Dickson, Hubert Vidal, Niklas Mejhert, Corneliu Henegar, Magdalena Taube, Caroline Hansson, Anke Hinney, Pilar Galan, Chantal Simon, Angela Silveira, Anna Benrick, John-Olof Jansson, Anne Bouloumié, Dominique Langin, Martine Laville, Cyrille Debard, Tomas Axelsson, Mikael Rydén, Juha Kere, Karin Dahlman-Wright, Anders Hamsten, Karine Clement, and Ingrid Dahlman*

**Context:** Previous studies suggest a role for fibroblast growth factor receptor 1 (\textit{FGFR1}) in the regulation of energy balance.

**Objective:** Our objective was to investigate whether \textit{FGFR1} is an obesity gene by genetic association and functional studies.

**Design:** The study was designed to genotype common \textit{FGFR1} single-nucleotide polymorphisms (SNP) in large cohorts, confirm significant results in additional cohorts, and measure \textit{FGFR1} expression in human adipose tissue and in rodent hypothalamus.

**Setting:** General community and referral centers for specialized care was the setting for the study.

**Participants:** We genotyped \textit{FGFR1} SNP in 2438 obese and 2115 lean adults and 985 obese and 532 population-based children. Results were confirmed in 928 obese and 2738 population-based adults and 487 obese and 441 lean children. Abdominal sc adipose tissue was investigated in 202 subjects. We also investigated diet-induced, obese fasting, and fed rats.

**Main Outcome Measures:** We analyzed the association between \textit{FGFR1} SNP and obesity. In secondary analyses, we related adipose \textit{FGFR1} expression to genotype, obesity, and degree of fat cell differentiation and related hypothalamic \textit{FGFR1} to energy balance.

**Results:** \textit{FGFR1} rs7012413*T was nominally associated with obesity in all four cohorts; metaanalysis odds ratio = 1.17 (95% confidence interval = 1.10–1.25), and \( P = 1.8 \times 10^{-6} \), which was \( P = 7.0 \times 10^{-8} \) in the recessive model. \textit{FGFR1} expression in adipose tissue \( (P < 0.0001) \). In this organ, but not in skeletal muscle, \textit{FGFR1} mRNA \( (P < 0.0001) \) and protein \( (P < 0.05) \) were increased in obesity. In rats, hypothalamic expression of \textit{FGFR1} declined after fasting \( (P < 0.0001) \) and increased after diet-induced obesity \( (P < 0.05) \).

**Conclusions:** \textit{FGFR1} is a novel obesity gene that may promote obesity by influencing adipose tissue and the hypothalamic control of appetite. \textit{(J Clin Endocrinol Metab} 96: E962–E966, 2011)

Fibroblast growth factor receptor 1 (\textit{FGFR1}) is activated by several fibroblast growth factors, and previous studies suggest a role for \textit{FGFR1} signaling in the regulation of energy balance. We have shown that human sc adipose tissue secretes the \textit{FGFR1} ligand FGF1 (1). Silencing of \textit{FGFR1} inhibits differentiation (adipogenesis) in human precursor cells (2, 3). Furthermore, adipocyte number is a major determinant for the fat mass in adults, and fat cells are continuously being renewed in adult humans (4). In addition, modulation of hypothalamic \textit{FGFR1} signaling in rodents decreases food intake (for details, see Supplemental Data, pub-

lished on The Endocrine Society’s Journals Online web site at http://jcem.endojournals.org) (5–7).

Against this background, we have investigated common single-nucleotide polymorphisms (SNP) in the FGFR1 gene for association with obesity. To further strengthen the notion of FGFR1 as an obesity gene, we studied the expression of FGFR1 in human adipose tissue, and also in the hypothalamic region of the rat brain, in relation to energy balance. Finally, we investigated the influence of FGFR1 genotype on adipose gene expression.

**Subjects and Methods**

The study was approved by the local ethics committees. All adults gave their informed consent to participation. For subjects under age 18, written authorization was obtained from the parents.

**Cohorts**

The cohorts for genetic studies are described in Supplemental Table 1 and Supplemental Methods. Cohort 1 comprised obese adults with body mass index (BMI) of 30.0 kg/m² or higher and lean with BMI under 25.0 kg/m², all having European ancestry and living in the greater Stockholm area. Cohort 2 comprised French obese and population-based control children (8). The obese population had BMI Z-score of 3 or higher. In this case, in the obese population, we used the Rolland and Cachera methodology who defined BMI curve and evolution in the French population (9). The control children participated in a population-based physical activity study (10). Phenotypes were collected before the intervention. Cohort 3 comprised adult French morbidly obese (BMI ≥ 40.0 kg/m²) cases and population-based control subjects. The adults in the control group were participants of SU.VI.MAX (11). Phenotypes were collected at study entry. Cohort 4 encompassed German extremely obese children and adolescents (BMI Z-score = 4.6 ± 2.3) and adult lean controls (BMI Z-score = −1.4 ± 0.4) (12). The BMI of the obese patients was above the 90th BMI percentile for German children and adolescents (see www.mybmi.de).

Subjects included in analysis of human abdominal SC adipose tissue were from cohort 1 (see above). In these studies, obesity was defined as BMI over 30 kg/m² and leanness as BMI under 25 kg/m². These subjects are described in Supplemental Methods. All subjects were healthy according to self-report. An abdominal percutaneous biopsies of the vastus lateralis muscle were obtained under local anesthesia in the morning. All subjects were healthy according to self-report. An abdominal fat biopsy was obtained under local anesthesia in the morning.

An abdominal fat biopsy was obtained under local anesthesia in the morning. All subjects were healthy according to self-report. An abdominal fat biopsy was obtained under local anesthesia in the morning. All subjects were healthy according to self-report. An abdominal fat biopsy was obtained under local anesthesia in the morning.

Percutaneous biopsies of the vastus lateralis muscle were obtained after an overnight fast from healthy never-obese lean controls (five men and five women) and age-matched obese subjects with normal glucose tolerance (two men and six women). All subjects had a stable body weight over the last 3 months and were not involved in heavy exercise programs.

**Studies in rodents**

For fasting studies, Sprague-Dawley rats (Charles River, Frankfurt, Germany; n = 19) were handled daily for 10 d after which half of the rats were subjected to an overnight (16 h) fast. In studies of diet-induced obesity, 4-wk-old male Wistar rats (Harlan, Blackthorne, UK; n = 16) were exposed to a cafeteria-style Western diet or normal chow for 16 wk (n = 8 per group). At the end of the study, the body weight of the cafeteria-fed group (mean ± SEM = 484 ± 15 g) was significantly higher than the chow group (mean ± SEM = 398 ± 14 g; P < 0.001).

**Genotyping**

The FGFR1 gene is encoded on chromosome 8 and is in Caucasian samples composed of two haploblocks separated by a region with low LD (www.hapmap.org). We genotyped markers that tagged the common (frequency > 10%) haplotypes as well as a number of markers in the region with low LD. See Supplemental Methods for details.

**Quantitative real-time PCR**

FGFR1 mRNA was quantified by quantitative real-time PCR as described in Supplemental Methods. We calculated relative changes of the target gene employing the comparative method (User Bulletin no. 2; Applied Biosystems, Foster City, CA).

**Western blot**

We performed Western blot as described (16) with commercial FGFR1 (catalog item Sc-121; Santa Cruz Biotechnology, Santa Cruz, CA) and β-actin (catalog item A2066; Sigma Chemical Co., St. Louis, MO) antibodies.

**Statistical analysis**

We used Haplovew (17) to test for Hardy-Weinberg equilibrium, and to evaluate association between single SNP or haplotypes and obesity. The χ² test was used to test for association between alleles and obesity. For metaanalysis, the inverse variance method was used for pooling of cohort results. The combination of data and the combined value of the odds ratio (OR) and 95% confidence interval (CI) were calculated using the random-effects estimate method implemented in the R package. Model-based tests were carried out to evaluate association of...
genotype with obesity using logistic regression implemented in PLINK (http://pngu.mgh.harvard.edu/~purcell/plink/) (18). Differences in specific quantitative phenotypes between genotypes were evaluated by analysis of covariance with age and BMI as covariates. Gender did not affect gene expression. The influence of genotype on specific mRNA according to the additive model was tested by Spearman Rank correlation. Student's t test was used for two-group comparisons. Values are mean ± SD unless otherwise indicated.

Results

**FGFR1 rs7012413 is associated with obesity**

We genotyped nine FGFR1 SNP in cohorts 1 and 2 (Supplemental Table 2). Two SNP were not in Hardy-Weinberg equilibrium and were therefore excluded from analysis. One SNP in intron 1 of FGFR1, rs7012413, was associated with obesity in both cohorts, nominal P = 0.0043 and 0.002, respectively (Table 1). Three more SNP were nominally associated with obesity in one cohort only: rs4733930 and rs6983315 in cohort 1 and rs10958700 in cohort 2 (Supplemental Table 2). No haplotype was associated with obesity. To confirm the association of rs7012413 with obesity, two more cohorts were investigated (Supplemental Table 2). No haplotype was associated with obesity in one cohort only: rs7012413*T was associated with obesity in both cohorts, nominal P = 0.0043 and 0.002, respectively (Table 1). Three more SNP were not in Hardy-Weinberg equilibrium and were therefore excluded from analysis. One SNP in intron 1 of FGFR1, rs7012413, was associated with obesity in both cohorts, nominal P = 0.0043 and 0.002, respectively (Table 1). Three more SNP were nominally associated with obesity in one cohort only: rs4733930 and rs6983315 in cohort 1 and rs10958700 in cohort 2 (Supplemental Table 2). No haplotype was associated with obesity. To confirm the association of rs7012413 with obesity, two more cohorts were investigated (Table 1); rs7012413 was associated with obesity in cohort 3 (P = 0.049) and in cohort 4 (P = 0.05). In a metaanalysis of all four cohorts, rs7012413*T was associated with obesity with P = 1.8 × 10⁻⁶, and OR = 1.17 (95% CI = 1.10–1.25). There was no statistical evidence for heterogeneity in impact on obesity between cohorts. Body fat in kilograms was measured in 1484 subjects from cohort 1 with bioimpedance. In this cohort, rs7012413*C allele was associated with lower body fat (P = 0.019) using a generalized linear model and adjusting for height squared, gender, and age.

The impact of rs7012413 on obesity under different genetic models was tested next in a joint analysis of all cohorts. The recessive but not the dominant model reached genome-wide significance [P = 7.0 × 10⁻⁸ (OR = 1.43; 95% CI = 1.26–1.63) vs. P = 0.003 (OR = 1.13; 95% CI = 1.04–1.22)] (Supplemental Table 3). rs7012413 was associated with obesity in both women and men (Supplemental Table 3). We performed bioinformatic analysis to explore a potential function of rs7012413. According to TFSEARCH (http://www.cbrc.jp/research/db/TFSEARCH.html), rs7012413*T is predicted to cause two extra transcription factor binding sites for nuclear transcription factor Y and CCAAT box binding proteins compared with rs7012413*C (Supplemental Fig. 1).

**FGFR1 mRNA in human adipose tissue is associated with rs7012413 genotype and obesity**

We next studied FGFR1 expression. FGFR1 mRNA in intact adipose tissue was increased by about one third in obese women (P < 0.0001) (Fig. 1A). Smaller cohorts were used to explore in more detail the pattern of expression of FGFR1. FGFR1 mRNA in isolated fat cells showed a trend toward increased expression in obese, but the results were nonsignificant (P = 0.10) (one-sided test gives P = 0.05; because the aim of this analysis was to confirm the results from intact adipose tissue, we think the one-sided test is appropriate to use) (Fig. 1B). Furthermore, FGFR1 protein in adipose tissue was increased 2-fold (P < 0.05) in obese women (Fig. 1C). By contrast, FGFR1 mRNA in human skeletal muscle was not influenced by obesity (results not shown). Finally, FGFR1 mRNA was increased during differentiation in vitro of precursor cells to adipocytes (P < 0.01) (Fig. 1E). There was a significant overall effect of rs7012413 genotype on adipose FGFR1 expression in all subjects combined (P < 0.001) and in the obese (P = 0.005). TT and CT genotype subjects showed higher FGFR1 mRNA levels than CC subjects (Supplemental Table 4). CT subjects had slightly higher expression levels of FGFR1 than TT subjects; this may be caused by the small number of TT subjects (n = 6). An additive model was significant (P = 0.018).

**Hypothalamic FGFR1 mRNA expression is regulated by energy balance in rodents**

The hypothalamic expression of FGFR1 was significantly decreased (P < 0.01) by an overnight (16 h) fast and

c Population-based controls. Cohort 2 population-based controls include 29 obese children, and cohort 3 population-based controls include five morbidly obese adults.
increased (P < 0.05) in diet-induced obese rats (Fig. 1, E and F).

**Discussion**

We report a common SNP, rs7012413, in the first intron of the FGFR1 gene that is associated with obesity in four cohorts, together comprising 4838 obese cases and 5827 lean or population-based controls. We show that FGFR1 mRNA in subcutaneous adipose tissue is associated with rs7012413 genotype and obesity status as well as fat cell differentiation. Furthermore, in rodent studies, we observe that hypothalamic expression of FGFR1 is correlated with energy balance.

Association of rs7012413 with obesity was observed in children and adolescents (19). FGFR1 SNP have previously been examined for association with BMI in 629 individuals from 207 families who were not ascertained based on obesity (20). The lack of association between FGFR1 and obesity in the study by Kaess et al. (20) is not surprising given the limited power of the sample and does not exclude an impact of FGFR1 on obesity.

rs7012413 could hypothetically affect gene expression because many genes have multiple transcriptional regulatory regions. *In vitro* experiments will be necessary to test the significance of the predicted binding sites associated with one allele of the SNP. Of note, we cannot rule out that rs7012413 is in close LD with another SNP that mediates the impact on obesity and mRNA levels. However, rs7012413 is located in a region spanning intron 1 to 2 that displays low LD between markers, and among other markers genotyped in the region, none is associated with obesity in both cohorts 1 and 2.

Previous studies have shown that FGFR1 regulates human preadipocyte differentiation *in vitro* (2, 3). We here report that FGFR1 genotype is associated with adipose tissue mRNA levels, and FGFR1 mRNA is up-regulated after differentiation of human adipose tissue precursor cells to adipocytes. Together, these results together are consistent with the hypothesis that FGFR1 could be a regulator of adipogenesis that contributes to obesity by regulating fat cell number. Fat cell number is a major determinant for fat mass (4).

FGFR1 gene variants may also influence obesity by other independent mechanisms, e.g., modulating central regulation of food intake. We demonstrate the novel finding that FGFR1 expression in the rat hypothalamus decreases during a short time of fasting and increases during long-time overfeeding.

In summary, we identified FGFR1 as a novel obesity gene that may promote obesity by influencing adipose tissue and the hypothalamic control of appetite.
