effects of exercise in those with cognitive impairments or who are at increased genetic risk for AD. We explore the literature regarding the effects of exercise being more or less potent to reduce dementia risk in those who possess one or more copies of the apolipoprotein E epsilon4 allele compared to non-carriers. We also address the effectiveness of exercise to affect brain function in older adults diagnosed with mild cognitive impairment.

EXERCISE AND BRAIN HEALTH AFTER STROKE
Baltimore VA GRECC/ RR&D MARYLAND EXERCISE AND ROBOTICS CENTER OF EXCELLENCE
R. Macko1, J. Smith1,2, M.C. Dux1, C. Hafer-Macko2, I. V.A Maryland Health Care System and University of Maryland, Baltimore, Maryland, 2. University of Maryland College Park, College Park, Maryland

Stroke is the leading cause of disability in the U.S. and cerebrovascular disease is a major contributor to cognitive declines our aging populations. Estimates are that nearly half of stroke survivors have vascular cognitive impairment non-dementia, and dementia rates are elevated up 10-fold. Baltimore GRECC has developed exercise models that: restore fitness 17-33% back toward normal, reverse impaired glucose tolerance and non-insulin dependent diabetes in 58% of cases, and walking velocity by ~30%- even years post-stroke by activating subcortical brain networks. These exercise programs can increase bilateral brain vasomotor reactivity and improve elements of cognitive function to enhance motor learning, years after a stroke. This presentation will present public health rationale and operational approach toward implementing exercise at community levels to improve brain health for individuals aging with cerebrovascular disease.

SESSION 785 (PAPER)

DEMENTIA

MENTAL STATUS EVALUATION IN THE ELDERLY: A RETROSPECTIVE STUDY IN AN ITALIAN EMERGENCY DEPARTMENT
N. Zaffarana1, M. Cavallini1, G. Bazzuva1, E. Moshello1, N. Marchionni1, S. Grifoni1, R. Pini1, M. Di Bari1, 1. Unit of Geriatrics, University of Florence, Careggi Hospital, Florence, Italy, 2. Emergency Department - Osservazione Breve, Careggi Hospital, Florence, Italy, 3. Osservazione Breve Intensiva, University of Florence, Careggi Hospital, Florence, Italy

Purpose and Methods: To estimate prevalence and accuracy of diagnoses of delirium and dementia in older patients presenting to the Emergency Department (ED) of an academic hospital in Florence, Italy, and to evaluate their associations with clinical and socio-demographic data, 1000 patient’s medical records (MR), randomly selected from the 13,837 registered in the year 2010, were analyzed retrospectively. Subjects with a “white” triage color code or communication disorders were excluded. The presence in MR of a formal diagnosis of delirium, and/or of ≥1 DSM-IV diagnostic criteria for delirium, was detected; each MR was judged as “adequate”, “partially adequate” or “inadequate” for delirium diagnosis. Based on the accuracy of DSM-IV criteria annotation. Dementia diagnosis was present when reported by a patient’s kin or when specific report and/or therapy were recorded in MR. Results: After application of the exclusion criteria, 839 MR out of 1000 were analyzed. Mean age was 83.2±5.4 y; 53.9% of cases were hospitalized after ED access. Prevalence of delirium and dementia in MR was 3.7% and 15.9%, respectively. Agreement between diagnosis of delirium formally reported in MR (35 subjects) and diagnosis presumed on the basis of DSM-IV symptoms/signs (9 subjects) was poor (kappa statistics:0.39). Conclusions: In the present study, the prevalence of delirium (but not that of dementia) in elderly subjects admitted to ED was lower than that reported in the international literature, probably because of under-utilization of
THE SUBJECTIVE EXPERIENCE OF LIVING WITH A DIAGNOSIS OF BEHAVIORAL VARIANT FRONTAL-TEMPORAL DEMENTIA
J.R. Oyebode1, J. Griffin1, I. University of Bradford, Bradford, United Kingdom, 2. University of Birmingham, Birmingham, United Kingdom

Psychological research into behavioural-variant frontotemporal dementia (bvFTD) has focused largely on cognitive changes and confirms the presence of dysexecutive difficulties such as disinhibition, loss of empathy and lack of awareness. This combination can be very challenging for relatives and carers. However, little is known about what it is like for the person with bvFTD to live with the condition. Our aim in this study was to gain in-depth understanding of the subjective experience of living with bvFTD. To do this, we undertook qualitative interviews with a small sample of five participants and used interpretive phenomenological analysis to analyse the data. We derived two superordinate themes labelled ‘Bewilderment’ and ‘Relationships with others’. Bewilderment comprised two main sub-themes of ‘Awareness of change: What’s the problem?’ and ‘Threats to self: This is not me’. Relationships with others also comprised two sub-themes of ‘Family and friends: Things haven’t changed . . . but do I say anything wrong?’ and ‘Copings with threats to self: Blame others or just avoid them’. Overall, these themes demonstrate the paradoxical position in which these participants with bvFTD lived. Whilst they were aware that their lives had changed and were now restricted, and that others behaved differently towards them, they had limited awareness of changes in themselves such as their own risk-taking behaviour or loss of empathy. This led to a sense of bewilderment and anger. In this paper we will present the research findings with illustrative examples and discuss the implications for practice.

VARIATION IN FACTORS INFLUENCING INSTITUTIONALISATION FOR PEOPLE WITH DEMENTIA ACROSS EUROPE: A RIGHT TIME PLACE CARE STUDY
H. Verbeek, J.P. Hamers, R. Consortium, Department of Health Services Research; CAPHRI School for Public Health and Primary Care; Maastricht University, Maastricht, Netherlands

Background. Increasing evidence suggests that factors influencing institutionalisation could be country-specific. This study examines variation in factors influencing institutionalisation of people with dementia (PwD) at admission to institutional nursing care in Europe. Methods. A prospective cohort study was conducted in eight European countries (England, Estonia, Finland, France, Germany, Netherlands, Sweden, Spain). Data were collected at baseline and after three months, with PwD and their informal caregivers (n=2014). Outcome measures were selected based on the literature as shown to influence institutionalisation (e.g. cognition, functional status, behavior, caregiver burden and sociodemographic characteristics). Results. Considerable differences were found between the countries in characteristics of PwD who have been recently admitted and their informal caregivers. Sociodemographic differences were mainly found in living situation prior to admission and income. Hierarchical modelling showed that country itself affected factors associated with institutionalization (estimate random-effect country=0.31; 95%CI 0.16-0.60). Country-specific analyses showed that a higher dependence in ADL activity was the only factor consistently associated with being recently admitted in all countries (p<.05). All other characteristics showed variability: a factor that was statistically significant in some countries, was not significant in other countries and vice versa. Conclusion. This study showed that there is a wide variation in factors associated with institutionalization of PwD within European countries and only few factors can be characterized as universal predictors for institutionalization. Therefore tailored best-practice strategies are needed to enable people to reside in their own home for as long as possible but also to identify appropriate timing of admission.

APATHY AMONG PERSONS WITH ALZHEIMER DISEASE AS MEASURED BY THE NEUropsychiatric INVENTORY AND APATHY INVENTORY

Apathy is a prevalent behavioral symptom among persons with Alzheimer Disease (AD), defined as a disorder of motivation with deficits in behavioral, emotional, and cognitive domains. Apathy occurs across the disease trajectory and is associated with serious complications, including physical deconditioning, uncooperativeness with care, and social isolation. Challenges exist in measuring apathy, and a wide range of apathy prevalence among persons with AD has been reported. The purpose of this report is to compare the performance of the Apathy Inventory (IA) Caregiver and Neuropsychiatric Inventory – Apathy subscale (NPI-Apathy) in a cohort of persons with AD. Both NPI-Apathy and IA Caregiver scores were available for 21 participants who were recruited as part of a larger project to examine apathy, genetics and functional status among persons with AD. Data analyses were conducted to compare apathy scores between the two instruments. NPI-Apathy and IA Caregiver total scores were significantly correlated among this sample (r = 0.78, p = 0.001). NPI-Apathy Frequency x Severity (FxS) scores were significantly correlated with FxS scores for each of three IA Caregiver items including emotional blunting (r = 0.73, p = 0.001), lack of initiative (r = 0.62, p = 0.002) and lack of interest (r = 0.84, p = 0.001). The prevalence of apathy as measured by the IA Caregiver was 71.4%, compared to a prevalence of 51.7% as measured by the NPI-Apathy subscale, suggesting the IA Caregiver may be a more sensitive measure of apathy. While further analysis is needed, these
results support the use of both the NPI-Apathy and IA Caregiver scales among persons with AD.

SESSION 790 (PAPER)

END-OF-LIFE

FACTORS ASSOCIATED WITH END-OF-LIFE CARE AND HOSPICE USE IN A COMMUNITY: RESULTS FROM THE ALLEGHENY COUNTY HEALTH SURVEY

J.B. Seaman1, T.M. Bear2, P.L. Documet2, S.M. Sereika1, S.M. Albert2, 1. University of Pittsburgh, Department of Health and Community Systems, School of Nursing, Pittsburgh, Pennsylvania, 2. University of Pittsburgh, Department of Behavioral and Community Health Sciences, Graduate School of Public Health, Pittsburgh, Pennsylvania

Background: Hospice utilization (HU) and benefits of hospice may not be equally distributed across populations. The purpose of this study is to describe: the proportion and characteristics of those who arrange and provide care at EOL and the association of HU with the demographics of care providers, location of death, and satisfaction with care at EOL. Methods: The 2009-2010 Allegheny County Health Survey, a population-based telephone survey of 5,442 residents, included an 8-item EOL caregiver module. Results: Survey results indicated that 7.8% (95%CI=7.0, 8.6) of Allegheny County adults had arranged/provided care for a close friend or family member who died in the previous 12 months. These caregivers were more likely to be older and female, compared to bereaved non-caregivers. Caregivers in deaths with HU were more likely to have annual household incomes above $25,000 (OR=1.5; 95%CI=1.0, 2.4) but did not otherwise differ demographically from caregivers in deaths without HU. With HU: the odds of dying at home or a non-hospital location were 3 times greater (OR=3.08; 95%CI=1.9, 5.2); and the odds of reporting excellent quality of dying and satisfaction with decisions about care or treatment were significantly greater (OR=2.0; 95%CI=1.1, 3.6 and OR=3.0; 95%CI=1.9, 4.8, respectively). Conversely, caregiver burden was greater for caregivers with HU; caregivers were more likely to report time off work and medication giving (OR=1.9; 95%CI=1.0, 3.6 and OR=1.7; 95%CI=1.1, 2.9, respectively). Conclusions: Overall, HU at EOL was associated with beneficial outcomes; however, the burden for caregivers, especially older adults, is noteworthy.

PROFESSIONAL, ORGANIZATIONAL, AND REGIONAL DIFFERENCES IN ADVANCE CARE PLANNING PRACTICES

K.R. Baughman1, R.E. Ludwick2, B. Palmisano1, M. Sanders1, S. Hazelett3, 1. Family & Community Medicine, Northeast Ohio Medical University, Rootstown, Ohio, 2. Robinon Memorial Hospital, Ravenna, Ohio, 3. Summa Health System, Akron, Ohio

Cultural differences between professions, organizations, and geographical regions may impede the uniform adoption of advance care planning (ACP) best practices by healthcare providers. We administered surveys to 458 registered nurses (RNs) and social workers (SWs) working as care managers at 10 Area Agencies on Aging and conducted phone interviews with directors of the organizations. RNs were less likely than SWs to discuss ACP with more than half of their consumers (p=0.01). RNs tended to be older (p=.001) and less likely to have a graduate degree (p=.003) than SWs. Two of the 10 organizations had more than half of their care managers report high levels of ACP discussions (p=.0001) and higher levels of confidence in discussing ACP (p=0.05) than the other 8 organizations. Telephone interviews with the organization directors indicated that both sites had ACP training programs, follow-up protocols, and informational packets available for consumers that were not consistently available at the other organizations. There were no geographical differences in percent of caseload in which ACP discussions took place or in confidence in discussing ACP, but Appalachian care managers were significantly less likely to have held an ACP discussion in the past month than those in urban and rural regions (p=0.03). The findings point to the need for consistent educational programs on the vital role of care managers in ACP and more in depth examination of the values, beliefs, and resources that may account for the professional, organizational and regional differences in ACP.

PALLIATIVE CARE IN DEMENTIA: ASSOCIATION OF A COMFORT CARE GOAL UON NURSING HOME ADMISSION WITH RESIDENT'S OUTCOME WHEN DYING

M. Van Soest-Poortvliet1, J.T. van der Steen1, H.C. de Vet1, C.M. Hertogh1, L. Deliens1,2, B. Onwuteaka-Philipsen1, 1. VU University Medical Center, EMGO Institute for Health and Care Research, Department of General Practice & Elderly Care Medicine, Amsterdam, Netherlands, 2. VU University Medical Center, EMGO Institute for Health and Care Research, Department of Epidemiology and Biostatistics, Amsterdam, Netherlands, 3. VU University Medical Center, EMGO Institute for Health and Care Research, Department of Public and Occupational Health, Amsterdam, Netherlands, 4. Ghent University and Vrije Universiteit Brussels, Brussels, Belgium

Background: Admission of people with dementia to a nursing home provides the opportunity to (re-)evaluate care goals. A comfort care goal, consistent with palliative care, may be appropriate. Little research has examined the effectiveness of care focussed on comfort. Objective: To assess whether a comfort care goal shortly after admission (within 8 weeks) is associated with families' satisfaction with end-of-life care and quality of dying in nursing home residents dying with dementia. Method: Prospective data-collection in Dutch nursing homes (the Dutch End of Life in Dementia (DEOLDi) study) from admission to death. Families and physicians collected data about treatment, care, and outcome, including families' satisfaction (End-Of-Life in Dementia (EOLD)-Satisfaction With Care scale and quality of dying (EOLD-Comfort Assessment in Dying). We selected 178 residents who died during data collection for regression analyses adjusted for factors related to a comfort care goal, such as illness severity. Results: Family of residents who died within a half year were more satisfied with end-of-life care when a comfort care goal was assessed shortly after admission. There was no such association with longer length of stay, nor with quality of dying. Conclusions: A care goal focussed on comfort established within weeks after admission was associated with families' higher satisfaction with end-of-life care in residents who died within a half year of admission. Given that death is difficult to predict, and families better appreciate care consistent with a comfort care goal, early setting of a comfort care goal may involve benefits.

PREDICTORS OF DEPRESSION IN PALLIATIVE HOME CARE AND HOSPICE CLIENTS IN ONTARIO

D. Guthrie1, K. Fisher1, T. Frise Smith2, S. Freeman1, K. Brazil1, 1. Kinesiology and Physical Education, Wilfrid Laurier Univ, Waterloo, Ontario, Canada, 2. Nipissing University, North Bay, Ontario, Canada, 3. University of Waterloo, Waterloo, Ontario, Canada, 4. Queen's University Belfast, Belfast, Ireland

Background. Depression reduces the quality of life for individuals who are dying, impairing their ability to interact with others, organize their affairs, and benefit from treatments for pain and other symptoms. Depression is frequently under-diagnosed and under-treated in palliative care (PC) clients even though depression can be treated and clients' experiences may improve, even in the later stages of end-of-life. Methods. We examined the predictors of signs/symptoms of depression in a sample of 5,700 home and hospice PC clients. Clients were assessed using the interRAI Palliative Care (interRAI PC) tool which is mandated for PC clients receiving home care in Ontario. The interRAI PC is client-focused and collects data on multiple domain areas including...
physical symptoms, mood, pain, and cognition. Depression was determined based on a score of 3+ on the Depression Rating Scale (DRS), a 7-item validated scale embedded within the interRAI PC. Theory, past research and examination of bivariate associations was used to identify the independent variables that were included in a logistic regression model to predict depression. Results. The prevalence of depression was 9.5%. Our preliminary model identified 9 independent risk factors for depression including daily pain (adjusted OR=2.0), more fatigue (2.27), less family support (1.89), less progress towards completing life goals (1.82) and caregiver distress (1.67). Conclusion: Depression is not uncommon among PC clients in the community and is related to multiple factors encompassing physical symptoms as well as psychosocial and interpersonal factors, many of which can be addressed by care providers in the community.

CHANGES IN GLOBAL AND COMPARATIVE SELF-RATED HEALTH FOLLOWING SPAWAL LOSS
D.A. Heller1,2, F. Ahem1, J. Ding3, T.V. Brown4, I. Magellan Health Services, Harrisburg, Pennsylvania, 2. Penn State University, University Park, Pennsylvania, 3. Pennsylvania Department of Aging, Harrisburg, Pennsylvania

Prior research has shown that bereavement increases mortality risk. However, data are limited regarding the impact of bereavement on self-rated health, particularly for comparative self-ratings. The goal of this study was to examine short-term change in several self-assessed health measures following spousal loss. Subjects included 23,943 married persons enrolled in Pennsylvania’s Pharmaceutical Assistance Contract for the Elderly program who completed two surveys approximately one year apart between 2009 and 2011. Measures included the CDC’s Healthy Days questions, as well as global, age-comparative, and time-comparative (present vs. year ago) self-rated health. Widowhood was determined from vital records. ANCOVA and polynomial logistic regression were used to examine associations between bereavement and health change, controlling for demographics and comorbidity. 1,023 respondents became widowed between Time 1 and 2. Compared to non-widowed, widowed respondents had greater increases in poor mental/ emotional health days (0.34 vs. 1.57 days out of 30, p<.001). However, widowed were more likely than non-widowed to report physical self-ratings at Time 2 that were better than baseline (global OR=1.46, age-comparative OR=1.41, both p<.001). Despite these differences, widowed and non-widowed respondents did not differ significantly in their Time 2 assessment of whether health-related changes had occurred. These results suggest that spousal loss affects survivors’ assessments of their own health in complex ways. While widowed individuals were no more likely than non-widowed to report that their physical health had changed, they were more likely to report Time 2 ratings that exceeded Time 1. Additional findings regarding the timing of bereavement and spousal health will be presented.

SESSION 795 (PAPER)

MEMORY PAPERS

SUBJECTIVE PERCEPTIONS OF THE EFFECTS OF AN AEROBIC EXERCISE INTERVENTION IN ALZHEIMER’S DISEASE
C. Schenk, F. Yu, University of Minnesota, Minneapolis, Minnesota

Background: Interest in examining the effects of exercise in Alzheimer’s disease (AD) has grown recently. However, little is known about how people with AD and their family caregivers perceive exercise programs. A previous exercise study concluded that improvement in cardiorespiratory conditioning from aerobic exercise is possible in persons with AD. Qualitative data was needed to further understand the impact the exercise program had on the participants and their caregivers and to determine the feasibility of implementing such an exercise program for people with AD. Method: This study used focus group interviews to examine the perceived effects on persons with AD (n=14) and their primary family caregivers (n=21) six months after completing an exercise intervention. Data from seven focus groups were audio taped, transcribed, and then analyzed using the Atlas.ti program. Results: Three themes emerged from the participant and caregiver interviews respectively. Participants reported that the exercise program: 1) facilitated increased socialization, 2) gave them a sense of hope, and 3) motivated them to do more. Caregivers reported that the exercise provided: 1) a much appreciated respite from caregiving, 2) structure and routine for participants, and 3) a positive change in the participant’s temperament. Neither participants nor caregivers perceived improvements or deterioration in cognition. Conclusion: Participants and caregivers perceive many benefits from participating in the exercise intervention. The lack of change in cognition might be important since AD results in ongoing cognitive decline and could be further explored using quantitative measures.

CHANGES IN PHYSICAL FUNCTION PREDICT IMPROVEMENTS IN COGNITIVE FUNCTION AFTER 12 WEEKS OF RESISTANCE EXERCISE IN COMMUNITY DWELLING OLDER ADULTS
M. Chang1,2, A. Ramel1, A. Arnarson1, O.G. Geirsdottir1,4, P.V. Jonsson1,2, I. Thorisdottir1,1, J. University of Iceland, Reykjavik, Iceland, 2. Reykjavik University, Reykjavik, Iceland, 3. Landspitali - University Hospital, Reykjavik, Iceland, 4. The Icelandic Gerontological Research Center, Reykjavik, Iceland

Background: Cognitive function is an independent predictor of mortality in older adults. Physical activity is negatively correlated with cognitive function and aerobic exercise has been reported to increase cognitive function. Little is known on the potential of resistance exercise. We investigated this issue in community dwelling older adults. Methods: Subjects (N=237;73.7+-5.7years;58.2% female) participated in a 12-week resistance exercise program (3 times/week; 3 sets, 6-8 repetitions), designed to increase strength and muscle mass. Participants were randomly assigned to one of three dietary supplements consumed after each training. The supplements were a whey-protein drink (20g whey-protein + 20g carbohydrates), a milk-protein drink (20g milk-protein + 20g carbohydrates) or a carbohydrate drink (40g carbohydrates). Cognitive function was assessed using the Mini Mental State Examination (MMSE). Physical function was assed using 6-minute-walk-for-distance (6MWD) Results: At baseline MMSE was 27.6+-2.0 and 6MWD was 462+-73m. After the intervention both MMSE and 6MWD increased significantly (28.0+-2.2 and 496+-76m, both P=0.001). Changes were similar in male and female participants. According to multivariate analysis, improvements in 6MWD predicted improvements in MMSE (MMSE score 0.24 for the mean improvement of 34m, P=0.032, corrected for gender, age and dietary supplement). Baseline MMSE and improvement in MMSE were negatively correlated (r=-0.341;P=0.001). Conclusion: In community dwelling older adults with high baseline MMSE, a 12-week resistance exercise programme can further increase MMSE with similar improvements in men and women. The changes experienced in physical function after 12 weeks of resistance exercise predict the improvement in cognitive function.

TRAJECTORY OF MOBILITY DECLINE IN OLDER ADULTS WHO PROGRESS TO DAT VS. NON-AD DEMENTIA
M. Tolea, J. Galvin, Psychiatry, New York University, New York, New York

Individuals with dementia of the Alzheimer’s type (DAT) have lower levels of functionality and higher rates of functional decline compared to cognitively normal older adults. To investigate whether these patterns extend to other types of dementia we compared trajectories of change in mobility in patients who progressed to DAT (p-DAT) and those who
progressed to non-DAT dementia (p-nonDAT) in 766 participants in studies of cognitive and functional aging conducted at Washington University in St. Louis with at least one follow-up visit. 73% of initially normal participants remained cognitively normal (r-normal), 25% p-DAT, and 2% p-nonDAT by the end of the study. Total PPT score was lower in p-DAT compared to r-normal (p<0.05) or p-nonDAT (p<0.05). Mixed-effects models showed that patterns of change in mobility differed between these groups (overall p =0.017) with adjustment for covariates. Pair-wise comparisons revealed that the difference was restricted to the r-normal/p-DAT comparison (p=0.002). We next compared the p-DAT group against those who progressed to Lewy body/Parkinson dementia (p-LB/PD), vascular dementia (p-VD), or frontotemporal dementia (p-FTD). Although patterns of change in mobility differed (e.g. more decline in p-LB/PD and p-FTD, and less in p-VD vs. p-DAT), differences were not significant probably due to small numbers in the non-DAT subgroups. In conclusion, we replicated findings of steeper decline in mobility with AD progression. Patients who progress to certain non-DAT dementias may experience mobility decline at higher levels than those seen in patients who progress to DAT, and therefore could be targeted for interventions to prevent mobility decline.

PERCEIVED STRESS AND MEMORY IN OLDER ADULTS
B.N. Sprague1, S. Scott1, M. Slivinski1, M.J. Katz2, R.B. Lipton2, 1. The Pennsylvania State University, University Park, Pennsylvania, 2. Albert Einstein College of Medicine, Bronx, New York

Although stress is hypothesized to negatively affect cognition, findings are mixed. Further, previous work has focused primarily on physiological stress markers and life events—surprisingly few studies have examined the effects subjective stress on cognitive aging. The current study examined perceived stress and memory function in a longitudinal study of older adults. We hypothesized that higher PSS scores would be associated with poorer memory performance and greater decline. We examined data from the Einstein Aging Study, a longitudinal prospective study examining cognition in a diverse sample of older adults. Participants (N = 373, baseline M[SD] age = 80.56[5.01]) completed annual assessments, including memory tests (Boston Naming, Free and Cued Selective Reminding Task, and Logical Memory) and the Perceived Stress Scale (PSS). Using multilevel modeling, we found that people with higher levels of perceived stress scored worse on the Boston Naming task (b = -0.04, p < .05). We also found a longitudinal relationship between PSS and Logical Memory, such that increases in PSS were associated with concurrent decreases in LM (b = -1.2, p < .05). These results provide novel evidence that subjective stress is related to both level and change in memory

WHY DO PEOPLE WITH DEMENTIA RATE THEIR OWN QUALITY OF LIFE DIFFERENTLY THAN THEIR RELATIVES DO?
J. Gräské1, F. Laporte Uribé2, S. Heinrich2, A. Schmidt1, S. Meyer1, K. Wolf-Ostermann1, 1. Alice Salomo University of Applied Sciences Berlin, Berlin, Germany, 2. DZNE Witten - German Center for Neurodegenerative Diseases, Witten, Germany

Background Available quality of life (QoL) instruments differ in various aspects, including the perspectives of rating. Due to the subjective nature of QoL, self-rated instruments are considered to be the best option measuring QoL. But their applicability depends on sufficient cognitive abilities of the person with dementia (PwD); alternatively only proxy-ratings can be used. However, it is known that there are only weak correlations between self- and proxy-rated QoL-scores. The objective is to assess QoL of PwD using self and proxy ratings and to analyze differences and interfering factors between both perspectives. Methods: Data were collected at baseline of the DemNet-D study (2012-2015) using face-to-face interviews with PwD and their family members throughout Germany. The self- and proxy-rated QoL-AD were used to evaluate the QoL of PwD. Besides socio-demographic variables interfering factors were estimated using, e.g. challenging behavior (CMAI) and depression (GDS) for PwD and burden of care (BIZA-D) for relatives. Results: Using a sample of up to 715 community-dwelling PwD, both ratings indicate a moderate QoL. The QoL-self-ratings of PwD differed from the family members proxy-ratings. Challenging behaviors are interacting with the level of agreement between the two ratings. Further results and factors explaining these differences will be presented. Conclusion: The study generated new findings concerning a better understanding of QoL ratings. Research projects focusing on the measurement of QoL in dementia care are not yet exhaustive. Further studies identifying confounding variables of proxy-ratings are needed in order to optimize a tailored care for PwD.

SESSION 800 (SYMPOSIUM)

ATTITUDES, STAFFING LEVELS, AND REIMBURSEMENT: REDUCING ANTIPSYCHOTIC MEDICATION USE IN NURSING HOMES
Chair: K. Hyer, Florida Policy Exchange Center on Aging School of Aging Studies, University of South Florida, Tampa, Florida
Co-Chair: N. Castle, University of Pittsburgh, Pittsburgh, Pennsylvania
Discussant: D.M. Dosa, Brown University, Providence, Rhode Island

The reduction of inappropriate antipsychotic drug use among older adults in nursing homes is a national priority. Antipsychotic drugs may be used to treat behavioral issues in this setting despite the FDA’s black box warning signifying an increased risk of mortality. Use among older adults is also associated with an increased risk for falls and stroke. Beginning in July 2012, as part of the Partnership to Improve Dementia Care in Nursing Homes, CMS sought to reduce the national prevalence of antipsychotic drug use (approximately 24% among long stay residents) in nursing homes by 15%. This symposium presents findings on the association between structural and market factors and deficiency citations for unnecessary medication use demonstrating that smaller nursing homes and high Medicaid reimbursement rates were significantly associated with fewer overall and repeat deficiency citations for inappropriate medication use. The second paper assesses the relationship between social support staff (social workers and activity staff) and the use of antipsychotic drugs demonstrating a significant negative relationship between social support staff and antipsychotic use. Finally, the third paper will present data collected from 276 nursing home administrators and directors of nursing during a statewide training for nursing homes in Florida. Results provide a more nuanced understanding of the challenges faced by providers seeking to reduce antipsychotic drug use. The discussant, a practicing geriatrician who also does research in this area, will provide comments on the challenges, regulatory issues and policies that require a change in nursing home practice to achieve these goals.

SOCIAL SUPPORT STAFFING AND ANTIPSYCHOTIC MEDICATION USE
K.M. Smith, K. Hyer, M.L. Ellis, V. Molinari, University of South Florida, Tampa, Florida

Despite FDA black box warnings signifying an increased risk of mortality in older adults, antipsychotic medications are commonly prescribed in nursing homes eliciting a significant patient safety concern. The use of antipsychotic drugs in this population has been linked to poor outcomes (e.g., increased risk of falls, stroke). A resident centered culture in nursing homes fosters an individualized approach and may lead to less antipsychotic medication use. Using the Online Survey Certification and Reporting data from 2006 to 2010, this project examined the relationship between social workers and activity staff, as a measure of resident centered culture, and the use of antipsychotic medication. Using hierarchical linear modeling, we found that a higher level of
full-time equivalent (FTE) qualified activities professionals (Est. = -0.011, p <0.001), other FTE activities staff (Est. = -0.001, p=0.0005) and FTE qualified social workers (Est. = -0.012, p<0.001) were associated with reduced antipsychotic drug use.

ASSESSING APPROACHES AND BARRIERS TO REDUCING ANTIPSYCHOTIC DRUG USE IN FL NURSING HOMES

K.M. Smith, M.L. Ellis, V. Molinari, K. Hyer, University of South Florida, Tampa, Florida

An FDA black box warning suggests the consumption of antipsychotic medications by older adults increases their risk of mortality. Almost 40% of nursing home residents are prescribed antipsychotic drugs without an appropriate diagnosis. A new Centers for Medicare and Medicaid (CMS) initiative seeks to reduce antipsychotic medication by 15% in all nursing homes. Florida Nursing home administrators, Directors of Nursing, and other pertinent staff were surveyed using a 19-item questionnaire to assess effective approaches, barriers, and resources that may assist or obstruct compliance with the new CMS mandate. A total of 275 surveys were collected for this study. Overall, findings showed respondents were supportive of new restrictions, but reported barriers of inadequate staff and poor care coordination. Ongoing education was cited as the most effective assistance nursing homes could receive to reduce antipsychotic drug use among their residents.

SESSION 805 (SYMPOSIUM)

CONGREGATE MEAL PROGRAMS: A POTENTIAL RESILIENCY FACTOR IN SUCCESSFUL AGING FOR LGBT OLDER ADULTS

Chair: K. Porter, UMASS Boston, Quincy, Massachusetts
Discussant: S. Cahill, Fenway Institute, Boston, Massachusetts

Congregate Nutrition Services are Title III funded programs of the Older Americans Act. The purpose of this federal program is to support older adults in maintaining independence by reducing nutritional deficiencies while fostering social engagement. The Massachusetts LGBT Aging Needs Assessment Coalition (M’LANA) initiated two research studies (one state and one national) to examine the participation and experiences of underserved populations, including lesbian, gay, bisexual, and transgender (LGBT) older adults, in congregate meal programs. The findings from the five papers presented will provide a comprehensive overview of what is known about the experience of LGBT older adults. The first paper reports on a national analysis of state-level diversity initiatives in congregate meal programs. The second provides insight into unique methodologies that can capture information about this hard-to-reach population. The third and fourth analyze data collected from a Massachusetts study of LGBT and heterosexual attendees of congregate nutrition programs (N=257) and report on differences between these two groups, with a focus on demographics, experiences of social isolation, perceptions of care and social support resources and value placed on the congregate meals. The concluding paper describes existing policies that support services for LGBT older adults, details the known public health effects of such services, and analyzes policy implications. All together, the papers demonstrate the vital role played by congregate nutrition services in meeting the needs of underserved older adults and connecting them with mainstream elder care resources. The findings suggest the need for enhanced funding for training and research.

SEXUAL ORIENTATION AND PERCEPTIONS OF CARE RESOURCES AMONG CONGREGATE NUTRITION PROGRAM UTILIZERS

A. Van Wagenen1, S.A. Keary1, K. Conron1, S. Sass1, K. Porter2, J. Driskell4, J. Bradford1

1. Center for Population Research in LGBT Health, The Fenway Institute, Boston, Massachusetts
2. Boston College, Chestnut Hill, Massachusetts
3. University of Massachusetts, Boston, Boston, Massachusetts
4. Salem State University, Salem, Massachusetts

This study compared 121 lesbian, gay, or bisexual (LGB) adults age 60 and older surveyed at LGBT-friendly congregate nutrition sites with 136 heterosexual participants at mainstream sites. LGBs were more likely to be younger, male, white, employed, more educated, and have no children. LGBs were less likely to report that they could a call a child if they needed help (16% vs. 51%, x2=33.14, p<0.001) and more likely to report they could call friends (71% vs. 37%, x2=33.00, p<0.001). LGBs were more likely to report general concerns about accessing aging services like in-home help (4.55 concerns vs. 3.02 concerns, t=4.11, p<0.001) and concerns about discrimination (1.83 concerns vs. 1.07 concerns, t=2.71, p<0.001). The study suggests that sexual orientation may be salient in perceptions of care and support resources among older adults. Congregate nutrition programs may be good sites for interventions to facilitate access to culturally competent services for LGB older adults.

A STATE-LEVEL REVIEW OF DIVERSITY INITIATIVES IN CONGREGATE MEAL PROGRAMS

K. Porter, UMASS Boston, Quincy, Massachusetts

Congregate meal programs incorporate a biopsychosocial approach to optimal aging, thus the importance of sites to meet the needs of the most vulnerable cannot be overstated. This descriptive study is the first to document state-level diversity initiatives at congregate meal programs for older adults. A national self-administered electronic survey was distributed to each State Unit on Aging; responses were obtained from all but 3 states. Sixty-four percent of states’ congregate meal programs target a racial, ethnic or cultural community. Initiatives include: serving foods of a specific ethnic group (60.4%), observing cultural traditions (56.3%), incorporating culturally-specific entertainment (52.1%), and providing non-English meal sites (56.3%). Five states offered sites targeting lesbian, gay, bisexual, and transgender (LGBT) older adults. Of these states, 43.8% protect LGBT from employment discrimination; 14.6% legalized same-sex marriage, and 60.4% have LGBT hate crime laws. Qualitative responses to open ended questions about barriers and cultural competency will be discussed.

SERVING VULNERABLE OLDER ADULTS: LGBT PARTICIPATION IN TITLE III CONGREGATE MEAL SITES

K. Porter1, S. Sass1, A. Van Wagenen1, 1. UMASS Boston, Quincy, Massachusetts
2. Fenway Institute, Boston, Massachusetts

This study compared the value of congregate meal programs for 120 lesbian, gay, or bisexual (LGB) adults with 136 heterosexual participants. Independent sample t-tests show heterosexual attendees placed higher value on the food (t(232)=1.97, p<.05); nutritious aspect (t(220)=2.88, p<.01); sense of belonging (t(228)=3.6, p<.001); and social aspect (t(230)=4.87, p<.001) than LGB attendees. Linear bivariate regressions revealed significant higher value on both social and nutritional indices’ for heterosexual participants compared to LGB participants; although, differences in the social index were insignificant after controlling for income and education. Yet, LGBs traveled significantly further to attend meal programs (t(237)=9.28, p<.001). Demographics show LGB attendees are significantly younger with higher incomes, more education and more likely to have partners than heterosexual attendees. This may explain the higher value placed on the social and nutritional value of meals by heterosexual attendees who are more likely to be single and have lower income than LGB attendees.

The Gerontological Society of America
HEALTH POLICY AND ELDER POLICY BENEFITS OF LGBT-SPECIFIC CONGREGATE MEAL PROGRAMS
S. Cahill, 1. Fenway Institute, Boston, Massachusetts, 2. New York University, New York, New York

While most states offer congregate meals catering to racial/ethnic, cultural, and linguistic minorities, few states offer congregate meals targeted toward LGBT older adults. This presentation will describe existing policies that support services for LGBT older adults, the known public health effects of such services, and make further policy recommendations. Congregate meals funded by the Older Americans Act (OAA) combat social isolation and support social networks, a resiliency factor for LGBT elders. Because social isolation is a risk factor for depression and poor treatment adherence, congregate meals support LGBT health and aging in place. Because of higher rates of anti-gay prejudice among older adults, targeting of culturally competent services toward LGBT elders is essential. Listing LGBT elders as a population of “greatest social need” in the OAA could enhance funding for training and research on LGBT elders. US DHHS has encouraged state aging departments to make this designation now.

INNOVATIVE METHODOLOGY FOR CONDUCTING RESEARCH WITH SEXUAL MINORITY OLDER ADULTS
J. Bradford1, A. Van Wagenen1, J. Driskell2, S. Sass1. 1. Center for Population Research in Lesbian, Gay, Bisexual and Transgender Health, The Fenway Institute, Boston, Massachusetts, 2. Salem State University, Salem, Massachusetts

An international call for effective methods to study “hard-to-reach populations” coincided with the 2011 IOM “LGBT health report” noting lack of research about LGBT elders. The “Meal Sites Study” surveyed LGB elders at the 6 LGBT-friendly congregate nutrition sites in Greater Boston. One mainstream site was randomly selected from each agency supporting an LGBT site; a random number generator determined which mainstream sites would be invited to participate. Study team members worked closely with site staff to avoid interference with meal presentation and socializing. The study purpose was described differently at LGBT and mainstream sites. A question module on LGBT experiences was included in the LGBT sites questionnaire but not at mainstream sites. 294 valid returns and an overall response rate of 81% were achieved (79% LGBT, 82% mainstream). Randomization of matched comparison sites within the full population design increases confidence in statistically significant differences on responses to key questions. Objectives: Participants will understand the value of best practice methodology in gathering data from sexual minority older adults. Participants will consider how they may utilize increasingly rigorous methods for conducting research with hard-to-reach and other underserved populations of concern.

SESSION 810 (SYMPOSIUM)

HEALTH CARE IN ASSISTED LIVING: WHAT’S HAPPENING, WHAT’S NECESSARY, WHAT’S POSSIBLE
Chair: S. Zimmerman, Univ North Carolina Chapel Hill, Chapel Hill, North Carolina
Discussant: P. Sloane, Univ North Carolina Chapel Hill, Chapel Hill, North Carolina

Across the nation, virtually all residential care/assisted living (RC/AL) communities provide basic health monitoring, and slightly more than one-third provide skilled nursing services. However, little is known about the “black box” of health care services and needs, including nursing, dental, and preventive care – all of which are critical for the almost one million dependent RC/AL residents. This symposium will begin with two presentations related to nurse staffing and service provision in a stratified random sample of 240 RC/AL communities from eight states. Beyond descriptive statistics, the presentations will discuss the relationship of nurse staffing and services to resident outcomes (e.g., falls, infections, hospitalizations, nursing home transfer), and consider the extent to which there is additional capacity and need to provide services and augment staffing. The remaining two presentations highlight RC/AL resident unmet need in areas other than nursing services: cancer prevention and dental assessment. They will address the need to improve colorectal cancer screening among RC/AL residents based on data indicating notable underuse, and consider strategies to do so in the context of ongoing care. In addition, attention will be paid to the important health care impact of oral hygiene and the need to understand the extent to which RC/AL residents require support with their daily mouth care; a new measure will be presented to assess dental-related function that can be incorporated into routine care planning. Together, these presentations address an expanse of important health care topics that have implications for future care needs of an increasing vulnerable population.

EXAMINING THE LANDSCAPE: NURSE STAFFING AND NURSING SERVICES IN ASSISTED LIVING
A.S. Beeber1,2, S. Zimmerman3,2, C. Mitchell7, D.A. Reed2. 1. School of Nursing, the University of North Carolina at Chapel Hill, Chapel Hill, North Carolina, 2. Cecil G Sheps Center for Health Services Research UNC at Chapel Hill, Chapel Hill, North Carolina, 3. School of Social Work - UNC at Chapel Hill, Chapel Hill, North Carolina

While variation exists in nurse staffing and nursing services in residential care/assisted living (RC/AL) communities overall and in relation to other characteristics of the setting, information in this area is sorely lacking. This session presents results from an eight state (CA, FL, IL, KS, NC, NH, NJ, OR) stratified random sample of 240 RC/AL communities that examined the relationships between community characteristics, nurse staffing, and nursing service availability. The total number of services available related to the number of staff employed (r=.43, p = .018). Similarly, the number of nursing assessment services (physical, cognitive, dental, depression screening, mental health services, ulcer staging) related to the number of staff (r=.42, p = .020) as well as to the staff/resident ratio (r=.41, p = .029). Additional data will be presented to describe the variability of services and staffing across settings, and discuss the implications of these findings for resident care.

RESIDENT OUTCOMES IN ASSISTED LIVING: DO STAFFING AND SERVICES MATTER?
A.S. Beeber1,2, S. Zimmerman3,2, C. Mitchell7, D.A. Reed2. 1. School of Nursing, the University of North Carolina at Chapel Hill, Chapel Hill, North Carolina, 2. Cecil G Sheps Center for Health Services Research - UNC at Chapel Hill, Chapel Hill, North Carolina, 3. School of Social Work- UNC at Chapel Hill, Chapel Hill, North Carolina

Given increasing acuity among residents in residential care/assisted living (RC/AL), there is a need to understand the extent to which nurse staffing and nursing services relate to potentially avoidable resident outcomes. Using data from a stratified random sample of 240 RC/AL communities in eight states, this session will present the associations between nurse staffing and nursing services and resident outcomes (fall rates, infections, emergency department use, hospitalizations, nursing home transfer). Preliminarily, the RC/AL communities reported a median of 33 falls per 100 residents per year (interquartile range 14 – 66) and a median of 1.3 injurious falls per 100 residents per year (interquartile range 0.0 – 4.2). The nurse:resident ratio related to injury rate (r=.39, p < .05), suggesting that nurse staffing and resident outcomes may be attributed to resident acuity. Additional results will be reported for other outcomes in relation to staff intensity, mix, and nursing services.
THE APPROPRIATENESS OF COLORECTAL CANCER SCREENING IN TWO ASSISTED LIVING SETTINGS

Little is known about the appropriateness of colorectal cancer screening (CRC) screening rates in residential care/assisted living (RC/AL). We conducted a cross-sectional retrospective study of 93 persons aged 50+ in two RC/AL communities with resident/surrogate interviews and chart review, asking about their CRC screening history and screening attitudes. A modified Charlson comorbidity index assessed screening appropriateness, categorizing residents into three health status groups: good, intermediate, and poor. Approximately 30% of residents had never received CRC screening. Only 50% of residents in good health were up-to-date with CRC screening, while 20% of those in poor health were up-to-date. Additionally, 46% of residents versus 14% of surrogates believed CRC screening would prolong the resident’s life (p<0.001). While older adults in good health were more likely to be up-to-date with screening, work needs to be done to improve these rates. Differences in CRC screening attitudes occurred between RC/AL residents and their surrogates. Overall Objectives: 1. To be able to discuss appropriate CRC screening in older adults in assisted living settings. 2. To consider the variety of older adults/surrogate attitudes in assisted living settings towards CRC cancer screening.

ASSESSMENT OF DENTAL-RELATED FUNCTION IN ASSISTED LIVING RESIDENTS

It is challenging for individuals with cognitive impairment to sufficiently attend to their oral health care needs, and similarly challenging to assess and integrate the impact of dental-related functional loss into care. Given that 90% of residential care/assisted living (RC/AL) residents have some cognitive impairment, a screening tool would be helpful to identify the extent of support needed with oral care. To address this need, we developed and validated the Dental-related Function (DRF) Assessment. Nine candidate items were identified through literature review and focus groups, and evaluated for content validity and clinical usefulness by eight geriatric and special needs dental professionals. A cognitive interview was then completed with five cognitively-intact residents. The DRF assessment provides helpful cutpoints to indicate care needs.

SESSION 815 (SYMPOSIUM)

NATIONAL DISSEMINATION OF EVIDENCE-BASED HEALTH PROMOTION PROGRAMS FOR OLDER ADULTS: SUCCESSES, CHALLENGES, AND IMPACT
Chair: K. Kulinski, National Council on Aging, Washington, District of Columbia
Co-Chair: J. Frank, University of California, Los Angeles, Los Angeles, California
Discussant: M.L. Boutaugh, U.S. Administration for Community Living/Administration on Aging, Washington, District of Columbia

Fueled by positive outcomes and participant satisfaction, the adoption of evidence-based healthy aging programs is rapidly spreading. Implementation of evidence-based programs is an effective strategy to help to mitigate the health challenges confronting the older adult population such as chronic disease, falls, and behavioral health issues. Since 2006, over 200,000 individuals have participated in these impactful programs, funded primarily through the U.S. Administration on Aging (AoA) and the Centers for Disease Control and Prevention. This symposium will present evaluation data from two national initiatives and one prospective study of these programs, highlighting both qualitative and quantitative indicators. The first presentation (Frank) will concentrate on AoA’s Empowering Older People to Take More Control of Their Health through Evidence-Based Prevention Programs initiative, highlighting best practices and lessons learned as a result of this multi-year grant program. The next presentation (Kulinski) will speak to how AoA’s subsequent American Recovery and Reinvestment Act (ARRA) Communities Putting Prevention to Work: Chronic Disease Self-Management Program funding opportunity leveraged the infrastructure developed via the prior initiative to expand access to Stanford University’s Chronic Disease Self-Management Program (CDSMP) and develop an integrated, sustainable national infrastructure for program delivery. The third presentation (Ory) will discuss outcome findings from a national study that took place concurrent to the ARRA CDSMP initiative demonstrating the effectiveness of CDSMP to improve health-related indicators over a 12-month period. To conclude, the Discussant (Boutaugh) will provide perspective about these initiatives in context of federal and private partnerships for future growth and sustainability.

NATIONAL EVALUATION OF THE “EMPOWERING OLDER PEOPLE TO TAKE MORE CONTROL OF THEIR HEALTH THROUGH EVIDENCE-BASED PREVENTION PROGRAMS” INITIATIVE
J. Frank, C. Lau, University of California, Los Angeles, Los Angeles, California

In 2006, the Administration on Aging (AoA) began their “Empowering Older People to Take More Control of Their Health through Evidence-Based Prevention Programs” initiative, funding 24 states to expand and create sustainable systems to support evidence-based health promotion and disease management (EBHP) programs for older adults. Results from an evaluation study utilizing secondary data documented the successes, challenges, accomplishments, lessons learned, and products produced by states within this initiative. The evaluation employed both quantitative (descriptive) and qualitative (content analyses) methods. The 24 states focused on 21 total EBHP programs and reached over 135,000 people, many from rural and underserved minority populations. States established important infrastructure protocols, aging and public health partnerships, and statewide coalitions. Seventeen states went beyond grant expectations to provide participant level program outcomes. All states identified challenges, with many noted for implementation and sustainability. Best practices and lessons learned will assist future expansion of these important programs.

NATIONAL EVALUATION OF THE AMERICAN RECOVERY AND REINVESTMENT ACT COMMUNITIES PUTTING PREVENTION TO WORK: CHRONIC DISEASE SELF-MANAGEMENT PROGRAM INITIATIVE
K. Kulinski, National Council on Aging, Washington, District of Columbia

The Communities Putting Prevention to Work: Chronic Disease Self-Management Program, funded by the American Recovery and Reinvestment Act of 2009, was an initiative led by the U.S. Administration on Aging in collaboration with the Centers for Disease Control and Prevention and the Centers for Medicare and Medicaid Services. Units on aging and health departments in 45 states, the District of Columbia, and Puerto Rico worked together to assure prevention programs are part of the nation’s health and long term care system. These agencies collaborated with area agencies on aging, health care organizations, and other community partners to develop a distribution and delivery system that increased the availability of, and access to, CDSMP workshops, especially for low-income, minority, and other underserved populations.
Qualitative and quantitative results from a comprehensive assessment of grantee successes, challenges, and best practices will be shared, informing current and future program implementation and evaluation activities.

INFLUENCE OF CHRONIC DISEASE SELF-MANAGEMENT PROGRAMS (CDSMMP) ON HEALTHCARE OUTCOMES AND COSTS: FINDINGS FROM THE NATIONAL STUDY OF CDSMP

This presentation reports on the 12-month health outcomes, healthcare and cost savings derived from the Chronic Disease Self-Management Program (CDSMP) when disseminated nationwide. Data were analyzed from the National Study of CDSMP which included 1170 adults across 22 delivery organizations in 17 states from 2010-2012. Significant improvements were seen in illness symptomatology, quality of life, lifestyle behaviors, and the quality of health care (p<.05). Significant reductions in health care utilization were reported: 5% reduction in ER use from baseline to 6-months and from 6-months to 12-months and 3% reduction in hospitalization from baseline to 6-month follow-up. Using aggregate national cost estimates, preliminary analyses indicate approximately $400 per/person net savings in healthcare costs may be achieved after deducting program costs at $350 per/person. These promising results suggest that the widespread dissemination of evidence-based disease self-management programs can improve health and health care while reducing the nation’s burgeoning healthcare costs.

SESSION 820 (SYMPOSIUM)

POLICY SERIES: CONGRESSIONAL AGING ISSUES UPDATE

Chair: G. O’Neill, National Academy on an Aging Society, Washington, District of Columbia

This panel will present an update on aging and health legislation from the first session of the 113th Congress. Speakers will address key issues such as Social Security, Medicare, Medicaid, the Older Americans Act and more, then give the audience a sense of what can be expected during the second session in 2014.

SESSION (SYMPOSIUM)

THE IMPACT OF CUTBACKS IN RESEARCH FUNDING AND WHAT YOU CAN DO?

Chair: G. O’Neill, GSA, Washington, District of Columbia

Unprecedented increases in age-related diseases as the population ages is one reason the Congressional Budget Office projects that total spending on health care will rise to 25% of the U.S. GDP by 2025 (it is 17% today). Research that can be translated into effective prevention and efficient health care could help reduce this financial burden. Yet, research dollars at the National Institute on Aging have declined by more than 20% (in constant dollars) over the last 10 years. Unfortunately, this is a trend likely to continue. What has the impact been thus far? This presentation reports on the 12-month health outcomes, healthcare and cost savings derived from the Chronic Disease Self-Management Program (CDSMP) when disseminated nationwide. Data were analyzed from the National Study of CDSMP which included 1170 adults across 22 delivery organizations in 17 states from 2010-2012. Significant improvements were seen in illness symptomatology, quality of life, lifestyle behaviors, and the quality of health care (p<.05). Significant reductions in health care utilization were reported: 5% reduction in ER use from baseline to 6-months and from 6-months to 12-months and 3% reduction in hospitalization from baseline to 6-month follow-up. Using aggregate national cost estimates, preliminary analyses indicate approximately $400 per/person net savings in healthcare costs may be achieved after deducting program costs at $350 per/person. These promising results suggest that the widespread dissemination of evidence-based disease self-management programs can improve health and health care while reducing the nation’s burgeoning healthcare costs.

SESSION 825 (PAPER)

LEGAL ASPECTS AND PERSPECTIVES ON ELDER ABUSE, NEGLECT, AND FINANCIAL EXPLOITATION

MIND THE GAP – IMPROVING CRIMINAL JUSTICE AGENCIES AND SOCIAL SUPPORT AGENCIES RESPONSES TO INTIMATE PARTNER VIOLENCE AGAINST OLDER WOMEN

B. Penhale, W. Goreham, University of East Anglia, Norwich, Norwich, Norfolk, United Kingdom

Context: This EU-funded (Daphne III programme) study on Intimate Partner Violence (IPV) and Older women includes partners from Austria, Germany, Great Britain, Hungary, Poland, and Portugal. The project ran from 2011 until 2013 and addressed the issue of how to improve responses by criminal justice and social support agencies to intimate partner violence against older women. Until now, comparatively little has been known about this issue and this project helps to address that knowledge deficit. This work builds on previous work in this area, specifically a study undertaken between 2009-2011. Method: The first phase of the study consisted of analysis of case files held by the police and other criminal justice agencies in each country. Phase two consisted of the development of guidance and training material for criminal justice agencies. The final phase consisted of the development of guidance and PR and awareness raising material in conjunction with social support agencies. Results: The case file analysis was undertaken in 7 different police forces across England and Wales and 150 cases were analysed across a number of different domains. Likewise the expert workshops with criminal justice and social support agency representatives consisted of representatives from both countries, who contributed to the development of guidance, training and awareness raising materials concerning intimate partner violence and older women, and also involved seeking the views of older women. The results of the case file analysis will be presented and the subsequent phases of the project will be considered and explored.

TRICKS OF THE TRADE: MOTIVATING AGENTS TO CON OLDER ADULTS AND FEEL PROUD ABOUT IT

M. Riparetti-Brown, K. Wilber, Davis School of Gerontology, University of Southern California, Los Angeles, California

Background: In 1996, the State of California and the California Bar Association sued The Alliance for Mature Americans for scamming $200 million from nearly 10,000 older adults by selling them inappropriate annuities. The purpose of this qualitative study is to systematically analyze sales tactics used to convince older adults to purchase questionable retirement products that may not serve their financial interests. Methods: Transcribed recordings from Alliance’s two-day training program for new insurance agents were submitted to the court as evidence of the company’s duplicitous business practices. Using Atlas.ti, transcripts were coded inductively and analyzed to explore emergent themes. Results: Emergent themes included: 1) establishing legitimacy of the sale; 2) morally inoculating salesmen; 3) using the clients’ personal information against them; 4) appealing to aging-related fears/ emotions; and 5) overcoming the clients’ objections. Findings suggest that sales training focuses on both financial incentives and normalization of dishonest sales tactics to make agents believe their financial product helps clients achieve a secure retirement. Ageist stereotypes about losing autonomy help pressure seniors into disclosing private financial information, thereby facilitating the sale. Implications: A rise in the number of predatory insurance companies and other fraudulent businesses that target elders is threatening the economic security of older Americans. Knowledge of their sales manipulation strategies can inform the
development of novel interventions that educate seniors and protect them from solicitation by deceptive sales agents.

PROSECUTORS ATTITUDES AND BELIEFS: THE ROLE OF AN ELDER ABUSE FORENSIC CENTER
A.E. Navarro1, M. Riparetti-Brown2, M. Markloff, K. Wilber, 1. Azusa Pacific University, Azusa, California, 2. Davis School of Gerontology, Univ. of Southern California, Azusa, California

State and federal mandates operating within local elder abuse response communities have been fraught by layers of bureaucracy, impacting the delivery of public services. Little is known about the elder abuse forensic center model, despite national and international interest. Prosecution is one of several outcomes that aids in justifying the value of sustaining and growing the model. This research builds on recent findings that the Los Angeles County Elder Abuse Forensic Center has been able to focus on both goals of protection and prosecution, increasing Deputy District Attorney (DA) reviews in preparation for filing charges by ten-fold (OR 11.0, CI:4.7-26.0, p<.001). It is suspected that some centers are not using the model to aid in prosecution outcomes. This study contextually explores the attitudes and beliefs of six prosecutors, using semi-structured interviews, to determine what approaches have yielded such significant prosecution outcomes. Three reviewers independently reviewed and coded transcripts using NVivo10, to review prosecutors’ views on their role within the multidisciplinary team, strategies used with financial exploitation cases, and insights on the value-added from working within an elder abuse forensic center’s multidisciplinary team. These results provide specific themes in an effort to increase understanding to maximize opportunities and strategies for collaboration to enhance elder justice.

INDIVIDUAL AND CONTEXTUAL RISK FACTORS IN THE PSYCHOLOGICAL ABUSE OF OLDER ADULTS IN NURSING HOMES
L.B. Schiamberg, G. Chee, L. Heydrich, Michigan State University, East Lansing, Michigan

The current study examined prevalence and risk factors of psychological abuse (e.g. being treated disrespectfully, not being allowed contact with family or friends) among elderly individuals in nursing homes. A random sample of 452 adults with an older adult relative (65 years and above) in a nursing home completed a telephone survey including staff psychological abuse experienced by an elder family member. Some 18.6% of family member respondents indicated that an older adult relative experienced one or more incidents of psychological abuse by nursing home staff over the course of their residence. SEM was used to estimate the contribution of both older adult characteristics and contextual risk factors in determining nursing home psychological abuse, including demographic characteristics of the older adult (e.g. age, gender), health/behavioral status of the older adult (e.g. ADL/IADL limitations, behavioral problems), contextual factors beyond the focal adult-caregiver interaction (e.g. resident-on-resident abuse, family member visits to the nursing home) and other types of staff abuse (e.g. physical abuse, verbal abuse). Statistically significant factors were older adult behavioral problems ($\beta = 0.21, t = 2.11, p = .001$), resident-on-resident abuse ($\beta = 0.12, t = 1.96, p = .001$), caretaking abuse (e.g. inappropriate use of physical restraints, forced feeding) ($\beta = 0.29, t = 2.71, p = .001$), staff verbal abuse ($\beta = 0.59, t = 10.89, p = .0001$), and family member satisfaction with the nursing home ($\beta = -0.05, t = -1.92, p = .001$). Findings point to the value of an ecological or contextual perspective in framing risk factors of nursing home psychological abuse and in developing sensitive interventions.

SESSION 830 (SYMPOSIUM)

ASSESSING PHYSICAL FUNCTION ACROSS SPECIES: MICE, MONKEYS AND MAN
Chair: C.S. Carter, Univ of FL-Aging and Geriatric Research, Gainesville, Florida
Co-Chair: J. Justice, University of Colorado-Integrative Physiology Department, Boulder, Colorado

Decline in motor function is a primary contributor to increased risk of disability in older adults, and thus identifying novel interventions to minimize functional decline is a top priority. Given the many limiting factors of relying solely on humans in aging research (e.g. long lifespan, environmental influences, ethical issues), animal models of aging have been developed to investigate the biology of aging and effectiveness of interventions. Many of these models incorporate physical function as a primary outcome of interest, particularly for assessing late-life interventions. However, one barrier to translating the behavioral changes observed in animal models to humans is the absence of a model of motor function relevant to both aging animals and human health.

Standardized motoric batteries have been developed in humans to establish a “common currency” among studies through a recent NIH-wide initiative referred to as the “Toolbox” (NIH Toolbox motor domain, www.nihtoolbox.org); however, no analogous battery exists which is capable of translation from animals to humans. Dr. Matteo Cesari will present an overview of how physical function is assessed using standardized performance measures in humans. Dr. Christy Carter will present data from preclinical rodent intervention studies using physical function as a primary outcome and how these findings were translated to the development of human clinical studies. Dr. Thomas Register will present a novel model of non-human primate aging and functional decline: the green vervet monkey. Drs. Jamie Justice and Douglas Seales will present an NIH toolbox approach to assessing physical performance in aged mice.

ASSESSMENT OF PHYSICAL FUNCTION IN HUMANS
M. Cesari, Université de Toulouse III Paul Sabatier, Toulouse, France

Over the last three decades, an increasing amount of evidence has documented the importance of functional physical function in older persons, both as a crucial component of the clinical assessment as well as a specific outcome for intervention. The evaluation of physical function is indeed starting to be considered as relevant as other clinical and biochemical parameters. Multiple instruments have been developed in order to measure physical function in a standardized fashion. The heterogeneity of available tests of physical function may be justified by the different purposes for which they were originally designed and currently used. For example, some instruments are highly specific for selected functional domains (e.g., balance, resistance), whereas others more comprehensively estimate the individual’s status. Or, besides of clinical friendly tests, some are more suitable for research activities. In this presentation, an overview on how physical function can be assessed in elders is provided.

LATE-LIFE INTERVENTIONS FOR IMPROVING PHYSICAL FUNCTION IN AGED RATS
C.S. Carter1, D. Morgan2, 1. Univ of FL-Aging and Geriatric Research, Gainesville, Florida, 2. Univ of FL-Dept. of Psychiatry, Gainesville, Florida

The assessment of behavioral outcomes is essential to measuring the efficacy of any late-life intervention in the context of mitigating declining performance and/or sarcopenia. Despite its importance, there is still much debate as to a universal set of criteria that defines sarcopenia. However most clinical researchers agree that improved physical functioning is the major determinant of whether an intervention for sarcopenia is successful given that measures of muscle strength and mass are often uncorrelated with changes in performance. Furthermore, like
any respectable biomarker, behavior may be considered both a predictor and an outcome measure of response to treatment. Preclinical models, especially those for which function is a primary outcome, represent a critical translational link for the rapid translation of treatments to the clinical arena insofar as they may serve as a tool for the relatively rapid systematic assessment of traditional and nontraditional interventions, initiated late in life.

**BATTERY OF BEHAVIORAL TESTS TO QUANTIFY AGE-ASSOCIATED CHANGES IN MOTOR FUNCTION IN MICE**

Motor function in humans can be characterized by locomotion, strength, balance, and endurance, and standardized test batteries and norms have been established for individuals aged 3-85 yrs (NIH Toolbox, Motor Function Domain). The aim was to establish an initial, analogous test battery to assess motor functions in mice. Male C57BL/6 mice were studied at 3 (n = 87), 20 (n = 48) and 26 (n = 43) months of age. Tests assessed locomotion, strength, balance/coordination, and endurance capacity in mice. Motor function declines were observed with advancing age for the locomotion, strength, and endurance subdomains (p < 0.001). A motor function summary score was calculated and demonstrated declines of 7.4% between 3-to-20-month mice and 13.5% between 20-to-26-month mice. Based on comparison with previously published data in humans, the magnitude and relative time course of changes were similar in mice and humans in each subdomain except balance/coordination.

**AGING AND PHYSICAL FUNCTION IN NONHUMAN PRIMATES: A TRANSLATIONAL MODEL**

C.A. Shively, S.B. Kritchevsky, T.C. Register. 1. Pathology, Wake Forest University School of Medicine, Winston-Salem, North Carolina; 2. Wake Forest University School of Medicine, Winston-Salem, North Carolina

We developed a battery of physical mobility measurements to evaluate function in nonhuman primate models of aging. Locomotive behaviors of 24 young (mean=9 yrs) and 21 old (mean=20 yrs) socially housed adult females representing three Old World monkey species were recorded. Walking speed was 17% slower and climbing was less frequent in older than younger adults. Overall activity levels did not vary significantly by age. In subsequent studies, climbing rate and walking speed were correlated with single muscle fiber contractile properties; time spent climbing, hanging, and walking speed were correlated with shoulder mobility. Of all the mobility phenotypes, walking speed measured in a simple and inexpensive manner appeared to be the most sensitive to age and the least affected by differences in housing characteristics. Thus, walking speed may be a useful indicator of decline in physical mobility in nonhuman primate models of aging.

**SESSION 835 (PAPER)**

**CNS AND BRAIN AGING**

**CNS AGING IN AN ENRICHED ENVIRONMENT LEADS TO IMPROVED NEURAL COMMUNICATION IN MOBILITY-RELATED CIRCUITS**

S.L. Hong, G.V. Rebec. 1. Biomedical Sciences, Ohio University, Athens, Ohio; 2. Indiana University, Bloomington, Indiana

Environmental enrichment in aging has been shown to improve learning and memory, but little is known regarding its effects on neural circuits related to motor function and mobility, specifically, motor cortex and striatum. We tested the hypothesis that aged mice raised in an enriched environment (EE) will have lower unpredictability in corticostriatal activity while actively making decisions during plus maze exploration. Three groups of mice were tested: 1) EE (age 60-68 weeks, n = 19); 2) running wheel (RW: age 73-82 weeks, n = 7); and 3) isolated housing (IH age 68-85 weeks, n = 14). We measured the level of unpredictability in cortical and striatal local field potentials (LFP) using approximate entropy (ApEn) and corticostriatal synchrony by obtaining phase locking values (PLV) at 4 timepoints relative to a choice point in the plus maze: A) 2s-1s prior; B) 1s prior-choicepoint; C) choice-point-1s after; and D) 1s-2s after. Using age as covariate, we found that the EE mice exhibited significantly lower ApEn values across cortex and striatum, indicating lower unpredictability in comparison to IH, but not the RW. These results provide initial evidence that EE preserves mobility-related neural function in aging by: A) reducing unpredictability in the transmitted signals; and B) improving corticostriatal synchrony.

**CNS: TOR AND NO AS REGULATORS OF BRAIN VASCULAR FUNCTION IN A MOUSE MODEL OF AD**

V. Galvan, A. Lin, W. Zheng, J.J. Halloran, R. Burbank, S. Hussong, M.J. Hart, J.D. Lechleiter. Physiology and The Barshop Institute, University of Texas Health Science Center at San Antonio, San Antonio, Texas

Vascular pathology is a major feature of Alzheimer’s disease (AD) and other dementias. We recently showed that chronic administration of the target-of-rapamycin (TOR) inhibitor rapamycin, which extends lifespan and delays aging, halts the progression of AD-like disease and reduces amyloid-beta accumulation in (h)APP transgenic mice modeling AD. To investigate the effects of reduction of mTOR activity by rapamycin on hemodynamic, vascular and metabolic functions in brains of hAPP mice we used multi-metric imaging systems (MRI and PET). Our results demonstrate that hAPP mice have significantly reduced cerebral blood flow (CBF) and vascular density that is not related to metabolic changes, especially in areas that have a prominent role in learning and memory. Chronic rapamycin restored vascular density and CBF, reduced vascular amyloidosis and microhemorrhages, decreased amyloid burden, and relieved AD-like cognitive deficits in hAPP mice. Reduction of mTOR activity also restored CBF in aged rats and in a model of atherosclerosis, suggesting that the mechanisms by which attenuation of mTOR activity restores CBF are common to different models of vascular disease, and to brain aging. In vivo multiphoton imaging of brain vessels revealed that rapamycin induced an increase in nitric oxide (NO) in vascular endothelium that was followed by vasodilation. Both rapamycin- and acetylcholine-induced NO release and vasodilation could be blocked by L-NAME, an inhibitor of NO synthases. Administration of L-NAME reversed the protective effects of rapamycin on brain blood flow and vascular density, indicating that rapamycin preserves vascular integrity and CBF in AD mouse brains through NO signaling. Our data suggest that the preservation of vascular density and brain blood flow may be key to the maintenance of cognitive function in the hAPP mouse model of AD. Rapamycin, an FDA-approved drug that is already used in the clinic, may have promise as a therapy for AD and possibly for age-associated brain diseases beyond AD alone.

**DISRUPTION OF SYNAPTIC TRANSMISSION IN THE AGING BRAIN: RELEVANCE OF IGF-1 TO COGNITIVE IMPAIRMENT**

F. Deak, W.E. Sonntag. 1. Reynolds Oklahoma Ctr on Aging, Oklahoma City, Oklahoma; 2. Dept. Geriatric Medicine, Univ. Oklahoma Health Sciences Ctr, Oklahoma City, Oklahoma

Age is a major risk factor for cognitive impairment and dementia. Alzheimer’s and other neurodegenerative diseases affect millions of
The role of the apolipoprotein E4 allele, cancer, CVD and neurodegenerative disorders in human lifespan

Enduring interest to the apolipoprotein E (APOE) polymorphism is ensured by its evolutionary-driven uniqueness in humans and its prominent role in lifespan and risks of major human diseases. We use large samples of participants of the Framingham Heart Study original (FHS, N=1258 with 1056 deaths) and offspring (FHSO, N=3924 with 741 deaths) cohorts followed for up to 60 years to characterize sex-specific effect of the APOE e4 allele on lifespan. We also investigate whether or not cardiovascular disease (CVD, N=1790), cancer (N=1303), and neurodegenerative disorders (ND, N=378) mediate the effect of this allele on lifespan. The analyses show that the e4 allele is significantly associated with women’s lifespan but not with men’s lifespan. The risks of death for women carrying the e4 allele are higher in the FHSO (relative risk [RR]=1.59 and p=2.4×10^-4) than in the FHS (RR=1.25, p=0.027). The effect of the e4 allele on women’s lifespan in the FHS is limited to ages younger than about 95 years (RR<95=1.37, p=1.7×10^-3 vs. RR>=95=0.94, p=0.794). Our preliminary analyses suggest also the same age- and women-specific role of the e4 allele beyond the Framingham population. Major human diseases including CVD, ND, and cancer, which risks are shown to be sensitive to the e4 allele, do not explain the association of this allele with women’s lifespan (RR<95=1.41, p=5.6×10^-4 when adjusted for all these diseases in the FHS). Our results show that the APOE e4 allele can affect human lifespan in sex- and age-specific manner independently of CVD, cancer, and ND.

SESSION 840 (SYMPOSIUM)
EXAMINATION OF FAMILY CARE NETWORKS DEALING WITH CHRONIC ILLNESS
Chair: J. Savla, Center for Gerontology, Virginia Tech, Blacksburg, Virginia
Co-Chair: K.A. Roberto, Center for Gerontology, Virginia Tech, Blacksburg, Virginia
Discussant: C.A. Berg, The University of Utah, Salt Lake City, Utah

Little attention has been paid to the sources of variability in family care networks, particularly how social connections between caregivers and their family, community and the wider social setting affect the care process and outcomes. The four papers in this symposium advance the family caregiving literature by focusing on the caregiving context (dimensions, temporal process), and related outcomes for care recipients, caregivers, and other family members. The goal of this symposium is to broaden the view of how caregiving occurs, the variability in family care networks, and enhance understanding of the conditions under which families manage the multiple challenges of care. The first paper, K. Allen and Roberto use qualitative interviews with older women to gain an understanding of the composition and dynamics of the older women’s support systems as they move from diagnosis through post-treatment care for gynecological cancer. In the second paper, using longitudinal data from families dealing with mild cognitive impairment and early dementia, Savla and her colleagues examine the temporal process of care network activation and its outcomes for the care partner. In the third paper, Wilson and her colleagues use daily diary data to examine the role of spousal depressive symptoms in responding to daily experiences of osteoarthritis pain. In the final paper, R. Allen and her colleagues examine the role of care networks in prostate cancer screening decision among rural African American men. Drawing from her own research on health and care networks, Cindy Berg will integrate the session papers and facilitate discussion.

GYNECOLOGICAL CANCER SURVIVORSHIP AMONG OLDER WOMEN IN APPALACHIA: FAMILY DYNAMICS AND SUPPORT
K.R. Allen, K.A. Roberto, Virginia Tech, Blacksburg, Virginia

Our study of 20 older women, aged 51 to 82, from rural Appalachia, explored how participants perceived their experience with gynecological cancer in the context of their family relationships. We analyzed data from in-depth interviews with the women and created family genograms related to their cancer experience. Examining the composition and dynamics of the women’s support system at three points in time (pre-cancer diagnosis, cancer treatment, and post-treatment) revealed that cancer is not an isolated event, but enters into a family system with multiple challenges. The people to whom the women turned for instrumental support were determined by their family context, and family relationships were influenced by the cancer experience.

The Gerontological Society of America
and emotional support often were coping with their own stresses, requiring the women to summon additional strength and fortitude in dealing with their own treatment and recovery. Findings suggest that researchers and practitioners must broaden their understanding of the older women cancer survivors’ needs and availability of support in order to develop effective care strategies.

TEMPORAL PROCESS OF CARE NETWORK ACTIVATION: IMPLICATIONS FOR CARE PARTNERS OF PERSONS WITH MCI

J. Savla, K.A. Roberto, R. Bleszner, N. Brossie, J. Lorenzi, Center for Gerontology, Virginia Tech, Blacksburg, Virginia

Family care providers rely on kin for assistance in times of need; however little is known about the temporal process in which care networks become activated when a relative has mild cognitive impairment. We examined whether care-related stresses mobilize support from immediate family members and whether mobilized care networks protect care partners against burden. Analyses are based on a 4-yr longitudinal study of 112 family care partners aged 25-92 at T1. Autoregressive cross-lagged models were used to examine associations among care-related stresses, anticipated care network support, and caregiver burden. Care partners had low expectations for help from family early in coping with MCI. However, increased caregiver burden at T2 was related to increased anticipated support from the care network at T3, which reduced caregiver burden at T3. Discussion will focus on the importance of care networks early in the care process and implications for interventions to promote care partner support.

THE ROLE OF SPOUSAL DEPRESSIVE SYMPTOMS IN RESPONDING TO DAILY EXPRESSIONS OF OSTEOARTHRITIS PAIN

S.J. Wilson1, M. Barrineau1, L.M. Martire1, M.P. Stephens2, R. Schulz3, 1. Human Development & Family Studies, Penn State University, University Park, Pennsylvania, 2. Kent State University, Kent, Ohio, 3. University of Pittsburgh, Pittsburgh, Pennsylvania

Research shows that when pain is chronic, nonverbal pain expression may elicit punishing responses. This 22-day diary study of 145 osteoarthritis patients and spouses hypothesized that the positive association between patient nonverbal pain expression and punishing spouse responses would be stronger on days when the previous day’s expression was high. Spousal depressive symptoms were proposed to exacerbate the cumulative effect of nonverbal pain expression on punishing responses. Contrary to prediction, on average spouses were not susceptible to an accumulation effect of nonverbal expression on punishing responses. However, as hypothesized, spouse depressive symptoms significantly moderated this association, such that more depressed spouses were more punishing when both previous-day and same-day nonverbal pain expression was higher than usual, as compared to less depressed spouses. In short, spouses with elevated depressive symptoms may be vulnerable to daily accumulation of pain expression and respond in a way that is maladaptive for both members.

CARE NETWORKS IN PROSTATE CANCER SCREENING DECISIONS AMONG RURAL AFRICAN AMERICAN MEN

R.S. Allen1, J.S. Oliver2, L. Tang1, L.M. Mieskowski1, M.K. Eichorst1, T. Coleman-House1, S.S. Martin1, M.Y. Martin1, 1. The University of Alabama, Tuscaloosa, Alabama, 2. University of Alabama at Birmingham, Birmingham, Alabama

African American (AA) men are at increased risk with higher mortality rates from prostate cancer in comparison with Caucasian men. We examined the influence of 35 “health care advocates” (M age = 54.51; SD = 10.48) on the prostate cancer screening decisions of 33 rural AA men (M age = 54.61; SD = 8.30). Advocates were uniformly women, the spouse or significant other (54.6%), and had greater health literacy, t(32) = -2.04, p = .05. Paired comparisons between men and their primary advocate revealed significant differences with regard to developing preferences for future care, t(30) = -3.36, p = .002. Advocates were more likely to consider and make plans. Men and advocates agreed that the advocate should be involved in prostate cancer screening decisions (r = .35; p = .04), but the men preferred to take the most active role in their own health care decision making.

SESSION 845 (SYMPOSIUM)

EXPERIENCING LATE LIFE: INDIVIDUAL AND COHORT DIFFERENCES

Chair: D. Gerstorf, Humboldt University, Berlin, Germany
Co-Chair: H. Wahl, Heidelberg University, Heidelberg, Germany
Discussant: R.S. Wilson, Rush University Medical Center, Chicago, Illinois

The fundamental issue of how late life shapes human developmental potentials continues to be controversial. An important step forward are recent findings that different well-being indicators show on average steep loss trajectories with approaching death. However, large individual differences are prevalent and the contributing factors still not well understood. Specifically, limited knowledge is available on those being more resilient than others in late life and what kind of resource constellations may explain such differences. This symposium pursues various different angles on the issue by exploring dynamics operating at the biological, psychological, and societal levels relevant for late life. First, cardio-vascular functioning is shown to add to the explanation of terminal cognitive processes. Second, a differential analysis targeting how neuroticism at the end of life unfolds indicates a nuanced picture of precipitous increases in some groups, but stability in others. Third, key social indicators of quality of life such as family goals, social participation, and perceived attachment to neighborhood are shown to contribute to maintaining well-being into the last phase of life. The final contribution complements and extends these studies by moving from a consideration of objective lifetime remaining to the subjective representation of this remaining lifetime and by examining secular trends therein. The objective is in particular to explore how different cohorts of older adults perceive their “staging” in the final periods of life. The discussion by Robert Wilson integrates the four papers, highlights the potentials and limits of current research on late life, and considers future routes of inquiry.

BEYOND COGNITIVE TERMINAL DECLINE IN LATER LIFE: SEARCH FOR CONTRIBUTING AND UNDERLYING MECHANISMS

B. Johansson1, V. Thorvaldsson1, T. Svensson2, 1. Dept of Psychology, University of Gothenburg, Gothenburg, Sweden, 2. Lund University, Lund, Sweden

There is strong evidence from previous studies that older individuals experience terminal decline in cognitive performance before death. However, we are still searching for underlying contributors and mechanisms involved in the cortical de-vitalization that we capture by cognitive measures. We are currently exploring the role of various factors related to vascular health in relation to cognitive decline in later life. In these analyses we examine data from two population-based Swedish studies in which individuals have been followed until death with a cognitive battery encompassing several common tests and with information about age of death and detailed information about various aspects of health and functioning, especially vascular health. Preliminary results indicate moderate to strong interdependency between cognitive measures. Besides certain biomarkers of compromised cognition we also find that vascular factors are significant mediators. Our analyses suggest that that underlying vascular factors have a significant role contributing to observed terminal decline trajectories.
This study focused on terminal change in neuroticism, challenging the prevalent notion of high stability and uniformity of trait development across adulthood. Using data from the Longitudinal Aging Study Amsterdam (LASA; N=1,715 deceased subjects; initial ages 55-85; neuroticism measured by the Dutch Personality Questionnaire), we analyzed intradividual trajectories of neuroticism across age versus time-to-death (TTD), and run group-based (growth mixture) analyses to detect prototypical trajectories of neuroticism. Both, age and TTD revealed significant effects, pointing to a tendency of increasing neuroticism across the terminal phase of life. The group-based analyses revealed 4 prototypical trajectories, pointing at substantial heterogeneity in terms of subgroups of individuals increasing versus maintaining their level of neuroticism when death comes close. The findings suggest that increasing neuroticism may be a marker of "problematic" terminal developments among those with high psychological vulnerability to processes of degradation leading to death.

INDIVIDUAL DIFFERENCES IN TERMINAL WELL-BEING DECLINE: THE ROLE OF FAMILY GOALS, SOCIAL PARTICIPATION, AND THE LIVING ENVIRONMENT

D. Gerstorf1,2,3, N. Ram1,2,4, F.J. Infurna1,2, J. Schupp2, G.G. Wagner1,4.
1. Institute of Psychology, Humboldt University Berlin, Berlin, Germany, 2. German Institute for Economic Research (DIW Berlin), Berlin, Berlin, Germany, 3. The Pennsylvania State University, University Park, Pennsylvania, 4. Max Planck Institute for Human Development, Berlin, Berlin, Germany

Recent research has repeatedly demonstrated that well-being typically evinces precipitous deterioration at the end of life. Yet, individual differences in well-being terminal declines are very substantial and to-date poorly understood. Our aim was to identify characteristics of by now deceased participants in the German SocioEconomic Panel who did not experience well-being decline in the last five years of life (n = 588). Using propensity score matching, we identified case-matched controls who reported well-being decline, but did not differ in sociodemographic characteristics, disability, and well-being five years prior to death. Logistic regression analyses revealed that over and above additional health factors (self-rated health, few doctor’s visits), those in psychosocial domains (family goals, social participation) and neighborhood characteristics (satisfaction with living environment) were each independently associated with an increased likelihood of maintaining well-being late in life. We discuss possible pathways by which individual and contextual factors may protect against late-life decrements.

EXPERIENCING LATE LIFE: INDIVIDUAL AND COHORT DIFFERENCES

D.J. Deeg1, H. Galenkamp1, F. Janssen2, M. Huisman1, 1. LASA, VU University Medical Centre, Amsterdam, Netherlands, 2. University of Groningen, Groningen, Netherlands

In most developed countries, life expectancy is increasing, particularly in the older population. The question addressed in this study is how this objective prospect of a longer life is reflected in older people’s subjective experience of their remaining life time. Using data from four waves (1999 through 2009), each wave including ages 65-90 of the nationally representative Longitudinal Aging Study Amsterdam, it is examined if older people in 2009 feel they are in an earlier stage of life than same-aged people in previous years. Self-perceived life stage (SPLS) was measured on a scale from 0 (earliest possible) to 100 (latest possible). Age-adjusted generalised estimating equations with SPLS as the dependent variable and wave year as the independent variable showed a curvilinear trend over time. It is concluded that the trend in self-perceived life stage follows the trend in objective life expectancy across the period studied, but with a delay.

SESSION 850 (SYMPOSIUM)

HEALTH LITERACY AND AGING: DIVERSITY AND SIGNIFICANCE
Chair: R.L. Owney, Nova Southeastern University, FORT LAUDERDALE, Florida
Co-Chair: S.J. Czaja, University of Miami School of Medicine, Miami, Florida, Co-Chair: D. Waldrop-Valverde, Emory University School of Nursing, Atlanta, Georgia

Health literacy has recently been recognized as an important factor in health care that may be especially important for older persons. A number of studies have shown that while elders have the largest number of interactions with the healthcare system, they have lower levels of health literacy compared to younger counterparts. This symposium will explore the relations among health literacy, cognition, and health in persons aged 50 and older, presenting data on the relation of basic cognitive abilities, academic skills, and conceptual knowledge to health literacy. Presentations will also examine issues related to health literacy and aging with HIV and the effect of Hispanic ethnicity and acculturation on health literacy. Specific presentations will evaluate the relation of cognition to health literacy in community dwelling volunteers and in older adults treated for HIV infection. Another presentation will review issues encountered in assessing health literacy in Hispanic elders. In light of the increasing importance of electronic applications in health, data will be presented from several studies that have evaluated the relation of health literacy to elders’ ability to use eHealth applications.

HEALTH LITERACY AND E-HEALTH MANAGEMENT TOOLS
S.J. Czaja, University of Miami Miller School of Medicine, Miami, Florida

Recent healthcare trends emphasize the increased involvement of consumers in the management of their own healthcare. For example, the numbers of providers and patients now using electronic medical records (EMRs) to perform health management tasks is growing daily. Internet-based health information websites are also growing at the rapid pace. Despite the widespread and growing use of these systems, little is known about the ability of consumers particularly those with low health literacy to “meaningfully use” these systems to engage in self-management activities. This paper will discuss the important role of health literacy in electronically mediated patient centered care. Data will be provided from several studies that included diverse samples of middle-aged and older adults regarding the impact of health literacy on the performance of common “eHealth” tasks. Overall, the results indicate that despite participant’s perceived value of these systems poor health literacy is a barrier to meaningful access.

FACTORS ASSOCIATED WITH HEALTH LITERACY IN PERSONS AGING WITH HIV/AIDS
D. Waldrop-Valverde1, R.J. Jacobs2, J. Caballero2, R. Owney2, 1. Nell Hodgson Woodruff School of Nursing, Emory University, Atlanta, Georgia, 2. Nova Southeastern University, Fort Lauderdale, Florida

Persons aging with HIV/AIDS (PAWH) are at risk for low health literacy. Emerging evidence suggests that PAWH are also at risk to develop cognitive deficits. Studies show that health literacy is partially explained by cognitive factors. This study examined the cognitive functions associated with health literacy, measured by the Test of Functional Health Literacy in Adults (TOFHLA) among 66 PAWH aged 47 and above. Seventy-nine percent of the sample was men and 62% were Black. Results showed that, adjusting for age, race, and gender, a measure of crystallized intelligence (general knowledge) and mental flexibility/working memory were associated with health-related read-
ing comprehension on the TOFHLA [R² = 0.61; F [8,54] = 5.60, p < 0.001]. Only a measure of crystallized intelligence was associated with health-related numeracy on the TOFHLA [R² = 0.34, F [8,54] = 3.47, p = 0.003]. Findings suggest that among PAWH, low health literacy is affected by general knowledge.

ASSESSMENT OF HEALTH LITERACY IN THE HISPANIC OLDER ADULT

A. Acevedo, R. Ownby, D. Loewenstein, D. Waldrop-Valverde, S.J. Czaja, A. Homs, I. Center for Psychological Studies, Nova Southeastern Univ.; Fort Lauderdale, Florida, 2. University of Miami, Miami, Florida, 3. Emory University, Atlanta, Georgia

The number of individuals of Latino background residing in the United States has increased significantly in the past several decades. Unfortunately, there is a paucity of data on factors that need to be addressed to accurately assess health literacy in this population, particularly among the older Hispanic adult. The purpose of this presentation is threefold: a) to describe ongoing efforts from our laboratory to develop a computer-administered health literacy measure with psychometric equivalence when used with Hispanic and non-Hispanic adults; b) to identify factors (e.g., cognitive, socio-demographics) that need to be considered in the assessment of health literacy in older Latinos in the United States; and c) to present preliminary data on health literacy and associated variables from a sample of Latino elders from heterogeneous backgrounds.

THE ABILITIES, SKILLS, AND KNOWLEDGE (ASK) MODEL OF HEALTH LITERACY IN OLDER ADULTS

R.L. Ownby, A. Acevedo, D. Waldrop-Valverde, S.J. Czaja, R. Davenport, J. Caballero, R.J. Jacobs, I. Nova Southeastern University, FORT LAUDERDALE, Florida, 2. Emory University School of Nursing, Atlanta, Georgia, 3. University of Miami School of Medicine, Miami, Florida

Health literacy has increasingly been recognized as an important factor in healthcare and may be especially important for older adults. Health literacy has often been implicitly defined by the measures used in studies. We hypothesized that cognition, academic skills, and general medical knowledge would be related to performance on standard measures of health literacy, including the Test of Functional Health Literacy in Adults (TOFHLA) reading and numeracy scales and the Rapid Estimate of Adult Literacy in Medicine (REALM). Generalized linear models were used to assess this hypothesis among participants in a study of a new measure of health literacy. Results provide preliminary support for the ASK model, showing that measures of general cognitive ability, attention, academic skills, and general knowledge were related to performance on standard measures of health literacy. Differences among models highlight the importance of understanding the relation of patient characteristics to these measures.

SESSION 855 (SYMPOSIUM)

IMPROVING THE PROVISION AND MEASUREMENT OF END-OF-LIFE CARE ACROSS SETTINGS

Chair: L.W. Cohen, Cecil G. Sheps Center for Health Services Research, The University of North Carolina at Chapel Hill, Chapel Hill, North Carolina
Co-Chair: S. Zimmerman, Cecil G. Sheps Center for Health Services Research, The University of North Carolina at Chapel Hill, Chapel Hill, North Carolina
Discussant: J.T. van der Steen, VU University Medical Center, EMGO Institute for Health and Care Research, Amsterdam, Netherlands

This symposium presents findings from five studies conducted to improve the provision and measurement of end-of-life care across settings. The first presentation shares results from a study that tested 11 instruments to measure end-of-life care and outcomes in nursing home (NH) and assisted living (AL) settings. Two measures of care and two measures of outcomes performed better than others, and the authors discuss the considerations and implications for choosing amongst measures. The second presentation describes the development and validation of a new measure – the Quality of Spiritual Care (QSC) scale. Preliminary testing suggests the QSC scale is a valid, reliable outcome measure of the quality of spiritual care at the end-of-life in NH and AL settings. The next presentation reviews end-of-life care and outcomes in Green House NHs, and will compare and contrast Green Houses with traditional NHs. This study found some differences in structures and processes between settings, but also substantial areas of similarity. The fourth presentation reviews results of a group-randomized trial testing the fidelity and efficacy of an intervention to address barriers to pain management in Hospice. Intervention fidelity was high, and preliminary findings suggest it is efficacious for Hospice staff and care recipients. The final presentation summarizes the evidence around oral health changes for several dying trajectories, and proposes a palliative oral health model for these different trajectories. Together, these presentations will highlight the diversity of promising opportunities to improve end-of-life care practices and also the important role that measurement holds for doing so.

MEASURING END-OF-LIFE CARE AND OUTCOMES IN ASSISTED LIVING AND NURSING HOMES

S. Zimmerman, L.W. Cohen, J.T. van der Steen, D.A. Reed, M. Van Soest-Poortvliet, L. Hanson, P.D. Sloane, I. The University of North Carolina at Chapel Hill, Chapel Hill, North Carolina, 2. VU University Medical Center, EMGO Institute for Health and Care Research, Amsterdam, Netherlands

Despite the fact that more than one-quarter of all U.S. deaths occur in long-term care settings, and that information in this area has been growing, the comparative suitability of different measures to guide this care is unknown. This project examined 20 scales from 11 instruments to determine optimal measure(s) to assess end-of-life care and outcomes in nursing homes (NHs) and assisted living (AL). Data from interviews with 264 family members of decedents from 118 settings were examined to determine each scale’s psychometric properties and the extent to which it discriminated important characteristics. Prioritizing measures that distinguish the assessment of care from dying, and secondarily that exhibit an acceptable factor structure, two measures of care – FPFFC and EOLD-SWC – and two measures of outcomes – EOLD-SM and EOLD-CAD – performed better than others. This presentation will help researchers, clinicians, and administrators understand the implications of choosing various measures for their work.

DEVELOPMENT AND PRELIMINARY TESTING OF THE QUALITY OF SPIRITUAL CARE SCALE

Though the provision of spiritual care is considered a key element of hospice and palliative care, empirically-developed quality of care measures are lacking. This study describes the development and reliability and validity of the 10-item Quality of Spiritual Care (QSC) scale. We conducted analyses of after-death interviews using the QSC scale and other measures with 91 family members of residents who died in long-term care settings (nursing homes and assisted living). Reliability analysis yielded a Cronbach’s alpha of 0.87, and all item-total correlations exceeded 0.55. Factor analysis identified two factors, personal spiritual enrichment and personal capacity enrichment. Significant correlations with items from previously-validated instruments conceptually associated with the quality of spiritual care provided evidence in
support of the validity of the QSC. Thus, preliminary testing suggests the QSC scale is a valid, reliable outcome measure of the quality of spiritual care at the end-of-life.

END-OF-LIFE CARE IN GREEN HOUSE NURSING HOMES
L.W. Cohen, S. Zimmerman, K. Ward, Cecil G. Sheps Center for Health Services Research, The University of North Carolina at Chapel Hill, Chapel Hill, North Carolina

Anecdotal reports suggest the structures and processes inherent in Green House (GH) nursing homes permit greater person-centeredness and better outcomes. However, there is a relative paucity of empirical evidence to support these claims, perhaps most notably around end-of-life care. To address this shortcoming, we conducted semi-structured interviews about end-of-life care structures, processes, and perceived outcomes with staff from 15 GH campuses, comprising 69 homes, and compared these with data obtained from a study of 32 traditional nursing homes (NH). GH staff reported greater prevalence of some structures of person-centered care, including availability of private rooms for dying residents (100% vs 48%, adjusted p<.001), however no differences were observed in other care processes, such as staff continuity at end-of-life. GH staff reported providing higher quality care than did NH staff (p=.003). The similarities and differences in GH and NH end-of-life care and outcomes help focus future quality improvement and research efforts.

EMPOWER: AN INTERVENTION TO ADDRESS BARRIERS TO PAIN MANAGEMENT IN HOSPICE
J.G. Cagle, S. Zimmerman, L.W. Cohen, L. Porter, D.A. Reed, School of Social Work, University of Maryland, Baltimore, Maryland. 2. Cecil G. Sheps Center for Health Services Research, University of North Carolina, Chapel Hill, Maryland. 3. School of Social Work, University of North Carolina, Chapel Hill, Maryland. 4. Duke University, Durham, North Carolina

Concerns about pain medications are major barriers to pain management in hospice, but few efforts have identified and addressed these concerns. We conducted a group-randomized trial to test fidelity and preliminary efficacy of the EMPOWER intervention that included hospice staff education; staff screening of barriers to pain management at admission; and clarification about misunderstandings regarding pain management. We recruited 126 family caregivers and interviewed them at 2 weeks post-admission (55 intervention; 71 control). If patients survived 3 months post-admission, caregivers were re-interviewed. Intervention fidelity was high (95%). At 2 weeks, the intervention group had better knowledge about pain management (p<.001), fewer concerns (p=.003), and reported lower patient pain over the past week (p=.015); of note, the intervention effect on lowering concerns about stigma was greater for Black subjects compared to Whites. At three months, the intervention group trended better on study outcomes. Implications of results will be presented.

ORAL HEALTH IN OLDER ADULTS AT THE END OF LIFE
X. Chen, C. Kister, Department of Dental Ecology, Univ North Carolina Chapel Hill, Chapel Hill, North Carolina. 2. Univ North Carolina Department of Family Medicine, Chapel Hill, North Carolina

Because oral health worsens in older adults at the end of life, older adults may suffer reduced quality of life. However, the trajectory of oral health changes in older adults with different dying trajectories and their management through the dying process remain unclear. This review summarizes the evidence around oral health changes in the dying trajectories of sudden death, cancer-related death, end-stage organ failure, and advanced frailty. Dental caries slightly increase in sudden death, though xerostomia and oral soft pathologies are common in terminal cancer. Dental caries, oral pain/infection and oral functional loss intensify in end-stage organ failure or advanced frailty. To decrease the suffering of older adults at the end of life, we propose a palliative oral health model for these different dying trajectories. The appropriate management of these changes is conceptually framed from an individualized approach based on their personal values and current stage in the dying process.

SESSION 860 (SYMPOSIUM)
INTERDISCIPLINARY PERSPECTIVES ON RESILIENCE INADULthood AND OLD AGE
Chair: F. J. Infurna, Humboldt University, Berlin, Berlin, Germany, German Institute for Economic Research (DIW Berlin), Berlin, Berlin, Germany
Co-Chair: D. Gerstorf, Humboldt University, Berlin, Berlin, Germany
Discussant: C. Ryff, University of Wisconsin, Madison, Wisconsin

When confronted with challenging life circumstances, such as daily stress, being a caregiver or experiencing spousal loss, some individuals may exhibit decrements in functioning, whereas others are resilient and able to maintain their functioning, be it in the physical health, well-being, or activity domain. Our objective in this symposium is to bring together a collection of papers that focus on factors that promote maintenance or improvement of functioning during challenging life circumstance from various perspectives. Moore and colleagues use micro- and macro-longitudinal data to examine the interplay between affect reactivity and recent life events for mental and physical health and found that higher affect reactivity was linked to better mental and physical health for those who experienced recent positive events. Gaugler and colleagues target various psychosocial factors associated with resilience outcomes of better mental and physical health in caregivers caring for a loved one with dementia. Infurna and colleagues use data from the German Socio-Economic Panel Study to investigate multiple phases of life satisfaction change in relation to spousal loss and various psychosocial factors that enable resilience and illustrate the importance of adaptive capabilities as resources in the process. Aldwin and colleagues use longitudinal data to examine trajectory patterns for intensity and exposure to hassles and uplifts with individual differences being observed in the trajectories of emotion regulation. The discussion by Carol Ryff integrates the four papers, highlights the importance of and various sources of resilience in adulthood and old age, and considers future routes of inquiry.

WHO BENEFITS FROM POSITIVE EXPERIENCES?
EXPLORING AFFECT REACTIVITY TO DAILY STRESSORS
AS A POTENTIAL MARKER OF VANTAGE SENSITIVITY

Recently, Pluess and Belsky (2013) introduced the term “vantage sensitivity” to capture the notion that some individuals benefit more than others from advantageous life experiences. Building on this theoretical concept, the current study examines individual differences in response to positive environmental influences. Using data from the Midlife in the United States Survey (MIDUS), the paper focuses on affect reactivity to daily stressors as a potential contributing factor to sensitivity to positive life events. Results suggest that individual differences in affect reactivity moderate the impact of recent life events in a manner reflecting disproportionate responsiveness to positive influences (i.e., higher vantage sensitivity). Specifically, among adults high in affect reactivity (heightened NA and dampened PA in response to daily stressors), recent positive events had a promotive effect on mental health outcomes. Discussion focuses on the benefits of putative “risk factors” in the context of positive environmental exposures.
RESILIENCE IN DEMENTIA CAREGIVING: AN UPDATE
J.E. Gaugler, University of Minnesota, Minneapolis, Minnesota

Multiple disciplines have described family care for persons with dementia and the health implications of this process. Longitudinal studies have examined how dementia caregivers experience stress and mental health over time. However, how resilience operates to influence key caregiving outcomes over time is less understood. This presentation will summarize prior research on 1,979 dementia caregivers over a 3-year period that determined how resilience was associated with important transitions from dementia caregiving, including care recipient institutionalization or death. This work found that high baseline resilience (low burden, high care demands) was predictive of less frequent institutionalization and more frequent care recipient mortality. These findings emphasize that dementia caregivers should identify “resilient” family caregivers when considering how these individuals experience and adapt to key transitions during the course of dementia. This presentation will conclude with an update on resilience research in dementia caregiving that has emerged since these findings were first reported.

DECLINE AND ADAPTATION OF LIFE SATISFACTION AFTER LOSING A SPOUSE: MODERATED BY SOCIAL AND HEALTH RESOURCES AND PREDICTING LONGEVITY

Losing a spouse is considered one of the most devastating life events. Repeated measures of life satisfaction from the German Socio-Economic Panel Study (N=1,224, M age=65, 71% women) are used to describe anticipation, reaction, and adaptation to spousal loss, how those processes are moderated by socio-demographic, social, and health resources, and how they relate to mortality hazards. Individuals typically showed anticipatory declines in life satisfaction 2.5 years preceding (anticipation), steep declines in the months surrounding (reaction), and sustained lower levels after spousal loss (adaptation). Older age was associated with stronger anticipation, but less reaction. Younger age, better health, poorer partner health, and social participation were associated with quicker adaptation following spousal loss. Higher pre-loss life satisfaction, less reaction and greater adaptation were uniquely associated with survival. We discuss anticipation, reaction and adaptation stages in the context of life events and pathways underlying moderators of life satisfaction change with spousal loss.

DO HASSLES AND UPLIFTS CHANGE WITH AGE? LONGITUDINAL FINDINGS FROM THE NORMATIVE AGING STUDY
C.M. Aldwin1, Y. Jeong1, H. Igarashi1, A. Spira2, 1. Oregon State University, Corvallis, Oregon, 2. VA Boston Healthcare System, Boston, Massachusetts, 3. Boston University Schools of Public Health and Medicine, Boston, Massachusetts

To examine emotion regulation in later life, we contrasted the modified hedonic treadmill model with developmental theories, using hassles and uplifts to assess emotion regulation in context. The sample was 1,315 men from the VA Normative Aging Study aged 53 to 85 years, who provided 3,894 observations between 1989 and 2004. We computed three scores for both hassles and uplifts: intensity (ratings), exposure (count), and summary (total) scores. Marked differences in trajectory patterns for intensity and exposure scores were found, with exposure levels decreasing in later life, but intensity scores increasing. Growth mixture models (GMM) showed complex patterns of individual differences in exposure, with relative stability in uplifts intensity and nonlinear changes in hassles intensity. Support was found for both hedonic treadmill and developmental theories, showing that emotion regulation in later life is a complex function of both developmental processes and contextual exposure.

SESSION 865 (SYMPOSIUM)

KEY OUTCOMES FROM THE BALTIMORE EXPERIENCE CORPS TRIAL
Chair: G. Rebok, Mental Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland
Co-Chair: M. Carlson, Mental Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland
Discussant: J. Haaga, National Institute on Aging, Bethesda, Maryland

This symposium will discuss key outcomes of the Baltimore Experience Corps® Trial (BECT), an innovative approach to health promotion embedded in volunteering opportunities for adults ≥60 in city public elementary schools. The Experience Corps (EC) program was designed with generative appeal to enhance physical, cognitive, and social activity for older adults, while also improving literacy, math skills and behavior management for children in the exposure schools. Over 4 years, the BECT randomized 702 adults ≥60 to either participation in the EC program over 2 years for 15hrs/week in K-3 grades vs. a usual activity control condition. About 50% (352) were randomized to the intervention group, and 50% (350) to the control group, with a mean age of 68. 85% were female and 89% were AA. In two talks, we will report intervention effects over 2 years on domains of cognition (executive function & processing speed) and on a primary social outcome (levels of reliable alliance) and selected secondary psychosocial outcomes (e.g., depression, purpose in life, personal growth, generativity/usefulness). A third talk examines whether EC participation led to hypothesized increases rather than decreases in lifestyle activity relative to controls. All analyses include intention to treat (ITT) and complier average causal modeling (CACE) analyses, which incorporate degree of intervention exposure in effect evaluation. The fourth talk will test the hypothesis that children in EC schools will have improved academic achievement and behavior compared with children in schools without EC involvement and that these improvements are associated with greater volunteer retention, program satisfaction, and personal efficacy.

EXPERIENCE CORPS AND DOSE-DEPENDENT IMPROVEMENTS IN COGNITIVE HEALTH
M. Carlson1, J. Betz2, Y. Chuang3, G. Rebok1, Q. Xue1, V.R. Varma1, J.M. Parisi1, L.P. Fried2, J. Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland, 2. Columbia University Mailman School of Public Health, New York City, New York, 3. Johns Hopkins School of Medicine, Baltimore, Maryland

The Baltimore Experience Corps (EC) randomized, controlled Trial evaluated whether a high-intensity volunteer service in elementary schools over 1 and 2 academic years helped to maintain or improve executive function (Stroop interference), speed of processing, and memory. Through meaningful service, the EC program incorporate cognitive, social, and physical activity, each of which has been independently associated with maintenance of cognitive health. We examined in 702 older adults the impact of EC participation relative to no participation on the outcomes, above, using Intention-to-Treat and complier average causal modeling (CACE) at 1 and 2 year follow-ups. Results revealed dose-dependent improvements in most outcomes that were specific to one demographic group. These trial results are among the first to show...
that a lifestyle activity intervention can yield general cognitive improvements on tests that were not directly trained, suggesting that environmental enrichment exercises many cognitive abilities important to delaying the onset of dementia.

SOCIAL AND PSYCHOLOGICAL WELL-BEING BENEFITS OF EXPERIENCE CORPS (EC) PARTICIPATION

T. Seeman¹, T.L. Gruenewald², E. Tanner¹, J.M. Parisi¹, Q. Xue³, W. Yao¹, S. Merkin¹, D.L. Roth¹, ¹. UCLA, Los Angeles, California, 2. University of Southern California, Los Angeles, California, 3. Geriatricrs., Los Angeles, California.

The EC RCT provides a unique opportunity to experimentally evaluate whether a “naturalistic” civic engagement intervention can enhance social and psychological well-being. EC volunteerism is characterized by intensive engagement in a socially and personally meaningful role within a context that promotes social connectedness and psychological well-being. We will present analyses of intervention effects on our primary social outcome (levels of reliable alliance) and selected secondary psychosocial outcomes (e.g., depression, purpose in life, personal growth, generativity/usefulness). Our overview will include a comparison of intention to treat (ITT) and compliant average causal modeling (CACE) analyses, which incorporate degree of intervention exposure in effect evaluation. For example, preliminary analyses indicate no significant intervention effect for our primary social outcome in ITT analyses but a robust significant effect of greater levels of reliable alliance (B = 1.30, p = .000) in CACE models incorporating intervention exposure dose (positive outcome robust to varying exposure/compliance definitions).

CHANGES IN LIFESTYLE ACTIVITIES AS A RESULT OF EXPERIENCE CORPS PARTICIPATION

J.M. Parisi¹, J. Kuo¹, L.P. Fried², G. Rebok¹, T. Seeman¹, T.L. Gruenewald⁴, E. Tanner⁵, M. Carlson¹, ¹. Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland, 2. Columbia University Mailman School of Public Health, New York, New York, 3. David Geffen School of Medicine at the University of California at Los Angeles, Los Angeles, California, 4. University of Southern California, School of Gerontology, Los Angeles, California, 5. Johns Hopkins University School of Nursing, Baltimore, Maryland.

Experience Corps (EC) is a high-intensity senior service program in elementary schools designed to capitalize on older adults’ generative motives and simultaneously increase physical, social, and cognitive activity in daily life. We examined intervention-related changes in self-reported lifestyle activity at one- and two-year follow-ups using intention-to-treat (ITT) analyses. Compared to the control group, EC participants reported modest increases (approximately 1/2 day per month) in overall activity level on the Lifestyle Activity Questionnaire, as well as in the intellectual activities subdomain one-year post-baseline and small increases (approximately one day per month) in passive activity (looking at art, listening to radio) at the two-year follow-up (all ps < 0.05). Over the two-year period, we did not observe decreases in any activities or increases in television watching. Results confirm earlier EC pilot trial data showing that this community-based, health promotion intervention positively impacted activity levels, which may benefit a range of health outcomes.

CHILD AND SCHOOL OUTCOMES OF EXPERIENCE CORPS PARTICIPATION

G. Rebok¹, J.M. Parisi¹, M. Carlson¹, W. Roman⁵, D.L. Roth¹, S. McGill¹, L. Xing¹, Q. Xue¹, 1. Johns Hopkins Center on Aging and Health, Baltimore, Maryland, 2. AARP Experience Corps, Baltimore, Maryland, 3. Greater Homewood Community Corporation, Baltimore, Maryland.

The Experience Corps (EC) program was designed to support the needs of children in grades K-3 in public schools while simultaneously promoting the health and well-being of older volunteers. Hypothesized benefits of EC participation to children and schools are expected to result from core program features, including placing a critical mass of trained older volunteers in schools and having them fulfill meaningful roles to meet school needs. Schools in the EC randomized, controlled trial have participated in the program an average of 4.3 yrs, and school size ranges from 206-767 (M = 423) with 84% African American and 82% on free/reduced lunch. Using archival data collected from the school system, we will test the hypothesis that children in EC schools will have improved academic achievement and behavior compared with children in schools without EC involvement and that these improvements are associated with greater volunteer retention, program satisfaction, and personal efficacy.

SESSION 870 (SYMPOSIUM)

TAKING THE MEASURE OF ART’S HEALTH EFFECTS ON OLDER ADULTS: NEA/NIH WORKSHOP HIGHLIGHTS AND A RESEARCH NEEDS ASSESSMENT

Chair: L. Nielsen, Division of Behavioral and Social Research, National Institute on Aging, Bethesda, Maryland
Co-Chair: S. Iyengar, National Endowment for the Arts, Washington, District of Columbia
Discussant: M. Lachman, Brandeis University, Boston, Massachusetts.

This symposium will examine the impact of arts participation on physical, cognitive, and psychological outcomes in aging. Specifically, it will highlight what is known about the ability of theater-acting to improve cognitive outcomes among older adults, how to assess the long-term impacts of music training on auditory working memory, and what factors must be taken into consideration to account adequately for the costs, cost-effectiveness, and public health impact of arts programs for older adults. Recently, the National Endowment for the Arts and NIH co-sponsors (NIA, OBSSR, NCCAM) convened a National Academics workshop to identify gaps and opportunities for better understanding the relationship between arts, health and well-being in older adults. This symposium will address key concepts and recommendations from that workshop, with the goal of highlighting promising directions for new research, including the consideration of appropriate study designs and outcome measures, to enhance our understanding of the mechanisms underlying the impact of arts on health and well-being in later life. Nina Kraus, Northwestern University, discuss how musical experience offsets biological effects of aging in the brain, and enhances hearing speech in noise and auditory working memory. Tony Noice, Elmhurst College, will discuss the impact of acting on cognitive function in retirement-home residents as assessed by RCTs (randomized controlled trials). Tom Prohaska, George Mason University, will review cost/scalability issues for translating arts interventions into evidence-based programs in a community. Margie Lachman, Brandeis University, will serve as discussant, offering her perspectives on future research needs and opportunities.

PARTICIPATORY ARTS FOR OLDER ADULTS: A REVIEW OF BENEFITS AND CHALLENGES

Abstract This presentation reviews the current state of participatory-arts research in terms of enhancing wellness, lowering risk factors for dementia, and ameliorating symptoms of mental/physical disease in older adults. We provide an in-depth look at our cognitive theatre interventions carried out over many years, including a current fMRI assessment. This is followed by a detailed review of both wellness and therapeutic studies on theatre, music, dance, visual arts, and writing. We explain why relatively few of those investigations used randomized controlled trials, a surprising finding considering the dramatic results some RCT studies have produced. Finally, we offer suggestions designed to
PARTICIPATION IN THE ARTS: QUALITATIVE AND QUANTITATIVE RESEARCH PERSPECTIVES ON BENEFITS AND VALUE
T. Prohaska, M. Castora-Binkley, 1. Department of Aging Studies, University of South Florida, Tampa, Florida, 2. George Mason University, Fairfax, Virginia

This paper examines findings from qualitative and quantitative research on the impact, cost effectiveness and perceived value of participation in the arts by older adults. A systematic literature review of outcomes from randomized and non-randomized trials involving performance in the arts by older adults and compares these findings to qualitative studies exploring more open self-reported perceived value of participation in the arts. The findings show that measures of cognitive performance, depressive symptomology and functional capacity are used in randomized trials while altruism, creative expression and quality of life are reported in the qualitative studies. While the clinical trials are more likely to focus on clinically meaningful outcomes, the qualitative studies provide insight into the perceived value in arts-based computer games, raising the question of the benefits of music training initiated in older age. Supported by NIH, NSF, and the Hugh Knowles Hearing Center. www.brainvolts.northwestern.edu

THE TIMING OF LIVES: AGING IN PRISON THROUGH THE LENS OF THE LIFE COURSE PERSPECTIVE
Chair: J.B. Frank, Gerontology/ Family and Consumer Sciences, Eastern Illinois University, Charleston, Illinois
Discussant: J.B. Frank, Gerontology/ Family and Consumer Sciences, Eastern Illinois University, Charleston, Illinois

Aging while incarcerated is not simply about growing older—it is about time. While inmates would not necessarily be classified as older adults on the outside, within the confines of prison individuals’ sense of age, time, and relationships are simultaneously interwoven yet suspended in a limbo of sorts. Because the life course perspective details how time, context, process, and meaning all impact human development and family life (Bengston and Allen, 1993), it is particularly salient for the experience of aging in prison. When men and women are living 25, 35 or even 45 years in prison their entire life course is impacted in ways that make their experience of aging quite different from those in the general community. This symposium will explore how the six principles of the life course perspective (socio-historical and geographical location; timing of lives; heterogeneity or variability; “linked lives” and social ties; human agency and personal control; how the past shapes the future) impact the experience of aging in prison. Specifically, findings from four research studies will focus on separate life course principles (specifically human agency and locus of control, the timing of lives, socio-historical location, and how the past shapes the future) to illustrate not only how these principles play out in prison settings, but also how inmates and the prison environment itself can help scholars to understand the life course perspective through a new and different lens.

A LIFE COURSE ANALYSIS OF INTERPERSONAL, HISTORICAL, AND STRUCTURAL TRAUMA AMONG OLDER ADULTS IN PRISON
T.M. Maschi, Graduate School of Social Service, Fordham University, New York, New Jersey

Older adults in prison are a human rights/ social justice issue in need of attention in the gerontological professional community. Using a life course and critical theory perspectives, this mixed methods study examines the life course experiences of interpersonal, historical, and structural trauma among older men and women in prison. Using a constructivist ground theory approach, participants commonly reported still being affected by earlier life trauma, such as being a victim or witness to violence, neglect, experiencing the sudden and unexpected death of a loved one. Participants commonly reported stress related to stressful conditions of confinement, which included health and healthcare neglect, violence, harassment, and exploitation by staff and younger inmates, fear of victimization and dying in prison, and age, racial and gender discrimination. Participants also reported resilient coping creative and spiritual coping. These findings suggest that gender and age sensitive trauma informed care and criminal justice reform are warranted.

THE INMATE CODE: THE LIFE COURSE PERSPECTIVE OR HOW TO GO FROM “FRESH FISH” TO SCHOOLED CONVICT
P. Matthey, Communication, Clemson University, Clemson, South Carolina

As the life course perspective sees humans as capable of making choices and constructing one’s own life journeys within systems of opportunities and constraints, this paper takes a critical look at the ways in which prisoners coordinate their journeys with those of others. From a communication perspective, this paper is rooted in the theoretical framework of Coordinated Management of Meaning. While incarcerated, prisoners of a maximum-security male prison in Indiana are constantly deciding whether to align with the rules of the facility or those dictated by the inmate code. Stuck between the constraints of two sets of contradictory rules imposed simultaneously by the facility and the prison culture, inmates encounter few opportunities through which they can coordinate their journeys with those of correctional officers and staff and those of other inmates. This paper maps conditions of incarceration that foster strategies to successfully allow for the coordination of life course perspectives.
OFF-AGE TRANSITIONS AND LIFE TRAJECTORIES: A PHENOMENOLOGICAL STUDY OF AGING AMONG LONG-TERM PRISONERS
J.B. Frank, Gerontology/ Family and Consumer Sciences, Eastern Illinois University, Charleston, Illinois

Time is a central concept within the life course perspective. Within the realm of time, Elder (1985, 1994, 1998) focused on the role of transitions and trajectories as critical to framing people’s experiences across the life course. Many long-term prisoners (those incarcerated fifteen years or longer) have been in prison since their teenage years and thus while they are not “old”, they perceive the aging process and the passage of time in a manner much different than those on the outside. The researcher postulates that much of this reality is due to “off-age” transitions they have experienced within their broader life trajectories. The findings from the present longitudinal, qualitative study of 12 long-term male inmates support this claim and offer gerontologists a new window on the intersection between aging, time, and the physical environment as they influence trajectories within the life course.

TALKING ABOUT THEIR LIVES: USING ART EXPRESSION GROUPS WITH WOMEN AGING IN PRISON
A. Katz, A. Hongo, University of Southern California, Los Angeles, California

Prisons are not built for the vulnerable aging population especially older women. A prison environment deeply rooted in violence and fear is not conducive to self-disclosure or trust. Along with mental illness, inmates, especially women, often exhibit difficulties with locus of control, which is the degree of control that people feel they can express themselves with others in their environment. Research indicates that the use of the arts or art therapy enables participants to increase their sense of control and problem-solving and socialization skills (Gussak, 2009). This pilot study evaluates the influence of an art expression group for a sample of women aged 55 and older at the California Institution for Women. It was found the women freely expressed their thoughts and feelings about their past and current lives and felt the arts provided a safe and nonjudgmental arena to do so. As these findings suggest that art expression groups can provide a safe means of expression for older women in prison.

SESSION 880 (PAPER)

EMOTION

AGING, AFFECT, AND SELF-RATED HEALTH: A MULTILEVEL, MULTIVARIABLE, LONGITUDINAL INVESTIGATION
S.C. Segerstrom, Department of Psychology, University of Kentucky, Lexington, Kentucky

Self-rated health (SRH) predicts mortality above and beyond objective health risks and as such comprises an important aspect of health. Established contributors to self-rated health include affect, age, and disease, but neither their dynamic nor their synergistic contributions to SRH have been comprehensively tested. The present study employed older adults (N = 150; M age = 75 years) and a longitudinal design with 6-month waves over up to 5 years. Positive and negative affect (PA, NA), chronic disease, and SRH were assessed at each wave. Older age, more chronic disease, and higher NA predicted worse SRH, whereas higher PA predicted better SRH. Affect predicted SRH both between and within people. In multilevel models with interactions between affect and age or disease, individual differences in NA predicted worse SRH more with older age. Within people, changes in NA were associated with changes in SRH, but less so with older age. Within people, changes in PA were associated with changes in SRH, but only when health was better than usual. These were dynamic and synergistic relationships between affect and SRH that could only emerge in a multilevel, multivariable design. Between-person, trait NA had larger effects on SRH with older age compared with within-person, state NA, which had smaller effects with older age. Which component predicts mortality is an important question for future research, and the suggestion to measure SRH repeatedly on older adults should be considered seriously in the clinical setting as an additional piece of prognostic information.

FEELING THE SQUEEZE? THE EFFECT OF COMBINING WORK AND CAREGIVING ON PSYCHOLOGICAL WELL-BEING
T. Hansen, S. Daatland, Norwegian Social Research (NOVA), Oslo, Norway

As a result of population aging and increasing female employment rates, growing numbers are facing the competing demands of work and caregiving. This study explores the effect of providing regular personal care by employment status on multiple dimensions of psychological well-being. We separate between in-household (partner, parent) or out-of-household (parent) caregiving. We use cross-sectional data from the Norwegian Life Course, Ageing and Generation (LOGG) study (N = 10,000, age 30–64). Results indicate that out-of-household caregiving has no significant effects on well-being among employed and non-employed individuals. In-household caregiving has more deleterious effects, and particularly among non-employed individuals. Work thus seems to add respite rather than stress to caregivers. Aspects of being in paid labor, such as financial security and social support, may ease the burden of the caregiving role. We conclude with implications for future research, interventions, and policy-making in this area.

AGE-RELATED DIFFERENCES IN EXPOSURE AND REACTIVITY TO DAILY STRESS ACROSS 60 DAYS AND 70 YEARS

Exposure (the amount and diversity of stressors) and reactivity (within-person negative affect change) to daily stressors influence health and well-being. As such, it is important to understand how individuals at different phases of the life span are exposed and react to a variety of stressors. Using 9 weeks of daily reports (M = 56.1 days) of affective and stressor experiences provided by 150 adult participants in the PSU Intraindividual Study of Aging, Health, and Interpersonal Behavior (iSAHIB), we examined age-related differences in exposure and reactivity to eight different stressor types. We found that older adults have significantly lower overall diversity of stressors than younger adults. Older adults also tend to have less exposure than younger adults to each stressor type, except health and accident stressors, to which they are exposed more. Further, older adults are more detrimentally affected by greater exposure to financial stressors, interpersonal tensions, health/accident stressors, network stressors, evaluation stressors, and other stressors. In contrast, reactivity tends to be similar across ages, though older adults are more reactive to network and evaluation stressors than younger adults. Future analyses will examine the effects of stressor residue (carry-over from the previous day) and spells (multiple consecutive days of stressors). Our analyses further the understanding of dynamic stress processes associated with specific daily stressors and how those processes differ by age.
INTRAINDIVIDUAL VARIABILITY IN AFFECTIVE VALANCE AND AROUSAL ACROSS AGE GROUPS: THE STEADYING EFFECTS OF AGE

Introduction: Emotion can be studied across affective (positive and negative) and arousal (activation and deactivation) dimensions. Research examining age differences in these two components of emotion has primarily relied on mean values. However, beyond examining magnitude, meaningful information can be gained by examining fluctuations within the individual (intraindividual variability; IVV). Methods: 50 younger and 50 older community-dwelling adults completed 14-consecutive-daily diaries assessing affect and arousal. IVV was calculated using predictor-free multilevel modeling analyses. The intraclass correlation coefficient from each model was used to determine IVV in affect (PANAS positive and negative scales) and arousal (UMACL_R energetic and tense scales). Independent-samples t-tests were run to compare IVV across ages. Results: The percent of total variability attributed to intraindividual fluctuations in positive and negative affect, respectively, were 42% and 59% for younger adults, and 20% and 11% for older adults. The amounts of variability attributed to fluctuations in arousal were 54% and 64% for younger adults and 22% (for both scales) for older adults (for the UMAC-L_R energetic and tenseness scales, respectively). Younger adults had significantly more fluctuations in affect (PANAS positive t(97)=6.82, p<.001 and negative t(97)=4.18, p<.001) and in arousal (UMACL-R energetic t(97)=4.18, p<.001 and tenseness scales t(97)=4.18, p<.001) compared to older adults. Conclusions: Younger adults experienced greater day-to-day fluctuations in both positive and negative affect and psychological arousal compared to older adults. Explanations for greater stability for older adults include greater lifestyle regularity, use of emotional regulation skills, and a selectivity bias for engaging in activities that are emotionally meaningful.

COGNITIVE AND EMOTIONAL SOURCES OF WISDOM IN DECISION MAKING ACROSS THE LIFESPAN

Given well-documented age-related cognitive declines, it is critical to investigate whether other forms of knowledge may help to compensate for and mitigate declines in decision-making. Whereas the effects of declines in fluid intelligence on decisions are well understood, the current research examines what components of crystallized intelligence contribute to wisdom in decision making in older adults. This research also examines whether individual differences in emotional regulation and personality are influenced by other abilities that change with age, including components of both fluid and crystallized intelligence. Using a broad sample of adults between 18-94 years of age, we collected a battery of standard cognitive measures and measures of economically and emotionally important decision-making "traits"—including temporal discounting, loss aversion, affective forecasting ability, and emotional regulation. Structural equation modeling revealed that fluid intelligence, crystallized intelligence, and affective variables were significant partial mediators of decision-making age differences. Specifically, we found that older participants' greater crystallized intelligence offset their lower levels of fluid intelligence for financial and debt literacy as well as temporal discounting. Notably, personality, goal orientation, and affective forecasting were partially mediated by changes in future time perspective, improved emotional regulation, and other measures of crystallized intelligence. By understanding what components of individual and lifespan differences in crystallized intelligence lead adults across the lifespan to make better decisions—both economically and emotionally—across a wide range of domains (including retirement and healthcare), these findings provide directions for the development of interventions that can aid decisions and improve the welfare of older adults.

SESSION 885 (SYMPOSIUM)
ENERGETIC, PHYSIOLOGIC AND BIOMECHANICAL THREATS TO GAIT SPEED: LONGITUDINAL ANALYSES FROM THE BLSA
Chair: E.M. Simonsick, National Institute on Aging, Baltimore, Maryland
Discussant: L. Ferrucci, National Institute on Aging, Baltimore, Maryland

Age-related mobility decline is often insidious. Apparently well-functioning older adults may harbor subclinical impairments in one or more systems that left unchecked may lead to premature mobility limitation. This symposium uses longitudinal data from the Baltimore Longitudinal Study of Aging (BLSA), a continuous enrollment cohort study of initially healthy well-functioning individuals evaluated every 1-4 years depending on age during a 2-3 day clinic stay, to examine the association between novel indicators of energy expenditure, muscle quality, gait mechanics and balance and proprioception and meaningful decline or change trajectory in gait speed. Gait speed was measured over a 6m course with participants instructed to walk “at your normal pace” or in a state-of-the-art gait laboratory. In analyses on up to 600 men and women age 55 years or older, evidence of impaired balance and ankle proprioception from challenge test performance and double-stance time, stride-width and non-optimal hip power from gait lab evaluation predicted meaningful gait speed decline. Greater energetic cost of walking and lower maximal quadriceps muscle strength but not poor muscle quality (strength/cross-sectional area) independently predicted steeper gait speed decline. From the gait lab, fast gait and hip range of motion (ROM) were found more sensitive to short-term change with ROM predictive of fast gait speed decline. Subtle deficiencies in key systems identified using challenge and/or sensitive tests may prove valuable for understanding and ultimately limiting the progressive of mobility decline.

MUSCLE STRENGTH, MUSCLE AREA, AND TRAJECTORIES OF GAIT SPEED IN OLDER ADULTS
A.Z. Moore, S. Makrogiani, E.M. Simonsick, L. Ferrucci, National Institute on Aging, Baltimore, Maryland

Muscle strength is associated with mobility and predicts decline of mobility in older adults. However, the independent contributions of muscle mass and quality to mobility decline are unclear. The relationships between baseline quadriceps strength (isokinetic dynamometry), muscle cross-sectional area (computed tomography), and muscle quality, the ratio of strength to area, with change in gait speed over time was evaluated in 528 BLSA participants aged 50 or older (mean at baseline = 70.1 years) with at least two measurements of usual gait speed over 6 meters (1450 observations). In mixed effects models adjusted for sex, height, and weight each muscle characteristic was positively associated with the level (p<.01) and rate of decline in speed (p<.05). However, after the effect of strength was considered, area and quality were not independently associated with decline in gait speed, reaffirming the unique importance of muscle strength for mobility in older adults.

GREATER ENERGETIC COST OF WALKING PREDICTS LONGITUDINAL GAIT SPEED DECLINE
J.A. Schrack, E.M. Simonsick, L. Ferrucci. 1. Epidemiology, Johns Hopkins School of Public Health, Baltimore, Maryland. 2. National Institute on Aging, Baltimore, Maryland

Greater energetic cost of walking has been cross-sectionally associated with slower gait speed and reduced activity with age, but the directionality of this association has not been established. We modeled the longitudinal association between the energetic cost of customary
walking (EE ml/kg/m) and usual gait speed in 562 participants of the Baltimore Longitudinal Study of Aging (51% male, mean age 73.1, range 31–98) using energy expenditure per meter (EEM) and its squared term (EEM2) as predictors adjusting for age, sex, age-squared, sex, height, balance, and comorbidities. The net effects of EEM and EEM2 were negatively associated with usual gait speed ($\beta$ = -3.43, $p < 0.01$) indicating that higher energetic cost of walking is predictive of gait speed decline. These results shed light on the well-established age-related slowing of gait speed and indicate that slowing down may be a compensatory mechanism to conserve energy with age.

### Balance, Proprioception and Gait Speed Decline in the BLSA

E.M. Simonsick1, J.A. Schrack2, A.Z. Moore3, S. Ko1, L. Ferrucci1, 1. National Institute on Aging, Baltimore, Maryland, 2. Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland, 3. Chonnam National University, Seoul, Republic of Korea

Instability due to impaired balance or proprioception is thought to reduce walking efficiency and hasten gait speed decline. In over 500 non-mobility-limited BLSA participants aged 60-97 (51% men, 24% black), we examined the association between narrow (20cm) 6m walk and graduated standing balance performance (90s maximum) and meaningful decline in gait speed (>0.05m/s/year) over a mean follow-up of 2.2 years. Accounting for age, age-squared, sex, race, initial gait speed and follow-up time, narrow walk failure and submaximal standing balance (each 10s deficit) predicted gait speed decline (OR:3.63; 95%CI:2.04-6.48; P<.001 OR:1.11; 95%CI:1.01-1.23; p=.035). In a subset with proprioception evaluated using a novel device, those with worst proprioception – slowest quartile perception of ankle movement tended to be more likely to decline (49.2% v. 26.2%; p=.079). Findings indicate older persons with impaired balance and proprioception face increased risk of meaningful gait slowing and argue for balance and proprioception evaluation in mobility intact older adults.

### Gait Laboratory Parameters and Meaningful Gait Speed Decline in the BLSA

G.J. Jerome1, E.M. Simonsick2, S. Ko3, A.Z. Moore2, L. Ferrucci1, 1. Towson University, Towson, Maryland, 2. National Institute on Aging, Baltimore, Maryland, 3. Chonnam National University, Yeosu, Republic of Korea

Subtle abnormalities and defects in gait mechanics may create inefficiencies that lead to gait speed decline. Using data on 280 BLSA participants (51.1% men, 28.0% black) aged 60-97 who received a gait lab [3D motion capture system with 10 cameras and 20 anatomical markers] assessment, we examined indicators of gait inefficiency and hip biomechanics as predictors of meaningful decline in gait speed (>0.05m/s/year) over a mean follow-up of 2.08 years. Accounting for age, age-squared, sex, race, initial gait speed and follow-up time, double stance time (quintiles) (OR:1.40; 95%CI:1.11-1.76; $p=.005$) and stride width (upper tertile) (OR:2.56; 95%CI:1.20-5.44; $p=.015$) predicted gait speed decline. Both high and low total work performed by the hip was associated with increased likelihood of decline (OR:2.5; 95%CI:1.16-5.18; $p=.018$; OR:2.13; 95%CI:1.03-4.3; $p=.041$). Results indicate that traditional markers of inefficient gait predict gait speed decline.

### Short-Term Change in Gait Laboratory Parameters in the BLSA

S. Ko1, E.M. Simonsick2, L. Ferrucci1, 1. Mechanical Engineering, Chonnam National University, Yeosu, Republic of Korea, 2. National Institute on Aging, Baltimore, Maryland

Age-related slowing of gait speed may stem in part from biomechanical impairments including reduced joint range of motion (ROM) while walking. Studies of age-associated change in gait parameters have relied on cross-sectional data when full understanding of actual deteriorations in gait patterns requires longitudinal comparison. This study examines change in gait parameters ascertained in a gait lab [3D motion capture system with 10 cameras and 20 anatomical markers] over two visits approximately 2 years apart in BLSA participants aged 60-95 (men N=27, women N=31). Although normal pace walking over 10 meters did not change over follow-up, maximum speed walking showed significant decline (1.65 vs. 1.53m/s; $p=0.041$) as did hip range of motion (p=0.032) at maximal speed. Findings suggest that over the short term, gait deterioration may be best observed under the challenge of fast walking and that compressed hip ROM while walking may play a contributing role.

### SESSION 890 (SYMPOSIUM)

**Epidemiology of Pain in Older Adults**

Chair: K. Patel, University of Washington, Seattle, Washington

Discussant: C. Reid, Cornell University, New York, New York

Pain is one of the most commonly reported symptoms by older adults and is associated with significant reduction in quality of life. Although clinicians widely recognize pain as a disabling condition, the epidemiology of pain in older adults is not well established. In this symposium, we present original findings from 3 major data sources on the population distribution, characteristics, and impact of pain in older adults. First, Dr. Patel will present the prevalence of bothersome pain in a national survey of Medicare beneficiaries, and will report the associations of pain with various self-reported and performance-based measures of physical function. Second, Dr. Thielke will describe the extent to which several common disabling symptoms and conditions are attributable to pain using data from the large Medicare Health Outcomes Survey. Third, Ms. Thakral will identify descriptors of pain symptoms (e.g., nagging, aching, soreness, etc.) that are most often endorsed by older adults, and will relate these descriptors to global measures of pain using data from the population-based MOBILIZE Boston Study. Fourth, Dr. Leveille will provide insights on the effects of chronic pain on cognitive function using a battery of neuropsychological measures in the MOBILIZE Boston Study. Lastly, Dr. Reid will discuss the 4 papers and provide a clinical perspective on chronic pain and aging. The overall symposium will provide a comprehensive set of analyses of contemporary data that characterize the high burden of pain and patterns of pain reporting in the older adult population.

### Prevalence and Impact of Pain Among Older Adults in the United States

K. Patel1, J. Guralnik2, E.J. Dansie1, D. Turk1, 1. University of Washington, Seattle, Washington, 2. University of Maryland, Baltimore, Maryland

The study sought to determine the prevalence and impact of pain among older adults in the United States (US). Data on 7,601 older adults participating in the 2011 National Health and Aging Trends Study were analyzed. Prevalence of bothersome pain was 52.9%, affecting 18.7 million older adults. Pain did not vary across age groups (P=0.21), but prevalence was higher in women and in older adults with obesity, musculoskeletal conditions, and depressive symptoms (P<0.001). Self-reported inability to walk 3 blocks was 72% higher in participants with than without pain [adjusted Prevalence Ratio=1.72 (95% Confidence Interval: 1.56-1.90)]. Participants with 2, 3, and >4 sites of pain had gait speeds that were 0.03, 0.05, and 0.08 meters per second slower, respectively, than older adults without pain, adjusting for potential confounders (P<0.001). In summary, bothersome pain was reported by half of the US older adult population and was strongly associated with decreased physical function.
ATTRIBUTABLE RISK FRACTIONS DUE TO PAIN IN THE MEDICARE HEALTH OUTCOMES SURVEY

Pain has been strongly associated with adverse health outcomes in older adults, but the broad role of pain in health has been hard to quantify. We calculated unadjusted and adjusted population attributable risk fractions (PAR) due to pain for selected symptoms, functional impairments, and diagnoses (dyspnea; depressed mood; low energy; mobility impairment; low accomplishment due to physical or emotional problems; and poor self-rated health). We analyzed data from 258,295 participants in the Medicare Health Outcomes Survey, a survey of Medicare managed care recipients across the country in 2009. Pain was assessed by the SF-36 Pain Interference question. Adjusted models included sociodemographic characteristics, comorbidities, and the other variables. Across all the factors, high pain interference accounted for about 40-50% of the unadjusted and 30% of the adjusted PAR. Pain is this population was the strongest risk factor for diverse aspects of negative health.

EXPLORATORY FACTOR ANALYSIS OF PAIN DESCRIPTORS IN THE ELDER POPULATION
M. Thakral1, L. Shi2, R.H. Shmerling2,3, J.F. Bean1,2, S.G. Leveille1,2, 1. University of MA, Boston, Boston, Massachusetts, 2. Harvard Medical School, Cambridge, Massachusetts, 3. Spaulding Rehabilitation Hospital, Cambridge, Massachusetts, 4. Beth Israel Deaconess Medical Center, Boston, Massachusetts

The purpose of this study is to examine whether categories of pain descriptors derived from exploratory factor analysis are related to global pain characteristics endorsed by older adults. In the population-based MOBILIZE Boston Study, 765 persons aged ≥70y underwent an extensive assessment of health and function that included measures of persistent pain. A modified version of the McGill Pain Questionnaire listed 20 pain quality descriptors commonly endorsed by older adults. Four categories were derived, accounting for 100% of variance: (1) musculoskeletal (65%), (2) sensory (17%), (3) pain fatigue (10%) and (4) physically limiting pain (8%). For example, Factor 1 (musculoskeletal) was most strongly associated with “troublesome” pain (r=0.77), and included “nagging,” “aching,” and “ soreness.” We will present correlations and multivariable analyses comparing pain descriptors to global pain measures. Our findings present new information about the range of pain symptoms and their correlates that are commonly reported by older adults.

CHRONIC PAIN AND COGNITIVE FUNCTION IN AN OLDER POPULATION
S.G. Leveille1,2, L. Shi3, L. Eggermont2, W. Milberg3,4, 1. Nursing, CNHS, Univ Mass Boston, Dorchester, Massachusetts, 2. Vrije University, Amsterdam, Netherlands, 3. Harvard Medical School, Boston, Massachusetts, 4. Veterans Affairs Medical Center, Boston, Massachusetts

Studies suggest that chronic pain may influence cognitive function in older adults. We examined the relationship between chronic pain characteristics and measures of cognitive performance in the MOBILIZE Boston Study, a population-based study of 765 persons aged 70 and older living in the Boston area. Chronic pain was measured according to musculoskeletal locations and using the Brief Pain Inventory subscales for pain severity and interference. Neuropsychological measures included the Hopkins Verbal Learning Test, Trailmaking A and B, Clock-in-a-box, and verbal fluency. Cognitive domains of memory, executive function, and general cognitive function were determined using Factor Analysis and Principal Components Analysis. After adjusting for age, sex, race and education, pain severity and interference scores were associated with poorer cognitive function across the cognitive domains and in selected neuropsychological tests. Our findings provide important new insights about aspects of chronic pain that may contribute to poorer cognitive function in older adults.

SESSION 895 (SYMPOSIUM)
FIVE YEAR OUTCOMES OF THE FACILITATED LEARNING TO ADVANCE GERIATRICS (FLAG) MENTORSHIP PROGRAM
Chair: M.J. Kaas, University of Minnesota School of Nursing, Minneapolis, Minnesota
Discussant: N. Shearer, Arizona State University College of Nursing and Health Innovation, Phoenix, Arizona

Recent national reports have highlighted the increased need for a competent nursing workforce to provide health care to a growing aging population in the United States. One of the problems of increasing this geriatric nursing workforce is the lack of nursing faculty with expertise in teaching geriatric nursing. Over the last 5 years, the University of Minnesota Hartford Center for Geriatric Excellence, Facilitated Learning to Advance Geriatrics (FLAG) program has taught over 150 nursing faculty how to incorporate geriatric nursing into their nursing curriculum through the FLAG Summer Institute and the FLAG Mentorship program. The FLAG Mentorship program is aimed at developing the academic leadership skills needed to implement an education project to improve geriatric nursing education in the mentee’s home school of nursing. Across the country, in rural and urban locations, and among a variety of educational settings, the FLAG Mentorship program has resulted in significant outcomes of improved geriatric nursing education and enhanced professional careers in geriatric nursing. Using evidence from 5 years of FLAG mentorship evaluations and reports, the symposium presentations will provide an overview of the FLAG Mentorship program and participants, mentorship educational product and career outcomes, and challenges and successful strategies of developing a distant FLAG mentor/mentee relationship. One FLAG Mentor will discuss in-depth her experience as FLAG mentee and mentor. The Discussant will draw upon previous mentorship experience and geriatric nursing expertise to facilitate discussion about this FLAG program in light of current Hartford Center Collaborative initiatives and national health care needs.

FLAG MENTORSHIP PROGRAM OVERVIEW: DEVELOPMENT, PARTICIPANTS, AND SUSTAINABILITY
M.J. Kaas, University of Minnesota School of Nursing, Minneapolis, Minnesota

Developing nurse educators who can effectively improve geriatric nursing education is a major goal of the Facilitated Learning to Advance Geriatrics (FLAG) program at the University of Minnesota Hartford Center for Geriatric Nursing Excellence. This presentation will summarize the initial development of this distant, year-long mentorship program and compare it to other national nursing mentorship programs. We will describe the mentor and mentee FLAG participants, the methods for assigning the mentor/mentee groups, the year-long mentorship process, and the training and development process of FLAG Mentor from FLAG Mente. This presentation will also describe the objectives and methods used to enhance and sustain FLAG mentorship program over 5 years with recommendations for evaluation methods and future sustainability.

STRATEGIES OF A SUCCESSFUL FLAG MENTOR/MENTEE RELATIONSHIP
C. Cheung1, W. Kopp1, 1. University of Minnesota, Minneapolis, Minnesota, 2. Sanford College of Nursing, Bismark, North Dakota

Successful mentorships require an understanding of the mentorship process, matching of the mentor and mentees, individual assessment and planning, and on-going evaluation. Yet even with careful planning, there are significant challenges in distant mentoring. Presenters will describe the FLAG mentorship process from their perspective as two current FLAG mentors. Both FLAG mentors were previous FLAG mentees. One (CC) has been a mentor for four years and one (WK) is...
training to be a FLAG mentor. The presentation will examine the opportunities and challenges of FLAG mentor/mentee relationship including the developmental process of becoming a mentor and that of a mentee, and the personal and professional outcomes of this relationship. Both presenters will identify strategies they use to ensure a successful mentoring experience and to help their mentees 1) grow in gerontological nursing, 2) successfully complete their gerontological education projects, and 3) be equipped and empowered in gerontological nursing education

FLAG MENTORSHIP OUTCOMES: EDUCATIONAL PRODUCTS AND ENHANCED CAREERS

Outcomes associated with the FLAG Mentorship program will be described in this presentation. Outcomes include improved or increased geriatric nursing educational course offerings in the mentees’ schools of nursing, enhanced professional career opportunities for the FLAG mentors and mentees, and increased self-efficacy of teaching geriatric nursing as measured by the College Teaching Self-Efficacy Scale (CTSES). Educational project outcomes include new core graduate curricula in geriatric nursing, development of new community and institutional geriatric nursing clinical settings, and geriatric nursing content infused across various levels of nursing curricula. As a result of their FLAG experience, participants have enrolled in doctoral programs, assumed new academic leadership positions, received state and national awards, and become more active in professional and local advocacy organizations for care of older adults.

SESSION 900 (PAPER)

CARDIOVASCULAR

LONGITUDINAL ELEVATIONS IN THE HEART RATE AT REST AND RISK OF DEATH FROM ALL-CAUSES IN OLDER ASYMPTOMATIC ADULTS
B.W. O Hartaigh, M. Trentalange, G. McAvay, H. Allore, T.M. Gill, Internal Medicine, Yale University, New Haven, Connecticut

A faster resting heart rate (RHR) has long been associated with adverse health outcomes. Nevertheless, it remains unclear whether longitudinal elevations in RHR are predictive of mortality in older persons. In this study, therefore, we assessed the relationship between changes in RHR and risk of dying from all-causes in an older (aged 65 years and older) population. Data was obtained from the Cardiovascular Health Study (CHS), comprising 5,691 asymptomatic individuals enrolled from 1989-1993 in the United States. RHR was measured annually for 6 consecutive years by validated electrocardiogram. Using Cox regression models, we evaluated the hazard ratio (HR) for total mortality according to changes in RHR. During a median 6.9 (interquartile range, 6.7-7.1) years of follow-up, 974 (17.1%) participants died. Following adjustment for potential confounders, each 10 beat/min increment in time-varying RHR heightened the risk (HR, 95% CI = 1.34, 1.27-1.42) of death; comparable results were observed for the uppermost quartile (HR, 95% CI = 2.26, 1.91-2.67) of RHR relative to the lowest. For participants whose initial RHR measurement was ≥65 beats/min, the adjusted risk of death was 1.37 (95% CI, 1.09-1.73) and 1.82 (95% CI, 1.20-2.76) when subjects final RHR measurement changed to >65<80 beats/min and ≥80 beats/min, respectively. Participants with a RHR ≥80 beats/min at baseline and final examination had an adjusted HR of 2.46 (95% CI, 1.86-3.26), compared with those whose RHR was constantly ≤65 beats/min. Elevations in the RHR over time are associated with increased risk of global mortality among older asymptomatic adults.

CORONARY ARTERY CALCIUM AND PHYSICAL PERFORMANCE AS DETERMINANTS OF MORTALITY: AGES-REYKJAVIK STUDY
M. von Bonsdorff1,2, D.A. Groffen1,3, T. Rantanen1, P.V. Jonsson1,2, T. Aspelund1, J.L. Launer2, V. Gudnason2, T. Harris1, 1. Gerontology Research Center and Health Sciences, University of Jyväskylä, University of Jyväskylä, Finland, 2. National Institute on Aging, Bethesda, Maryland, 3. Maastricht University, Maastricht, Netherlands, 4. The Icelandic Heart Association, Kopavogur, Iceland, 5. The University of Iceland, Reykjavik, Iceland

Background Coronary artery calcium (CAC) and physical performance have been shown to be associated with mortality, but it is not clear whether one of them modifies the association. We investigated the association between the extent of CAC and physical performance among older individuals and explored these individual and combined effects on cardiovascular disease (CVD) and non-CVD mortality. Methods We studied 4074 participants of the Age, Gene/Environment Susceptibility-Reykjavik Study (AGES-Reykjavik Study) who were free from coronary heart disease, had a CAC score calculated from computed tomography scans and had data on mobility limitations and gait speed at baseline in 2002-2006 at a mean age of 76 years. Results Odds for mobility limitation and slow gait increased according to the extent of CAC. Altogether 645 persons died during the follow-up. High CAC, mobility limitation and slow gait were independent predictors of CVD and non-CVD mortality. The joint effect of CAC and gait speed on non-CVD mortality was synergistic, i.e. compared to those with low CAC and normal gait, the joint effect of high CAC and slow gait exceeded the additive effect of these exposures on non-CVD mortality. For CVD mortality, the effect was additive i.e. the joint effect of high CAC and slow gait did not exceed the sum of the exposures. Conclusions The extent of CAC and decreased physical performance were independent predictors of mortality and the joint presence of these risk factors increased the risk of non-CVD mortality above and beyond the individual effects.

VASCULAR AGING AND CEREBRAL OXYGEN RESERVE DURING SLEEP IN COMMUNITY DWELLING OLDER ADULTS, AGE 70+ YEARS: A PILOT STUDY
B. Carlson1, J.V. Neelon1, J. Carlson1, H.L. Roth2, A. Hindler3, M.A. Beck4, D. Bliwise1, 1. School of Nursing, The University of North Carolina at Chapel Hill, Chapel Hill, North Carolina, 2. School of Medicine, The University of North Carolina at Chapel Hill, Chapel Hill, North Carolina, 3. School of Public Health, The University of North Carolina at Chapel Hill, Chapel Hill, North Carolina, 4. School of Medicine, Emory University, Atlanta, Georgia

Background/Aims: Vascular aging depletes stores of antioxidants and limits the delivery of neurotrophic factors; leaving neurons vulnerable for injury. This pilot study compared biomarkers of vascular aging, antioxidant activity, and neurotrophic factors in 20 older adults, with normal and marginal cerebral oxygen reserve (COR). Methods: Subjects (5M/15F, age 70-96 years) underwent two nights of polysomnography including measures of COR (percent regional cerebral oxyhemoglobin saturation [rcSO2] by cerebral oximetry). Bio-markers of vascular aging included measures of flow mediated dilation of the brachial artery (FMD) on Morning 1, and on Morning 2, measures of inflammation (serum C-reactive protein [CRP]) and oxidative stress (plasma reduced-to-total glutathione ratio [GSH/GSSG]). We also measured antioxidant activity (serum glutathione peroxidase [GPX]) and serum levels of brain derived neurotrophic factor [BDNF]. Findings: Fourteen subjects had normal (rcSO2 ≥60%) and six had marginal (rcSO2: 51%-60%) COR; all had apnea-hypopnea indexes <5/hour and maintained arterial oxyhemoglobin saturations [SaO2] ≥92%, CVD was <4.0% in 71% with normal COR and 83% with marginal COR. CRP was >3.0 mg/dl in 42% with normal COR and 83% with marginal COR (X2(df=1)=3.0, p=.05). GSH/GSSG did not differ by group. GPX

The Gerontological Society of America

Downloaded from https://academic.oup.com/gerontologist/article-abstract/53/1/NP/563183 by guest on 30 April 2018
was higher in the marginal COR group ($t_{df=18}=2.1$, $p$.05). In marginal,
was lower rscO2 during sleep was associated with higher BDNF ($r=-.90$).
Conclusions: Disruption in blood flow regulation is common in older adults. Declines in CDR may evoke the inflammatory-oxidative stress pathways; leading to increased antioxidant activity and circulating neurotrophic factor. This may represent a protective response to chronic intermittent hypoxia. Funding: UL1RR025747.

CUMULATIVE SOCIOECONOMIC DISADVANTAGE OVER THE LIFE COURSE AND CARDIOVASCULAR DISEASE MORTALITY

V. Johnson-Lawrence1, G. Kaplan2, S. Gales1, 1. University of Michigan, Ann Arbor, Michigan, 2. University of Michigan, Ann Arbor, Michigan, 3. Columbia University, New York, New York

Purpose: Life course models suggest that socioeconomic disadvantage is associated with increased cardiovascular disease (CVD) mortality risk. Although socioeconomic mobility has been linked with CVD mortality, the associations between cumulative disadvantage that incorporate socioeconomic instability over the life course and CVD mortality is unclear. This study examined gender stratified associations between cumulative socioeconomic disadvantage (CSD), measured as an index (range 0–3) of the number of markers of disadvantage in relation to CVD mortality risk among older adults. The markers of disadvantage were based on adulthood household income trajectories (low versus high patterns), education (0–12 or 13+ years), and father’s education (grammar school or less versus some high school or more). Methods: Data from 2530 (men=1086, women=1427) Alameda County Study respondents in 1994 were used in these analyses. Latent growth curve models were used to identify income trajectories from 1965–1994. Results: Controlling for age, race/ethnicity, and marital status, proportional hazards models suggested greater cumulative disadvantage was significantly associated with greater CVD risk for women (HR3 markers=4.05, 95% CI=1.84–8.91, HR2 markers=2.34, 95% CI=1.08–5.07, HR1 marker=1.82, 95% CI=0.82–4.05) but no significantly associations were suggested among men (HR3 markers=2.00, 95% CI=0.72–5.57, HR2 markers=1.21, 95% CI=0.59–2.48, HR1 marker=0.96, 95% CI=0.48–1.95). Conclusions: The results suggest more negative impacts of disadvantage over the life course on CVD mortality among women compared to men. Future work should continue to investigate measures that capture the variation in social mobility over the life course, and how these patterns shape chronic disease risk within genders in later life.

SESSION 905 (PAPER)

COMMUNICATION AND LANGUAGE

ASSOCIATION OF HEARING LOSS WITH HOSPITALIZATION AND BURDEN OF DISEASE IN OLDER ADULTS

D.J. Genther1, K.D. Frick2, D. Chen1, J. Betz2, F.R. Lin2,1, 1. Otolaryngology-Head and Neck Surgery, Johns Hopkins University School of Medicine, Baltimore, Maryland, 2. Johns Hopkins University Bloomberg School of Public Health, Baltimore, Maryland

Background: Hearing loss (HL) affects nearly 2 of every 3 adults aged 70 years or older in the U.S. Epidemiologic studies have demonstrated that HL is independently associated with poorer cognitive and physical functioning in older adults. However, the association of HL with broader health economic outcomes, such as healthcare utilization, and an individual’s perception of her own health is unstudied. Methods: We analyzed data from the National Health and Nutrition Examination Survey (NHANES), an epidemiological study of the civilian, non-institutionalized U.S. population. Audiometry was performed according to established NHANES protocols. Hearing loss was defined per the WHO definition of impairment. Hospitalization was defined as any hospitalization (yes/no) and number of hospitalizations (0/1/>1 times). Burden of disease was defined by self-reported number of days of poor physical health, poor mental health, and inactivity due to health (0–10/10 days). Results: Fully adjusted multivariate models demonstrated that HL (per 25 dB loss) is significantly associated with any hospitalization (OR: 1.32, 95% CI: 1.07 – 1.63), number of hospitalizations (OR: 1.35, 95% CI: 1.09 – 1.68), >10 days of self-reported poor physical health (OR: 1.36, 95% CI: 1.06 – 1.74), and >10 days of self-reported poor mental health (OR: 1.57, 95% CI: 1.20 – 2.06). Conclusion: This is the first nationally representative study to demonstrate increased healthcare utilization and burden of disease among older individuals with HL. Additional research is needed to investigate the basis of these observed associations and whether hearing rehabilitative therapies could possibly help reduce hospitalizations and improve self-reported health in older adults with HL.

ASSOCIATION BETWEEN HEARING AND AUTONOMY OUTDOORS IN OLDER MEN AND WOMEN

T.M. Mikkola, E. Portegis, M. Rantakokko, T. Rantanen, A. Viljanen, Gerontology Research Center and Department of Health Sciences, University of Jyväskylä, Jyväskylä, Finland

The possibility to live as one wants to, is an essential element of active aging. Deficits in sensory functions, such as impaired hearing, potentially restrict older person’s autonomy but only little research exists on this issue. Therefore, the purpose of this study is to investigate whether perceived problems in hearing are associated with sense of autonomy outdoors. Structured face-to-face interviews were conducted for 75- to 90-year old community-dwelling men and women (n=848). Self-rated difficulty in hearing when discussing with another person in noisy environments and perceived autonomy outdoors (Impact on Participation and Autonomy questionnaire, IPA) were assessed. The domain Autonomy in IPA questionnaire contains questions regarding opportunities to travel, visit friends, meet people, spend leisure-time and live life the way a person wants (score 0 to 20, higher scores indicating poorer autonomy). Data on age, gender, number of chronic diseases, vision, Mini-Mental State Examination, activities of daily living and Short Physical Performance Battery test were used as covariates. Persons reporting at least some difficulty in hearing in noisy environments experienced more restricted autonomy outdoors than persons reporting no hearing difficulty (autonomy score, mean±SE, 6.7±0.17 vs. 5.5±0.20, ANOVA p=0.001). The difference remained significant after adding the covariates into the model (6.4±0.14 vs. 5.8±0.17, ANCOVA p=0.007). Perceived difficulties in hearing may lead to more restricted autonomy in older people. Therefore, attention should be paid to acoustic environments and adequate aural rehabilitation to enhance their possibilities for participation.

COMMUNICATION INTERVENTIONS FOR OLDER MULTILINGUAL POPULATIONS: A LITERATURE REVIEW

M. Roche-Dean, K. Magilvy, College of Nursing, University of Colorado, Aurora, Colorado

Purpose: This integrative literature review provides a synthesis regarding the communication needs of multilingual older persons in acute care settings, asking: What communication interventions are provided for multilingual older persons within the healthcare system? Background: The multilingual older population includes English as second language speakers (ESL), and those not fluent in English. Data indicates multilingual older persons with cognitive impairment revert to their primary language (McMurtry, 2009). These factors are thought to be related to cognitive decline, dementia or other neurological disorders. The healthcare needs of this population lead to unique caregiving challenges. Method: Search terms such as multilingual, bilingual, elderly, cognitive impairment, communication, health services, hospital, acute care, healthcare system, ESL, and video
COMMUNICATION DISORDERS IN NURSING HOME RESIDENTS: THE EFFECTS OF FUNCTIONAL AND COGNITIVE STATUS

E.A. Reis, D.S. Nogueira, I.I. Lopes, Quaitative Methods, Lisbon University Institute, Lisbon, Portugal

Recent studies have found a high prevalence of communication disorders in nursing home residents. This study sought to investigate the relationship between functional and cognitive status and the performance on verbal fluency and verbal comprehension tests. The sample was conducted in Lisbon-Portugal and the was constituted by 110 elderly that gave the consent to participate. For the purpose of this study we used to evaluate verbal comprehension, the Token Test and, to evaluate verbal fluency, tests of controlled oral association were performed (semantic and letters association). The Barthel Index (BI) and the Mini Mental Examination (MMSE) were passed to evaluate functional dependency and the cognitive status respectively. The study design is descriptive and correlational and univariate and multivariate statistic were used to analyze the relationship between sociodemographic variables and the scores of the BI and the MMSE. Results pointed to a high prevalence of verbal comprehension and verbal fluency disorders in nursing home residents. Data showed a strong correlation between language tests scores, the Barthel Index and MMSE scores and a statistic significant relation was also found between the language tests performance and scholarly. No differences were found between genders.

THE RELATIONSHIP BETWEEN WORKING MEMORY AND COMMUNICATION IN NOISY ENVIRONMENTS

Perhaps the most life-impacting aspect of hearing loss in older adults is an inability to communicate in noisy environments. The magnitude of communication difficulties varies dramatically across individuals with similar amounts of hearing loss, but the reasons for that variability are unclear. This project explored how cognition affects communication in difficult environments (such as noisy restaurants). We focused on working memory, which facilitates information processing during active listening. Fifty healthy community-dwelling older adults completed a full audiometric exam, along with measures of speech-in-noise listening and subjective reports of their communication difficulties. Working memory was measured using a reading span test. Participants with poor working memory had more difficulty understanding speech in noise even when hearing was relatively good. This finding suggests that individual cognitive ability should be considered as a contributing factor to reported communication difficulties, and that integrating cognitive and auditory solutions might improve communication. [Work supported by NIH].

SESSION 910 (PAPER)

HEALTH PROMOTION

GENERATIONAL DIFFERENCES IN HEALTH STATUS AND LIFESTYLE HEALTH BEHAVIORS AMONG BABY BOOMER AND GENERATION X UNIVERSITY EMPLOYEES

C. Huang1, M. Carter2,3, L. Jacobs1, R.K. Kelly1, M.R. Crowther1, 1. Department of Psychology, University of Alabama Office of Health Promotion and Wellness, Tuscaloosa, Alabama, 2. Department of Nursing, University of Alabama, Tuscaloosa, Alabama, 3. Office of Health Promotion and Wellness, University of Alabama, Tuscaloosa, Alabama

Objectives: This study examined generational differences in health outcomes and lifestyle health behaviors among Baby Boomer and Generation X employees. Methods: Data were drawn from the 2009–2012 WELIBAMA employee health screening surveys (N=1,495). A total of 730 Baby Boomers and 765 Generation X employees of a southeastern university who voluntarily enrolled in a university-wide health promotion program were included in the study. Ordered logistic regressions were conducted separately for five health status outcomes and lifestyle health behaviors: self-reported health, body mass index (BMI), fiber intake, cholesterol intake, and cardio exercise. Results: Controlling for demographic characteristics such as job role, gender, race, education, income, and health behaviors including drinking and smoking habits; Baby Boomers had greater odds than Generation Xers of having better self-reported health status, healthier dietary habits, and engaging in weekly cardio exercises (p <.001). Despite demonstrating a positive self-reported health profile, Baby Boomers were more at risk of being overweight and obese in comparison to their Generation X colleagues, especially among African American (OR=2.05, 95% CI: 1.31–3.21, p <.001), male (OR=1.79, 95% CI: 1.28–2.52, p <.001), and staff employees (OR=1.96, 95% CI: 1.27–3.03, p <.001). Conclusions: Our findings suggest that while Baby Boomers engage in more health improving behaviors and report better perceived health as compared to Generation X, they are more likely to be overweight or obese. Suggestions for health promotion programs targeting middle-aged and older minority and staff employees are discussed.

PREVENTIVE HEALTH BEHAVIORS AND OVERALL HEALTH IN THE ALASKAN SENIOR POPULATION: EVIDENCE FROM A NATIONAL SURVEY

S.A. Cohen1, K.K. Chu2, C. Orr1, 1. Department of Family Medicine and Population Health, Virginia Commonwealth University, Richmond, Virginia, 2. Tufts University School of Medicine, Boston, Virginia

From 1970 to 2010, the Alaskan population more than doubled from 302,583 to 698,473. During that time, the growth rate of seniors (65+) was four times higher than the national growth rate for seniors. Aging in Alaska requires confronting unique environmental, sociodemographic, and infrastructural challenges, including an extreme and rapidly changing climate, geographic isolation, and less developed health care infrastructure compared to the continental US. The objectives of this analysis are to compare the health needs of Alaskan seniors to those in the continental US. We abstracted 180,685 records of individuals age 60+ from the 2009 Behavioral Risk Factor Surveillance System (BRFSS), of which 621 were Alaska residents. We used generalized linear models to adjust for demographic differences and survey weighting procedures. We examined three representative outcomes—general health status, health care coverage status, and length of time since last routine checkup. After adjusting for age, sex, BMI, and socioeconomic status, Alaskan seniors were 16.1% (95% CI: 12.7, 19.5%) less likely to have any health care coverage, 39.6% (38.7, 40.6%) less likely to have had a routine checkup in the past year, and 6.2% less likely (4.3, 8.1%) to...
CNS: HIGH VOLUME ADAPTED TANGO BENEFITS MOBILITY, BALANCE AND DUAL TASKING IN PARKINSON DISEASE
M.E. Hackney, K.P. Revill, 1. Rehab R&D, Atlanta VAMC, Decatur, Georgia, 2. Emory University School of Medicine, Atlanta, Georgia, 3. GaTech/GA State University Center for Advanced Brain Imaging, Atlanta, Georgia

Adapted tango (AT) improves mobility in individuals with Parkinson disease (PD). This study examined the effects of a novel dose, 3 weeks of high volume, moderate intensity AT, on mobility, spatial cognition and dual task ability. In a pre-post, repeated baseline measures, with removed treatment design, 20 participants with PD (age: 64.5(13.2); Hoehn & Yahr stage: 2.3(4.4); PD duration: 5.9(3.6) y) assigned to AT (fifteen, 1.5h classes). Participants were tested while "ON" medications 3 weeks before (n=7), immediately before and after (n=20), and 3 weeks after (n=13) for disease severity (Unified Parkinson Disease Rating Scale), dynamic postural control (Dynamic Gait Index), balance (Berg Balance, Fullerton Advanced Balance), endurance (six-minute walk test), mobility (Timed Up&Go), cognitive and manual dual tasking (Timed Up&Go cognitive and manual), leg strength (30-s chair stand, two-footed jump), spatial ability (Corsi blocks, Brooks task), and balance confidence (Activities-specific Balance Confidence). Forward, backward and fast gait speed and cadence were measured. Measures were stable pre-intervention (ICC>.813). All participants completed 15 classes in 3 weeks and significantly improved from pretest on dynamic postural control (p<.004), balance (p<.001), advanced balance (p<.001), forward cadence (p=.025), fast gait speed (p=.037), fast cadence (p=.011) and two-footed jump (p=.006). Marginal improvements were noted in leg strength (p=.053), mobility (p=.056), cognitive dual tasking (p=.053), and endurance (p=.097). No changes were noted in balance confidence or cognitive measures. Improvements were maintained at follow-up (post to follow-up; p=.106). 3 weeks of high volume AT is feasible, and may improve mobility, balance and dual tasking ability.

ASSOCIATION OF NEIGHBORHOOD WALKING WITH ACTIVITY OF DAILY LIVING DISABILITY IN HEALTHY OLDER ADULTS
M. Miyake, Y. Yamada, M. Kimura, Kyoto Prefectural University of Medicine, Kyoto, Japan

Objectives: The purpose of this cross-sectional study was to examine whether neighborhood walking habits was associated with reducing disability in activities of daily living (ADL) among community dwelling elderly. Methods: Data were from inventory study of community dwelling elderly aged over 65 years old in Kameoka City in 2011. 13,159 individuals responded and 1,221 samples of those who have a condition of need for long-term care or support condition were eliminated. 11,938 samples were divided with walking and non-walking group. Walking group (n=5,148) was defined by responding “Yes” to the question “Do you have a neighborhood walking ordinarily?” Non-walking group (n=5,969) was responding “No” to same question. Basic ADL (ADL) and Instrumental ADL (IADL) evaluated using Barthel Index and Functional Capacity TMIG (Tokyo Metropolitan Institute of Gerontology) Index of Competence. Odds ratio (OR) of ADL disability and IDL disability were calculated by logistic regression analysis. Results: 49.8% of men and 43.4% of women had ordinary walking habit. 38.7% of men and 31.6% of women were in risks of ADL disability. 38.7% of men and 31.6% of women were in risks of ADL disability. Non-walking group showed higher risk of Basic ADL disability (OR=3.3, 95% CI 1.76-6.20), falling down risk (OR=1.62, 95% CI 1.47-1.79) and social role risk (OR=1.57, 95% CI 1.43-1.72). Conclusion: ADL disability and falling risk and social role risks of IADL were associated with ordinary neighborhood walking among community dwelling elderly.

SESSION 915 (SYMPOSIUM)
COMBATTING ALZHEIMER’S DISEASE STIGMA
Chair: P.B. Harris, Sociology, John Carroll University, Cleveland, Ohio
Co-Chair: M.S. Mittelman, Department of Psychiatry, NYU Langone Medical Center, New York City, New York
Discussant: M. Spline, Spline Consulting, Columbia, Maryland

Once a person receives a diagnosis of Alzheimer’s disease (AD), often that label then defines the person, resulting in feelings of social exclusion, “otherness”, and marginalization of the person with AD, as well as their family members. This experience leads to AD stigma, and though public awareness about AD is increasing, AD stigma is still present, resulting in the need for the 2012 World Alzheimer’s Report to focus on this occurrence. This symposium seeks to add to our understanding about AD stigma by further explicating the concept and experience, focusing on its multiple causes, and suggesting programmatic interventions and policy solutions to lessen the stigma. Mittelman provides an overview of the concepts and research findings on the impact of stigma on people with dementia and family members and the health and social care implications based on her survey research for the World Alzheimer’s Report. Sabat discusses how the prevailing biomedical understanding of AD and mass media add to the proliferation of AD stigma. Morhardt explains an educational program for first year medical students and persons diagnosed with early dementia, “the Buddy Program,” which entails experiential learning and mentorship experiences that result in increasing empathy and changing attitudes about AD. Harris describes an intergenerational choir composed of college
students and people with early stage AD and their family members formed to overcome AD stigma in college students, which increases positive attitudes and lessens misunderstandings about AD. Finally, Spline, the discussant, discusses national anti-stigma campaigns emerging from the National Alzheimer Plan.

**COMBATTING ALZHEIMER’S STIGMA**

S.R. Sabat, Psychology, Georgetown University, Washington, District of Columbia

Biomedical Understanding of Alzheimer’s Disease Proliferates Stigma People with diagnoses of Alzheimer’s disease (AD) are beset by dysfunction due to the brain injury that results from the disease itself. They have been shown also to exhibit excess disability, which is defined as dysfunction beyond that which is predicted by the effects of brain damage. Excess disability can be traced to dysfunctional social treatment that has its roots in the stigma that attends the diagnosis. Such stigma will be explored in this presentation and I will suggest that it is due to (1) the predominant biomedical understanding of AD, (2) the dysfunctional attributes that are emphasized by (1) and mass media communication, and (3) the obfuscation of positive attributes that remain despite the diagnosis even into the moderate to severe stages of disease.

**EXAMINING THE EFFECTS OF AN EXPERIENTIAL LEARNING AND MENTORSHIP PROGRAM ON FIRST-YEAR MEDICAL STUDENTS PAIRED WITH COGNITIVELY IMPAIRED ADULTS**

D.J. Morhardt, Cognitive Neurology and Alzheimer’s Disease Center, Northwestern University, Chicago, Illinois

There is evidence that teaching interventions in geriatrics can improve knowledge, skills and attitudes of medical students, but few interventions include learning outcomes relevant to dementia. An experiential learning and mentorship program was developed to provide an opportunity for first year medical students and persons diagnosed with early dementia. Students are paired with diagnosed individuals and plan an academic year of regular meetings around mutually satisfying activities. Students submit semi-structured journal entries following activities with their ‘buddy’. A qualitative content data analysis was applied to three years of journal data (N =107 journals and 27 students). Principal themes included: 1) expressions of empathy; 2) sensitivity to buddy’s reaction to symptoms; 3) student’s emotional reactions; 4) recognition of strengths; and 5) comfort with buddy, including increasing comfort over time. Results demonstrate the experience influences first year medical students’ reactions to, concern for and comfort with persons with dementia.

**AN INTERGENERATIONAL CHOIR FORMED TO LESSEN AD STIGMA AMONG COLLEGE STUDENTS: A PILOT STUDY**

P.B. Harris, Sociology, John Carroll University, Cleveland, Ohio

Public awareness about AD is growing; however, there are still misunderstandings about AD and a diagnosed person’s capabilities, leading the person and family member to experience AD stigma. College students with their emphasis on youth culture, ageist beliefs, and limited contact with people with AD are also affected by these misunderstandings. This qualitative study formed an intergenerational choir of 13 students and 13 people with early stage AD and family members to combat AD stigma in college students. The choir meets the recommendations of the 2012 World Alzheimer’s Report to lessen stigma by: educating, reducing isolation, building community, and giving a voice to people with AD. Data were gathered through semi-structured open-ended questions on attitudes about AD, collected at three points over 8 weeks of rehearsals. Results show a decrease in negative attitudes, an increase in positive attitudes and themes of: recognizing capabilities, expanded understanding, increased empathy, and reduced discomfort.

**A PSYCHOSOCIAL RESEARCHER’S PERSPECTIVE ON STIGMA IN DEMENTIA**

M.S. Mittelman, Psychiatry, NYU Langone School of Medicine, New York, New York

Stigma causes an individual to be classified by others in an undesirable and leads to labeling, stereotyping, separation, status loss, and discrimination. While there is now greater public awareness of dementia, that has not, as yet, led to a greater acceptance those affected. Cultural attitudes towards illness, old age and women, who comprise a majority of older adults lead to devaluation of people with dementia, their families and those who are paid to care for them. Stigma has been identified as a major barrier to seeking a diagnostic evaluation, utilizing services and seeking support from family and friends and promotes social exclusion. The stigma associated with dementia also leads to a focus on the ways in which the person is impaired, rather than on remaining strengths. We will review research findings on the impact of stigma on people with dementia and family members and the health and social care implications.

**SESSION 920 (SYMPOSIUM)**

**INNOVATIVE MENTAL HEALTH INTERVENTIONS WITH UNDERSERVED OLDER POPULATIONS: OPTIMAL AGING FOR ALL**

Chair: J.G. Gonyea, Social Work, Boston University, Boston, Massachusetts

Reducing mental health care disparities among older underserved populations, particularly elders facing cultural or linguistic barriers, is an important public health priority. Research has consistently shown that older minorities have less access to mental health services than older whites. While the possession of health insurance is associated with access to care, research suggests that insurance alone will not close this gap. Innovative clinical interventions and community programs are also needed to better identify, reach, and provide care to underserved populations. Achieving this goal requires an openness and flexibility to adapt research and intervention protocols to be sensitive or tailored to the needs of the targeted populations. This sensitivity often begins with enlisting and partnering with community members and adoption of a core belief that partner organizations are the experts in the community. In this symposium, the panelists will share insights, results and lessons learned in their randomized controlled trial clinical (RCT) interventions with traditionally underserved populations: (1) a tele-delivered (Skype video) problem solving therapy with depressed, low-income homebound older adults; (2) Program Mano Amiga, a problem solving treatment for primarily Spanish-speaking older Latinos with major depression; (3) Círculo de Cuidado (Circle of Care), a Spanish-language, cognitive behavioral intervention teaching Latino family caregivers strategies to better manage the neuropsychiatric symptoms of Alzheimer’s disease; and (4) the replication and adaptation of Healthy Ideas, an evidence-based depression care management program developed in Houston with predominantly low-income English and Spanish-speaking elders to needs of Asian-American elders in Chicago and Los Angeles.

**TELEHEALTH PROBLEM-SOLVING THERAPY FOR DEPRESSED, LOW-INCOME HOMEBOUND OLDER ADULTS**

N.G. Choi1, N.L. Wilson2, J. Social Work, University of Texas at Austin, Austin, Texas; 2. Baylor College of Medicine, Houston, Texas

Despite their high rate of depression, homebound older adults have difficulty accessing clinic-based psychotherapy because of limited mobility. In a 3-arm randomized controlled trial with 121 low-income homebound older adults with moderately severe and severe depressive symptoms, we tested the acceptance and efficacy of tele-delivered problem-solving therapy (tele-PST via Skype video call), compared to in-person PST and telephone care calls. At 12-week follow-up, the 24-item...
Hamilton Rating Scale for Depression (HAMD) scores of tele-PST and in-person PST participants were significantly lower than those of care call participants and the PST groups did not differ in their HAMD scores. The treatment effects were maintained at 24-week follow-up, with standardized mean difference effect sizes of 0.66 for tele-PST and 0.45 for in-person PST. Treatment acceptance was measured with the 11-item Treatment Evaluation Inventory (TEI). The TEI score was significantly higher among tele-PST than in-person PST participants (72.14±6.64 vs. 68.08±8.27, p = 0.024).

PROGRAM MANO AMIGA: A DEPRESSION CARE PROGRAM FOR OLDER LATINOS WITH MAJOR DEPRESSION

M.P. Aranda, School of Social Work, University of Southern California, Los Angeles, California

Depression is a significant source of late-life disability and mortality. We describe the design and preliminary results of a geriatric depression treatment study for older Spanish-speaking Latinos with major depression. Based on a randomized behavior trial of 100 primarily Spanish-speaking geriatric patients, we test the feasibility, acceptability, and efficacy of adding individual counseling—Problem Solving Treatment (PST)—to enhanced usual care as an approach for treating depression in low-income Latinos with significant comorbid medical illnesses. Our results show high feasibility and acceptability of initial screening/identification, and depression care sessions, as well as significant improvements in mental health status, (i.e., 50% decline in SCID-rendered depression diagnosis) as well as HDRS depression severity scores at the 16-week follow-up. Clinical improvements were observed in both treatment groups. Implications for sociocultural adaptations to depression care and the utilization of non-graduate level interventions in the provision of mental health services will be addressed.

CIRCULO DE CUIDADO: A COGNITIVE BEHAVIORAL GROUP INTERVENTION FOR LATINO ALZHEIMER’S DISEASE FAMILY CAREGIVERS

J.G. Gonyea, L. Lopez, Social Work, Boston University, Boston, Massachusetts

By 2050, Alzheimer’s disease rates among Latinos in the U.S. are projected to increase from 200,000 to 1.3 million. Yet, many Latino elders are not receiving services to reduce their risk or manage their dementia. To address this gap, we developed and tested Circulo de Cuidado, a Spanish-language, cognitive behavioral group intervention, focused on teaching families how to manage neuropsychiatric symptoms to improve caregiver well-being. Using a RCT design, participants were assigned to one of two study arms: the cognitive behavioral (CBT) experimental condition or the educational (ED) control condition and assessed at baseline, post-intervention and 3-month follow-up. Multivariate repeated measures ANOVA revealed that caregivers in the CBT condition reported significantly fewer neuropsychiatric symptoms and lower levels of distress about these symptoms, greater gains in caregiver self-efficacy and lower levels of depression over time than did caregivers in the ED condition. No significant difference was found, however, in caregiver anxiety.

HEALTHY IDEAS: LESSONS LEARNED IN ADAPTING AND DELIVERING A DEPRESSION PROGRAM FOR ASIAN-AMERICAN ELDERSTERS

N.L. Wilson1, D. Chow2, A. Phillips3, J. Huffington Center on Aging, Baylor College of Medicine, Houston, Texas, 2. Houston VA Health Services Research and Development Center of Excellence, Michael E. DeBakey VA Medical Center, Houston, Texas, 3. Chinese American Services League, Chicago, Illinois, 4. Little Tokyo Service Center, Los Angeles, California

Healthy IDEAS (www.careforelders.org), a home-based depression care management program, was developed to address barriers limiting reach and engagement of low-income older adults with functional limitations. Original research findings with English- and Spanish-speaking older adults demonstrated improvements in self-reported depressive symptoms, and pain, as well as increased skills in self-management. However, many community agencies serve a growing number of older adults from other cultural and linguistic backgrounds. In Chicago and Los Angeles, ethnic community agencies serving Asian American elders confronted stigma associated with mental health and expanded their services to address depressive symptom distress among their clients. In collaboration with the program developer, they made cultural and linguistic adaptations to the Healthy IDEAS program and reached over 300 clients in two years. This paper will highlight the adaptations, report data on client engagement and changes in severity of depressive symptoms, and discuss the challenges confronted.

SESSION 925 (SYMPOSIUM)

MACRO AND MICRO LEVEL CONDITIONS FOR OPTIMAL COLLABORATION BETWEEN FORMAL AND INFORMAL CARE

Chair: M. Broese Van Groenou, Sociology, VU University Amsterdam, Amsterdam, Netherlands
Discussant: A. Horowitz, Fordham University, New York, New York

Rationale: Social care policy focuses increasingly on supporting family caregivers to provide long term care to their older relatives. Empirical evidence on how current policy aims are reflected in actual and potential collaborations between formal and informal caregivers are still limited. This symposium will fuel the debate regarding the optimal conditions of collaboration between informal and formal care. It presents data on the context of care provision from both a macro and micro level perspective. National data from Canada will provide the macro level policy context by showing the economic, social and health costs of informal caregiving. US-based data on pairs of older adults and their caregivers provides insight in how and when professional home care is used and valued. Data from the Netherlands provides insight in how informal and formal caregivers cooperate and tune the care in care networks of frail older adults. Discussion will be focused on how national and local social policy can improve the conditions of collaboration between formal and informal caregivers.

CAREGIVERS ‘AT RISK’: ECONOMIC, SOCIAL AND HEALTH COSTS OF FAMILY/FRIEND CAREGIVERS

N. Keating, S. Lucas, J. Fast, Human Ecology, University of Alberta, Edmonton, Alberta, Canada

Within the context of population aging, there has been much rhetoric about the ability of the family/friend care sector to sustain high levels of care to older adults with chronic health problems. Yet there has been little analysis of the full set of costs that might be incurred by these caregivers nor of those who may be at high risk of incurring costs across multiple domains. We report on findings from two systematic reviews of research on economic (project 1) and social and health (project 2) costs of care. Each was a scoping review of the past 15 years of research on costs of care and included the development of a taxonomy of domains of costs and an analysis of risk factors for high costs across domains. Findings showed variation in risk of incurring high caretaker costs across 6 cost domains and by characteristics of caregiver, recipient and context.
CHARACTERISTICS OF MIXED CARE NETWORKS OF FRAIL OLDER ADULTS

M. Broese Van Groenou¹, D.J. Deeg², P. Groenewegen¹, 1. Sociology, VU University Amsterdam, Amsterdam, Netherlands, 2. VU medical centre, Amsterdam, Netherlands

Frail older adults in need of long term and complex care are likely to receive help from multiple informal and formal caregivers. Variations in size, composition, and function of these care networks may be associated with characteristics of the care receiver and informal caregiver, but also with policy of the home care organization regarding task differentiation and views on informal care. In structured interviews with 75 community dwelling frail older adults from 8 different home care organisations, we identified on average nine helpers (range 2-22) in their care networks, of whom 33% were informal caregivers (range 8%-71%). Task overlap and contact between formal and informal caregivers was low. Care networks in which formal caregivers perform multiple types of tasks are smaller and contact between formal-informal caregivers is more likely. Implications for allocation and organization of home care services are discussed.

CONTACT AND COOPERATION BETWEEN FORMAL AND INFORMAL CAREGIVERS IN OLDER ADULTS’ MIXED CARE NETWORKS

M. Jacobs, M. Broese van Groenou, Sociology, VU University, Amsterdam, Noord-Holland, Netherlands

Social care policy aims to increase collaboration between formal and informal caregivers, but little is known about when and why caregivers of frail older adults actually consult each other on the care provision. We use quantitative data on the care network provided by 74 community dwelling older adults, and their most important informal and formal caregivers (114 dyads). Analyses are performed on the frequency of contact in the formal-informal caregiver dyad. In 50% of the 114 dyads no contact existed. Preliminary multilevel logistic regression analyses indicated that informal-formal contact is more likely when the care receiver’s disability is worse, both caregivers conduct different types of tasks with high intensity, both caregivers feel supported and respected by each other, and the number of formal caregivers is higher. These results imply that both care context and personal efforts matter to sustain the formal-informal bond.
END-OF-LIFE CARE IN CARE AND ATTENTION HOMES: PERCEPTIONS FROM FORMAL CAREGIVERS AND RESIDENTS

V. Lou1, T. Amy, K.M.2, S.H. Lam2, S. Wong2, J. Tang2. 1. Department of Social Work & Social Administration, The University of Hong Kong, Hong Kong, Hong Kong. 2. Elderly Services Section, Community Services Division, Tang Wai Group of Hospitals (TWGHs), Hong Kong, Hong Kong.

Objective: This study aims to investigate perceptions of formal caregivers and residents on end-of-life care in Care and Attention Homes in Hong Kong. Method: Standardized questionnaire was conducted among 135 formal caregivers, 50 residents and 51 family caregivers on their perceptions and expectations. Trained research assistants administered face-to-face interviews to residents and family caregivers. A staff survey was self-administered. Results: Even though 68% of surveyed residents and 80% of surveyed family caregivers showed a preference to die in the Care and Attention Home instead of a hospital, only 2% of the surveyed residents and 29% of the surveyed family caregivers were aware of advance-directives. 56% of surveyed residents and 84% of surveyed family caregivers said family members were expected to be involved in the decision-making process. Conclusion: Residents and their family caregivers desired to enhance end-of-life care in Care and Attention homes. However, they seemed to lack an understanding of relevant knowledge.

PHYSICIAN ORDERS FOR LIFE SUSTAINING TREATMENT EXPANSION: LESSONS LEARNED FROM STAKEHOLDERS NATIONWIDE

D.M. Dosa, 1. Medicine, Brown University, Providence, Rhode Island. 2. Providence VA Medical Center, Providence, Rhode Island.

Background: Numerous studies have documented that medical care at the end of life is often disjointed and discordant with a patient’s values. The Physician Orders for Life-Sustaining Treatment (POLST) program was developed as a tool to complement a patients’ existing advance directive and provide a vehicle for honoring patient preferences across health care environments. Formal POLST programs have been adopted in 12 states, with 21 more in various stages of development. As part of an initiative to promote this expansion the Retirement Research Foundation (RRF), working with the Oregon Health Sciences University, developed a funding mechanism to promote growth in developing states. In order to better understand barriers to POLST expansion, we queried stakeholders from states who applied for funding. Methods: A series of one hour qualitative telephone interviews were conducted with leadership from organizations in 14 states involved with POLST dissemination. Respondents were identified from a list of states having received either a State POLST Coalition Advancement Grant or a smaller Innovative State Grant from the Retirement Research Foundation between April 2012 and March 2013. Stakeholders were queried from the following states: New Hampshire, Louisiana, Tennessee, Idaho, Maine, Illinois, Missouri, Kansas, Colorado, Iowa, Michigan, Rhode Island, Virginia, and Pennsylvania. During taped interviews, respondents were asked to rate the complexity of barriers in their state to POLST expansion from a legislative/legal perspective and from a medical perspective (encompassing provider response, difficult with educational efforts, etc.). Respondents were further asked to describe barriers to POLST expansion and lessons learned from efforts to circumvent them. Results: On a scale of 1 (no barriers) to 10 (insurmountable barriers), respondents felt that the perceived level of legal/legislative barriers ranged from 1 to 5 (mean=2.8, median=2). Respondents rated medical barriers between 2 to 8 (mean=4.5, median=4). Representatives from all 14 states noted that the biggest operational need to advance POLST expansion in their state was increased funding to promote educational initiatives and infrastructure. Other common barriers included the lack of standardization of a metric to measure the expansion of POLST use in their state, and concerns about legislative undermining.

SESSION 935 (PAPER)

HOME AND COMMUNITY BASED CARE RESEARCH

THE JIMMO CASE: OPENING THE PORTAL FOR MEDICARE HOME HEALTH COVERAGE OF EVIDENCE-BASED INTERVENTIONS FOR PERSONS WITH ALZHEIMER’S DISEASE AND THEIR CAREGIVERS

In January 2013 a final settlement agreement was signed by the U.S. Department of Health and Human Services in the Jimmo case. The agreement changes the coverage focus of Medicare home health from “improvement” to patient “need” as the basis for ongoing eligibility and coverage. The change has the potential to create coverage of previously non-covered evidence-based interventions for persons with Alzheimer’s disease and their caregivers. The paper presents the evidence-based interventions and strategies for obtaining coverage under the new Jimmo case criteria. Implications for policy and practice are discussed.

THE LIMITS OF AGING IN PLACE FOR LOW-INCOME OLDER ADULTS: UNMET NEEDS FOR COMMUNITY DWELLING OLDER ADULTS

A. Choi1,2, K.G. Kietzman3, S. Wallace2, C. Mendez-Luck4, A. Benjamin4, J. Torres5, C. Chang1. 1. Department of Interdisciplinary Studies, California State University Dominguez Hills, Carson, California. 2. UCLA Center for Health Policy Research, Los Angeles, California.

The focus on consumer driven care in the US is part of the larger “aging in place” movement that emphasizes independence for older adults. However, for community dwelling older adults who rely on publicly financed programs to “age in place,” budget cutbacks of these programs have contributed to an increase in unmet needs. Drawing on a sample of qualitative interviews from a study of California older adults, who qualify for publically financed in-home supportive services (IHSS), this paper examines the impact of unmet needs on the quality of life of these older adults and explores how these individuals address these gaps in care. Data were collected over a two year-period on older adults (age 65 and over) who are consumers of public programs that provide long-term in-home care services and supports. In-depth, face-to-face interviews were conducted with the older adult and their paid caregiver. Data were independently coded by two researchers. The results of thematic analyses suggest that budget cutbacks to publicly financed programs contribute to the increase in unmet needs. Additionally, it was discovered that even for individuals with the maximum allotted hours of in-home supportive services had significant unmet needs. Finally, it was also discovered that unmet needs varied widely from individual to individual.

USE AND COST OF HEALTH CARE SERVICES FOR MEDICARE BENEFICIARIES IN DIFFERENT TYPES OF HOUSING

H.B. Degenholtz1, S.E. Hardy1, J. Torres2, C. Chang1. 1. University of Pittsburgh, Pittsburgh, Pennsylvania. 2. Summit ElderCare, Wooster, Massachusetts. 3. University of Massachusetts, Boston, Massachusetts.

This paper examines the use and cost of health care services among different groups of Medicare beneficiaries, based on their type of housing. Over the past decade, along with the aging of the population, there...
has been dramatic growth in the number of elderly people living in community settings that also provide personal care services. This broad category includes assisted living, personal care homes, board and care, and other facilities that provide assistance with Instrumental Activities of Daily Living (meals, cleaning, laundry, medication assistance, transportation). In addition to the elderly, the Medicare program covers people with end stage renal disease (ESRD) and the disabled. This paper compares these three populations across setting: people living in their own home or the home of a relative; people living in settings that provide personal care services; and people living a facility (e.g., nursing facility, psychiatric facility, or MF/DD facility), using data from the Medicare Current Beneficiary Survey. We found that 92.2% of the aged, who make up 83% of Medicare beneficiaries, live in the community, compared to 83.5% of the disabled and 91.1% of the ESRD population. The aged are more likely to use community-plus-services (4.3%), compared to 2.7% of disabled people and 3.9% of ESRD. The analyses also found significant differences in their utilization of and costs associated with their use of other service categories, including inpatient, outpatient, home health, and other services. For example, the aged who live in community-plus-services are twice as likely to be hospitalized as other groups.

MEDICAID LONG TERM CARE HOME AND COMMUNITY BASED SERVICES FOR THE ELDERLY: TRENDS IN PROGRAMS AND POLICIES, 1999-2010
C. Harrington, T. Ng, University of California, San Francisco, California

In response to consumer demand, the Supreme Court decision in the Olmstead case, the New Freedom Initiative and the ACA, states have unevenly expanded combinations of three Medicaid home and community based services (HCBS): home health, state plan personal care services (PCS), and 1915(c) waivers. By 2010, the federal-state Medicaid program paid for 34 percent of the nation’s estimated $235 billion total long-term care (LTC) expenditures while institutional care (e.g., nursing homes) consumed 55 percent of those expenditures. As states strive for balanced budgets, the ACA and its provisions for continued HCBS growth reflects growing concerns about the need to preserve and expand Medicaid HCBS and the need for information on program and policy trends. This paper draws from a unique national dataset to present the latest trends in participants, expenditures and policy for the three Medicaid HCBS programs serving the elderly. While data for 2010 show a steady increase in participants and expenditures, these growth rates have slowed since 2001. Inequities in access to services and limited funds have also resulted in unmet needs for HCBS among the elderly. Findings from the survey of policies such on the programs in 2012 show that states are increasing the number of waiting lists for elderly waiver services even as the number of available “slots” increases. Cost caps such as service and cost limits are also used in almost half the state plan personal care programs and almost a third of home health programs.

SESSION 940 (PAPER)
QUALITATIVE AND QUANTITATIVE STUDIES OF SOCIAL INCLUSION, SEXUALITY AND ACTIVITY PROFILES IN HEALTHY AND SUCCESSFUL AGING

ST-AGE-ING MATTERS: THE PROCESS AND OUTCOMES OF DEVELOPING ELDER ACTORS TO ADDRESS SOCIAL INCLUSION
M. Murphy, Social Work, UBC, Kelowna, British Columbia, Canada

The purpose of this paper is to examine the formation process, creative product and outcomes (on actors and audience) of a peer-led, elder actors’ troupe developed and evaluated in 2012-13. Outcomes include the overall impact on actor/participants’ awareness of the issues, health, acting skills, confidence and knowledge and well being, as well as the impact on audiences. The complex concept of social inclusion has been described as combining elements of belonging, participation, community and civic engagement, the elimination of discrimination, the promotion of independence and quality of life (UN, 1991 & Social Care Exclusion Unit, 2006). These elements include access to services including health, education, transportation and security. An inclusive society is one where it is common to find attitudes of mutual respect and the development of friendships and communication across the generations regardless of race, religion, gender etc. (Government of Ireland, National Action Plan for Social Inclusion, 2008; European Social Watch, 2010).

The paper examines the use of drama as peer-led creative public education, awareness and advocacy on this theme of social inclusion. The paper presentation will include video clips illustrating how particular ‘collective creations’ and rehearsed improvisational techniques were used to illustrate elements of social inclusion.

PROFILES OF AGING ARTISTS: HEALTHY AGING THROUGH THE ARTS

Objective: The aim of this paper is to explore contributions of the arts to the aging process. What can be learned from active artists of their craft, as it relates to the aging process, spirituality, and creativity? Methods: Using a phenomenological-hermeneutic methodology, forty-six aging artists (active creative writers, visual artists-painters) between the ages of 65 and 104, to reflect stages of aging, were interviewed in depth about how experiences with their craft facilitates personal meaning and self-world engagement amidst psychological and physical changes of aging. Results: Qualitative analysis involving open, hierarchical coding and thematic analysis as well interrater reliability between coders, revealed both internal (identity, creativity, spirituality) and external factors (enhanced community support and connections with their audience). Creative processes also facilitated artists’ stereotype-defying discovery of self and voice. The findings suggest that aging artists may be particularly rich informants of creativity, spirituality, relationships, and healthy aging. Implications: This study will enrich current theoretical underpinnings by making explicit the contributions of the arts and humanities to the aging process, laying foundations for training of future professionals. Understanding the arts from the perspective of aging artists who benefit from inclusion of their life-long passions into daily living will contribute to inclusive, interdisciplinary, and coordinated professional strategies to assist older adults at risk of depression, social isolation and/or loss of meaning. This project was supported by the Social Sciences and Humanities Research Council.

SUCCESSFUL AGING: MULTIPLE TRAJECTORIES AND POPULATION HETEROGENEITY
F. Tang, Y. Lee., Pittsburgh, Pennsylvania

Successful aging has been a subject of increasing public and research interest since Rowe and Kahn put forth this aging model in the late 1980s. Although there is no consensus on how to define successful aging, the three-component model developed by Rowe and Kahn (1997) is widely accepted. However, previous research is limited in capturing the multiple trajectories of multidimensional indicators of successful aging and examining the population heterogeneity in cognitively, physically, and social functioning. Using the data from the Health and Retirement Study (2000–2008), we applied group-based trajectory analysis to identify multiple aging trajectories among adults aged 65 years and older (N=7,140). Successful aging was operationalized in accordance with Rowe and Kahn’s definition, which encompasses multiple indicators, including chronic diseases, physical functioning, disabilities in activi-
ties of daily life, depressive symptoms, cognitive functioning, social connections, and productive activities. Results show that the study subjects fell into three groups: successful aging, usual aging, and unsuccessful aging. Members in the successful aging group were in best health and functioning at baseline and did not experience significant change over time, whereas members in the other groups had gradual or rapid declines in cognitively, physical, and social functioning. We also investigated relations of demographic and socioeconomic characteristics to membership in the aging trajectories. This study helps to improve our understanding of successful aging and to identify the profiles and trajectories of successful aging in comparison to usual and unsuccessful aging.

FEMALE SEXUALITY IN MIDLIFE: THE POWER OF VARIABILITY
C.S. Daruna, Communication, Tulane University, New Orleans, Louisiana

The physical changes accompanying the aging process impact women’s experience of sexual activities, both quantitative and qualitative dimensions. Mainstream representations of female sexuality at midlife assume diminished sexual experiences but there is a much richer story to tell about female sexuality at midlife. My study examines women’s experiences by drawing from structured interviews with 60 middle-aged women yielding 140 hours of data. A systematic analysis reveals three ways of positioning oneself in relation to sexual experiences in midlife. First, Decline and Disappointment, chronicles a lessening of sexual desire and capacity to engage in sexual activities, with women expressing frustration and disappointment with the new reality. Second, in Adaptation and Acceptance, women note a reduction in the frequency of sexual activity but see it as a natural outgrowth of aging and a change that is better suited to their current lives. In the third group, Renewal and Transformation, women say their sexual practices have been enriched by aging since they are freed from narrow cultural visions of female sexuality. Taken together, the three sections offer a sampling of women’s sexual experiences in middle-age and show different ways of embracing and challenging cultural notions of what it means to be sexual in midlife.

ACTIVITY PROFILES OF OLDER ADULTS: AN EMPIRICAL EXPLORATION
N. Morrow-Howell1, M. Putnam2, Y. Lee2, J.C. Greenfield2, M. Inoue2, H. Chen1, 1. Washington University in St. Louis, St. Louis, Missouri, 2. Simmons College, Boston, Massachusetts, 3. Boston College, Boston, Massachusetts, 4. Incheon University, Seoul, Republic of Korea

Aims: In this study, we advance knowledge about activity engagement by considering many activities simultaneously to identify profiles among older adults. Three aims of this research are 1) to identify profiles of activities among older adults, 2) to explore factors associated with these profiles, and 3) to test the effects of activity profiles on subsequent well-being outcomes. Methods. We used the core survey data from the years 2008 and 2010, as well as the 2009 Health and Retirement Study Completion and Activities Mail Survey (HRS CAMS). The HRS CAMS includes information on types and amounts of activities. We used factor analysis and latent class analysis to identify activity profiles. Based on the WHO model of Active Ageing, we identify categories of antecedent factors potentially related to the profiles. We used regression analyses with cross-sectional data to explore factors associated with activity profiles and then regression analyses with prospective data to explore activity profiles and well-being outcomes. Findings. We identified five activity profiles: Low Activity, Moderate Activity, High Activity - Retired, Working, and Physically Active. These profiles varied in amount and type of activities. Demographic and health factors were related to profiles. Activity profiles were subsequently associated with self-rated health, depression symptoms, and functioning. Implications. The use of a five-level categorical activity profile variable may allow more complex analyses of activity that capture the “whole person.” There is clearly a vulnerable group of low-activity individuals as well as a High Activity - Retired group that may represent the “active ageing” vision.

SESSION 945 (POSTER)

BIOLOGICAL SCIENCES 2

OSTEOPROTEGERIN INHIBITS CALCIFICATION OF VASCULAR SMOOTH MUSCLE CELL VIA DOWN REGULATION OF NOTCH1-RBP-JK/MSX2 SIGNALING PATHWAY
S. Zhou1, W. Li1, H. Qiu1, S. Guan1, 1. Department of Gerontology, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China, 2. Cardiovascular Research Institute, Department of Cell Biology and Molecular Medicine, University of Medicine and Dentistry of New Jersey, New Jersey Medical School, 185 S Orange Street, Newark, New Jersey

Objective: Vascular calcification is a common pathobiological process among the elderly and patients with diabetes and chronic kidney disease. Osteoprotegerin, a secreted glycoprotein that regulates bone mass, has recently emerged as an important regulator in the development of vascular calcification. However, the mechanism of osteoprotegerin on vascular calcification is not fully understood. This study is to explore novel signaling mechanisms of osteoprotegerin in the development of calcification in rat aortic vascular smooth muscle cells. Methods and Results: Vascular smooth muscle cells (VSMCs) were isolated from thoracic aorta of Sprague Dawley rats. Osteoblastic differentiation was induced in cultured cells in an osteogenic medium. We confirmed by Von Kossa staining that calcification was increased in VSMCs cultured in osteogenic medium, with the enhanced Alkaline Phosphatase activity and calcium content. These enhanced calcification indexes were significantly reduced by the addition of osteoprotegerin in a dose response manner. Consistently, we identified, by real-time qPCR and western blotting, that expression of Notch1 and RBP-JK were significantly up-regulated in VSMC cultured in osteogenic medium at both mRNA and protein levels, these effects were abolished by the treatment of osteoprotegerin dose-dependently. Furthermore, we identified that Msx2, a downstream target of Notch1/RBP-JK, was markedly downregulated by the treatment of osteoprotegerin. Conclusion: Osteoprotegerin inhibits vascular calcification through the down regulation of Notch1-RBP-Jk signal pathway.

LOW SKELETAL MUSCLE CAPILLARIZATION AND AEROBIC CAPACITY IN OLDER ADULTS WITH SARCOPENIA
S. Prior1,2, A. Ryan1,2, J. Blumenthal1,2, L. Katz1,2, A. Goldberg1,2, 1. Department of Medicine, Division of Gerontology and Geriatric Medicine, University of Maryland School of Medicine, Baltimore, Maryland, 2. Baltimore VA Geriatric Research, Education and Clinical Center, Baltimore, Maryland

Sarcopenia contributes to frailty and functional impairments in older adults. This may be worsened by low skeletal muscle capillarization because adequate transcapillary transport is necessary for maintaining physiological function. We tested the hypothesis that skeletal muscle capillarization and aerobic capacity (VO2max) are lower in sarcopenic than in non-sarcopenic older adults. Seventy-six men and women [(age 61±1 years, BMI 31±1 kg/m2 (mean ± SEM)] underwent vastus lateralis biopsies for measurement of capillarization, DXA scans for determination of body composition, and graded treadmill exercise tests for measurement of VO2max. Subjects were classified as sarcopenic if their sarcopenic index (appendicular lean mass/height2) fell within the sex-specific lowest 20% of the distribution. Regression analyses tested for...
correlations between sarcopenic index, capillarization, and VO\textsubscript{2max} in all 76 subjects. ANCOVA tested for differences between sarcopenic (SP, \(6.7\pm0.3 \text{ kg ALM/m}^2\), \(n=15\)) and sex-age- and BMI-matched non-sarcopenic subjects (NSP, \(7.7\pm0.3 \text{ kg ALM/m}^2\), \(n=15\)). SP subjects had 17\% fewer capillary contacts per fiber (3.6\pm0.2 vs. 4.4\pm0.2 cap/fiber, \(p<0.05\)), 13\% lower capillary to fiber perimeter exchange index (4.6\pm0.1 vs. 5.3\pm0.2 cap/mm, \(p<0.001\)) and 14\% lower VO\textsubscript{2max} (22.3\pm1.3 vs 25.9\pm1.2 ml/kg/min, \(p<0.05\)) than NSP, respectively. In all 76 subjects, indices of capillarization directly correlated with sarcopenic index (\(r=0.54-0.58\), \(p=0.001\)), and VO\textsubscript{2max} (\(r=0.37-0.46\), \(p=0.01\)). Thus, low skeletal muscle capillarization is associated with the presence and degree of sarcopenia in older adults. Moreover, reduced capillarization may affect sarcopenia and aerobic capacity because transcapillary transport of substrates, hormones and nutrients is essential to maintain metabolic and physical function.

**SKELETAL MUSCLE WEAKNESS IN MICE WITH HIFPEF IS ASSOCIATED WITH INCREASED ATROGIN AND PRO-INFLAMMATORY CYTOKINES**

G. Azhar\textsuperscript{1,2}, X. Zhang\textsuperscript{1,2}, S.C. Rogen\textsuperscript{1,2}, Y. Wei\textsuperscript{1,2}, S. Luo\textsuperscript{1,2}, 1. UAMS, Little Rock, Arkansas, 2. CAVHIS, Little Rock, Arkansas

Background: SRF is a key transcription factor in cardiac and skeletal muscle and has been shown to be slightly increased with advancing age in the heart. Young adult transgenic mice with mild cardiac specific over-expression of SRF (Mild-O-SRF Tg) develop features of old mouse hearts with diastolic dysfunction after sexual maturation and exhibit accelerated physical functional decline. Hypothesis: We hypothesized that Mild-O-SRF Tg mice with high cardiac SRF level will have increased inflammatory markers because of impaired cardiac function and a proinflammatory state. Methods and Results: Skeletal muscles (quadriceps femoris) of 4 mos young and 12 mos old Mild-O-SRF Tg (n=3) were subjected to real-time PCR analysis of genes associated with atrophy and inflammation. SRF was significantly increased in 12 mos old Mild-O-SRF Tg vs. Non-Tg and the 4 mos group, Tg and Non-Tg (\(p<0.05\)). Atrogin-1 was significantly increased in older Mild-O-SRF Tg vs. older Non-Tg and also showed an age-associated increase (\(p<0.05\)). IL1beta and IL6 were significantly increased in older Mild-O-SRF Tg vs. old Non-Tg. In addition, IL1beta was also increased in an age-associated manner in old Tg and Non-Tg vs young (\(p<0.05\)). Conclusions: SRF increases with age in the skeletal muscles of Mild-O-SRF Tg and this increase is also associated with increase in atrophy genes and inflammation. SRF might regulate both atrogin-1, IL1beta and IL6 in an age-associated or age-independent manner.

**AGE RELATED DEFECTS IN HUMAN NAÏVE T CELLS**

J.S. Davies\textsuperscript{1}, V. Palko\textsuperscript{1}, J. Nikolich-Zugich\textsuperscript{1,2}, 1. Immunobiology, University of Arizona, Tucson, Arizona, 2. Arizona Center on Aging, Tucson, Arizona

The T cell response is known to wane with age in both mice and humans. Aging of the immune system involves a myriad of factors that are collectively termed “immune senescence.” While there are many contributors that are under intense study (e.g. thymic involution and consequent reduced T cell production with age, the intrinsic physiology of long-lived cells attempting to maintain homeostasis, or extrinsic effects such as repeated exposure to antigens including cytomegalovirus and chronic, low grade systemic inflammation), it remains challenging to separate cell-intrinsic defects from indirect or organism-wide defects associated with immune senescence, and this is particularly the case in humans. Currently, much of the human data draws conclusions from mixed populations of cells rather than isolated naïve cells, which clouds interpretation and allows for extrinsic effects. This study aims to address whether there are intrinsic defects in proliferation, survival or apoptosis among stimulated aged human naïve CD4 and CD8 T cells compared to adults. Preliminary data indicates greater age-related differences in CD4 cells compared to CD8 cells. Adult CD4 cells tend to have higher levels of active caspase 3, but also higher levels of Ki67, which is a marker of proliferating cells, and higher levels of the anti-apoptotic factor BCL-xL. Adult CD4 cells also exhibit better mitochondrial fitness and less annexin V staining which is a measure of cells undergoing apoptosis. These data indicate that there are measurable defects in aged human naïve T cells and that these differences are more pronounced among CD4 cells.

**INVESTIGATING THE ROLE OF BECLIN 1 IN AMYLOID PRECURSOR PROTEIN TRAFFICKING**

E. Plowey, W. Zhu, G. Swaminathan, Stanford University School of Medicine, Stanford, California

Neurodegeneration occurs when genetic and environmental stressors overwhelm the capacity of neurons and glia to compensate for these challenges. Macroautophagy, the sequestration of cellular constituents into autophagic vacuoles that are trafficked for lysosomal degradation, is thought to provide important means of neuroprotective compensation by disposing of protein aggregates, injured mitochondria and other cell stressors. Beclin 1 is an important autophagy regulatory protein that interacts with class 3 phosphatidylinositol-3-kinase Vps34 to catalyze critical lipid phosphorylation during autophagosome induction. Recent reports have implicated beclin 1 deficiency in neurodegeneration and Alzheimer’s disease (AD). Furthermore, recent studies have suggested that activation of autophagy by overexpression of beclin 1 is beneficial in several models of neurodegeneration. In AD models, beclin 1 reduces surface APP and amyloid-beta secretion by as yet unknown mechanisms. Our laboratory is interested in understanding how beclin 1 impacts the trafficking of APP. We hypothesize that beclin-dependent autophagy shunts APP towards autophagolysosomal degradation in lieu of endosomal amyloidogenic metabolism. We have identified interactions between autophagy proteins and APP which suggest to us that autophagic degradation of APP may not simply result from bulk cellular autophagy but possibly by targeted autophagy. Furthermore, we are examining strategies to upregulate beclin 1 expression to reduce amyloid-beta secretion. We will present recent experimental data on this work.

**NORMAL RESPONSIVENESS OF NAÏVE CD8+ T CELLS TO HOMEOSTATIC CYTOKINES IN HUMAN AGING**

V. Pulk, J. Nikolich-Zugich, Immunobiology, University of Arizona, Tucson, Arizona

The ability of immune system to respond to novel pathogens depends on continuous presence of a diverse pool of naïve T cells. It is well established that the quantity of a naïve cell pool decreases with age, which renders elderly more susceptible to various infections and also limits their responses to vaccinations. In addition, based on observations in mice and a few inconclusive studies in humans it has been proposed that there are intrinsic age-related defects, which may also limit responsiveness of already reduced naïve T cell pool in elderly to signals controlling its activation, expansion, and homeostatic maintenance. The exact characteristics of these defects and their underlying mechanisms, however, are still unclear. We have set up a system, which allowed us to exclusively compare intrinsic differences between naïve CD8 T cells from adult and old donors in their responsiveness to homeostatic cytokines IL-7 and IL-15. Results that we generated in these studies did not reveal any significant age related defects. More specifically, naïve CD8 T cells from adult and old donors expressed similar levels of IL-7 and IL-15 receptors, and upon addition of cytokines activated Jak/Stat signaling pathway with similar intensities, which ultimately resulted in comparable proliferation. Moreover, similar responsiveness to homeostatic cytokines was also manifested comparable upregulation of activation markers CD95 and CD69 as well as anti-apoptotic molecules Bcl-2 and Bcl-xL. Taken together, our results suggest that with age, T cells maintain their responsiveness to homeostatic signals driven by cytokines.
GLUCOSE STRESS ALTERS mTOR EXPRESSION AND HUVEC MORPHOLOGY ASSOCIATED WITH THE SENESCENCE PHENOTYPE

S.C. Rogers1, X. Zhang1, G. Azhar1, S. Luo1, J.Y. Wei1,2, 1. Donald W. Reynolds Institute on Aging, University of Arkansas for Medical Sciences, Little Rock, Arkansas, 2. GRECC, CAVHS, Little Rock, Arkansas

Background: Aging is associated with endothelial dysfunction which increases the risk of diabetes and associated cardiovascular diseases. The nutrient signaling protein, mammalian target of rapamycin (mTOR), has recently been shown to be involved in the progression of cellular senescence and may be an important regulator of endothelial cell growth arrest. Although the mechanism of the anti-diabetic drug Metformin is unknown, it may target the mTOR pathway. Methods: We investigated the effects of mTOR on endothelial cell senescence and cytoskeletal reorganization upon exposure to high and/or low glucose stress. Additionally, we analyzed the effects of metformin treatment in ameliorating glucose stress induced endothelial cell senescence and morphological alterations. We used a HUVEC in-vitro model to investigate effects of high and/or low glucose on mTOR expression and cytoskeletal changes. Cells at passage 3 (population doubling 6) and passage 15 (population doubling 35) were used as early and late controls, respectively. Results: Both high and low glucose significantly increased expression of mTOR in middle to late passage cells. Additionally, glucose stress was shown to increase vimentin and decrease the presence of actin fibers in later passage HUVECs. Simultaneous treatment of metformin with high glucose was shown to protect against these cytoskeletal changes and decrease mTOR expression. Conclusion: These results indicate that mTOR may play an important role in the development of endothelial morphological changes associated with glucose stress and the senescence phenotype. This research will help to identify potential new targets for more effective therapy for elderly diabetics with microvascular complications.

FOXP3 DEMETHYLATION SHOWS QUANTITATIVE DEFECT OF REGULATORY T CELLS IN OLD PATIENTS WITH ACUTE CORONARY SYNDROME

C. Li, C. Zhang, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China

Background: The contribution of regulatory T cells (Tregs) to the pathogenesis of acute coronary syndrome (ACS) remains poorly understood. One core obstacle is the lack of Treg-specific markers that distinguish Tregs and activated conventional T cells. A highly conserved CpG enriched element in the Treg cell-specific-Demethylated-Region (TSDR) of the FOXP3 locus is unmethylated only in Tregs, and measuring the unmethylation of TSDR can be used to identify the role of Tregs in clinical diseases. This study investigated whether analyzing the demethylation status of TSDR is a more reliable means than using Treg-specific surface markers in ACS. Methods: We evaluated circulating Tregs percentages on different levels including cell frequencies (CD4+CD25highCD127−) and FOXP3 mRNA, TSDR demethylation status and related cytokine secretion in 70 old patients with ACS and 35 age-matched controls. Results: TSDR demethylation assay showed that the amount of Tregs in ACS patients was significantly reduced than that in controls (p=0.001). This test displayed high sensitivity and specificity in distinguishing ACS patients from the controls (p=0.05). However, flow cytometry analysis did not identify any reduction of CD4+CD25highCD127−Tregs in ACS patients than that in controls. Furthermore, 5-aza-2′-deoxycytidine, a DNA hypomethylation agent, increased the amount of CD4+CD25highCD127−Tregs and Tregs related cytokine IL-10 by inducing TSDR demethylation in vitro. Conclusion: A quantitative defect of Tregs, suggestive of decreased peripheral tolerance, could be a potential hallmark of ACS disease.

SYNERGISTIC EFFECTS OF HYPERTENSION AND AGING ON COGNITIVE FUNCTION AND HIPPOCAMPAL EXPRESSION OF GENES INVOLVED IN BETA-AMYLOID GENERATION AND ALZHEIMER’S DISEASE

A. Csiszar1,2, Z. Tuscek1, P. Toth1, D. Sosnowska1, A. Koller2, F. Deak2, W.E. Sonntag1,2, Z. Ungvari1,2, 1. Reynolds Oklahoma Center on Aging, Donald W. Reynolds Department of Geriatric Medicine, University of Oklahoma Health Sciences Center, Oklahoma City, Oklahoma, 2. Department of Pathophysiology and Gerontology, Medical School and Szentagothai Research Centre, University of Pecs, Pecs, Hungary, 3. The Peggy and Charles Stephenson Cancer Center, University of Oklahoma Health Sciences Center, Oklahoma City, Oklahoma

Strong epidemiological and experimental evidence indicate that hypertension in the elderly predisposes to the development of Alzheimer’s disease (AD), but the underlying mechanisms remain elusive. The present study was designed to characterize the additive/synergistic effects of hypertension and aging on the expression of genes involved in beta-amyloid generation and Alzheimer’s disease in the hippocampus, an area of brain contributing to higher cognitive function, which is significantly affected by AD both in humans and in mouse models of the disease. To achieve that goal, we induced hypertension in young (3 mo) and aged (24 mo) C57BL/6 mice by chronic (4 weeks) infusion of angiotensin II and assessed the demethylation status of TSDR in hippocampal Tregs. Results: TSDR demethylation assay showed that the amount of Tregs in ACS patients was significantly reduced than that in controls (p=0.001). This test displayed high sensitivity and specificity in distinguishing ACS patients from the controls (p=0.05). However, flow cytometry analysis did not identify any reduction of CD4+CD25highCD127−Tregs in ACS patients than that in controls. Furthermore, 5-aza-2′-deoxycytidine, a DNA hypomethylation agent, increased the amount of CD4+CD25highCD127−Tregs and Tregs related cytokine IL-10 by inducing TSDR demethylation in vitro. Conclusion: A quantitative defect of Tregs, suggestive of decreased peripheral tolerance, could be a potential hallmark of ACS disease.

OBEITY IS ACCOMPANIED BY INCREASED BASAL MITOCHONDRIAL RESPIRATION IN OLDER ADULTS

M.S. Bharadwaj, B. Nicklas, A.J. Molina, Internal Medicine - Gerontology, Wake Forest School of Medicine, Winston-Salem, North Carolina

Obesity has been identified as a risk factor for declining physical function with age. The goal of this study was to examine whether there are differences in the bioenergetic profile of mitochondria isolated from the skeletal muscle of overweight/obese and lean older adults. Bioenergetic profiling was performed by measuring basal respiration (state 2), maximal respiration (state 3), ATP coupled respiration, and uncoupled respiration in isolated mitochondria. Participants were older (65-79 years) individuals who were either overweight to obese (BMI = 27.0-34.9 kg/m2; n=17) or lean (BMI ≤ 25 kg/m2; n=5). Biopsy of the vastus lateralis muscle was performed in a fasted state and mitochondria were isolated immediately for oxygen consumption measurements using a Seahorse Bioscience XF analyzer. We found that basal, state (2), respiration was significantly higher in obese compared to lean individuals (251.0 ± 50.0 vs 148.9 ± 6.9 pMoles/min). Comparing state 2 relative to state 3 maximal respiration (State 2/State 3) indicated that mitochondria from obese older adults were respiring closer to their respiratory limit compared to mitochondria from lean older adults (0.25 ± 0.04 vs 0.40 ± 0.06). This would limit the ability of skeletal muscle mitochondria to increase energy production in response to stress or stimulation and may play a role in the aging-related decline of physical ability associated with obesity.
AGE-RELATED AUTOREGULATORY DYSFUNCTION AND CEREBROMICROVASCULAR INJURY IN MICE WITH ANGIOTENSIN II-INDUCED HYPERTENSION

P. Toth, Z. Tucsek, D. Sosnowska, F. Deak, A. Koller, W.E. Sonntag, A. Csizsar, Z. Ungvari, 1. Reynolds Oklahoma Center on Aging, Donald W. Reynolds Department of Geriatric Medicine, University of Oklahoma Health Sciences Center, Oklahoma City, Oklahoma, 2. Department of Pathophysiology and Gerontology, Medical School and Szentágothai Research Center, University of Pecs, Pecs, Hungary, 3. The Peggy and Charles Stephenson Cancer Center, University of Oklahoma Health Sciences Center, Oklahoma City, Oklahoma

Hypertension in the elderly substantially increases the risk for cerebrovascular damage and promotes the development of vascular cognitive impairment (VCI). Despite the paramount importance of the myogenic mechanism in cerebrovascular protection, it is not well understood how aging affects the functional adaptation of cerebral arteries to high blood pressure. To test the hypothesis that aging impairs autoregulatory protection, hypertension was induced in young (3 mo) and aged (24 mo) C57/BL6 mice by chronic infusion of angiotensin II and changes in myogenic constriction of middle cerebral arteries (MCA) autoregulation of cerebral blood flow were assessed. In young hypertensive mice, the range of cerebral blood flow autoregulation was extended to higher pressure values and the pressure-induced tone of MCA was increased. In aged hypertensive mice autoregulation was markedly disrupted, and MCAs did not show adaptive increases in myogenic tone. In young mice the mechanism of adaptation to hypertension involved up-regulation of the 20-HETE/TRPC6 pathway and this mechanism was impaired in aged hypertensive mice. Downstream consequences of cerebrovascular autoregulatory dysfunction in aged angiotensin II-induced hypertensive mice include exacerbated disruption of the blood-brain barrier and neuroinflammation (microglia activation, up-regulation of pro-inflammatory cytokines and chemokines), which were associated with impaired hippocampal cognitive function. Collectively, aging impairs autoregulatory protection in the brain of mice with angiotensin II-induced hypertension, potentially exacerbating cerebrovascular injury and neuroinflammation.

The Gerontological Society of America

LEFT ATRIAL SYSTOLIC FUNCTION DECREASES WITH AGE IN MICE

P. Mejia Osuna, T. Pham, G.E. Taffet, Baylor College of Medicine, Houston, Texas

Heart failure is an epidemic in the elderly population, affecting more than 6-10% of people older than 65. Only about half of them show evidence of reduced EF, indicating the need to look for alternate markers of impaired cardiac function. With age, left ventricular diastolic function becomes impaired and the systolic function of the left atrium (LA) plays an increasingly important role in Left Ventricular Filling. We followed 12 healthy male C57Bl/6 mice, initially at 9 months old and repeated the measures at 23 months of age. We assessed Left Atrial Systolic Function with 2 D guided m-mode echocardiography using the Visualsonics Vevo 770 and 1% Isoflurane anesthesia. Data are mean ± SEM. (* p<0.05) 9 Months 23 Months Heart Rate, min-1 411 ±12 398±16 LA Internal diameter in diastole, mm 2.47±0.09 2.88±0.10 * Fractional Shortening, % 18.3 ±1.3 12.6±1.0 * We found that Left Atrial antero-posterior dimension increased modestly (16%) with age while LA systolic function decreased dramatically (-30%) over the same period. These data suggest that not only does LA size correlate with age, but LA fractional shortening may be a more sensitive indicator of impaired cardiovascular function in the old mouse.

THE INFLUENCE OF MICROBIOTA ON THE AGING IMMUNE SYSTEM

The microbial species in the gut are different with age, place of residence, diet, and onset of frailty. The immune system must differentiate between commensal bacteria and pathogenic bacteria, and bacteria have been shown to heavily influence immune responses, yet we still do not understand how potential age-related changes in gut microbiome may influence the maintenance and function of the immune system. Immunity declines with age, and infectious disease remains one the leading causes of death in the elderly. To address how age-dependent microbiota differences contribute to decreased immunity, and whether altering the microbiota can benefit the aging immune system, we investigated gut microbiome in mice of different ages and from different housing colonies. We have found that the number of potentially anti-microbiobial cross-reactive immune cells increases with age in mice, with increased potential to migrate to the gut. Antibiotics and bacterial reconstitution can change the microbiota present in mice, and may impact homeostasis, homing, and function of immune cells with age, providing a promising possibility for improving immunity in the elderly.

ROLE OF CMV SEROPOSITIVITY IN ACUTE VS CHRONIC INFLAMMATORY DISEASES IN ELDERLY SUBJECTS

T. Fulop, S. Baehl, P. Vermette, F. Cabana, D. Lorrain, J. Morais, G. Dupuis, 1. Centre de Recherche sur le vieillissement, Sherbrooke, Quebec, Canada, 2. McGill University, Montreal, Quebec, Canada, 3. CHUS, Sherbrooke, Quebec, Canada

Aging is associated with changes in immune responses often accompanied by dysregulations that can result in “immunosenescence” that lary-like structures. Overexpression of Dicer1 in aged CMVECs partially restored miRNA expression profile and significantly improved angiogenic processes. In young CMVECs, downregulation of Dicer1 (siRNA) resulted in altered miRNA expression profile associated with impaired proliferation, adhesion, migration, and tube formation, mimicking the aging phenotype. Collectively, we found that Dicer1 is essential for normal endothelial angiogenic processes, suggesting that age-related dysregulation of Dicer1-dependent miRNA expression may be a potential mechanism underlying impaired angiogenesis and cerebrovascular rarefaction in aging.
FAGHRKO MICE ARE PROTECTED FROM AGE-RELATED FRAILTY DESPITE LIFELONG OBESITY

Michael B. Stout, Thomas A. White, Edward O. List, Tamar Pirtskhalava, Allyson K. Palmer, Vojtech Mezera, Darlene E. Berryman, Nathan K. LeBrasseur, Tamara Tchkonia, John J. Kopchick, and James L. Kirkland (There are 3 more authors than allotted so GSA told me to list everyone here so they can be included in the conference booklet, abstract is still less than 250 words) Growth hormone receptor gene disrupted or knockout (GHRKO) mice have provided dramatic insight into the link between GH induced intracellular signaling and longevity. These mice are dwarf in stature, moderately obese, and are extremely long-lived (1). Despite increased adiposity, GHRKO mice possess tremendous metabolic flexibility (2) and are resistant to age-associated functional declines in the adipose tissue, particularly senescent cell accumulation (unpublished observation, Kirkland JL). To dissect the role of adipose tissue in the phenotypes described above, mice with adipocyte-specific deletion of the growth hormone receptor were generated (FaGHRKO) (3). The goal of the current study was to characterize age-related phenotypes in FaGHRKO mice at 18 months of age. As was observed in younger counterparts (3), FaGHRKO mice were dramatically obese into old age yet maintained normal glycemia, insulin-responsiveness, aerobic work capacity, basal energy expenditure, and basal oxygen consumption. Interestingly, only male FaGHRKO mice had increased lean body mass which translated into increased forelimb grip strength. Both genders of FaGHRKO mice had reduced respiratory exchange ratios during the dark cycle indicating increased lipid oxidation throughout their active phase. Of note, adipose tissue inflammation was significantly increased in FaGHRKO mice of both genders, suggesting a possible resistance to metabolic dysfunction induced by obesity-related inflammation in these animals. In conclusion, aged FaGHRKO mice are metabolically healthy and do not demonstrate age-related frailty in spite of severe obesity and increased adipose tissue inflammation. Further research is needed to understand the role that growth hormone is playing in adipose tissue related metabolic dysfunction.

LIFELONG CMV INFECTION IMPACTS NAÏVE AND MEMORY TCRVβ REPERTOIRE DIVERSITY IN MICE

P. Samadder, S. Smith, J. Padilla-Torres, B. Park, J. Nikolich-Zugich, 1. Immunobiology, University of Arizona, Tucson, Arizona, 2. Oregon Health & Science University, Portland, Oregon

A diverse naïve TCR population facilitates antigen-specific cellular immunity to a variety of pathogens. Protective immunity declines with age and is associated with defects in T-cell immunity. Cytomegalovirus (CMV) is a ubiquitous herpesvirus that infects the majority of the human population. Our understanding of the impact of CMV infection on immune aging, while growing, remains incomplete. Persistent pathogens, such as CMV, might contribute to immune senescence, possibly by further restricting the T-cell repertoire diversity with advancing age. The long-term objective of this study is to precisely define the relationship between lifelong persistent viral infections, TCR repertoire diversity and protective T-cell responses. To evaluate the TCRVβ repertoire diversity at the molecular level, the CDR3 spectratype analysis of twelve TCRVβ genes was performed on naïve and memory CD8+ T-cell compartments of mice at 6, 12 and 16 months following infection with mouse CMV (MCMV). Our spectratype profiles of naïve CD8+ T-cells from uninfected 6-month old adult mice showed a Gaussian distribution of all tested TCRVβ repertoires. There were no significant CD8+ naïve T-cell repertoire perturbations in mice with persistent CMV infection at 6 and 12 months post infection. However, the development of clonal expansions in the memory CD8+ T-cells pool was observed. Upon examination of infected mice with CMV and/or co-infected with CMV+HSV-1 16-months previously, we observed global perturbations to the composition of both the naïve and memory CD8+ T-cell compartments. CMV alone and co-infection with both pathogens appears to synergistically accelerate the age-related loss of TCR diversity.

HORMESIS: AN ESSENTIAL MECHANISM OF CALORIE RESTRICTION?

D. Ingram, C.M. Elks, A. Nair, R. Dange, J. Francis, 1. Pennington Biomedical Res Center, Baton Rouge, Louisiana, 2. Louisiana State University Health Science Center, New Orleans, Louisiana, 3. Louisiana State University School of Veterinary Medicine, Baton Rouge, Louisiana

Long-term calorie restriction (CR) attenuates damage due to reactive oxygen species (ROS) and enhances antioxidant protective systems. Mitigation of oxidative stress (OS) has been hypothesized to explain the anti-aging effects of CR. In preliminary studies, we have been investigating hormesis as an essential mechanism of CR. As applied to aging research, hormesis has been defined as beneficial effects resulting from cellular responses to mild repeated stress. Hormesis has emerged as a unifying concept for explaining the anti-aging, anti-disease effects of CR, but also as a mechanism explaining beneficial effects of exercise and botanicals. Using rodent models, we find evidence of hormesis associated with CR, specifically as increased production of reactive oxygen and nitrogen radicals (RONS) measured by electron paramagnetic resonance (EPR) and also a blood pressure (BP) spike during introduction of CR (40%, 2-10 days). Additionally, we note evidence of an age-related decline in hormesis associated with specific molecular signaling events. Using rtPCR to measure gene expression, we observe major increases in NFkB, Nrf2, and eNOS in young (3-4 mo) mice after 2 days of CR (40%) that were absent in aged (23-24 mo) mice. Moreover, we have found that feeding the antioxidant, α-tocopherol (4X control level), prior to or at the time of CR initiation, will block hormesis. Thus, the primary question to be pursued is whether this initial mild OS is necessary to activate protective pathways, including antioxidant defenses, and whether feeding of excess levels of an antioxidant will attenuate the beneficial effects of long-term CR?
ADIPOSE TISSUE REGULATION OF PGC-1α IN CALORIC RESTRICTION

P. Howell, M. Polewski, L. Willoughby, K. Miller, R. Anderson, University of Wisconsin-Madison, Madison, Wisconsin

Caloric Restriction (CR) is a dietary intervention shown to delay the onset of aging and extend lifespan in mice. Previous work has shown that adipose tissue from CR mice is metabolically distinct compared to age-matched control mice. We hypothesize that the alteration in white adipose tissue in response to CR is coordinated through an activation of mitochondrial genes by the master regulator PGC-1α. In mature adipocytes, where increased respiration is favored, the levels of PGC-1α are higher. We show that during the process of adipogenesis in 3T3-L1 cells, PGC-1α is temporally regulated. The levels of PGC-1α increase later in adipogenesis suggesting that there is a requirement for PGC-1α during distinct phases of the transition to a mature adipocyte. Disruption of this transition by overexpression of PGC-1α impedes the adipogenic process of lipid accumulation. Rapamycin, an inhibitor of mTOR signaling, is known to impede adipogenesis. We show that treatment with rapamycin disrupts PGC-1α levels during adipogenesis and shows a similar phenotype to overexpression. Furthermore, rapamycin also disrupts the normal transition of GSK3α, which have previously been shown to regulate PGC-1α turnover. These data put PGC-1α and its regulator, GSK3β downstream of mTOR signaling in the regulation of adipose specific modulation in response to CR.

LONG TERM CULTURE LEADS TO MITOCHONDRIAL FUSION AND ALTERED METABOLISM IN PRE-SENESCENT FIBROBLASTS

C.G. Van Horn, M.S. Bharadwaj, J.W. Strober, A.J. Molina, Internal Medicine - Gerontology and Geriatrics, Wake Forest School of Medicine, Winston-Salem, North Carolina

Mitochondria have emerged as central regulators of the aging process. We hypothesized that changes in mitochondrial structure and function lead to bioenergetic decline as cells approach replicative senescence. We examined human embryonic lung fibroblasts (WI38) at various passage numbers (p) up to the onset of senescence. WI38 cell doubling time increased from 1.35 days for p20 to 6.59 days for p34. Western blot analysis for mitochondrial dynamics proteins revealed an increase in the expression of the inner membrane fusion protein, OPA1, with higher passage numbers, and a decrease in the mitochondrial fission protein, FIS1, consistent with observed mitochondrial hyperfusion. Knockdown of OPA1 using shRNA resulted in increased cell proliferation, suggesting that mitochondrial fusion plays an important role in replicative capacity. To determine the functional consequences of long term culture, we measured cellular respiration using a Seahorse XF24-3 analyzer. We found that basal respiration was 15.8% lower at P24 and 21.9% lower at p29 compared to p19 (1.45±0.05 SEM pmol/min/protein). FCCP induced oxygen consumption was 4.4% lower at p24 and 27.5% lower at p29 compared to p19 (2.34±0.03 SEM pmol/min/protein). Respiratory measurements also revealed that glycolysis was unchanged in the 3 different cell passages. With palmitate as a substrate the oxygen consumption rate increased by 50% in both low and high passage cells. Our results indicate that long term subculture of cells leads to increased doubling time, mitochondrial hyperfusion, changes in the expression of mitochondrial dynamics proteins, and decreased maximal respiration prior to the onset of replicative senescence.

INHIBITION OF ISW2-MEDIATED CHROMATIN REMODELING BY CALORIE RESTRICTION EXTENDS LIFESPAN BY POTENTIATING STRESS RESPONSE

W. Dang1, S. Berger2. 1. Huffington Center on Aging, Baylor College of Medicine, Houston, Texas, 2. University of Pennsylvania, Philadelphia, Pennsylvania

ATP-dependent chromatin remodeling is a highly conserved process involved in all aspects of DNA transactions and linked to a range of human diseases and developmental disorders. Here we explored possible functions of chromatin remodelers during cellular aging, finding that deletion of ISW2 or mutations inactivating the Isw2 enzyme complex extend yeast replicative lifespan. This extension by ISW2 deletion is epistatic to the longevity effect of calorie restriction (CR) and this mechanism is parallel to the suppression of TOR signaling by CR. We find that CR both lowers the intracellular ATP concentration and inhibits Isw2 enzymatic activity. Transcriptome analysis indicates that isw2Δ mimics an up-regulated stress response in CR cells. Intriguingly, inactivating the homologous complex in worms also extends lifespan, suggesting that this may be a conserved longevity regulation mechanism. This study represents the first evidence that ATP-dependent chromatin remodeling plays an important role during aging and in calorie restriction.

THE AMBIENT TEMPERATURE INFLUENCES THE LIFESPAN OF WORKER HONEYBEES (APIS MELLIFERA)

C. Hsu, Y. Chan, Department of Biomedical Sciences, Chang Gung University, Tao-Yuan, Taiwan

Ambient temperature reduction has been demonstrated to extend the lifespan of organisms, but the optimal low ambient temperature for lifespan extension has not yet been determined. In the current study, we reared newly emerged worker honeybees (Apis mellifera) in thermostats at different temperatures (42–10 °C, at intervals of 4 °C) and recorded their survival to establish their survival curves. Aging-related molecules were also assayed in the trophocytes and fat cells of workers reared at 22, 30, and 38 °C. The results showed that low ambient temperatures prolonged the lifespan and that high ambient temperatures shortened the lifespan; however, very low ambient temperatures also shortened the lifespan as higher ambient temperatures. Low ambient temperature prolonged the lifespan due to a reduced accumulation of aging-related molecules, whereas high ambient temperature shortened the lifespan due to the increased accumulation of aging-related molecules. This study demonstrates that ambient temperature influences the lifespan of worker honeybees (Apis mellifera), the lifespan extension promoted by ambient temperature reduction has a limit, and 22 °C is the optimal low ambient temperature for lifespan extension in worker honeybees.

SESSION 950 (POSTER)

AGEISM AND ATTITUDES TOWARD AGING

AN ATTEMPT ON MEASURING AGEISM: A STUDY OF YOUNG KOREAN PEOPLE

J. Kim, SEOUL National University, SEOUL, Republic of Korea

Discussions on ageism, which is the practice of social discrimination according to age, have been taking place since the mid-20th century. A majority of studies on the elderly in Korea have found that Koreans generally hold a negative view of the elderly. However, there have been only few attempts to develop corroborative measures of ageism. This study attempts to fill that gap by developing measures of ageism in Korean society. It then verifies the reliability and feasibility of these measures by employing data from the Korean General Social Survey of 2011(KGSS). Going further, it intends to utilize these measures to review the effect factors of ageism. Using data from the Korean General Social Survey of 2011 (KGSS), which included 587 respondents, aged between 18 and 39 years, this study employs factor analysis and regression models. The major findings are summed up as follows. Firstly, the study extracts main factors including anxiety about aging, change of appearance, acceptance of aging, prejudice, evasion/avoidance, separation, and discriminatory behavior. Secondly, women revealed stronger ageism than men, and ageism was weaker for those who were in better health and had greater levels of happiness. Good health and happiness proved to be consistently significant factors that lower levels of ageism.
from the data. Finally, those who were in regular contact with the elderly showed statistically significant levels of ageism in terms of discriminatory behavior, change of appearance, separation, and evasion/avoidance. Ageism can have a variety of effects on the elderly and their quality of life. It can affect their relationship with other members of society as well as their own sense of self. This study will be instrumental in understanding the status and condition of the elderly as a social group. Moreover, those findings herein will enable researchers to revisit social perceptions and attitudes toward the elderly and influence policy and practice regarding the elderly.

SOCIAL WORK STUDENTS’ INTEREST IN GERONTOLOGY: AN INTERNATIONAL COMPARISON

J. Chonody1, D. Wang2, J. Chonody1, D. Wang2, C. Liou, K.J. Kalaw

1. University of South Australia, Traralgon, South Australia, Australia, 2. Long Island University, Brooklyn, New York

As the number of older adults increases, the need for social workers with a specialization and interest in geriatrics and gerontology has been made a global priority. In a 1996 study, only 3% of the 34,480 graduating masters-level social workers selected gerontology as their area of concentration (Scharlach et al., 2000). The purpose of this study was to further explore the degree to which students have an interest in aging. This cross-sectional descriptive study was administered to students (N = 1,042) in the U.S., U.K., and Australia. Only 5.4% of the sample indicated aging as their primary interest. The following variables were not related to student interest: educational level, sex, personal relationship with an older adult, country, degree of religiosity/spirituality, death anxiety and positive and negative ageism. Significant variables were: age, time spent with an older adult, quality of the relationship, and personal aging. Results of the logistic regression found that only personal aging and frequency of time spent with an older adult were significant. A key contribution of this study is the updated estimation of social work students interested in aging and the inclusion of international data. The infusion of aging content and presentations of older adults may facilitate further advancement in gerontological social work, but additional strategies are likely needed. The creation of service learning opportunities may offer an opportunity to engender lasting interest. Students may need an ongoing experience with older adults to generate that positive relationship that was shown to influence gerontological interest.

A COMPARATIVE STUDY OF UNDERGRADUATES’ ATTITUDES ON AGING FROM THE UNITED STATES AND TAIWAN

C. Liou, K.J. Kalaw, Miami University, Oxford, Ohio

Ageist biases or misconceptions toward elders have been found to be widespread around the world. Yet, it remains unclear how different societies’ attitudes are toward aging and elders. The purpose of this study is to compare similarities and differences of the attitudes toward aging among college students from the United States and Taiwan. Data were collected from undergraduates at two public universities: one is in the Midwest of the United States, and the other is located in northern Taiwan. We asked a total of 100 students from each university to draw what were their first thoughts about aging and examined features of drawings as reflections of attitudes on aging. The findings indicate significant country differences. American participants tended to view aging much more negatively than Taiwanese students by drawing images of aging that involved physical decline and need for aid devices. Taiwanese student drawings showed more positive attitudes by sketching elders having rich experiences to share with their grandchildren. For American students, aging is a developmental linear process; however, for Taiwanese students, aging is a cyclic process from infant to death and back to being a new born. One of the similarities in the drawings was that older men were overrepresented in the drawings. The study adds on to the existing literature that the influence of ageism and different cultural stereotypes of aging on students’ attitudes toward aging remain prevalent. Further, the study may inform different cultures on how to lessen or correct ageist stereotypes over time.

EXPERIENCES OF AGEISM, SEXISM, AND RACISM AS PREDICTORS OF WOMEN’S HEALTH AND WELL-BEING

R. Walker, T. Bisconti, University of Akron, Akron, Ohio

Our country is experiencing rapid increases in the proportion of older adults with the emergence of the Baby Boom generation and increased life expectancy (U.S. Census Bureau, 2011). This is particularly true for women who outlive their male counterparts and make up a large proportion of the older adult population. As women age they are more likely to experience the effects of both sexism and ageism (Butler, 2009; Duncan & Loretto, 2004; Hurd Clarke & Griffin, 2008). Additionally, older women of Color are also subject to the combined effects of ageism, sexism, and racism (Whitfield, 2004). Past research has demonstrated the devastating effects that discrimination can have on health and well-being (Golub & Langer, 2007; Levy, 1996; Levy, Haussdorff, Hencze, & Wei, 2000; Ory et al., 2003; Smedley, Stith, & Nelson, 2003); however, much of that research has not considered the individual at the intersection of their social locations, instead focusing on the additive effects of age, gender, and race but oftentimes overlooking the impact of age. Thus, this study examined multiple types of discrimination as potential predictors of health and well-being in a community sample of young, middle-aged, and older adult women. Analyses were completed using hierarchical regression models and mediation models. Significant results and potential implications will be discussed.

PERCEPTIONS OF COMPETENCE: LABELS OF ‘HEALTHY AGING’ AND ‘ALZHEIMER’S DISEASE’ MODERATE AGE DIFFERENCES

J.M. Berry1, H.L. Williams2, K. Thomas1, J. Blair1, 1. University of Richmond, Richmond, Virginia, 2. University of Victoria, Victoria, British Columbia, Canada

Objectives. We investigated age-related differences in perceptions of aging and competence of an older adult labeled as ‘in good health’ (healthy) or ‘has Alzheimer’s disease’ (AD). Research and theory suggest that older adults will provide more differentiated assessments of the two targets than younger adults. Method. Younger and older adults (N = 152) rated activities of daily living (ADL), instrumental activities of daily living (IADL), and memory abilities of a female target aged 75 years, described as healthy or with AD. Anxiety about aging, knowledge of aging and AD, and positive and negative biases toward aging and AD were also measured. Results. Older adults perceived the healthy target as more capable of cognitively effortful activities (e.g., managing finances), and with better memory abilities, than the AD target. As predicted, these differences were greater than differences between targets perceived by younger adults. Additionally, older adults held more positively-biased views of aging and less positively-biased views of AD than younger adults. Discussion. These results demonstrate that mere labels of ‘healthy’ and ‘Alzheimer’s’ produce significant and subtle age differences in perceived competencies of older adults, and that biases vary by age group and target type. Theoretical and applied implications are discussed.

EXPLORING THE INTERPLAY OF SUBJECTIVE AGE AND HEALTH DIMENSIONS IN THE MIDDLE AND OLD AGED

S.M. Spuling1, M. Miche2, S. Wurm1, H. Wahl2, 1. German Centre of Gerontology, Berlin, Germany, 2. Heidelberg University, Heidelberg, Germany

Findings from cross-sectional studies emphasize a stable relationship between subjective age and health. However, only few longitudinal studies exist which usually test only one causal pathway. The goal of the present study was to compare cross-sectional relationships between subjective age and different health dimensions in the second
half of life and to disentangle the causal relationship between these variables. Longitudinal data of 3,038 community-dwelling adults aged 40 years and older from the German Aging Survey (DEAS) were used. Cross-lagged panel analyses were employed to analyze predictive relationships of subjective age and different health dimensions, namely physical conditions, functional health, self-rated health and depressive symptoms, in two age groups (40-64 years, 65+ years). Cross-sectionally, a younger subjective age consistently correlated with fewer physical conditions, better functional and self-rated health, and less frequent depressive symptoms with stronger associations in the old aged. Longitudinally, subjective age predicted physical conditions, depressive symptoms, and self-rated health, whereas the reverse effect was found only for self-rated health. Self-rated health, rather than physical conditions, thus seems to become incorporated into subjective age. This dynamic relation holds across the second half of life. Our results show that the relationship between subjective age and health is actually more complex than cross-sectional correlations world suggest. Subjective age seems to be an important resource for preserving health in the second half of life.

“IT’S BECAUSE OF MY AGE.” THE INFLUENCE OF EXPERIMENTALLY INCREASED SALIENCE OF AGE-RELATED CHANGES IN COGNITIVE FUNCTIONING ON SELF-PERCEPTIONS OF AGING

M. Michte, H. Wahl, Department of Psychological Aging Research, Heidelberg University, Heidelberg, Germany

According to labeling theory confronting older adults with negative age stereotypes results in deteriorated self-perceptions. Some studies extended labeling theory to the field of subjective aging research often using one-item measures of subjective age as a proxy of aging self-perceptions. The aim of this study was to investigate effects of the confrontation with age-stereotypical information on cognitive functioning on a broader range of indicators of subjective aging. Forty-eight older adults, 60-70 years old, were randomly assigned to two age-stereotype conditions or a control group. Participants completed a speed-accuracy trade-off task measuring attention with positive or negative feedback comparing their performance to that of younger adults. No feedback was given in the control group. Four dimensions of subjective age (felt age, look age, do age, and interest age) were measured before and after stereotype activation. Between-group comparisons were conducted on additional indicators of aging self-perceptions. As intended, age-stereotype feedback increased the salience of age-related changes in cognitive functioning. Compared to pre-test, participants who received negative feedback about their test performances reported older subjective “do ages” at post-test, whereas younger subjective “do ages” at post-test were found in the positive feedback group. No such effect was found for felt age, look age, interest age, and alternative measures of subjective age. To understand conceptual distinctions between constructs, different measures of aging self-perceptions should be used in experimental studies. “Signs of aging” in the cognitive domain seem to become integrated predominantly into the momentary and less conscious indicators of aging self-perceptions.

CHANGING SELF-PERCEPTIONS OF AGING ENHANCES EFFECTIVENESS OF EXERCISE INTERVENTIONS FOR OLDER ADULTS

J.K. Wolff1, L.M. Warner1-2, J.P. Ziegelmann1, R. Schwarzer1, C. Tesch-Romer1, S. Wurm1, 1. German Centre of Gerontology, Berlin, Germany; 2. Freie Universität, Berlin, Germany; 3. University of Social Sciences and Humanities, Wroclaw, Poland

Recently, several studies have pointed to the importance of positive self-perceptions of aging (SPA) for health and health behavior in older adults. However, promotion of health behavior in older adults does not consider such factors. Our randomized-controlled trial with adults aged 65 and older aimed at increasing exercise by including a technique to change SPA. An intervention group with SPA-component (IGSPA; n=101), an intervention group without SPA-component (IG; n=31), and a control group (CG; n=76) were compared at baseline, and at two and six weeks after the intervention. Multilevel modeling indicates significant time*group effects: After the intervention, IGSPA had better outcome expectancies for exercise and more positive SPA than CG and IG. Further analyses will include mediation processes of SPA on exercise eight month after the intervention. Results underline the importance of SPA for health and health behavior in research and practice. Changing SPA seem to be a promising pathway to improve health behavior and thereby health in older adults. Conclusions will be drawn about factors that are especially relevant for the development of health behavior interventions for older adults. Mechanisms that underlie the SPA-health link will be discussed.

BRIDGING THE GAP: PERCEPTIONS OF YOUNG ADULTS ON AGING AND INTERACTIONS WITH OLDER ADULTS

S. Spalding, C.M. Clifton, M. Plikuhn, Department of Law, Politics, and Society, University of Evansville, Evansville, Indiana

As the Baby Boomers enter the older years in greater numbers, they serve as the model of aging and the aging process. Yet despite the increased life expectancy and healthier older years that the Baby Boomers are experiencing, current cultural messages regarding aging continue to paint a picture of the frail, sickly older adult that can adversely impact the views of younger generations about their own aging process. In turn, these perceptions of older adults by younger generations can play an important role in intergenerational interactions and the views that younger generations place on the value of older adults in their lives. This study builds on the National Council on the Aging’s 2000 study, “American Perceptions of Aging in the 21st Century.” Using 200 college-age adults, we investigated levels of intergenerational contact, perceptions of older adults and the aging process, and concerns regarding self-aging. Preliminary findings indicate that young adults have strongly negative perceptions of the process of aging and exaggerated self-aging concerns, yet report positive interactions with older adults. This juxtaposition of positive role model interaction yet fears of future aging presents an interesting picture of the persistent negative cultural messages of aging despite overall increases in healthful living into the later years. These negative perceptions of early transitional adults can offer a glimpse into the ways in which they might interpret the experience of aging across the life course. We conclude with suggestions for changing these negative perceptions to be more realistic to the realities of aging.

CORRELATES OF ATTITUDES ON AGING IN OLDER ASSISTED LIVING RESIDENTS

N. Park1, Y. Jang2, B. Lee1, D.A. Chiriboga1, V. Molinar1, 1. University of South Florida, Tampa, Florida, 2. The University of Texas, Austin, Texas

Purpose: Individuals’ subjective perception of aging is known to be linked with physical and mental health and even mortality. The purpose of this study was to examine the effect of selected factors (demographics, stress-related, social perception, and health perception) on individuals’ attitudes about aging among older assisted living (AL) residents. Method: We used data based on face-to-face interviews with a sample of 150 older residents from 17 AL settings in Florida (Mage=82.8, SD=9.4). Hierarchical multiple regression analyses included the following sets: demographics (age, gender, marital status), stress-related (functional disability, hearing impairment, and negative life events), social perception (satisfaction with facility and satisfaction with social support), and health perception. The mediation effect of health perception was tested between significant stress-related variables and attitudes on aging. Results: Functional disability and hearing impairment negatively affected positive attitudes on aging while satisfaction with support had a positive influence. When health perception was entered, only
satisfaction with support and health perception significantly affected attitudes on aging. In subsequent analyses, health perception mediated the role between functional disability/hearing impairment and attitudes about aging. Implications: Given that stigma related to aging strongly influences residents’ health and quality of life in AL, the present study identified the protective and risk factors regarding positive attitudes towards aging. The important role of health perception and satisfaction with support suggests that practice with older residents in AL should focus on promoting better health habits and increasing social support to improve attitudes towards aging and thereby enhance quality of life.

**ATTITUDES TOWARD OLDER ADULTS AMONG AMERICAN AND TAIWANESE COLLEGE STUDENTS**

P. Allen, H. Ko, S. Choun, E. Gordan, K. Hooker, L. Richards, *School of Social and Behavioral Health Sciences, Oregon State University, Corvallis, Oregon*

Research shows that negative attitudes toward older adults are detrimental to older adults’ health and wellbeing (Levy, 2003) and that positive attitudes are important for intergenerational interactions (Lu & Kao, 2009). However, there is little agreement about relative positivity of attitudes toward older adults in American and Asian cultures (e.g., Levy & Langer, 1994; Boduroglu, 2009). To examine the largely untested assumption that a collectivistic Asian culture promotes more positive attitudes toward aging, we adapted the Taiwanese-developed Older People Scale (OPS; Lu & Kao, 2009) for use in English and tested equivalence in two groups of young adults (18-22) in the United States (N=936) and Taiwan (N=666). Alpha reliability were (cα=.68) for the US group and (cα=.84) for the Taiwanese group, which corresponded well with the original Taiwanese scale development sample. Consistent with the established one factor structure, brief 22-item OPS (Lu & Kao, 2009), our preliminary confirmatory factor analysis showed that the same 24 items load on one factor for our US and Taiwan samples. However, these items included on the one factor structure in our study differed from the established 22-item OPS. Regression analysis did not show a difference in positivity of attitudes between cultural groups but across cultural groups older age predicted negative attitudes (p <.05). This work aids our effort to compare the cross-cultural context of aging and could help guide gerontological education programs aimed at ameliorating negative impacts of aging stereotypes. (This study is funded in part by NSF grant DGE 0956820)

**OLDER AMERICANS AND SOCIOPOLITICAL ATTITUDES: MODELING AGE, PERIOD, AND COHORT EFFECTS**

N. Danigelis1, M. Hardy2, S. Cutler1, 1. *University of Vermont, Burlington, Vermont, 2. The Pennsylvania State University, University Park, Pennsylvania*

Recent evidence (Danigelis, Hardy & Cutler, 2007) has shown surprisingly consistent liberal trends among those aged 60 and older with respect to a wide range of sociopolitical attitudes. Unclear is the extent to which these trends reflect changes in attitudes that are due to aging (perhaps as a measure of exposure), a shared experience with other age groups in response to historical events, a transition of specific cohorts into older age ranges, or some combination of the three. Following Littell et al. (2006; see also Yang, 2008), we employ a generalized linear mixed models approach using piecewise regression to disentangle fixed aging effects from random period and cohort effects for three separate age groups (25-39, 40-59, and 60+) on 16 different attitudes using survey data from 28 different General Social Surveys between 1972 and 2010 (minimum N = 12,388). With composition effects controlled, our results show that attitudes of those 60 and older moved in a significantly more liberal direction 22% of the time (mostly on race matters), a significantly more conservative (less liberal) direction 9% of the time, and no differently from the other two age groups 69% of the time, net of period and cohort effects. Period effects were stronger than cohort effects. Both, however, were consistent regarding civil liberties, but there were unexpected period and cohort differences within attitudes relating to blacks, women, and boundaries of privacy. Results illustrate the complex ways in which social change is manifested across age groups, birth cohorts, and years.

**ALLOPHILIA: ASSESSING POSITIVE ATTITUDES TOWARD OLDER AND YOUNGER ADULTS**

L. Wagner, S. Lee, S. Rodriguez, *Department of Psychology, University of San Francisco, San Francisco, California*

Meaningful interactions between younger and older adults are becoming increasingly limited. Interventions to increase positive intergenerational interactions are growing, but one difficulty in assessing the effectiveness of these interventions is finding an appropriate measure of attitudes toward different age groups (both young and old). Many measures assessing attitudes toward older adults can remind participants of negative stereotypes of aging and are rarely used to assess attitudes toward younger adults (e.g., Palmore’s Facts on Aging quiz). When promoting positive interactions between different groups, an assessment of negative attitudes misses the positive changes that may occur. Pittinsky and colleagues coined the term allophilia to refer to “love or liking for the other.” They developed a measure of positive attitudes toward outgroups that includes five domains of positive attitudes (affection, comfort, engagement, enthusiasm and kinship). We adapted this measure to assess attitudes toward younger (18-25 years old) and older (over age 65) adults. Ninety-four traditional college age and 52 older adults completed this measure assessing attitudes toward older and younger adults. We found the measure distinguished between younger and older adults’ attitudes toward each age group. Younger adults reported significantly more affection and enthusiasm for older adults compared to older adults, yet less comfort, kinship and engagement. In contrast, older adults showed no preference for younger adults and reported significantly more affection, comfort, and kinship toward older adults. The allophilia measure differentiated between different domains of positive attitudes toward younger and older adults. Initial results suggest areas where intergenerational interventions are needed.

**THE CONTEXT OF SELF-PERCEPTIONS OF AGING: INDIVIDUALS AND THEIR SOCIAL ENVIRONMENTS**

H.L. Giasson, J. Smith, *Psychology, University of Michigan, Ann Arbor, Michigan*

Objectives: Most research on self-perceptions of aging has been done at an individual level. However, self-perceptions of aging develop in the context of both individuals’ perceptions and the beliefs and expectations of the societies in which they live. This study examines geographic variations in self-perceptions of aging. Method: Participants in the 2008 wave of the Health and Retirement Study (HRS) (N = 6800, mean age = 69.58, age range: 50-100) responded to questions about subjective age and satisfaction with their own aging. Individual level covariates included chronological age, gender, health, SES, and racial and ethnic background. Information about state and region of residence was also included, and linked to state level census information about population age composition. Results: Consistent with the literature, the majority of people felt younger than their actual age (mean difference = -10.45, SD = 11.74), and self-rated health was a primary indicator. After controlling for individual level covariates, there were significant unique effects in self-perceptions of aging associated with area of residence. Specifically, people residing in more urban areas of the U.S. had more positive self-perceptions of aging. Discussion: Findings are consistent with social ecological perspectives. Older adults who reside in more densely populated areas may have more positive attitudes about the aging process because of the greater availability of social support and opportunities to engage in community programs and activities. Future studies will use longitudinal data from HRS to examine the causal direction of these relationships over time.
STUDENT RESPONSES TO SERVICE LEARNING: UNIQUE LEARNING AND ATTITUDE BENEFITS FORM WORKING WITH OLDER ADULTS
K.J. Kimbler, A. Ehman, Social & Behavioral Sciences, Florida Gulf Coast University, Fort Myers, Florida

Previous research suggests that completing a psychology course addressing aging issues may not effectively reduce students’ negative attitudes toward aging (Cottle & Glover, 2007). Service learning, however, is becoming a more common component to aging related courses and involves students engaging in experience-based learning that helps meet community needs (Jacoby, 1996). Service-learning experiences that include serving and interacting with older adults could result in increased knowledge and more positive attitudes toward older adults (e.g., Beling, 2003). The current study examined student responses to service learning from 97 students taking an upper level psychology course covering aging issues (i.e. developmental psychology or psychology of adulthood and aging). The assignment involved completing 10 hours of service and writing a 2 page paper describing the experience. These papers were coded to assess the extent that students exhibited different statements out of 18 possible codes. Analyses involved comparing statements made by students working with older adults (n = 49) to students working with younger ages (n = 48). Students working with older adults were significantly more likely to report negative expectations prior to working with their age group but were more likely to describe positive interactions or experiences compared to students working with younger ages. Students working with older adults were also more likely to report increased understanding of course content and were more evaluative of the organizations. Results suggest that aging-related service learning could be more beneficial for education and attitude improvement than service learning experiences focusing on younger ages.

LESSON FROM THE WATCHED POT: DAILY MONITORING OF SUBJECTIVE AGE PREDICTED INCREASE SELF-ESTEEM AND ANXIETY

Research on subjective age, which addresses how old or young people experience themselves to be, has recently made great strides. For example, subjective age has significantly predicted self-esteem, self-confidence and self-control. Now it is important to explore how one’s self-monitoring of subjective age might affect these associations. As part of a larger examination of intra-individual variation in subjective aging, this study examines the effects of daily documentation of subjective aging on measures of aging attitudes, self esteem, and anxiety in 78 community dwelling adults ages 18-77 (M=43.45;SD=16.14). A series of paired-sample t-test assessed the effects of 14 days of daily age monitoring on these measures. Consistent with research on aging awareness training, no change in aging attitudes scores (t(77)=.61, p=.54, were found, suggesting that observation of one’s own age does not influence ageist beliefs. However, self esteem increased (t(77)=6.58, p<.001, from baseline (M=17.72, SD=4.57) to study’s end (M=24.27, SD=8.01) as did anxiety (t(76)=6.12, p<.001, with scores increasing from baseline (M=37.27, SD=9.43) to study’s end (M=44.90, SD=9.76). Increased age monitoring was linked with one favorable and one unfavorable outcome and not linked to greater ageism. These preliminary findings suggest that there may be some benefit in monitoring one’s subjective aging experience. Future research should explore the causes and generality of these effects.

MEASURING DIMENSIONS OF INTERGENERATIONAL CONTACT: FACTOR ANALYSIS OF THE QUEEN’S UNIVERSITY SCALE
S.E. Jarrott, R.H. Weaver, Human Development (0416), Virginia Tech, Blacksburg, Virginia

Intergenerational contact has been linked with a range of outcomes, but measures of contact are limited. Scales usually consist of 1-2 items related to the general population of elders, leaving respondents little room to discriminate meaningful aspects of contact. The Queen’s University scale (Knox, Gekoski, & Johnson, 1986) consists of 34 items on contact with the general population of elders and 24 items regarding a familiar elder. The scale taps dimensions associated with attitudes towards elders, including relationship qualities associated with positive attitudinal change (Petitgrew, 1998). We administered the scale to undergraduates as part of a study exploring how intergenerational contact influences attitudes towards aging (see Jarrott, Savla, Levy, 2012). Respondents demonstrating systematic responses or missing data were deleted, yielding a sample of 457. With a goal of shortening the Queen’s University scale, we randomly selected half the sample and conducted a principal component analysis of its items. Items regarding familiar versus general elders were highly correlated (r=.5); parallel items for familiar elders were excluded from the analysis. A six-factor model with 22 items accounted for 67.6% of variance. Results were replicated with a confirmatory factor analysis of the other half of the sample. Components reflected dimensions of intergenerational: (a) exchanges, (b) friendship qualities, (c) childhood contact, (d) contact in different settings, (e) contact quantity, and (f) recent contact. Components demonstrated good internal consistency (α ≥ .70). The modified scale provides a parsimonious means to capture important aspects of intergenerational contact and better understand the impact of contact with older adults.

SOCIAL GERONTOLOGY AS A USEFUL LENS IN WHICH TO CHALLENGE THE PREVAILING REPRESENTATION OF AGEING IN THE HUMAN COMPUTER INTERACTION (HCI) COMMUNITY
K. Brittain1, J. Vines2, G.W. Pritchard1, P. Wright2, P. Olivier1. 1. Newcastle University - Institute of Health & Society, Newcastle upon Tyne, United Kingdom. 2. Newcastle University - Culture Lab, Newcastle upon Tyne, United Kingdom

Increased life expectancies and lowered birth rates across the world have meant ageing has become a significant area of interest within computing disciplines and specifically the Human Computer Interaction (HCI) community. In this paper we provide a critical analysis on how ageing is framed over 30 years of research published at the leading venue for HCI publications, addressing four questions: (1) How much have issues to do with ageing permeated research within HCI? (2) How are older people framed within research presented within HCI? (3) How are the discourses underlying these framings shaping how we conceive of and address ageing in HCI? (4) Finally, how could we approach ageing HCI in the future? We explore these questions by integrating empirical methods with critical and theoretical ideas from the field of social gerontology. We found that the problem of ageing is typically focused on declines in ability, healthcare needs and concerns about social isolation. We draw from thinking within the discipline of social gerontology to problematize the prevailing discourse within HCI on what it means to age. We outline five challenges and propose a ‘third-age’ agenda for future research at the intersection of ageing and computing based upon social gerontology theories. We conclude by discussing the new research questions that arise and the resulting methodological implications that emerge from this critique.

LOVED TO DEATH? MEDIA PORTRAYALS OF MURDER SUICIDE: AGEISM, SEXISM AND DANGEROUS ROMANTIC THEMES
S. Salan, Family & Consumer Studies, University of Utah, Salt Lake City, Utah

Intimate Partner Homicide SuicideIPHSH is commonly described as “murder-suicide” by the news media. Comparative examination of 731 IPHS events indicated news report descriptions differed for young adults (18-44 years, 325 events), middle aged (45-59, 177 events) and elderly dyads (60 and over, 225 events). Reports of young and middle aged
IPHS events focused on the violence and perceived loss to the community. Content analysis revealed themes where romantic tones were used to describe the act among elderly dyads (17% of the cases studied). Romantic themes reflected ageism and sexism, but ignored the severe domestic violence. Men were the perpetrators in the majority of cases (young adult 97, middle aged 91, and elderly 96 percent). Female intimate partners (and ex-intimates) suffered severe loss of empowerment. Just over half of the elderly cases concerned a preexisting health condition and of those, 30% had only a perpetrator who was ill. CDC defines mercy killing as a hopeless condition with consent of party. Most elderly cases did not fit these requirements. "Suicide pacts" were also extremely rare (1% middle aged and 4% among elderly). Romantic rationalizations in the media were present only for elderly dyads. Examples included titles "Couple Died Very Much in Love" “Elderly Couple’s Death Called an Act of Love,” “Loved to Death” and quotes “he killed the love of his life.” Implications for public health: romantic portrayals convey ageism to the public and should be interpreted as a dangerous message for those who may be at risk of perpetration.

**SESSION 955 (POSTER)**

**ASSESSMENT ISSUES AND INSTRUMENTS**

**THE RELATIONSHIP BETWEEN COMPONENTS OF EXECUTIVE FUNCTIONING AND INSTRUMENTAL ACTIVITIES OF DAILY LIVING IN OLDER ADULTS**

A. Schwabenbauer, S. Venkataraman, M.H. Silver, E. Rosowsky, Massachusetts School of Professional Psychology, Newton, Massachusetts

In order to improve accurate assessment of instrumental activities of daily living (IADL) in older adults and better understand the relationship between executive functioning and IADLs, this study investigated whether a relationship exists between measures of verbal inhibition and cognitive flexibility and a caregiver report measure of IADLs. Using deidentified retrospective data from an outpatient neuropsychological practice, this study examined the relationship between the Lawton Activities of Daily Living Scale and Delis Kaplan Executive Functioning Scale (DKEFS) Color Word Interference subtest in ninety-four community dwelling older adults aged 60-89 (mean= 72.66 standard deviation= 7.58) using a linear regression analysis. Results of the analysis revealed that performance on the Inhibition and Inhibition/Switching Total Errors conditions of the DKEFS Color-Word Interference subtest were associated with older adults’ scores on an IADL scale. The Inhibition condition accounted for an additional 4% of the variance (F=18.977) and the Inhibition/Switching Total Errors condition accounted for an additional 3.9% of the variance (F=12.027) above demographic variables and baseline cognitive conditions. Performance on the Inhibition/ Switching condition was not significantly associated with IADLs. These results suggest that a decline in older adults’ capacity to complete IADLs is associated with poor verbal inhibition and difficulties with self-monitoring and impulsivity.

**DEMENTIA CAREGIVER BURDEN: ASSOCIATED WITH APATHY/DISINHIBITION VS NEUROPSYCHOLOGICAL TESTS OR IADLS**

M.E. O'Connell, J. Enright, M. Crossley, D.G. Morgan, Psychology, University of Saskatchewan, Saskatoon, Saskatchewan, Canada

Caregiver burden has been associated with persons with dementia’s neuropsychiatric behaviors and function in activities of daily living (ADL). Previous data suggest patients’ cognitive status is not associated with burden, but these are based solely on screening tests (e.g., Mini-Mental Status Exam; MMSE). The 12-item Zarit Burden Interview (ZBI) was administered to 213 caregivers of patients diagnosed with dementia from an interdisciplinary memory clinic after a comprehensive assessment of behavior, function, and neuropsychological status. We replicated previous findings that MMSE was not associated with caregiver burden (trivial association r = 0.02; p > 0.05), whereas the Total index score from the Repeatable Battery for the Assessment of Neuropsychological Status demonstrated a small association with ZBI scores (r = 0.17; p = 0.049). A composite measure of executive function (from the Trail Making Test – B and Stroop Interference Test) demonstrated a moderate association with ZBI scores (r = 0.31, p = 0.031), as did instrumental ADLs (iADLs) measured with the Functional Assessment Questionnaire; r = 0.38, p < 0.001. Although frontal behaviours of apathy and disinhibition (from the Neuropsychiatric Inventory) also approached to have a moderate association with burden (r = 0.41, p < 0.001), hierarchical regression analysis suggested that burden was best predicted by these frontal behaviours alone (R = 62, p < 0.001), and not iADLs or neuropsychological function. These data illustrate the limited contribution of neuropsychological function and iADLs in predicting caregiver burden and suggest that patients’ frontal behaviours are most associated with increased caregiver burden.

**FACTOR ANALYSIS AND ETHNO-RACIAL MEASUREMENT INVARIANCE OF THE MEANINGFUL ACTIVITY AND PARTICIPATION ASSESSMENT—FREQUENCY**

S.L. Schepens1, N.E. Pisca2, F.A. Clark1, 1. Division of Occupational Science and Occupational Therapy, University of Southern California, Los Angeles, California, 2. Davis School of Gerontology, University of Southern California, Los Angeles, California

Background: Daily activity is associated with health in older adults. The Meaningful Activity and Participation Assessment—Frequency (MAPA-F) evaluates activity engagement. There is limited research on this tool’s measurement properties among ethno-racial groups. Culturally-based response patterns may invalidate cross-cultural comparisons of activity behaviors and their relationships to health. Additionally, associations between MAPA-F domains and health in ethno-racial subgroups have not been established. Objectives: Examine both ethno-racial differences in the MAPA-F factor structure, and the associations between MAPA-F activity domains and self-rated health and function. Methods: A multi-group confirmatory factor analysis framework was used to identify underlying dimensions of the MAPA-F questionnaire for White and Hispanic elders. Measurement invariance was examined between groups. Post-hoc correlational analysis was conducted to compare resultant factor solutions with self-perceived health and function (SF-36 Health Survey). Results: Three activity domains—leisure, social, and transportation—emerged for Whites and Hispanics. Configural, measurement, and factor correlations invariance was found between groups. The strongest associations were observed between leisure activity and physical function for both groups. Significant associations between social activity and SF-36 subscales were present for Whites but not for Hispanics. Discussion: A three-factor model of MAPA-F exhibited invariance across Whites and Hispanics, which suggests conceptual equivalence and justifies mean comparisons between these groups. Health domains were differentially associated with leisure and social activity between groups. Examining types of activities cultural groups engage in may be important when studying health outcomes. Future studies should investigate causal relationships between MAPA-F domains and health in ethno-racial groups of older adults.
in complex ADL may already occur and indicate a higher risk of conversion to dementia. Thus, sensitive and reliable ADL assessment tools are needed. This study investigated the feasibility of a novel performance-based ADL assessment tool in a real-life setting. This setting consisted of a fully furnished two-room flat equipped with activity sensors, tracking devices and cameras. 21 participants (mean age: 70.5 years, range: 65-82; mean MMSE: 26.0 points, range: 22-30) with either Alzheimer’s disease (AD), mild cognitive impairment (MCI) or no cognitive impairment (NCI) had to complete seven standardized tasks, including meal preparation, telephone use, finding objects in the flat and operating the television. Analyses of the sensor data and the video clips revealed that AD participants needed more time and made more errors while solving the tasks than MCI participants, who in turn took longer and made more errors than NCI participants. Task performance was correlated with cognitive status, but not with age. Furthermore, the majority of participants found the flat and the tasks absolutely realistic (88% and 93% agreement, respectively). Assessment duration (mean: 23 minutes) was considered appropriate. In conclusion, this novel ADL assessment in a real-life setting was very well accepted by participants and feasibility was excellent. Results of this pilot study demonstrate that the novel tool offers the opportunity for an objective, partially automated and ecologically valid assessment of ADL.

A DISCRIMINATIVE DAILY ACTIVITY MEASURE FOR INDIVIDUALS WITH MILD COGNITIVE IMPAIRMENT

J. Rodakowski, E. Skidmore, M.B. Holm, P.E. Toto, J.C. Rogers, Department of Occupational Therapy, University of Pittsburgh, Pittsburgh, Pennsylvania

One factor that defines Mild Cognitive Impairment (MCI) is individual variability in performance of instrumental activities of daily living (IADL). Yet, few measures of IADL discriminate between older adults with MCI versus normal cognition. This secondary data analysis examined the discriminative validity of a performance-based observation measure of IADL performance among older adults with MCI and those with normal cognition. Participants had a history of major depression and completed the baseline assessment of an intervention study examining maintenance antidepressant therapy. Among these participants, 61 had MCI (M=75.9 years) and 96 had normal cognition (M=72.5 years). The Performance Assessment of Self-Care Skills (PASS) assessed IADL performance through standardized, criterion-referenced observations of 8 tasks (shopping, bill paying, checkbook balancing, bill mailing, telephone use, medication management, critical information retrieval, and small device repair). A composite score of the total number of cues required to complete the cognitively-focused IADL was calculated. Receiver Operating Characteristic curve analyses demonstrated good accuracy of the PASS in discriminating between older adults with MCI and those with normal cognition (Area Under the Curve=0.81, p<0.0001). An independent sample t-test indicated that there was a significant difference between the number of cues required by older adults with MCI (M=28.03) and those with normal cognition (M=11.75; t(155)=7.71, p<0.0001). Findings suggest that the PASS is a discriminative measure for assessing IADL performance among older adults with MCI and those with normal cognition who had a history of major depression.

USEFULNESS OF POSTURAL SWAY MEASUREMENTS WHEN STANDING UP FROM A CHAIR

T. Tsuji1, J. Okura, T. Miyama2, Y. Sakai1, M. Takahashi1, T. Shiokawa1, 1. Medical & Health Sciences, University of Tsukuba, Tsukuba, Ibaraki, Japan, 2. Faculty of Health and Sport Sciences, University of Tsukuba, Tsukuba, Ibaraki, Japan, 3. TANITA Corporation, Itabashi-ku, Tokyo, Japan

In this study, we measured postural sway while standing up from a chair using the maximum amount of effort and examined the association between sway in the lateral direction and experience of falling in the past year, lower limb pain and muscle volume. We performed cross-sectional analyses on 311 community-dwelling older adults, which included 155 men and 156 women (73.6 ± 5.0 years). We evaluated average displacement (mm) of the foot center of pressure from the center to the lateral direction while standing up from a chair. That is to say, those whose value was large tended to stand up with a disproportionate load on one leg. Average displacement was 9.4 ± 6.4 mm in the no fall group, 8.7 ± 4.5 mm in the one fall group, and 13.4 ± 14.2 mm in the two or more falls group, indicating a significant difference between groups (P = 0.04). Subjects with pain in one leg exhibited greater displacement than subjects with pain in both legs and subjects with no pain (P = 0.049). There was no association between displacement and lateral differences in lower limb muscle volume measured by bioelectrical impedance analysis (P = 0.88). These results suggest that postural sway measurements while standing up from a chair reflect imbalances in left-right leg muscle exertion as a result of pain, and can be useful in evaluating the risk of multiple falls.

AGE OF ONSET AND PREVALENCE OF DEMENTIA IN CENTENARIANS USING 3 DIFFERENT ASSESSMENT TOOLS

T.M. Neary1, S.L. Andersen1, J.D. Gass1, L. Feldman1, N. Schupf2, T.T. Perls1, 1. Medicine/Geriatrics, Boston University School of Medicine, Boston, Massachusetts, 2. G. H. Sergievsky Center & Taub Institute, Columbia University, New York, New York

Purpose: To determine the age of onset of dementia in centenarians using three different assessment tools. Methods: Data were collected using the Blessed Information-Memory-Concentration (BIMC) Test, the Dementia Questionnaire (DQ) and self-report. The total sample was n=872 subjects, mean age 104 ± 4 years (655 women, 217 men) from the New England Centenarian Study. For 869 subjects, they and/or their family were asked about presence of dementia and age of onset. Out of the 664 participants who were administered the BIMC, a subset of subjects (n=59) who initially had no cognitive impairment by the BIMC were then assessed with the BIMC annually for age of onset. The DQ, administered to n=136 living and recently deceased subjects, allows for the retrospective assessment of age of onset. Results: 29% (252/869) of participants provided a self-report of dementia with an average age of onset of 97 ± 6 years. 87% (576/664) met BIMC criteria for at least mild cognitive impairment with an average age of onset of 101 ± 4 years. 63% (86/136) were considered demented by the DQ with an average age of onset of 103 ± 5 years. Correlations between these three assessments were determined. Conclusions: The DQ, BIMC and self-report are valuable tools in determining the presence and age of onset of dementia in centenarians. However, self-report is adequately sensitive only for severe cognitive impairment. The DQ is especially useful in this population because it can be administered for subjects with sensory impairments that prevent testing with the BIMC.

MEASURING ELDER ABUSE: DOES CHANGING ABUSE THRESHOLDS AFFECT PREVALENCE LEVELS OR RISK FACTORS?

Y. Yon, K. Wilber, University of Southern California, Los Angeles, California

There is a lack of consensus in defining and measuring elder abuse. This lack of uniform definition makes it difficult to compare studies complicating the assessment of the actual prevalence and risk factors for elder abuse. This study examines the impact of different elder abuse definitions by adjusting the abuse thresholds (i.e. those who experience abuse at least once vs. twice or more and those who experience minor vs. severe abuse) in a sample of low-income immigrant Latino seniors (N=199) living in Los Angeles. Bivariate and logistic regressions were conducted to determine the impact of different thresholds on prevalence and risk factors. Increasing threshold definitions (i.e. to twice or more) resulted in lower prevalence estimates of overall abuse (35.7%...
to 17.1%) and its sub-types (psychological, physical/sexual and financial abuse), the study found that the risk factors generally remained consistent, especially for conflict abuse (i.e. combined psychological, physical and sexual abuse), suggesting a common set of predictors as indicated by Hosmer-Lemeshow tests. In contrast, increase in thresholds reduced the number of significant risk factors of physical and sexual abuse and, in some situations, strengthened the odds of risk factors in predicting conflict abuse, such as educational attainment (Odds Ratio [OR], 5.2 to 23.0) and history of past abuse (OR, 7.6 to 14.1). This study found limited impact of utilizing different thresholds in predicting abuse. Risk factors appeared to be relatively independent of the thresholds that were used. Further studies using larger datasets are needed to verify the findings of this study.

DO THE ELDERLY USE THE SAME STRATEGY TO PLANNING MOVEMENTS FOR REAL AND VIRTUAL TARGETS?

Objective: Virtual environments show promise for balance training in older adults. However, motor control strategies employed in real and virtual environments have largely been unexplored. For ballistic, constrained, target-reaching movements, end-effector motion typically follows bell-shaped velocity profiles. Scaling peak velocity (PV) to reach extent generally reflects the plan, while scaling time to peak velocity (ttPV) indicates feedback or feedforward use to adjust the plan for success. We investigated how older adults use these control strategies under varying balance conditions (standing/stepping) for reaches to real and virtual targets. Design: A cross sectional design wherein participants, while standing or stepping, reached for real or virtual targets arranged in a circular ring, in a counter-balanced order. Setting: California State University at Fullerton and the University of Southern California. Participants: 19 adults, aged 59 to 87. Outcome measures: Using processed kinematic data derived from the Kinect system, PV and ttPV of each reach were calculated (~190 total/participant). Results: PV and ttPV were greater for stepping than standing. The increase in ttPV from standing to stepping reaches was greater for real targets than virtual targets (balance condition x target interaction, p=.012). Conclusion: Anticipatory planning strategies vary with respect to balance condition but are similar for reaches to Real and Virtual targets. Feedback-based adjustments appear to depend on both balance condition and target type in older adults. We will discuss possible explanations for these findings and the effect of age on planning that was only seen in the virtual reaching task.

SESSION 960 (POSTER)

CHRONIC DISEASE MANAGEMENT

DIABETES SELF-MANAGEMENT BEHAVIORS AND INFORMAL SOCIAL SUPPORT AMONG OLDER CARIBBEAN WOMEN: A PILOT MULTI-METHOD STUDY

I.S. Harvey, University of Connecticut, Storrs, Connecticut
