We conduct digital studies on the drawings of the US-American artist Mark Lombardi (1951-2000) which depict networks of actors involved in various scandals of money laundering and weapons deals like the Iran-Contra affair.

To discover the knowledge contained in the drawings, Lombardi started with extensive research into publicly accessible sources on such affairs. Using index cards he took notes on the relations amongst persons and institutions involved. From these, he started with initial sketches of networks which then were developed over several versions into pencil on paper drawings. Nodes in the networks are persons or institutions and the edges represent a small number of vague relations such as “association”, “influence” or “financial transaction” and come in about 5-6 different graphic notations.

The works contain knowledge about the scandals depicted. Lombardi called them “narrative structures” since following the graphical paths in the networks tells a story of who was involved with whom to undertake specific transactions. The aesthetical value of the works stems from the way the networks are laid out.

Lombardi is well received, for example, he was exhibited at dOCUMENTA (13). Recently, a documentary containing valuable insights into his life and work was released [1]. From a computer science perspective one can understand a drawing as a datastructure representing a network. Nodes and edges are typed and carry labels. As a contribution to digital art history we started a project which addresses two basic layers of digital research into the works of Lombardi: - Make digital representations of the works in standardized dataformats publicly available. - Provide services on the digital representations that contribute to research on them.

Our project is an experiment in methods for digital art history that also offers new insights into the specific network drawings of Mark Lombardi.

**Digitization of the Drawings**

Digitization of the drawings as datastructures and not as pictures requires a specific process. We have developed a very small datamodel in which nodes and edges are typed according to a simple typology as found in the works. It is represented as an ontology based on the Web standard OWL [2].

We then work as follows:

1. We use scans or photographs of the original drawings and manually note all relations found. Figure 1 shows how we manually mark relations that are digitized. As a tool we use a simple spreadsheet that helps us with autocompleting the URLs of the edge types defined in our ontology. For each relation we use the labels from the drawings as node-identifiers. If existent, we also take down labels found at the edges in the drawings.
2. This simple representation is imported into the Cytoscape tool [3] to type nodes. Cytoscape also analyzes the resulting network and adds some standard network metrics.
3. Finally we export the network in the GraphML [4] format and publish it on the net at <http://www.lombardinetworks.net>.

We measured the speed of the process with the examples that we did. Taking down the relations and typing the edges takes about 30 minutes for 40 relations. In 10 additional minutes about 35 nodes can be typed. If we assume a certain density of the drawing based on its size, we can estimate that the famous Lombardi work *BCCI, ICIC & FAB, 1996–2000* with its size of 132 × 353cm can be digitized within about 75 hours of work.

The networks can be downloaded or used otherwise under the Creative Commons Attribution-ShareAlike 3.0 Unported License [5]. While we digitize each work as a complete network, each node and edge is provided with a unique identifier. Together with the URL of the network file this means that every specific single artifact in the drawings can be addressed with a URL. This allows it to add further information, for example if the same person is named differently in different works.

**Initial Services**

The networks provided are public and free to use. Their value is exhibited when used in services that help to explore the work of Lombardi further. We have set up an initial set of services to give an impression. The first services help to get an overview on the persons and institutions occurring in the drawings:

- Since the drawings are digitally represented with the labels used as strings, we implement a search on the drawings using a Google custom search limited to the GraphML files. By that we can do searches for specific actors in the drawings with link to the representations of the drawings as the result list.

Roadmap
Our project on Lombardi has the long-term goal of providing complete digital information on Lombardi’s works. The following results are aimed at:

1. Complete digital representations of all Lombardi works in all versions with a normalization of actors’ names. A path for this would be to contact all private and public collectors via gallerists and to have them provide scans or photographs of the works or allow their generation.

2. A scan of all ~14000 index cards from the MOMA archive. These could in turn be made processable via OCR software trained to Lombardi’s handwriting. The texts then could be analyzed using heuristics specific to Lombardi’s way of taking notes and referring to public sources.

3. A processable corpus of all public information that Lombardi used. This is a library of his books in digital form. From the references in the index cards, one would need digital representations of the texts used, e.g. via Google books. In turn, the text could be analyzed and linked with the index cards.

4. A processable corpus of all texts written on Lombardi. These include, for example, descriptions of his works by art historians. The corpus could be collected from public websites. It could then be linked with the other information sources to form a huge specialized information system.

All data and services are available at <http://www.lombardinetworks.net>.
