Edited by Dario Neri

Engaging inhibitory FcγRIIib by Fc region has been recently reported to be an attractive approach for improving the efficacy of antibody therapeutics. However, the previously reported S267E/L328F variant with enhanced binding affinity to FcγRIIib also enhances binding affinity to FcγRIIaR131 allotype to a similar degree because FcγRIIib and FcγRIIaR131 are structurally similar. In this study, we applied comprehensive mutagenesis and structure-guided design based on the crystal structure of the Fc/ FcγRIIib complex to identify a novel Fc variant with selectively enhanced FcγRIIib binding over both FcγRIIaR131 and FcγRIIaH131. This novel variant has more than 200-fold stronger binding affinity to FcγRIIib than wild-type IgG1, while binding affinity to FcγRIIaR131 and FcγRIIaH131 is comparable with or lower than wild-type IgG1. This selectivity was achieved by conformational change of the C12 domain by mutating Pro to Asp at position 238. Fc variant with increased binding to both FcγRIIib and FcγRIIa induced platelet aggregation and activation in an immune complex form in vitro while our novel variant did not. When applied to agonistic anti-CD137 IgG1 antibody, our variant greatly enhanced the agonistic activity. Thus, the selective enhancement of FcγRIIib binding achieved by our Fc variant provides a novel tool for improving the efficacy of antibody therapeutics.

Keywords: antibody engineering/FcγRIIib/Fc engineering/ inhibitory FcγR/platelet activation

Introduction

IgG-based monoclonal antibodies (mAbs) have become important therapeutic options for numerous diseases (Brekke and Sandle, 2003; Maggon, 2007). Fcγ receptors (FcγR)-dependent cytotoxicity plays an important role in the antitumor activity of mAbs for cancer immunotherapy (Nimmerjahn and Ravetch, 2012).

Several works describe engineering the Fc region to enhance the effector function of mAbs by increasing the binding affinity for active FcγRs (FcγRIa, FcγRIIa and FcγRIIIa) with amino acid substitutions. For example, antibodies engineered to have increased binding affinity for FcγRIIIa exhibited superior in vitro ADCC activity and in vivo antitumor activity compared with wild-type mAbs (Stavenhagen et al., 2007; Zalevsky et al., 2009). In addition to protein engineering, glyco-engineered tumor-specific mAbs with afucosylated N-linked oligosaccharides at Asn297 in the Fc region showed increased binding affinity for human FcγRIIIa and mouse FcγRIIV, which resulted in enhancing the therapeutic activity in mouse models (Nimmerjahn and Ravetch, 2005; Mossner et al., 2010).

In contrast to these activating FcγRs that function as immunostimulatory receptors, inhibitory FcγRIIB is reported to function as an immunomodulatory receptor (Li and Ravetch, 2011; White et al., 2011). The inhibitory receptor FcγRIIB is the only IgG Fc receptor expressed on B-cells and plays a critical role in regulating B-cell homeostasis (Heyman, 2003; Nimmerjahn and Ravetch, 2008). Immune complexes (ICs) coengage FcγRIIib and B-cell receptor (BCR) and then selectively suppress B-cells that recognize cognate antigen (Heyman, 2003). FcγRIIib also regulates other B-cell stimulators that amplify B-cell proliferation and differentiation and suppresses the expression of costimulatory molecules (Leibson, 2004; Crowley et al., 2009).

FcγRIIib also plays an inhibitory role in a homeostatic checkpoint of dendritic cells (DCs) for inducing tolerance or immunity by ICs, in contrast to FcγRIIa. While ligation of FcγRIIib led to DC maturation, targeting FcγRIIib alone did not activate DCs (Boruchov et al., 2005). FcγRIIib on DCs induced peripheral tolerance by inhibiting antigenic processing and DC activation to suppress T-cell activation (Desai et al., 2007).

Besides these inhibitory effects of FcγRIIib, several groups have recently reported that FcγRIIib enhances the agonistic activity of anti-tumor necrosis factor receptor (TNFR) superfamily antibody by working as a scaffold (White et al., 2013). Proliferation of antigen-specific T-cells induced by anti-CD40 antibodies was abrogated in FcγRIIib-deficient mice (White et al., 2011; Li and Ravetch, 2012). Anti-death receptor 5 (DR5) agonist antibody also required FcγRIIib to exert its agonistic activity and initiate apoptosis in lymphoma cells (Wilson et al., 2011). The FcγRIIib-expressing cells are considered to work as a scaffold to efficiently cross-link anti-CD40 or DR5 antibodies bound to target cells via FcγRIIB.

In order to exploit these properties, engineering Fc region to increase the binding affinity to FcγRIIib is considered to be a promising approach. Introducing S267E/L328F substitutions
into the Fc region of human IgG1 increased the binding affinity to FcγRIIb 430-fold without increasing that to FcγRI, FcγRIIAH131 or FcγRIIIm (Chu et al., 2008). Anti-CD19 antibody with the Fc promoted suppression of B-cell activation and proliferation in SLE mouse model by coengaging FcγRIIB with BCR (Horton et al., 2011). Recent reports noted that anti-IgE antibody with S267E/L328F Fc variant reduced the production of IgE in vivo (Chu et al., 2012) and that the Fcε domain fused with S267E/L328F Fc variant suppressed degranulation and calcium mobilization of mast cells (Cemerski et al., 2012). Moreover, agonistic antibodies against CD40 or DR5 showed more potent agonistic activity in vivo with enhanced FcγRIIB binding (Li and Ravetch, 2011, 2012). These reports clearly demonstrate that engineered Fc with enhanced binding to FcγRIIB has various therapeutic applications. However, it was reported that S267E/L328F substitutions to mAb therapeutics, the consequence of increasing the binding to FcγRIIa should be considered.

It is reported that a high incidence of thromboembolic complication was observed in patients treated with anti-CD154 or anti-VEGF antibody in clinical settings (Bournas et al., 2003; Scappaticci et al., 2007). The ICs composing of these antibodies and the antigens activated platelets and induced thrombosis in human FcγRIIa transgenic mice by crosslinking FcγRIIa expressed on the platelets (Meyer et al., 2009; Robles-Carrillo et al., 2010). Moreover, intravenous immunoglobulins also induced FcγRIIa-mediated platelet aggregation in vitro (Pollreisz et al., 2008). These results demonstrate that even wild-type IgG1 generally has a potential risk of inducing thromboembolism through an FcγRIIa-dependent mechanism, suggesting that this risk could be increased if the binding to FcγRIIa is enhanced. Therefore, considering the therapeutic applications, antibody with selectively enhanced binding to FcγRIIb relative to both FcγRIIaH131 and FcγRIIim is preferred.

In this work, we investigated antibodies with selectively enhanced binding to FcγRIIb over both FcγRIIaH131 and FcγRIIim. We screened a large set of single substituted variants of human IgG1 for binding to human FcγRs and found a distinct variant that distinguishes FcγRIIb from both FcγRIIa allotypes. We solved its crystal structure in complex with human FcγRIIb and elucidated the structural recognition mechanism by which it recognizes FcγRIIb over both FcγRIIa allotypes. In order to improve its FcγRIIb binding, we conducted further optimization and identified a novel antibody variant with over 200-fold more enhanced binding to FcγRIIb without increasing the binding to either FcγRIIa allotype. Structural analysis of this variant revealed the mechanism of the improved binding to FcγRIIb. We also report that antibody that also has enhanced binding to FcγRIIa is more likely to activate platelets and induce aggregation and would have a shorter in vivo half-life compared to wild-type IgG1. We also confirmed that this variant enhanced the agonistic activity of anti-CD137 antibody in vitro. Our results indicate that the novel Fc variant with purely selectively enhanced binding to FcγRIIb is applicable to a broad range of therapeutic antibodies, since it avoids increasing the potential to activate or aggregate platelets and to have rapid clearance in vivo.

**Materials and methods**

**Preparation of IgG1 variants**

IgG1 variants used in the experiments were expressed transiently in FreeStyle™ 293F cells transfected with plasmids encoding heavy and light chain and purified from culture supernatants using protein A. Site-directed mutagenesis of the Fc region was performed using QuickChange Site-Directed Mutagenesis Kit (Stratagene) or In-Fusion HD Cloning Kit (Clontech).

**Construction, expression and purification of FcγRs**

The genes encoding the extracellular region of human FcγRs were synthesized based on the sequence information obtained from the National Center for Biotechnology Information. FcγRs were fused with 6×His tag at their C-terminus. Vectors containing FcγRs were transfected into FreeStyle™ 293F cells. The receptors were purified from the harvested culture supernatants by using ion exchange chromatography, nickel affinity chromatography and size exclusion chromatography.

**Binding and affinity analysis for human FcγRs by surface plasmon resonance (SPR)**

The interaction of antibody variants with FcγRs was monitored using Biacore instruments (GE Healthcare), as previously described (Richards et al., 2008). Antibody variants were captured on the CM5 sensor chip (GE Healthcare) on which antigen peptide or protein A/G (Thermo Scientific) was immobilized, followed by injection of FcγRs. The binding of each variant to each FcγR was normalized by the captured amount of antibody on the sensor chip and was expressed as a percentage of that of IgG1. Kinetic analysis was performed by global fitting of binding data with a 1 : 1 Langmuir binding model using Biacore Evaluation Software (GE Healthcare).

**Crystalization, data collection and structure determination of the complex of Fc fragment of human IgG1 with P238D substitution, Fc(P238D) and FcγRIIb**

Crystals were obtained by 1 : 1 mixing of protein complex (10 mg/ml) with 0.1 M Bis-Tris pH6.5, 0.2 M ammonium acetate, 2.7% (w/v) β-galactose, 17% PEG3350 in sitting drop vapor diffusion setups at 20°C. For data collection, crystals were flash frozen at 95 K in precipitant solution containing 22.5% ethylene glycol. Diffraction data to 2.6 Å were collected using the Photon Factory beamline BL-1A. Data were processed with Xia2 (Winter, 2010), XDS Package (Kabsch, 2010) and Scala (Evans, 2006). The structure was determined by molecular replacement with PHASER (McCoy et al., 2007) using Fc part of Fc(rgf1)/FcγRIIa structure (PDB ID: 3SGJ) and FcγRIIa structure (PDB ID: 2FCB) as search models. The asymmetric unit was formed by a single 1 : 1 complex. A model was built with the program Coot (Emsley et al., 2010) and refined with the program REFMAC5 (Murshudov et al., 2011).

**Crystalization, data collection and structure determination of the complex of Fc fragment of V12 variant, Fc(V12) and FcγRIIb**

Crystals were obtained by 1 : 1 mixing of protein complex (10 mg/ml) with 0.1 M Bis-Tris pH6.5, 0.2 M potassium phosphate dibasic, 19% PEG3350 in hanging drop vapor diffusion...
setups at 20°C. For data collection, crystals were flash frozen at 95 K in precipitant solution containing 20% ethylene glycol. Diffraction data to 2.86 Å were collected at the SPring-8 beamline BL-32XU. After data processing and structure determination by molecular replacement using Fc(P238D)/FcγRIIb structure, a model was built with the program Coot and refined with the program REFMAC5. The asymmetric unit was formed by a single 1:1 complex.

Data collection and refinement statistics of both crystals are summarized in Supplementary Table S1. All graphical presentations were prepared with PyMOL (DeLano, 2002).

Preparation of Fc fragment and FcγRIIb complexes
We cloned recombinant Fc fragments corresponding to the heavy chain residues from 216 (EU numbering) to C-terminus for the crystallization. Cys 220 was replaced with Ser so that the free cysteine would not make disulfide bonds. FcγRIIb expressed by FreeStyle™ 293F cells in the presence of the mannosidase I inhibitor, kifunensine, was purified and treated with endoglycosidase F1 fused with glutathione S-transferase for deglycosylation as described previously to minimize the heterogeneity of the oligosaccharide (Grueninger-Leitch et al., 1996). The complexes of Fc fragment and the deglycosylated FcγRIIb were prepared by mixing Fc fragment with a little excess of the deglycosylated FcγRIIb, and purified by size exclusion chromatography.

Thermal shift assay
Melting temperature (Tm) of the Cε2 region was measured as previously described (He et al., 2010). The SYPRO orange dye (Invitrogen) was added to 0.1 mg/ml protein solutions at a final dilution of 1:500. Fluorescence measurements were employed using a real-time polymerase chain reaction instrument, Rotor-Gene Q (QIAGEN). The temperature was increased from 30 to 99°C at a heating rate of 4°C/min.

Stability study of high concentration antibodies
Antibodies were concentrated to 100 mg/ml in a histidine buffer (20 mM histidine, 150 mM NaCl, pH6.0) by ultrafiltration (Millipore). The solutions were stored at 25°C to assess the stability of the antibodies. High-molecular-weight (HMW) species were analyzed with TSK-GEL G3000SWXL column (TOSOH) by size exclusion high-performance liquid chromatography at initial time point and after 4 weeks. The mobile phase contained 300 mM NaCl in 50 mM phosphate at pH7.0. The percentage of HMW species peak in total protein peak area was calculated using Empower Waters software.

Binding affinity analysis of antibodies for human FcRn
Recombinant, soluble human FcRn (hFcRn) was expressed in HEK293 cells and prepared as described previously (Dall’Acqua et al., 2006). The interaction of soluble hFcRn was monitored as described previously (Igawa et al., 2010).

Pharmacokinetic studies of monoclonal antibodies in hFcRn transgenic mouse
Anti-human interleukin-6 receptor (hIL-6R) IgG1 or V12 variant was administered to human FcRn (hFcRn) transgenic mice (B6.mFcRn+/-/hFCRN Tg32 B6.Cg-Fcgrt<tm1Dcr> Tg(FCGRT)32Dcr; Jackson Laboratories) by single intravenous injection together with 1 g/kg Sanglopor (CSL Behring K.K.) to mimic endogenous IgG in human. Blood samples were collected. The concentration of each antibody was determined by capture with anti-idiotypic antibody (in-house), followed by addition of hIL-6R and biotinylated anti-hIL-6R antibody (R&D Systems) and detected by Streptavidin-Poly HRP80. The half-life was calculated from the plasma concentration–time data using non-compartmental analysis with WinNonlin Professional software (Pharsight).

Platelet aggregation and activation study using washed platelets
Fresh blood from healthy volunteers whose FcγRIIa genotype is R/R or H/H was anticoagulated with 0.5 ml of 3.8% sodium citric acid–citrate in blood collection tubes. Platelet-rich plasma (PRP) was obtained by centrifuging at 200 g for 15 min and then removing the supernatant. PRP was washed in modified Tyrode buffer (137 mM NaCl, 2.7 mM KCl, 12 mM NaHCO3, 0.42 mM NaH2PO4, 2 mM MgCl2, 5 mM HEPES, 5.55 mM dextrose, 0.35% bovine serum albumin) with 1.5 U/ml apyrase and resuspended at a concentration of 3 x 10^8/ml in modified Tyrode buffer. Washed platelets were then incubated with preformed IC for 5 min. The Preformed IC was prepared by mixing the anti-IgE mAb having different Fc variants (200 µg/ml) with its antigen (229 µg/ml), human IgE, at a molar ratio 1:1. Five minutes after the incubation, 30 µM ADP was added to induce the first wave of platelet aggregation. Platelet aggregation was measured by an aggregometer (MCM Hema Tracer 712; MC Medical) at 37°C with stirring at 1000 rpm.

Cells and reagents
CTLL-2 cells (mouse T lymphocyte cell line, No.RCB0637) were provided by the RIKEN BRC through the National Bio-Resource Project of the MEXT, Japan. Raji cells (human Burkitt’s lymphoma cell line, ATCC No.CCL-86) were purchased from the American Type Culture Collection. Both cell lines were cultured in RPMI 1640 medium (Nacalai tesque), supplemented with 10% heat-inactivated foetal bovine serum (Bovogen). The culture medium for CTLL-2 was supplemented with 10 ng/ml recombinant mouse interleukin (IL)-2 (PeproTech). The culture medium for Raji cells was supplemented with 10 mM HEPES, 1 mM sodium pyruvate (Nacalai tesque), 4.5 g/l D-glucose, 1.5 g/l sodium bicarbonate (Sigma-Aldrich).

Flow cytometry analysis of CD137 expression
To analyze mouse CD137 expression on CTLL-2 cells, anti-mouse CD137 clone 1D8 variable region fused with the Fc domain of human IgG1 (Shuford et al., 1997) or human IgG1 isotype control (Alexis, Lausen) was applied. Goat F(ab)2 anti-human IgG-FITC #732596 (Beckman Coulter) was used as the detection antibody. Cell Lab Quanta SC MPL system (Beckman Coulter) was used for cell acquisition and data analysis was conducted using FlowJo software (Tree Star Inc.).

Measurement of T-cell activation by anti-CD137 antibody by cytokine production
CTLL-2 cells (2 x 10^5/ml) and Raji cells (2 x 10^5/ml) were co-cultured in RPMI 1640 medium supplemented with 10% heat-inactivated foetal bovine serum (Bovogen), 10 ng/ml mouse IL-2 (PeproTech), 10 ng/ml phorbol 12-myristate 13-acetate, 0.5 µg/ml ionomycin (Sigma-Aldrich). The cells were treated with 3 µg/ml anti-CD137 antibodies with
different Fc (Fc of human IgG1, S267E/L328F or V12 variant) for 24 h at 37°C, 5% CO2. Mouse interferon (IFN)-γ concentration in the cultured medium was determined by ELISA system (PeproTech), according to the manufacturer’s protocol.

Results

Screening and characterization of variants to selectively enhance FcyRIIb binding by comprehensive mutagenesis

We screened a large set of over 500 variants prepared by replacing each of about 30 residues in the lower hinge and CH2 region with every naturally occurring amino acid except for cysteine, for binding to human FcyRIIaR131, FcyRIIaR131 and FcyRIIb in order to identify substitutions that selectively enhance FcyRIIb binding relative to both FcyRIIa allotypes. The effect of each substitution on the binding to FcyRIIaR131, FcyRIIaR131 and FcyRIIb is compared in Fig. 1A and B. Only two substitutions, P238D and L328E, were found to enhance FcyRIIb binding while decreasing the binding to both FcyRIIa allotypes, although previously reported S267E and L328F (Supplementary Table S2) and the changes in affinity from human IgG1, P238D variant and L328E variant for allotypes, although previously reported S267E and L328F (Supplementary Table S2) and the changes in affinity from human IgG1, P238D variant and L328E variant for all the active FcγRs and enhanced that for FcγRIIb more significantly than L328E variant.

Crystal structure of the FcγRIIb complex with IgG1 Fc fragment with P238D

Fc(P238D) bound to FcγRIIb in an asymmetric fashion between the two CH2 domains (CH1-A and CH1-B) like previously reported Fc(IgG1) and FcγR complexes. In Fig. 3A, the overall structure of Fc(P238D)/FcγRIIb was compared with known Fc(IgG1)/FcγRIIaR131 (PDB ID: 3RY6) (Ramsland et al., 2011). Despite the high-sequence homology between FcγRIIb and FcγRIIaR131 (Supplementary Fig. S1), the domain arrangement of CH2-B in Fc(P238D)-FcγRIIb interface was different from that in Fc(IgG1)/FcγRIIaR131.

Structural comparisons of both CH2 domains with those of Fc(IgG1) complexed with FcγRIIaR131 revealed conformational changes of loops around position 238 in both CH2 domains (Fig. 3B and C). Pro238 in wild-type human IgG1 formed an inside hydrophobic core with Val263, Val266, V323, Asn325 and Leu328. On the other hand, Asp238 in P238D variant shifted out of the core and it was exposed to the solvent region. Instead, Leu235 occupied the vacated space which Pro238 occupied in Fc(IgG1), forming another hydrophobic core in CH2-A, but not in CH2-B. As a result, there was a large cavity surrounded by Val263, Val266, Val273, Val323, Asn325 and Leu328 in CH2-B. Asp238 in CH2-B formed an electrostatic interaction with Lys334 in the same chain.

In the CH2-A domain, the main chain of Gly237 formed a novel hydrogen bond with Tyr160 of FcγRIIb (Fig. 3B). A weak hydrogen bond between the main chain of Asp238 and the side chain of Thr158 of FcγRIIb was also observed. In addition, the side chain of Asp238 formed van der Waals contacts with the side chain of Thr158 in FcγRIIb. In the CH2-B domain, the conformation of the loop around Asp270 changed from that of Fc(IgG1) complexed with FcγRIIaR131, and Asp270 formed a salt bridge with Arg131 of FcγRIIb (Fig. 3C).
In order to further enhance the affinity to FcγRIIb, we combined P238D with L328E or S267E/L328F, previously known variant to increase binding to FcγRIIb and FcγRIIaR131. Unexpectedly, the additive effect by combining P238D with those substitutions was not observed. Affinities for FcγRIIb of these variants are listed in Supplementary Table S3.

Then, we screened substitutions to improve FcγRIIb binding when they were combined with P238D by comprehensive mutagenesis using the P238D variant as a template. Approximately 400 variants with an additional single substitution onto the P238D variant were generated, and the affinity for FcγRIIb was determined. Six effective substitutions (E233D, G237D, H268D, P271G, Y296D and A330R) were identified. We further combined these substitutions to create V12 variant having all the six substitutions described above. The fold increases of the variants against FcγRIIb over P238D variant are listed in Table I.

Fold = K_D (P238D variant)/K_D (Fc variants).

**Table I.** Effect of additional substitution(s) into P238D variant on binding affinity for FcγRIIb

In order to further enhance the affinity to FcγRIIb, we combined P238D with L328E or S267E/L328F, previously known variant to increase binding to FcγRIIb and FcγRIIaR131. Unexpectedly, the additive effect by combining P238D with those substitutions was not observed. Affinities for FcγRIIb of these variants are listed in Supplementary Table S3.

Then, we screened substitutions to improve FcγRIIb binding when they were combined with P238D by comprehensive mutagenesis using the P238D variant as a template. Approximately 400 variants with an additional single substitution onto the P238D variant were generated, and the affinity for FcγRIIb was determined. Six effective substitutions (E233D, G237D, H268D, P271G, Y296D and A330R) were identified. We further combined these substitutions to create V12 variant having all the six substitutions described above. The fold increases of the variants against FcγRIIb over P238D variant are listed in Table I.

K_D of wild-type IgG1, S267E/L328F variant and the most potent variant, V12 variant, to all the FcγRs are listed in Supplementary Table S2 and the changes in affinity from IgG1 are shown in Fig. 4. V12 variant showed 217-fold increase in affinity for FcγRIIb, yet bound to FcγRIIaR131 with similar affinity to that of wild-type IgG1 and to the other
activating FcγRs with affinity significantly lower than that of IgG1. On the other hand, S267E/L328F variant increased the affinity for FcγRIIb 355-fold and that for FcγRIIa even greater, 864-fold.

**Crystal structure of the FcγRIIb complex with Fc(V12)**
The same conformational changes around Asp238 induced by P238D substitution in Fc(P238D)/FcγRIIb were also observed in Fc(V12)/FcγRIIb. In the C1α2-A domain, the introduced residues, Asp233, Asp237 and Arg330, were located in the interface with FcγRIIb (Fig. 5A). The weak electron density of Asp233, replaced from Glu, was observed. As Lys113 of FcγRIIb is located near Asp233, they might interact with each other. In the C1α2-A domain, Asp237, replaced from Gly, made van der Waals contacts with Trp87 and Tyr160 of FcγRIIb. In addition, the hydrogen bond distance between NH of the main chain at position 237 in Fc and OH of the Tyr160 side chain in FcγRIIb changed from 3.1 Å in Fc(P238D) (Fig. 3C) to 2.9 Å in Fc(V12) (Fig. 5A). A weak hydrogen bond between the side chain of Asp238 and the side chain of Thr158 of FcγRIIb was also observed. The electron density of the side chain of Arg330, which replaced Ala, was not clearly observed. As Glu86 of FcγRIIb is located near Arg330, a weak interaction between those residues could be present.

In the C1α2-B domain, H268D and P271G substitutions induced a further conformational change of a loop around Asp270 (Fig. 5B). The substitution from Pro to Gly at position 271 caused the main chain to flip and consequently rearranged the 266–273 loop and Arg131 of FcγRIIb, which also formed a salt bridge with Asp270 in C1α2-B of Fc(V12) as well as in Fc(P238D). In addition, the electron density of Gly271 in C1α2-B was clearly observed, though in Pro271 in Fc(P238D) it was not. This conformational change of the loop caused a rearrangement of Arg292 in C1α2-B of Fc(V12). The other substituted residue, Asp268, formed an electrostatic interaction with the shifted Arg292.

**Pharmacokinetic and biophysical property assessment of V12 variant**
In order to characterize the pharmacokinetic aspect of V12 variant, we measured the affinity for hFcRn and the pharmacokinetics in hFcRn transgenic mice. The binding affinity of V12 variant for hFcRn at pH 6.0 was comparable with that of wild-type IgG1 and the in vivo half-life was also comparable (Table II).

\[ T_M = \text{domain was measured by thermal shift assay}. \]

\[ T_M = \text{variant decreased by 8°C relative to wild-type IgG1 (Table II). To assess the real-time stability for pharmacological application of V12 variant, a stability study at an antibody concentration of 100 mg/ml was performed. The formation of HMW species of V12 variant after storage for 4 weeks at 25°C was comparable with that of wild-type IgG1 (Table II).} \]

**In vitro activation and aggregation of platelets by ICS consisting of IgE and anti-IgE antibody with S267E/L328F variant or V12 variant**
Platelets obtained from two donors homozygous for FcγRIIa genotype and incubated with IC consisting of IgE and anti-IgE S267E/L328F variant increased the expression of CD62p and PAC-1 on the platelets, but those incubated with IC consisting of IgE and anti-IgE with the V12 variant did not (Supplementary Fig. S2A and B). On the other hand, when we used platelets obtained from two donors homozygous for FcγRIIa genotype, IC consisting of IgE and anti-IgE S267E/L328F variant slightly upregulated the expression of CD62p and PAC-1 on the platelets but IC consisting of anti-IgE with the V12 variant did not after the incubation compared with the control (phosphate-buffered saline) (Supplementary Fig. S2C and D).

Next, the platelet aggregation induced by ICS was evaluated with an aggregometer. After the addition of ADP, only IC consisting of IgE and anti-IgE with S267E/L328F substitutions aggregated the platelets obtained from two donors homozygous for FcγRIIa genotype, while IC consisting of IgE and anti-IgE with V12 variant did not (Fig. 6A and B). On the other hand, IC consisting of either variant induced the aggregation of the platelets obtained from two donors homozygous for FcγRIIa genotype (Fig. 6C and D).

**Enhancement of agonistic activity of anti-CD137 antibody with enhanced FcγRIIb binding Fc**
Several reports have described that agonistic anti-TNF superfamily antibodies generally require FcγRIIb coengagement for their agonistic activity and that enhancing the binding affinity of the antibodies for FcγRIIb could increase the agonistic activity (White et al., 2011; Wilson et al., 2011; Li and Ravetch, 2012). Therefore, we tested whether V12 also has the same property using agonist antibody against CD137 (clone 1D8), which is one of the TNFR superfamily.

Mouse T lymphoma cell line CTLL-2 was used as mouse CD137-expressing cells (Fig. 7A), and human B lymphoma cell line Raji was used as human FcγRII-positive cells (Hernández et al., 2010). T-cell activating agonistic activity of anti-CD137 antibody was measured with the production of mouse IFN-γ production of CTLL-2 co-cultured with Raji cells. Consistent with the previous reports, V12 variant as well as S267E/L328F variant increased IFN-γ production induced by agonist anti-CD137 antibody compared with intact human IgG1 by more than 5-fold (Fig. 7B).

**Discussion**
Several efforts to improve FcγR binding by Fc engineering have been reported to date. While most of the engineering enhances the binding affinity for activating FcγRs (Stavenhagen et al., 2007; Zalevsky et al., 2009; Mossner et al., 2010), engineering to enhance binding affinity to inhibitory FcγR is limited (Chu et al., 2008). S267E/L328F variant, the Fc variant reported to have the highest affinity for inhibitory FcγR binding, enhanced the binding affinity for FcγRIIb by 355-fold; however, it also enhanced the binding affinity for FcγRIIa to the same level as FcγRIIb (Smith et al., 2012). The high similarity between FcγRIIb and FcγRIIa suggests that discriminating FcγRIIb and FcγRIIa by Fc engineering is challenging (Supplementary Fig. S1).

In this work, we investigated the substitutions to distinguish FcγRIIb from FcγRIIa by comprehensive mutagenesis and discovered a highly selective substitution, P238D, which provides the highest selectivity for FcγRIIb relative to all the other active FcγRs including FcγRIIa. Fc variants which discriminate FcγRIIb from FcγRIIa were extremely rare, probably because FcγRIIb is highly homologous to...
The group mean by Leu235 instead in CH2-A of Fc(P238D) complexed with its original position to achieve access to the solvent region. To avoid this free energy loss, Asp238 showed a large shift out of desolvation of Asp to maintain the same structure. To surrounding residues. Therefore, substituting this hydrophobic Fc(IgG1) structures, Pro238 forms a hydrophobic core with its FcRIIa (Supplementary Fig. S1) and the Fc-FcRIIb interface would be also highly homologous to the Fc-FcRIIaR131. To the best of our knowledge, this is the first report illustrating an Fc variant that enhances FcRIIb binding while distinguishing FcRIIb and FcRIIaR131 precisely.

To elucidate the structural mechanism by which P238D variant discriminates FcRIIb from FcRIIaR131, we solved the crystal structure of the complex of Fc(P238D) and FcRIIb. Our structural analysis indicated that the high selectivity of P238D variant was achieved by a dynamic conformational change of the Fc-FcRIIb interface that was induced by P238D substitution into wild-type IgG1. In reported Fc(IgG1) structures, Pro238 forms a hydrophobic core with its surrounding residues. Therefore, substituting this hydrophobic Pro238 to hydrophilic Asp should cause large free energy loss for desolvation of Asp to maintain the same structure. To avoid this free energy loss, Asp238 showed a large shift out of its original position to achieve access to the solvent region. Additionally, the position of Pro238 in Fc(IgG1) was occupied by Leu235 instead in C12-A of Fc(P238D) complexed with FcRIIb. As the result, the large conformational change of loop233–240 attached to the hinge region was observed. This change would affect the domain arrangement between the C12-A and B domains because both C12 domains connect by S–S bonds in the hinge region and cannot move independently. In fact, the relative arrangement of C12-A and B domains in the Fc(P238D)/FcRIIb complex was different from that of Fc(IgG1)/FcRIIaR131, despite FcRIIb having the highest homology to FcRIIaR131. As the result of these dynamic conformational changes, Fc(P238D) acquired two novel interactions with FcRIIb. One is the hydrogen bond between the main chain of Gly237 in C12-A and the side chain of Tyr160 in FcRIIb. Both FcRIIa allotype cannot make this hydrogen bond because corresponding residue of this Tyr is Phe in FcRIIa (Supplementary Fig. S1). So, this interaction would play a critical role for distinguishing FcRIIb from FcRIIa. The other one is the salt bridge between Asp270 in C12-A and Arg131 of FcRIIb. This salt bridge would contribute to improve not only the binding affinity to FcRIIb but also the selectivity over FcRIIaR131 because this allotype has His as the corresponding residue of Arg131 in FcRIIb. On the other hand, the S267E/L328F variant increased binding affinity to both FcRIIb and FcRIIaR131 to the same extent, while it did not increase binding affinity to FcRIIaR131 or other FcRIs. From the reported complex structure of Fc(IgG1)/FcRIIaR131, we elucidated that Glu267 of the Fc with S267E/L328F substitution would form a salt bridge with Arg131 of the FcRIIb and also of the FcRIIaR131. This might explain the reason for the lack of selectivity of the S267E/L328F variant to FcRIIb over FcRIIaR131, both of which have Arg at position 131. Large conformational change induced by P238D would also explain the reason for lack of additive effect of combining P238D with L328E or S267E/L328F.

Then, in order to further increase the binding affinity to FcRIIb, we conducted a second comprehensive mutagenesis using the P238D variant as a template rather than combining substitution(s) effective for wild-type IgG1 template, since the interface of Fc(P238D)/FcRIIb was considered to be significantly changed from that of Fc(IgG1)/FcRIIb. P238D-based comprehensive and combinatorial study identified V12 variant whose affinity for FcRIIb was significantly increased from P238D variant. Especially, P271G markedly increased affinity for FcRIIb. The substitution of fixed proline to flexible glycine would contribute to release conformational stress when a salt bridge between Asp270 in Fc (V12) and Arg131 in FcRIIb is formed, which is considered to contribute to the affinity improvement for FcRIIb.

Structural analysis of P238D suggests that P238D substitution seemed to destabilize the hydrophobic core of C12 domain, although this could be partially compensated by Leu235 as found in C12-A domain. The conformational changes seem to be the cause of decreased T_M for V12 variant. Although this reduced T_M raised concern regarding the storage stability of Fc(V12) for pharmaceutical application, its stability (aggregation tendency at 100 mg/ml) was comparable with that of wild-type IgG1.

It is known that, for IgG1 antibody to have a long half-life in vivo, binding to FeRn at acidic pH is important. The affinity of V12 variant for hFeRn was comparable with that of wild-type IgG1 and, consistently, the in vivo half-life of V12

![Fig. 5. Structure of Fc(V12)/FcγRIIb complex. (A) The binding interface between the C12-A domain of Fc(V12) and FcγRIIb. The substitutions in Fc(V12) and the residues in FcγRIIb with a minimum distance of 3.8 Å from these substitutions are shown as sticks. (B) The binding interface between the C12-B domain of Fc(V12) and FcγRIIb. The structural changes around Asp270 in the C12-B domains shown by comparing Fc(P238D)/FcγRIIb (green) and Fc(P238D)/FcγRIIb (cyan) complexes. FcγRIIb in each complex is shown in the darker color.](https://academic.oup.com/peds/article-abstract/26/10/589/1509874)
variant was also comparable with that of wild-type IgG1. However, it should be noted that because the binding affinity of V12 variant to murine FcγRIIb (the mouse counterpart of human FcγRIIb) was not increased, its effect on the pharmacokinetics was not addressed in this study.

ICs induce platelet aggregation and activation when antibody binds to FcγRIIa expressed on the platelet surface (Boumpas et al., 2003; Scappaticci et al., 2007). The previous studies suggest that ICs consisting of IgG with enhanced binding to FcγRIIa have the potential to induce platelet aggregation and activation more intensively than IC consisting of wild-type IgG. However, the effect of engineered Fc with enhanced binding affinity to FcγRIIa on platelet activation and aggregation induced by IC has not so far been investigated. In this report, IC consisting of IgE and anti-IgE antibody with enhanced binding affinity to both FcγRIIa and FcγRIIaR131 (S267E/L328F variant) induced the activation and aggregation of platelets obtained from FcγRIIa genotype of R/R131 homozygous donors, but not from FcγRIIa genotype of H/H131 homozygous donors. On the other hand, anti-IgE antibody with selectively enhanced binding affinity to FcγRIIb did not induce the activation or aggregation of platelets from donors with either genotype. Platelets whose FcγRIIa genotype is R/H131 are considered to express both FcγRIIa allotypes on their surface, while platelets whose FcγRIIa genotype is R/R131 express only FcγRIIaR131. Therefore, a similar tendency will be observed in the platelets from heterozygous donors, although the induction of the aggregation and activation might be milder.

It is known that FcγRIIa internalizes ICs by endocytosis and transfers them to lysosomal degradation (Zhang and Booth, 2010), while FcγRIIb recycles the internalized ICs.
(Bergtold et al., 2005; Mousavi et al., 2007). These reports suggest that an antibody with enhanced binding affinity to FcγRIIa would be more rapidly eliminated from plasma by FcγRIIa-mediated uptake and degradation than wild-type IgG1, while an antibody with enhanced binding only to FcγRIIB would have a longer half-life because the antibody would be recycled back to the cell surface. Indeed, an antibody with enhanced binding to both murine FcγRII and FcγRIII (counterpart of human FcγRIIa) exhibited more rapid clearance from plasma compared with an antibody with enhanced binding only to murine FcγRII (data not shown).

These facts indicate that therapeutic IgG with S267E/L328F substitution has the potential to induce platelet aggregation and activation and to be rapidly cleared from plasma in patients with FcγRIIaR131 genotype. One report described that the allelic frequency of R/R131, R/H131 and H/H131 is 31, 44 and 25%, respectively, among healthy Caucasians, and 26, 43 and 31%, respectively, among healthy African Americans (Lehrnbecher et al., 1999). Another report showed that in Japanese, Chinese and Asian Indian populations the R/R131 genotype occurs in 6, 6 and 31%, respectively (Osborne et al., 2014). Considering the proportion of populations with R/R and R/H genotypes, enhancing the binding affinity to FcγRIIaR131F would have a substantial impact.

Previous studies using S267E/L328F or S267E substitution(s) have demonstrated that enhancing affinity to FcγRIIB is a promising application for therapeutic antibodies against CD19, IgE, DR5 and CD40 (Li and Ravetch, 2011, 2012; Chu et al., 2012; Hammer, 2012). Consistent with these reports, V12 variant, as well as S267E/L328F variant, enhanced agonistic activity of antibody against CD137, one of TNFR superfamily molecules, compared with intact human IgG1. Since agonistic antibodies against TNFR superfamily are currently being explored for cancer immunotherapy, enhancement of the agonistic activity of these antibodies by selectively improving the binding affinity for FcγRIIB could be a promising approach. In addition, in BA/F3 cells expressing constitutively active mutants of the receptor tyrosine kinase, Kit, ICs that crosslinked FcγRIIB and Kit inhibited growth factor-independent proliferation (Malbec and Daéron, 2012). In another report, ICs suppressed the TLR4-mediated response of DCs in rheumatoid arthritis patients through FcγRIIB. Each of these effects of FcγRIIB could be enhanced by applying Fc with enhanced affinity for FcγRIIB. Moreover, ICs significantly suppressed expression of CD40, CD80 and CD86 on FcγRIIB-overexpressing DCs, suggesting that in DCs, using ICs consisting of an antibody variant with selectively enhanced FcγRIIB affinity relative to FcγRIIa might polarize IC-triggered activating signals to inhibitory signals (Zhang et al., 2011).

**Conclusion**

In this study, we screened antibody Fc variant which selectively enhances the binding affinity to FcγRIIB over both FcγRIIaR131 and FcγRIIaR131 by comprehensive mutagenesis. We identified a distinct substitution, P23BD, that could discriminate FcγRIIB from FcγRIIaR131 precisely, and crystal structural analysis revealed that this substitution substantially changed the recognition interface of Fc-FcγRIIB. We further designed an antibody variant with 200-fold higher affinity for FcγRIIB than IgG1 without increasing the affinity for other active FcγRs. The variant was comparable with IgG1 in terms of pharmacokinetics and storage stability. We also showed that an antibody with increased affinity for FcγRIIB has an increased possibility of inducing platelet activation and aggregation and of being rapidly cleared from plasma. Since previous studies and our study using agonist anti-CD137 antibody suggested that increasing the binding affinity to FcγRIIB has various therapeutic applications, our engineered Fc, which enhances binding selectivity to FcγRIIB, is expected to have a significant therapeutic potential.
